Bile thus constituted is being constantly secreted by the liver. There is still much difference of opinion as to the part played by the liver in the formation of bile. It is generally admitted that the biliary acids are formed in and by the liver; but many physiologists and physicians still maintain that the bile-pigment is preformed in the blood, and is merely separated from the blood by the liver; and they explain those cases of jaundice in which there is no obstruction of the bile-duct, by saying that bile-pigment accumulates in the blood from the liver ceasing to act, or from its function being suppressed. But it has long appeared to me that there are weighty objections to this view.

1. Although bile-pigment appears to be derived from the colouring matter of the blood, it has not yet been satisfactorily shown that bile-pigment, as such, exists ready formed in the blood of persons who have not jaundice. Frerichs denies that it ever has. Lehmann, who has investigated with great care the changes which the blood undergoes in passing through the liver, has never been able to detect the colouring matter of bile in portal blood, and infers that this, as well as the bile acids, must be formed in the liver itself. The blood of the hepatic artery has been examined with a like result. It is obvious that, if bile-pigment exist in healthy blood at all, its quantity must be very minute; and, when we consider that the quantity of bile secreted by the human liver daily is about two pints, and yet that jaundice is not a normal condition, it seems impossible that all the bile-pigment secreted by the liver can be formed in the blood; and it is not probable that part is formed in the blood and part in the liver.

2. The discovery by a few observers of a small quantity of bile-pigment in what appeared normal blood does not prove that it was formed in the blood. It is quite conceivable that it may have been formed in the liver, and been subsequently absorbed.

3. It often happens that, from various diseases, such as fatty and waxy degeneration, cancer, and cirrhosis, the secreting tissue of the liver is for the most part or entirely destroyed, bile is no longer secreted, and yet no jaundice results. Several cases of this sort are referred to by Haspel, where the gall-bladder and bile-ducts, after death, contained only a little white mucus. Frerichs records a case of fatty liver, where the contents of the bowels were pale, the gall-bladder empty, and the biliary ducts coated with a greyish mucus, notwithstanding which the skin was of a chalky paleness, and the urine contained no bile-pigment. Similar observations have been made by Budd in cases of waxy disease and cancer of the liver, and several instances of a like nature have come under my own notice. If bile-pigment be formed in the circulating blood, it is difficult to account for what becomes of it in these cases.

4. If the constituents of bile be formed in the blood, intense jaundice ought at once to follow the extirpation of the liver in any of the lower animals, in like manner as urea accumulates in the blood after removal of the kidneys. But, so far from this being the case, Müller, Kunde, Lehmann, and Moleschott have repeatedly extirpated the liver of frogs, and have invariably failed to find a trace of the biliary acids, or of the colouring matter of the bile, in the blood, the urine, or the muscular tissue.

The supposition that bile-pigment is formed in the blood appears to the author for these reasons to be untenable.

COMBINATION OF CHLORAL WITH ALBUMINOID MATTERS.*

BY M. PERSONNE.

The theory put forward by Liebreich, that chloral is decomposed into chloroform in the system, has been disputed on the ground that the blood does not possess sufficient alkalinity for the purpose, such a change not being affected by alkaline bicarbonates, as they exist in Vichy water, for example. The author having endorsed Liebreich's conclusions in a former communication to the Academy, was induced to investigate the subject afresh, the result of his new experiments being confirmatory of his former. They show that beside the stronger alkalies, all the weak alkalies, magnesia, akaline salts like the bicarbonates of potash and soda, borate and phosphate of soda, and all the alkaline animal liquids, such as blood or white of egg, are capable of converting chloral into chloroform when the mixture is heated to a temperature of 40° C.

To explain the difference of physiological action that actually exists between chloral and chloroform—the action of chloral being longer in duration than that of chloroform—another product of the decomposition of chloral, formic acid, has been brought in, and it has been admitted that this acid, burnt up in the system, yields carbonic acid, the hypnotic action of which is added to that of the chloroform. It is known, in fact, that the decomposition of chloral hydrate gives 72·2 per cent. of chloroform and 27·8 per cent. of formic acid, according to the following equation:—

$$C_2HCl_3O,H_2O = CHCl_3 + CH_2O_2.$$

Further, a more or less considerable portion of chloroform can be broken up, giving rise to formic acid and chloride of sodium.

* Abstract of a paper read before the French Academy (*Comptes Rendus*, vol. lxxviii., p. 129.)

$$CHCl_3 + 2Na_2O = CHNaO_2 = 3NaCl.$$

All the formic acid produced is far from being consumed, one portion is certainly eliminated by the urine, which possesses the property of reducing the copper solution, although glucose is absent. But even admitting that all the formic acid produced by the complete decomposition of the chloral is transformed into carbonic acid, should it be concluded that the action of this carbonic acid is added to that of the chloroform? The author thinks not, for the following reasons: 10 grams of chloral hydrate produce, upon complete decomposition, 5·6 grams of formic acid, a quantity that cannot always be administered to a dog of medium size. He has however administered to dogs as much as ten grams of dry formate of soda—representing 5·83 grams of formic acid—without observing the least anæsthetic symptom. Nevertheless the salt was always completely absorbed, for it never produced any purgative effect.

In the course of M. Personne's experiments he made an observation which he considers to throw a light upon the physiological action of chloral. Fresh blood, added to chloral hydrate and kept at the ordinary temperature, is completely coagulated, preserves its red colour and remains without alteration. A morsel of muscle immersed into a ten per cent. solution of chloral hydrate became slightly paler; a reddish liquid exuded from it which quickly deposited a brick-like sediment. After a few hours' immersion, the muscle, left at a temperature of 15° to 20° C., underwent no further putrefaction; it dried rapidly, took a brighter tint, and became sufficiently friable to pulverize. The dried substance contained chloral, and yielded chloroform with alkalies. An estimation of the chlorine, operating upon a specimen dried at 100° C., gave 8·30 to 8·38 per cent. of chlorine, corresponding to 11·50 per cent. of chloral.

Albumen also combines with chloral. The author has attempted to obtain a definite compound, but has hitherto failed to determine the precise conditions under which such a compound is formed. He therefore confines himself to stating that this combination dissolves in an excess of albumen as well as in an excess of solution of chloral, after the manner of the compound of albumen and bichloride of mercury. On one occasion he obtained a product which first dried during eight days at 40° or 45° C., then pulverized and dried at 100° C., yielded, upon analysis, 12·56 per cent. of chlorine, which represents 17·23 per cent. of chloral. The quantity of chloral led him to presume that this was a definite compound. In fact, if the formula for albumen given by Lieberkühn, $C_{72}H_{114}N_{18}O_{11}S$, be admitted, we have—

$$C_{72}H_{114}N_{18}O_{11}S + 2\,(C_2HCl_3O, H_2O) - H_2O;$$

which gives 12·65 of chlorine, corresponding to 17·36 per cent. of chloral.

It is now generally acknowledged that albuminoid matters are amides; therefore, as the aldehydes are capable of combining with those bodies, it is not unreasonable to suppose that chloral, which is a trichlor aldehyd, might form with them analogous compounds.

The author's experiments have led him to suggest the following explanation of the more prolonged action of chloral compared with that of chloroform. The first action of chloral hydrate upon the albuminoid matters with which it meets in the system produces chloroform at the expense of the alkali of those albuminoid matters. At the same time they, being impoverished or deprived of alkali, enter into combination with the undecomposed chloral, and this combination forms a sort of reservoir of chloroform, which is given up successively in proportion as the circulation destroys the combination thus formed. This would explain why only a small quantity of chloroform is met with in the blood of animals subjected to the action of chloral; it also justifies the employment of chloral in the dressing of wounds, as a powerful modifier of the tissues.

The author concludes by remarking that chloral can be advantageously employed for the preservation of the most readily alterable animal matters. A cerebellum, placed in a ten per cent. solution of hydrate of chloral, was preserved during a month without alteration, except that it became rather firmer without becoming hard. By using solution of chloral with glycerine, imputrescible products may be obtained, retaining a certain suppleness, which would allow of the preservation, under favourable conditions, of a number of anatomical preparations.

THE NIIN INSECT OF YUCATAN.*

BY M. DONDÉ.

Under the name of Niin, the natives of Yucatan designate a hemipterous insect of the Coccidæ family, which the author, who is a pharmacist at Merida, believes to be new to science, and proposes to name *Coccus Adipofera*. The male is small, red, ·015 millimetre long, with two wings, which shut horizontally upon the body, and are black in the interior and red on the exterior. The female is larger, ·025 millimetre long, and ·015 millimetre broad, and bright red in colour. They are found upon trees called "ciruelos," belonging to various species of the genus *Spondias*, of the family Terebinthaceæ. They adhere to the plants solely by a hard beak with which the lower part of the mouth is furnished very close to the thorax. They remain almost motionless, and are so numerous and crowded so closely together that often the greater part of the tree is hidden by them. From about July or August the female insects increase in size until November, which is the period of incubation. Each female deposits about fifteen hundred very small reddish oval eggs, of which two thousand weigh five centigrams.

From the females is extracted about one-fourth of their weight of a dark yellow fat, with an odour *sui generis*; this fat is homogeneous when recently melted, but shortly afterwards presents grains of a light yellow colour. Applied upon paper it dries in six or seven hours, forming a smooth, shining, inodorous surface. Mixed with copal or other resin and oil of turpentine it forms a golden yellow drying varnish.

This fat melts at 36° C and again solidifies at 30° C. Heated at between 200° and 210° C to the consistence of a syrup it loses 8 per cent. of its weight, and no longer renders paper transparent. Upon cooling it forms a golden yellow, glutinous mass, in thin layers, which is much less siccative than the crude fat. If the heating at the same temperature be prolonged until the substance acquires a glutinous consistence, it forms upon cooling a soft elastic mass (niin caoutchouc) nearly insoluble in oil of turpentine, perfectly soluble in carbon bisulphide. When the fat is heated with 6 per cent. of litharge it forms at first a deep yellow lather, which passes to a dirty yellow. Removed from the fire, when the froth subsides a yellow consistent glutinous mass is obtained, more siccative than the boiled fat, but less so than the crude.

The crude fat is soluble in 0·5 part of carbon bisulphide, 1 part of rectified sulphuric ether, and two parts by weight of oil of turpentine at 26° C. In the first two liquids solution takes place in an hour and a quarter, in the latter it requires two hours. Upon decrease of the temperature two or three degrees, light yellow particles are deposited. Alcohol of sp. gr. ·809 dissolves it slightly at ordinary temperatures, acquiring its colour and odour. 500 grams of alcohol dissolved at the boiling temperature, 3·06 grams of the fat, and deposited upon cooling yellowish white flocks, which when dried were reduced to a light yellow powder, insoluble in solvents of fats and soluble in a 10 per cent. solution of potash. The alcohol, however retains a very light yellow colour, and upon evaporation leaves a dark coloured slightly glutinous fat, which is not siccative.

Combined with caustic soda this fat forms a dirty yellow rather soluble soft soap, with a disagreeable odour;

* Abstract of paper in *L'Union Pharmaceutique*, vol. xv., p. 24.

upon exposure to the air this becomes reddish brown and then brown. Treated with hydrochloric acid this soap forms fatty acids, which, heated with water to wash them, change into a yellow, dry, friable substance nearly insoluble in ether and carbon bisulphide, and soluble in ten per cent. solution of caustic soda. Upon heating the fat with an equal weight of nitric acid, diluted with four parts of water, it gives in half an hour, without disengagement of nitrous vapours, a friable spongy mass, reddish brown on the exterior and yellow in the interior, which is soluble in ten per cent. solution of caustic soda.

These properties prove that this fat has a chemical constitution differing from that of any hitherto studied. Like the drying oils it forms a glutinous substance by the action of heat; but this preparation is required to render them more siccative, whilst the niin fat on the contrary loses that quality upon heating. The elastic substance of other oils is soluble in ether and oil of turpentine; that of niin fat is nearly insoluble in those substances. All other fats absorb oxygen from the air uniformly throughout their mass: those which are siccative consolidate and become diaphanous; those that are not turn rancid and lose their colour. Some niin fat which the author has preserved during twelve years presents now the same characters as formerly. It has neither acquired consistence or become rancid, the pellicle which has formed upon the surface having preserved it from further oxidation. In some parts of Yucatan niin fat is mixed with chalk and colouring matter and used as a paint for wood, which paint has been found very durable. The guitar makers also use this fat to varnish their instruments. It has not yet however received any application in pharmacy. It is thought probable that the former inhabitants of the Island used niin fat in the painting of their dwellings, and some of the decorations on the ruins remain after three centuries in a good state of preservation.

PROTECTION OF HYPODERMIC SOLUTIONS FROM CHANGE BY KEEPING.*

By Dr. Squibb.

It is supposed to be established by the investigations of Dr. Bourdon, M. Delpech, M. Gubler, and M. C. Paul, that the growth of confervæ is the only cause of the changes which commonly occur in solutions of the organic alkaloids and their salts; and that these confervæ decompose the alkaloids and consume a portion of their constituents, so that the solutions become weaker as the growths increase. Various methods have been proposed and used to prevent these growths, but thus far none seem more simple or more effectual than the addition of one or other of the phenols; and the crystallized carbolic acid is perhaps the most convenient if not the best of these. This carbolic acid being an irritant in proportion to quantity, and it being very important that solutions for hypodermic use should be as unirritating as possible, it becomes of some consequence to know how little of the protecting agent can be used with average success. The experience of several years in my laboratory, has shown that one volume of a five per cent. solution of crystallized carbolic acid in sixty-four volumes of a solution of sulphate of atropia of the strength of two grains in each fluid ounce, will generally, but not always, protect it from change. The carbolic acid here bears the proportion of about one-thirteenth of one per cent., and this proportion proves quite unobjectionable for the delicate purposes of eye surgery. But once or twice in an experience of about six years, it has proved ineffectual for protection.

In the endeavour to answer this query with accuracy, the first result reached was, that accidental circumstances from unknown causes sometimes prevent the growth of these confervæ in solutions not protected at all; and also admit of their presence in and absence from different bottles of the same solution, without discoverable relation to the proportion of the protecting agency. A series of solutions, prepared with care in August, 1872, some unprotected, and others with various proportions of carbolic acid, stood until May, 1873, many of them remaining without growths of any kind, while those which produced confervæ did so without discoverable relation to the protecting agency. Supposing that the atmosphere of a laboratory might be the cause of these confusing results, fresh solutions of acetate of morphia and sulphate of atropia were made; the former salt having proved to be the most easily attacked and the most rapidly changed. The bottles containing these solutions were placed for one week with stoppers out, in a hospital where such solutions were very liable to change. The solutions were then distributed into small vials, some without protection and others with various proportions of carbolic acid. These vials were observed every week during the months of May, June, and July, until they ceased to show any farther changes. One vial of the solution of sulphate of atropia which was entirely unprotected, failed, from first to last, to show any signs of change. Two vials of sulphate of atropia solution, and one vial of a pair of acetate of morphia solution, all protected with small quantities of carbolic acid, also failed to show distinct evidence of confervæ. But with these exceptions, the entire number of twelve pairs exhibited a diminution of confervoid growths, in proportion to the quantity of carbolic acid added; until the proportion of carbolic acid reached, in the solution of sulphate of atropia, about one-eighth of one per cent., and in the solution of acetate of morphia about one-seventh of one per cent., all with larger proportions remaining clear and unchanged. Hence it appears that solutions of some salts, though of the same strength, require more carbolic acid for protection; but the proportion which under ordinary circumstances will protect the most difficult ones of those tried, does not exceed about one-seventh of one per cent.

But these solutions were all made with distilled water, and with more than ordinary care, and were all filtered. When similar solutions were made with ordinary undistilled water, nearly double the quantity of carbolic acid was required to afford a doubtful protection. Hence these solutions should, under all circumstances, be made with distilled water, and be carefully filtered.

The query may then be answered as follows: When such solutions are properly made, the smallest proportion of carbolic acid which will protect them from change, is about one-seventh of one per cent.; but that a proportion of one-sixth of one per cent. is practically better and safer in ordinary practice; and that this latter proportion is unobjectionable in all known respects. To make these solutions with this proportion, the following formulas are suggested. First, to make a five per cent. solution of carbolic acid, which is useful for this and many other purposes:

Take of crystallized carbolic acid 10 parts, or 10 grammes, or, 54 grains; distilled water 200 parts, or 200 grammes, or 3086 grains. Weigh the distilled water in a glass-stoppered bottle, capable of holding one-fourth more than the sum of the quantities. Melt the crystallized carbolic acid in the stock bottle by setting this in water warmed to about 50°C.=122°F., and weigh the quantity by pouring it carefully into the bottle containing the water, as it sits upon the scale. Then shake the whole together until the carbolic acid is dissolved, and filter the solution through paper. Label it, "Solution of Carbolic Acid, five per cent."

Of this solution, about fifteen minims in each fluid ounce gives a proportion of one-sixth of one per cent.

For solution of sulphate of morphia, of the strength called "Magendie's Solution:"

Take of sulphate of morphia, solution of carbolic acid, 5 per cent., of each two parts, or 2 grammes, or 31 grains; distilled water, a sufficient quantity. Dissolve the sul-

* Read before the American Pharmaceutical Association, September, 1873.

phate of morphia in about 50 parts, or 50 grammes, or 775 grains, of distilled water ; add the solution of earbolie aeid, filter through paper, and pass distilled water through the filter, until the filtrate weighs 57 parts, or 57 grammes, or 883 grains. Label, "Solution of Sulphate of Morphia ; Magendie's ; about 3·51 per cent., or 16 grains in the fluid ounce."*

POISONING BY VANILLA-ICE.

BY DR. L. ROSENTHAL.†

I come before you with the open confession that, in spite of all the trouble I have taken, I have not sueeeeded in solving the problem of poisoning by vanilla-ice. Thc chemical investigations earried on under my direction, by order of the president of poliee, by Dr. Sehädler, have shown that the hitherto most current and plausible hypothesis—that the poisoning is to be attributed to eardol —is untenable ; but experiments whieh I have made in eonjunetion with that gentleman on rabbits and cats, have had a negative result. We fed the animals with decoetions both of the pod and of the pulp of vanilla ; we repeatedly administered to them vanilla-ice obtained from the Vienna *café* : in all eases, the animals subjected to experiment remained healthy, and showed no condition varying from the normal state.

In my opinion, poisoning by vanilla-iee is not so very rare as is generally assumed, espeeially when we consider that vanilla-iee is not one of the articles of food in every day use. Cases of poisoning of this kind were, within my knowledge, first observed and deseribed by Orfila, in Paris, more than twenty years ago ; and in that eity eases of poisoning by ices have repeatedly eome under notiee from time to time. Similar observations have been made, in some other plaees on several occasions—in Vienna, in Munieh, in Leipzig, in Ameins, in Erlangen, Altona, and Bergen. In Berlin, also, cases of poisoning by vanilla-ice have occurred more than once.

All these eases of poisoning have this peculiarity, that they always have one starting point ; all, or, I will say, nearly all the persons, who at a eertain time eat vanilla-iee in a eertain *café*, become ill ; while other persons in another place eat the iee with impunity. Here in Berlin, in the last days of August, 1873, an endemie of this kind prevailed ; all the persons, who at that time ate vanilla-iee in the Vienna *café*, suffered from more or less severe symptoms.

During the night of August 26 27, I was ealled to a family, in whieh I was attending one of the daughters in the last stage of phthisis ; I had visited on the evening of the 26th. With the exeeption of the eonsumptive patient, all the family, consisting of the father, mother, and two other daughters, were in perfectly good health. The messenger told me, that nearly the whole family had eholera. Even though, as you know, cholera was prevalent here at the time, the simultaneous and sudden attack of the whole of the members of a family was rather extraordinary ; and the next idea that oeeurred to me was, that it was a ease of poisoning. On inquiry, I was informed that the patients had eaten ices in the *café* in the evening. As, so far as we know, it is only vanilla-ice that eauses poisoning, I made inquiries as to whether they had taken vanilla-ice, and found they had done so.

The mother and one of the daughters had eaeh eaten a portion of vanilla-iee about 10 p.m. They had taken a third portion home, and had divided it into two equal parts. Of one of these the father ate two teaspoonfuls, and gave the remainder to his eonsumptive daughter ; the third daughter ate the other half ; and a little old dog lieked the one plate that was used. All the members of the family, ineluding the dog, were taken ill during the night. At 11 p.m. the eldest daughter began to vomit, and violent diarrhœa soon afterwards set in ; half an hour later, the same symptoms showed themselves in the mother, and the remaining members of the family followed. It is to be observed, that only the two healthy daughters slept together in the same room ; all the other patients had separate bedehambers. On the whole, the severity of the symptoms was in proportion to the quantity of the ice taken ; so that the mother and eldest daughter suffered most ; the father least. He had vomiting and diarrhœa twiee only ; then followed the phthisical daughter, and finally the third daughter and the mother. As no notice was taken of the dog during the night, I cannot say when the symptoms of the disease began in it ; but the next morning we found the room extensively soiled with vomited matters and fæees, and the symptoms continued through the whole of the next day.

I return now to the human subjects. The symptoms in the mother and one of the daughters were so violent that they nearly eompletely assumed the form of cholera. Vomiting followed vomiting, stool followed stool. To these were added violent cramps in the calves of the legs, eoldness of the extremities, lividity of the limbs and of the face, and the pulse eould hardly be felt. Under these cireumstanees, I am not surprised that other colleagues, who had not the opportunity of observing these cases of illness in the greater number of members of a family at the same time, have diagnosed the disease to be cholera or eholerine. I will, however, remark that both those who were most severely attaeked had violent gastralgic and enteralgie symptoms, and that the pupils (as also in the other cases whieh I have observed) were moderately dilated, and were slow in responding to the stimulus of light.

The prognosis, from the observations already made, was favourable ; for, hitherto, no ease of death from poisoning by vanilla-ice has eome to our knowledge.

In the same night, several quite similar cases occurred. I will here briefly relate those whieh have come to my knowledge. Herr Güterboek, senior, was kind enough to send me one of his patients after recovery. He and his wife had suffered from the same symptoms as have been deseribed above. It is remarkable, however, that this gentleman suffered for some time from a painful sensation as of burning, in the mouth and throat. In these parts, a number of red and inflamed spots were seen on the third day ; and, at the time, I was inclined to attribute them to the action of eardol, which, aecording to Sehroff, aets even more energetically than eantharidin. This observation in the meantime stands alone ; in the other cases I observed nothing of the kind.

Three other cases were observed on the same night by Herr Riedel, in a family which had eaten vanilla-iee. As, however, Herr Riedel deelared the patients to be suffering from eholera, and at the present day asserts that this was the disease, I will make no further eomment on his cases. The patients reeovered.

A day later another case eame under my observation. The patient had eaten some iee about 2 p.m., after his dinner at 5 o'eloek he was taken ill, but reeovered the next morning. Finally, two other eases came to me in the night of September 1st and 2nd.

Similar cases were eommunieated to me by Messrs. B. Fränkel, Steinauer, Danziger, O. Simon (who himself was poisoned), J. Meyer, Citron, and Oppenheim. Besides these, I have heard of a number of cases through the publie ; among them I will mention a family in the Chausseestrasse, of whieh all the eight members were taken ill in one night.

(*To be continued.*)

* The original "Magendie's Solution," as given in the 'Officine' of Dorvault, p. 242, is, 1 part acetate of morphia in 40 parts water, or about 16 grains in 640 grains of water. As used in the United States, however, it is made from either aeetate, muriate, or sulphate of morphia, and in the proportion of 1 part in about 28½ parts water, or 16 grains in a fluid ounce (of 455 grains) of water.

PHARMACY IN IRELAND.

THROUGH the courtesy of the Registrar of the King and Queen's College of Physicians in Ireland, we have been favoured with a copy of a draft Bill to Amend the Practice of Pharmacy in Ireland, and for the information of our readers, we publish this bill at page 747.

The means by which it is proposed to assimilate the position of the pharmacist in Ireland to that which he has in Great Britain are very simple, and the effect of them would be to extend the operation of our Pharmacy Act to Ireland. This is what has been suggested very frequently by several of our correspondents; and it seems to be a course, desirable not only on account of its simplicity, but also by reason of the admitted need there is in Ireland for compounders of medicine who are not necessarily medical men.

We are not at present aware what may be the attitude the Irish Apothecaries' Hall will assume in regard to this proposed bill; but from what has been reported lately in our columns, it may be inferred that body will not be altogether adverse to it. It is also worth mentioning that on the occasion of an interview with the Chief Secretary for Ireland last January, the Secretary of the Apothecaries' Hall stated of his own knowledge that there were some 28 or 30 important market towns in Ireland, with populations varying from 10,000 to 50,000, where there was no apothecary or other person competent to compound medicine. In fact the want of chemists and druggists' shops throughout the whole of Ireland is generally known to be a matter causing serious inconvenience.

According to the present state of the law in Ireland, the compounding of prescriptions and the sale of medicines are part of the art and mystery of the apothecary, and there is a penal clause in the Apothecaries' Act—31 GEO. III., cap. 34, clause 26—providing that if any person shall open shop or wareroom for the retail of medicine "within the kingdom of Ireland, without having obtained the proper certificate for that purpose, such person shall for every such offence forfeit the sum of twenty pounds." Under this clause frequent prosecutions have been instituted from time to time.

In order to obtain the requisite license to dispense prescriptions, it is necessary to spend four years in professional study, as follows:—

Chemistry, one Winter Session.
Anatomy and Physiology, two Winter Sessions.
Demonstrations and Dissections, two Winter Sessions.
Botany and Natural History, one Summer Session.
Materia Medica and Pharmacy, with instruction in a Laboratory, three months.
Practical Chemistry, three months.
Principles and Practice of Medicine, one Winter Session.
Midwifery, and Diseases of Women and Children, six months.
Practical Midwifery at a Recognized Hospital, with attendance on twenty cases.
Surgery, one Winter Session.
Forensic Medicine, one Winter Session.
Instruction in Practice of Vaccination, and attendance on a recognized Medico-Chirurgical Hospital for two years.

Such a protracted and expensive course of instruction is admitted to be totally unnecessary to qualify persons for compounding medicine, besides being beyond the means of those who would be disposed to open shop as chemists and druggists.

The dearth of such shops now felt in Ireland did not exist formerly, because the Apothecaries' Hall only required qualifications similar to those demanded by the Pharmaceutical Society of Great Britain.

The attempt now being made to establish reciprocity of rights between Great Britain and Ireland in regard to the practice of Pharmacy, similar to those enjoyed in Medicine, will doubtless call forth entire sympathy on the part of the Pharmaceutical Society. However, we imagine it will be necessary to have some more precise definition of the qualification for obtaining the licence of the Apothecaries' Hall of Ireland, by means of which it is, we observe, provided in the third section of the draft Bill that persons possessing that licence shall be qualified to keep open shop for the compounding of prescriptions in Great Britain as well as in Ireland. This will be necessary, because the Apothecaries' Hall, the Irish examining and licensing body, seems to possess considerable powers in regard to the examination standard. In establishing any such system of reciprocity as that contemplated, it will, of course, be desirable that it should be in every sense thorough, and that the practice as well as the aim of the several examining bodies shall be harmonious and consistent, so as to afford reasonable protection to competent educated pharmacists and due security to the public. Within these limits we heartily wish success to the Irish Pharmacy Bill, and are very glad to see that the introduction of the measure into Parliament has been taken in hand by so influential a body as the College of Physicians in Ireland.

THE CAMBRIDGE LOCAL EXAMINATIONS.

THE sixteenth Report of the Syndicate on the Local Examinations held in connection with Cambridge University, which has been recently issued, necessarily contains much that is interesting to the majority of our readers; for the subject-matter is the comparative success or failure of the directors of our middle-class schools to impart an education to

the scholars, based upon a clear apprehension of principles, such as shall enable them to apply advantageously in the battle of life the knowledge acquired. Every movement that appears likely to raise—whether by direct effort or by the exposure of faulty systems—the standard of the education obtained by those youths from amongst whom the present apprentices and future pharmacists must be drawn, is valued by the Pharmaceutical Society, not only as beneficial to the interests of its individual members but also as conducive to the attainment of the more general object for which the Society was established.

The total number of candidates last year was 3550, of whom 2481 were boys (2020 junior and 461 senior) and 1069 girls (668 junior and 401 senior). This was a larger number than presented themselves in any previous year, the total in 1872 having been 3075.

One very notable feature in these figures is the remarkable disproportion between the number of junior and senior boys, especially when compared with the proportion of junior to senior girls. The most obvious explanation of this disparity is that a much greater number of boys than of girls are withdrawn from school whilst yet very imperfectly educated.

Of the reports on subjects included in the Society's Preliminary Examination, that on English grammar speaks favourably of the senior candidates, but unfavourably of the junior; the parsing by the latter having been incompletely done at many centres, and the mistakes surprisingly bad. In the English subject (Richard II.) the boys showed signs of "unintelligent teaching," taking "much pains to evade giving direct answers on the one hand, and on the other to quote passages from the notes which they clearly did not understand. Their phonetic spelling of uncommon words seemed to show that they were writing them down for the first time, after many mechanical repetitions of them."

In Latin there appears to have been some improvement upon the work of former years, the translation of an English passage into Latin excepted. Here again, however, signs of "unintelligent labour" are noted; for, whilst the translations of a previously announced passage from Livy were carefully done, and evidently were the result of considerable pains in preparation, those of an unprepared passage were in the majority of cases signal failures, apparently because the pupils "had not been taught to think out translations for themselves." Moreover, the contrast between the former translations and the ignorance displayed in syntax and accidence is described as very remarkable. It is curious to observe that in both the preceding subjects the girls fully sustained the reputation of their sex for a more facile manipulation of language.

On the other hand, in arithmetic, whilst much of the work done was satisfactory, the percentage of failures was nevertheless high, and was considerably higher among the girls than the boys. This, it has been suggested, arises from arithmetic requiring a more sustained attention; but it may be attributed with at least equal justice to the "laborious and faulty methods" which some of the girls had been taught to use.

Notwithstanding that the teaching of science has, during the last few years, taken a much higher position in many schools, it cannot yet be said to be satisfactory, so far as it may be judged by the aid of the evidence in the present Report. Several candidates presented themselves for examination in Chemistry, Heat, etc., who seemed "almost absolutely ignorant of the subject;" and although the answers sent up by most of the others showed a fair knowledge of elementary facts, the questions on general principles were seldom successfully answered either by seniors or juniors. In Physics, all except three showed comparatively little grasp or range of knowledge. The results of the examination in Botany, also, illustrated a similar evil; in some cases a considerable knowledge of facts was evinced, but there was a marked deficiency in the answers to those questions which required thought rather than memory; and the almost universal failure of the attempts to describe plants from actual specimens, seemed to show that this part of the subject had scarcely been taught at all.

It would be difficult to attach too great importance to documents such as that under notice. Not only are they valuable to schoolmasters and parents, but they are pregnant with teaching to every student. In the present day, with its examination tests and its multitude of teachers and chaos of text books devoted to the express purpose of overcoming or sometimes evading those tests, there is danger that the student may place Captain Cuttle's advice to "make a note" of everything above the time-honoured injunction to "read, mark, learn, and inwardly digest." But the foregoing extracts afford fresh testimony to the truth that true education consists, not in the acquirement of a knowledge of certain facts to meet a special emergency, but in such a clear apprehension of the principles that everywhere underlie those facts, that the student, after having passed his examination, may be enabled to utilize and extend his knowledge by applying it to the varying needs of everyday life.

THE ADDITIONS TO THE BRITISH PHARMACOPŒIA.

As some of our readers may be apprehensive that the mistake in issuing the 'Additions to the Pharmacopœia,' which Mr. Bottle alluded to at the last Evening Meeting of the Pharmaceutical Society, may apply to other copies besides that which he had purchased, we may state, as the result of inquiries which have been made, that there was only one uncorrected sheet that could have got among those prepared for publication, and that must have been the one that fell into the hands of Mr. Bottle. It appears that twenty-five copies of the 'Additions,' in the form in

which they existed in 1873, were printed for the use of the members of the Medical Council, and that twenty-four of them were sent out for the purpose of eliciting further suggestions. The one remaining sheet, which was not so used, must have got mixed with those that were finally published after the suggested alterations had been made.

THE PHARMACY OF THE PHARMACOPŒIA.

It is satisfactory to find that the desirability of securing the services of practical pharmacists in the work of supplementing or amending our Pharmacopœia is recognised by a medical journal so fully as in the following quotation from the *British Medical Journal* in reference to the paper read at the late meeting of the Pharmaceutical Society—

"Many of the objections urged by Mr. Umney, seem to indicate the necessity of giving greater prominence to the element of practical pharmacy in the Pharmacopœia Committee of the Medical Council. This has long been done in other countries, and the adoption of such a course would certainly be advantageous here; for, though it is true that the decision as to the medicines to be comprised in the *Pharmacopœia* must always remain with those who have to prescribe their use, still questions as to the best means of preparing them for various purposes call greatly for the aid of the practical pharmacist, who, being daily occupied in such work, is enabled to bring to bear the results of his experience, so as to advantageously promote the objects of the physican. If this were properly done, we should then, perhaps, hear less of complaints that officinal formulæ were inferior to other methods of preparation. The material services which Professor Redwood has already rendered in this direction may, perhaps, not without advantage, be supplemented by the aid of other pharmacists."

SPIRITUS ÆTHERIS NITROSI.

We have on more than one occasion endeavoured, without success, to induce our contemporary, the *Practitioner*, to take up the inquiry into the causes which give rise to the sale of inferior qualities of pharmaceutical preparations, and now a medical correspondent, Mr. H. Maturin, of Hartley Row, Hants, writes to that journal as follows:—

"In the last number of the *Practitioner* you give an analysis of Sp. Eth. Nit. B. P. purchased from a famous wholesale establishment, and it appears that the preparation was anything but the Sp. Eth. Nitros. of the Pharmacopœia.

"I believe you would be doing the profession a good service if you would procure (from some of the wholesale druggists that chiefly supply general practitioners) and make an analysis of some of the B. P. preparations that are in the habit of being most frequently prescribed, and after doing so give the results of the experiments in the *Practitioner*, with the names of the druggists from whom the preparations were purchased, and the results of analysis. The practitioner in the country has no means of accurately verifying whether the drugs he purchases and prescribes are or are not such as they are represented to be, but has to accept everything for the most part in faith. The daily increasing desire for accurate therapeutical knowledge makes the question the more important."

We would also suggest that the *Practitioner* should obtain and publish statistics to show in what degree "practitioners in the country" promote the demand for B. P. preparations.

Only a few weeks since we had occasion to condemn the intemperate zeal with which the editor of the *Practitioner* dealt with this subject; it then became our duty to show that his statements were unfounded, his opinions incorrect, and his arguments illogical. Our worthy contemporary has not, however, received punishment with that humble fortitude which would have suited the circumstances of the case, but has responded to our criticism in a manner which can be illustrated only by allowing him to speak for himself, which he does as follows:—

[We are glad to observe that the vulgar abuse which was heaped upon us in a leading article of our hitherto decently conducted contemporary, the *Pharmaceutical Journal*, on account of our remarks on this subject in the February *Practitioner*, has not prevented sensible men from heeding our words. A letter from a druggist, in the very next number of the *Pharmaceutical Journal* to that which contained the explosion of editorial spite against us, simply and candidly took up a position which justifies our whole criticism. We are fortunately saved from any necessity of replying to the arguments of the *Pharmaceutical Journal* by the remarkable *exposé* which its editor gave of his own degree of qualification as a pharmaceutical critic. He supposes — it is impossible to imagine why—that officinal sp. eth. nitrosi should contain 10 per cent. of real nitrous ether. The fact is that it must contain about 3 per cent., in order that 2 per cent. may be separable by the Pharmacopœial test. After that, it does not seem worth while to trouble our readers any further about the editorial opinions of our contemporary.—Ed. *Pract.*]

With this quotation we leave our readers to judge who has most claim to the attributes of vulgarity and ignorance.

MEDICINE CHESTS FOR FISHING SMACKS.

Messrs. Dakin of Cree Church Lane have recently made and fitted up, under the direction of Mr. Henry Leach, Medical Officer of Health for the Port of London, a very simple medicine chest, containing only about a dozen drugs, and a few simple surgical appliances. It is intended solely for use in fishing smacks, and the measurements are so arranged that it can be stowed under the berth of the aft cabin, or in any other equally convenient corner. Although smacks are not compelled by law to carry medicine chests, it is expected that this practical idea will receive official attention and recommendation, and that some such chest with the "Ship Guide" will be put on board most of the good class smacks at Hull, Grimsby, Greenwich, Lowestoft, etc. Fishing boats of all classes form no inconsiderable item in our mercantile marine navy, for the last official return indicated no less than 40,446 boats of all classes, and 163,000 fishermen and boys on the list of the Registrar General of shipping and seamen.

THE DINNER AT THE CRYSTAL PALACE.

We are glad to be able to state that a considerable number of gentlemen have already expressed their wish to fill the office of steward on the occasion of the next annual dinner of the Members of the Pharmaceutical Society and their friends, which is to take place on the 19th of May. As it is desirable that a list of the stewards as complete as possible should be published next week, other gentlemen who wish to have their names included, are requested to communicate at once with the Secretaries, Mr. R. Bremridge and Mr. M. Carteighe, 17, Bloomsbury Square.

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

April 10th, 1874.

Present :—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Taylor, and Umney.

MODIFIED EXAMINATION.

Thirty-four candidates were examined. *Fifteen* failed. The following *nineteen* passed, and were declared duly qualified to be registered as Chemists and Druggists :—

Appleyard, William ....Hunslet.
Clarkson, Thomas.....Kingston-on-Thames.
Collins, Edward de Tedney.....Brighton.
Driver, John George .....Liverpool.
Ellis, Frederick..... .....Seacombe.
Evans, David Powell .....Knighton.
Harrison, William Dale ...Richmond, near Sheffield.
Horner, Robson.....Alne, Yorks.
Hughes, James .....Birmingham.
James, James Thomas ....Chelsea.
Kirk, Snowden ....Poplar.
Leman, Edmund .....Bath.
Lindley, Henry.....Liverpool.
Lowther, Maslyn Kelsey.....Leeds.
Munn, Charles .....Worcester.
Patten, William Henry .....Islington.
Streater, James Hobbs.....Sloane Street, S.W.
Williams, George .....Maidstone.
Wordsworth, Hewley Charles...Kensington.

PRELIMINARY EXAMINATION.

Certificates, as undermentioned, were received in lieu of the Society's examination :—

Certificates of the University of Oxford.

Alldridge, William Edward ...Birmingham.
Lawrence, George Richard .....Boston.

Certificate of the University of Cambridge.

Allwood, William Henry.....Wellington, Salop.

Certificates of the College of Preceptors.

Knights, George Ekins .....Ashby-de-la-Zouch.
Wilson, Griffith Phillips ....Merthyr.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.—Session 1873-74.

The last general meeting for the present session was held in Anderson's University on April 1st, Mr. John Currie, President, in the chair.

The minutes of previous meeting having been read, the chairman thought that it would be advisable to defer the discussion of the same till further on in the evening. He then called upon Dr. Fergus to deliver his lecture on "Pure Air and Water."

The lecture, which was experimentally illustrated, proved to be very interesting, and was listened to with marked attention. At the close, the lecturer was accorded a most hearty vote of thanks.

Mr. J. McMillan then, in the name of Messrs. Calvert (Bradford), presented to the Association a number of chemical specimens, and the secretary was instructed to forward the best thanks of the Association to Messrs. Calvert for the same.

The members of the Library Committee who were present, then handed in the money collected by them, which amounted to £30 16*s.* 6*d.*, there being still three subscription sheets to be taken into account. It is thought that there will be a total of about £40.

Mr. J. M. Fairlie exhibited the new preparations of the Pharmacopœia.

HULL CHEMISTS' ASSOCIATION.

A report on the Chemistry and Materia Medica classes held during the session 1873-74, under the auspices of the Hull Chemists' Association, has been presented to that Society by the teacher, Mr. H. J. Parson. In this report Mr. Parson states that he has delivered 17 lectures on chemistry, 7 on materia medica, and 1 on pharmacy, at which the attendance and attention of the students has been good. The lectures on the first named subject have been illustrated by experiments as far as the limited resources have allowed, but now experience in this department has shown the necessity for increased means of practical study.

There has been a decrease in the number of students compared with last year. Though there are many young men in Hull and its neighbourhood who have not passed the examinations of the Pharmaceutical Society, only nine have taken advantage of this means of instruction. The cause Mr. Parson attributes principally to the number of apprentices who have not passed the Preliminary Examination. The examinations for prizes were held on the 11th and 18th of March, with the following results :—

Senior Chemistry . . . Mr. F. W. Lambert.
Junior Chemistry . . . „ Septimus Walgate.
Senior Materia Medica . „ F. W. Lambert.
Junior „ . „ Not awarded.

In the junior chemistry the competitors failed to obtain sufficient marks for the prize. Mr. Padley, however, one of the competitors, is recommended as deserving some reward.

Proceedings of Scientific Societies.

NEWCASTLE-UPON-TYNE CHEMICAL SOCIETY.

At the meeting of the above Society on the 26th February, a paper was read, of which the following is an abstract, on—

The Rate at which Bleaching Powder Loses its Available Chlorine.

BY J. PATTINSON.

In dealing commercially with an article of such vast importance as bleaching powder, unstable in its composition, and the value of which is determined by the amount of chlorine it contains in a condition available for bleaching purposes, the question naturally very often arises—"How much available chlorine does it lose in a given time?" The examination of a number of samples of bleaching powder, from time to time during about twelve months, was undertaken by the author with the view of making a contribution towards the solution of this question, and also to the further one, "Does weak bleaching powder, say containing about 32 per cent. of chlorine, retain its strength better than a stronger bleaching powder?"

The samples examined were made by what is now known as the old process, in which the chlorine is generated in the ordinary stone stills by the action of hydrochloric acid on native peroxide of manganese. Three sets of samples were obtained from different manufactories on the Tyne, each set consisting of three samples. It was intended that the three samples of each set should be taken from the same portion of lime—one when it contained about 33 per cent. of available chlorine, one when it contained about 35 per cent., and the third when it contained about 37 per cent.—and with this object the lime was placed in a box in the chlorine chamber, so that it could be easily removed in order to take out the samples at each stage. The samples obtained, although not exactly of the strengths wished, were perhaps sufficiently near for the required purpose. They were placed in glass bottles holding about half a pound, and kept in these, loosely corked, in a room where they were never

exposed to the direct rays of the sun. At first they were tested about once a week, afterwards once a fortnight, and ultimately once a month during the last six months.

The process used for testing was that known as Penot's process, in which an alkaline solution of arsenious acid, with iodized starch paper as indicator, is employed.

As might have been anticipated, the loss of chlorine was found to be greater in the warm summer months than in the winter months. The *average* loss of chlorine, taking the whole of the samples into account, was, during the three months ending April 24th, 0·33 per cent. per sample per month; during the three months ending Sept. 8th, 0·86 per cent. per month; and during the three months ending Feb. 3rd, 1874, 0·28 per cent. per month. The greatest loss in any one month was in the month ending Aug. 8th; the average loss for this month being 1·4 per cent. of chlorine, taking the whole of the samples into account.

The average loss of chlorine per month in each sample during the whole time was tested was 0·63 per cent.

The total loss of available chlorine in each sample from the 20th of January to the 8th of September, a period of about eight and a half months, during which all the samples were tested, ranged from 3·3 per cent. to 6·1 per cent.

With reference to the question as to the relative stability of weak and strong bleaching powder, the author states that there is practically no difference in the rate at which they lose available chlorine. The weak 28·7 per cent. bleaching powder loses its strength at about the same rate as the 37 per cent. samples.

Whether the loss of strength goes on in the same ratio in large masses in casks as in the comparatively small quantities placed in bottles; the effect of using lime containing various amounts of water of hydration; the influence of different temperatures in the chamber during the time chlorine is being absorbed; and various other conditions affecting the stability of bleaching powder; and whether the bleaching powder made by the Deacon process keeps better than that made by the old process, as is sometimes asserted, are points which the author suggests for further investigation.

SOCIETY OF ARTS.

Cocoa and its Manufacture.*

BY JOHN HOLM, F.R.C.S., EDINBURGH.

(*Continued from page* 806.)

The chemical composition of cocoa is shown in the table at the foot of this page, which gives the different analyses of any importance which have been made.

* Reprinted from the *Journal of the Society of Arts.*

It is a table which is not very flattering to chemical science, the analyses being of the most contradictory character and containing discrepancies which cannot be at all reconciled with each other. I should judge that the analysis prepared by Drs. Playfair and Lankester is the most correct, while those of Tuchen and Muter appear least so. We thus see that, taking the important constituents, cocoa contains :—

	Parts.
Cocoa butter	50
Albuminoid substances	20
Starch, sugar, etc.	13
Salts	4
Theobromine	2
Other constituents	11
	100

Taking these in the order of their importance, we first notice the fat, or cocoa butter, which forms about half the substance of the nibs. It is a hard, fatty substance which, when clarified, is of a dead white colour. Its melting point is about 100° Fah., which being the heat of the body renders it of great value for therapeutical purposes. The fat never becomes rancid, however long it may be kept, a quality peculiar to itself. It is hardly necessary to point out how valuable this quality renders this portion of the bean, for it places cocoa-butter first in the list of the fatty class of our carbonaceous or heat-giving foods. The albuminoid constituents form about twenty per cent. of the nib. These are classed amongst the nitrogenous principles of food, and their presence renders cocoa one of the richest flesh-formers we have. The starch, gum, and sugar present, like the cocoa butter, belong to the non-azotised principles; they form about 13 per cent. of the whole. The alkaloid of cocoa, *theobromine*, is very similar in its physiological effects to its analogues, *théine* and *caffeine*, from which it differs very slightly in chemical composition :—

Essential Alkaloid Principles.

Yielded by	Name,	Composition.	Proportion.
Cocoa	Theobromine	$C_7H_8N_4O_2$	2 per cent.
Coffee	Caffeine	All identical	1 to 5 per cent.
Tea	Théine		
Guarana	Guaranine	$C_8H_{10}N_4O_2$	
Maté	...		In less quantities

In regard to these alkaloids, it is interesting to note that throughout the world the instinct of man has led him to seek some substance which contains one of these prin-

ciples, which owe their value to the specific influence they exert on the nervous system, stimulating it and checking waste of tissue. *Theobromine*, when extracted, presents the form of a white crystalline powder of almost amorphous appearance, differing from *caffeine* and *theine*, which have a very beautiful crystalline appearance.

In most of the analyses of cocoa the existence of a volatile oil has been overlooked. It is probably present only in small quantities, and appears to be developed by roasting; but upon it depends the flavour and aroma which exist in cocoa.

Having thus noticed the principal component parts of cocoa, a comparison with other foods, as given in the following table, will be of interest as showing its relative value to them.

TABLE SHOWING THE RELATIVE COMPOSITIONS OF

	Cocoa.	Milk.	Meat (Beef).	Wheaten flour.

Parts	100·0	100·0	100·0	100·0

By this it is apparent that in nutritive power cocoa holds an entirely exceptional position. It combines in a high degree of concentration nearly all the elements necessary to man's existence. It is deficient in moisture, which renders it comparatively richer in both nitrogenous and non-nitrogenous elements than any of those with which it is compared. Thus, although one half of its weight consists of cocoa butter, it still presents 20 per cent. of albuminoid material, as against 4 per cent. in milk, 20·75 in beef, and 14·6 in wheat. In addition it contains starch, which is present neither in milk nor beef, but in smaller proportion than in wheat, of which it forms 59·7 per cent. Comparing cocoa with milk, we thus see the former is richer in the nitrogenous substances analogous to those contained in milk, and that the fat also exists in a considerably larger proportion. The same remark applies to beef, and it further contains valuable substances which they do not possess. In wheat, the starch appears to hold the place the butter takes in cocoa; otherwise their composition has great similarities, but cocoa has again the advantage of possessing qualities which the other has not. The value of cocoa as a food is thus apparent, and fully justifies the high eulogiums which have been passed upon it by so many men eminent in science. I have noticed the large amount of fat that cocoa contains, and its especial value on account of its non-liability to become rancid. Its presence, therefore, constitutes cocoa as essentially a heat-giving food, of which class it is certainly the most valuable; and its value as such is fully recognized by the instincts of the people who use it much more largely in cold than in warm weather. Drs. Miller and Letheby, amongst many other authorities, state that cocoa owes its chief value to its cocoa butter, and to this is undoubtedly due the benefit which consumptive patients derive from its use. But its possession also, in so rich a degree, of albuminoid substance, theobromine, and phosphatic salts, renders it almost equally valuable in other ways. Unlike tea and coffee, whose virtues can be extracted by infusion, and the non-soluble parts of which are useless as food, the whole substance of the cocoa-nib, if properly prepared, can be taken into the stomach, and all but an inappreciable amount digested. The object of the manufacturer should therefore be, to prepare the raw cocoa in such a manner that the whole of its valuable properties shall be preserved to the consumer; that it shall be easy of preparation, and of such a price as to be within the means of the bulk of the population for whom it is especially valuable, and far superior to tea or coffee. We will therefore proceed to consider how this end is best gained, and the modes of manufacture practised in this country, with their influence in causing the great increase which has taken place in the use of this food.

For many years after the introduction of raw cocoa into England, its manufacture was conducted in a very rude manner, no attempt being made to separate the husks of the cocoa nut from the nib. The mode of manufacture was to grind the whole bean with sugar and farinaceous substances. This was then either run into rude block and called rock cocoa, or cut into cakes or long rolls somewhat of appearance of short rulers, and sold under the name of the cake or roll cocoa. Gradually an advance was made in this rude method of manufacture, and in the preparation of what was called chocolate an endeavour was made to imitate the Spanish manufacturers. This led to the husks being carefully removed, and the ground nibs alone incorporated with sugar, or sugar and farina, in the manufacture of what was called chocolate. The mode adopted in the manufacture of chocolate was to roast the nuts, and when cool to break them down and separate the shell from the nibs. The nibs were then again subjected to futher roasting, and the extent to which this process was carried, then gave the distinctive character to the chocolates produced in different parts of Europe. The cocoa nibs were now placed upon a heated smooth stone, and crushed with a roller until the nibs assumed the form of a smooth paste, which was then mixed with sugar, and sometimes some farinaceous substance. Various spices were also now incorporated, according to the flavour desired, and the mass when thoroughly mixed was placed into moulds, where it remained until cool and ready to be turned out.

Another form of cocoa, called flake, was also much used, and this consisted only of the cocoa beans, shell, and nib, crushed in a mill into the form of flakes.

Notwithstanding the inherent value of the food, none of these productions, however, met with any great consumption. They were all expensive, but the finer cake chocolates were of so high a price as to be only obtainable by the wealthy. The cocoas besides being dear were also unpalatable, and owing to the presence of the husk, very indigestible and irritating to the internal mucous membranes. Both kinds, in addition, laboured under the disadvantage of requiring boiling.

This drawback, which is common to all cocoas and chocolates of foreign manufacture, does not appear in Spain and France to have militated against their large consumption; but for some reason or other—it may be that we do not as a nation like trouble where it can be avoided—the tedious and somewhat unpleasant process of first having to scrape and then boil the cake of chocolate, carefully stirring the while, and afterwards milling it, has never found favour, and this is one of the reasons that its use was so limited until the last fifty years.

The removal of this drawback is due to Mr. Daniel Dunn. After a long series of experiments in relation to the treatment of cocoa, he found that by making a slight variation in the mode of the preparation and mixture of the sugar with the cocoa nibs, he was able to produce a substance in the form of paste, which only required the addition of boiling water to be ready for use. This cocoa or chocolate paste was the first form of soluble cocoa ever made. From the first, he discarded, in his preparations, the barbarism of grinding up the husk with the cocoa nib, a practice both wasteful and unwholesome.

Having succeeded in producing, in the form of paste, a cocoa which did not need boiling, it was found that a serious drawback existed from the need of its being contained in earthenware pots or other vessels. These were not only inconvenient, but being expensive and heavy, they added both to the cost of production and transit. Mr. Dunn therefore further pursued his experiments,

and found that by varying his process so as to reduce the amount of moisture, he was enabled to bring the paste into a condition sufficiently hard to enable it to be cut; at the same time the soluble properties still being retained. The cakes had the disadvantage, however, of requiring to be scraped into the cup, a somewhat sticky process; and were also not very pleasing to the eye.

Mr. Dunn, still pursuing his investigations, found that by adding some farinaceous substance (he preferred and only used arrowroot), he could bring the cocoa into the form of a powder, which was more readily miscible even than his previous preparations. This form is the most convenient one in which cocoa can be prepared, and although from the price usually paid, we are accustomed to preparations somewhat inferior in flavour to the finer French chocolates, there is no difficulty in making a soluble cocoa or chocolate powder quite equal in quality to them. The mode of manufacture of soluble cocoa or chocolate powder is as follows: The raw nuts are first picked in order to remove any mouldy or damaged nuts, the presence of which would injure the flavour of the cocoa. The picked nuts are then placed in revolving heated cylinders. When sufficiently roasted—a process which takes from three-quarters of an hour to an hour and a half—they are either spread out thinly on a grating, or placed in coolers so constructed as to offer a large conducting surface, and are thus rapidly cooled down. The roasted nuts are then conveyed to a kibbling mill supplied with fans; the cocoa is here broken down and the shell winnowed from the nib. When this operation is fully effected, the nibs are slightly warmed before being ground.

A cocoa mill, constructed to reduce the nibs into a fine paste, consists of two parts, viz., the feed-mill and the grinding-mill. The object of the feed-mill is merely to regulate the supply of cocoa sent into the grinding-mill. The latter is not unlike a flour-mill, consisting of a horizontal bed, on which revolves a runner. These mills have to be heated, and the cocoa runs from them in a smooth, semi-liquid condition, when it is ready for incorporation with the sugar and farinaceous substances with which it is to be mixed. It is afterwards reduced to a powder. This powder may be made either fine or coarse, it being a question of merely manipulative process, which has no relation to quality. If required very fine, it may have to be more completely pulverized in another mill. But whether coarse in grain or fine matters not; the cocoa is the same in quality. That is, either fine or common preparations may have either appearance. With slight variations of process, this is the only way in which soluble cocoa powder can be produced; that is, it must contain sugar and farina. The cocoa being in the first place very finely ground, the sugar causes it to mix readily, while the farinaceous substance holds the particles of cocoa in suspension, and the whole forms an emulsion.

This mechanical suspension renders the particles of cocoa more digestible, and keeping the globules of cocoa-butter in a finely-divided condition, they also are more readily assimilated. Thus the farina, in addition to its important office in aiding in the production of powder, has another distinct advantage. It really causes the cocoa-butter to be in a similar condition as regards the cup of cocoa that the fat globules of milk are in before rising to the surface as cream. And it does not need any deep physiological knowledge to know that we can take in milk a considerable quantity of these fat globules without inconvenience, whereas the same amount taken in the more concentrated form of cream, would produce indigestion and biliousness. Some chemists have denied that this effect is produced in cocoa by the addition of farina; but by practical experiment I can vouch for the fact. The reason they have fallen into this error is by looking at the subject only from the chemist's view, and not from that of the practical physiologist, and assuming that such a result could only arise from a definite chemical action produced by the farina on the fat. This is not so; there is probably no such action; but by separating the particles of fat, that is forming an emulsion, they are presented to the stomach in a form in which they can be readily assimilated.

As I have before said, soluble cocoa powder is of necessity a compound substance, and should consist only of cocoa, farina, and sugar. Unhappily, excessive competition, and the desire on the part of the public to obtain greater value for their money than is possible to be given, has caused several forms of adulteration to be practised in cocoa manufacture. The more harmless of these is the addition of animal fat to cover the use of a poor cocoa, and to enable the addition of an excessive quantity of sugar and farina; but, unfortunately, as one sin often leads to many, the result thus obtained requires further "doctoring" to render it acceptable to the public taste.

Cocoa, thus adulterated, would be poor in flavour and light in colour, and therefore the adulterating manufacturer must add something, which, while cheap, will impart a flavour which, under much disguise, may be mistaken for cocoa. With this view chicory is added, and this is the most harmless of the adulterants used for this purpose of disguise. It is, however, a fraud, as the only object of its addition is to impart a flavour which shall be mistaken by the consumer for that of cocoa, which he will imagine present in larger quantities. *Terra japonica*, or catechu, as well as other substances, has been used to produce the same effect. Curiously enough, these adulterations appear to have baffled the analytical chemists, and this probably because of their addition in the form of concentrated decoctions. We have thus got a cocoa adulterated with foreign fat and chicory, and other flavouring substances, but we have not yet reached the end of these additions. The cocoa now, although seemingly rich in butter and of strong flavour, is not yet sufficiently pleasing to the eye, and therefore the adulterator adds some mineral colouring substances, the most harmless in use being perhaps peroxide of iron. But there are others, amongst which figure such abominations as red-lead and cinnabar, or sulphide of mercury. But for the credit's sake of even our dishonest countrymen we must hope such fiendish modes of adulteration as those just mentioned are no longer practised.

I have thus sketched the mode of manufacture of soluble cocoa powder, and have glanced at some of the frauds practised in its manufacture. As I have already stated, soluble cocoa powder can only be obtained by the addition of certain substances to the cocoa. But the cocoa nib can be flaked or ground into a coarse powder by itself, or, a portion of the fat being extracted, it can then be reduced to a fine powder. This mode of preparation is practised in what are improperly called the pure cocoa powders, but these cannot be regarded as cocoa pure and simple any more than can these prepared with farina and sugar. In them a larger quantity of the most valuable portion of the substance of the cocoa bean is abstracted, and it is, indeed, thus rendered analogous to skim-milk. Now, skimmed cocoa, like skimmed milk, is very good in its way, and when it is required, as it is in some diseases; but as the principal object in most cases in drinking cocoa is, or should be, the consumption of all the good qualities of this valuable bean, the unnecessary abstraction of the fat is greatly to be deprecated. The mode in which these powders are prepared is by subjecting the ground nibs, which are usually placed in bags, to strong pressure, the press being heated. The cocoa-butter then slowly runs off in the form of oil, which quickly solidifies on cooling, and a hard mass is left in the press. This is afterwards broken up and powdered in mills, and after being dressed is ready for use. Unfortunately, this form of cocoa powder is as liable to adulteration as are the mixed ones, and one of these, which has at the present time a great reputation, contains ash greatly in excess of what would be yielded by pure cocoa so prepared, and thus points unmistakably to the use of some adulterant.

These powders also have the disadvantage of being very expensive, ranging from 2*s.* 8*d.* to 6*s.* the pound, while soluble cocoa powders range from 6*d.* to 1*s.* 8*d.* They are, further, not so miscible in boiling water, but require further boiling, and even then the particles sink to the bottom of the cup, and are thus wasted.

This objection also applies, but in a greater degree, to the use of flaked cocoa, and plain and ground nibs. However much these forms are boiled, but little substance is really dissolved, and the gluten is especially lost. When we also consider that in the cocoa made from the nibs or flaked cocoa, the fat is generally carefully skimmed off, and the residue or grounds are thrown away, we must see how sinful a waste is made of this food when used in such a manner. This is apparent when we remember that with the exception of about 5 per cent., the whole substance of the nib is valuable as food, and when properly prepared, digestible as such. In the beverages made in the way I have described, the nutritive value derived is reduced to its minimum, and is but slightly greater than could be obtained by an infusion of the shells, which contain a small proportion of theobromine, and can be obtained for 2*d.* per pound. I may here mention that these shells are largely used in Ireland for the purpose of calf feeding, and also by the poorer people. They make an infusion with them, which is not inappropriately called "miserable." There are a few persons who use even nibs and flaked cocoa, and perseveringly consume the whole substance of the nib or bean, as the case may be; but they very speedily have to give up the use of cocoa from the dyspepsia which results from taking it in so rich a form. A glance at the composition of cocoa will fully explain this fact, from the highly concentrated form of nourishment it presents.

The present mode of making French chocolate in cakes differs somewhat from the mode of producing soluble cocoas. The nibs are placed in a heated mill, called a *mélangeur*, formed of a revolving granite table, with two heavy granite runners. When brought to the consistency of a smooth paste, sugar, or sugar and farina (as is the case in the cheaper qualities) are added, and the whole well ground and mixed together. When thoroughly incorporated, the mill is cleared, and the partially prepared chocolate is passed between three horizontal rollers, which thoroughly crush any particles not previously sufficiently ground. This operation is repeated several times, to bring the chocolate into a perfectly smooth condition; it is then again placed in the *mélangeur* to be finally mixed, when it is ready to be moulded into cakes or fancy forms, or to be used for covering the bon-bons called chocolate creams. The mode of moulding the cakes is first to weigh the chocolate, which is then put into a number of moulds placed on a tray to receive it. It is then removed to a table, to which, by means of an intermittent action, a strong vibratory motion is communicated, and this shakes the chocolate well into the moulds, from which, when perfectly cool, the cakes can be turned out. A circumstance to be noted is that these are then in a highly electrified condition.

Having thus briefly explained the mode in which cocoa and chocolate are prepared, I would now conclude with a few words touching the operation of the "Adulteration of Food Act" as it affects cocoa.

This Act of Parliament, so ill-considered and faultily arranged, was not deemed of sufficient importance by the House of Commons to be worthy of their careful attention, and it was at an important stage shovelled through a bare House at two o'clock in the morning. Its further progress was then the result of a stratagem, participated in by one of its prominent supporters and a member of the Upper House; and the Bill was finally passed in the House of Commons by about twelve members. It is not, therefore, surprising that it should have proved impracticable in working, and been the cause of much oppression and injustice. The wonder is that it has produced any good results, although even these are already diminishing, owing to the odium it has excited having already caused the commencement of a laxity in its enforcement. The subject of food adulteration is one of the most intricate and difficult on which to legislate, and one on which hasty legislation is most strongly to be deprecated.

The result of the present Act has been not so much to check the real adulterations which are practised, as to harrass small tradesmen caught tripping on what are really technicalities. Whether it be that the amount of adulterations practised has been greatly exaggerated, or that the present race of analysts is unable to discover them, I know not; but certain it is, that almost the only adulterations they have detected have been the mixture of water with milk, and of chicory with coffee, the colour facings of tea, and the circumstance that wheat flour and turmeric frequently exist in prepared mustard, facts that were perfectly patent to everybody. An effort has also been made, but unsuccessfully, to bring mixed cocoas within the category of adulterated articles; but, unfortunately for the public, not a single case of really adulterated cocoa or chocolate has been prosecuted, although large quantities adulterated with chicory, animal fat, and mineral earths, are daily sold throughout the country. Of course I am aware that no Act of Parliament can supply discretion and intelligence to its administrators; but still it is to be regretted that one dealing with so all-important a subject should not have been more carefully prepared. Looking at it merely as it affects manufactured cocoa, we find all the prosecutions under it have broken down with the exception of two or three cases which were not properly defended, and in which adverse decisions were pronounced by country justices ignorant of the merits of the case.

(To be continued.)

Parliamentary and Law Proceedings.

The Juries Bill.

The Juries Bill which was brought in by Mr. Lopes, and set down for a second reading on the 22nd inst., has been issued. Mainly it is the same as that introduced last year by the Attorney-General of the late Government. The amounts of the proposed county qualifications, however, are reduced, and one of the greatest innovations in last year's Bill —that reducing the number of jurors to seven except in trials for high treason, treason felony, and murder—is omitted. The present Bill proposes to enact that in all criminal trials twelve jurors shall be impanelled, in trials in county courts five, and in all other trials seven. But in any of the latter cases a defendant would be able to claim twelve jurors by giving notice in writing twelve days before the sitting of the court. Another omission is a clause that stood in the former Bill providing that, in order to secure rotation of service, a juror having been once summoned was not liable to serve again until after all the other jurors in the same class had been summoned for a fresh term of service.

The exemptions in the present Bill include all those proposed last year, with the addition of schoolmasters of public schools, professors, college tutors resident in the universities to which they belong, and members of the Royal College of Veterinary Surgeons actually in practice. The clause containing the exemptions in which our readers are most concerned stands as follows:—

"Apothecaries certificated by the Court of Examiners of the Apothecaries' Company, dental surgeons certificated by the Board of Examiners in Dental Surgery of the Royal College of Surgeons in England, and all registered medical practitioners and registered chemists, if actually practising as apothecaries, dental surgeons, medical practitioners, and registered chemists respectively; also members of the Royal College of Veterinary Surgeons actually in practice."

Amongst other points of more general interest, it is

significant of the unsettled state of the question of local taxation that some of the charges which last year were to be thrown on the poor rates are now to be paid "out of moneys to be provided by Parliament for that purpose." Another provision, which would have quieted many speculative fears in a recent notorious trial, is that "In the event of the death or illness of any juror or jurors during any trial, civil or criminal, the judge presiding at such trial shall have power, except only in a trial for murder, if he shall think fit, to direct that the trial shall proceed with the reduced number of jurors, provided that such number be not in any case less than five. In all such cases the verdict of the remaining jurors shall be a sufficient verdict."

Proposed Bill to Amend the Practice of Pharmacy in Ireland.

The following is a copy of a Bill which is proposed by the King and Queen's College in Ireland, to amend the practice of pharmacy in Ireland:—

Whereas a great deficiency exists throughout Ireland of establishments and shops for the sale of medicines, and compounding of prescriptions, and great inconveniences thereby arise to the public, in many parts of the country:

1. It is hereby enacted, that from and after the passing of this Act, the provisions of the Pharmacy Acts of England, 15th and 16th Vict. c. lvi., 30th June, 1852; 31 and 32 Vict. c. xxi, 31st July, 1868; and 32 and 33 Vict. c. xvii., 11th August, 1869, be extended to Ireland as follows:—

2. That from and after the passing of this Act every person duly qualified and registered under the aforesaid Pharmacy Acts, as chemists, or chemists and druggists, being thereby entitled to keep open shop in Great Britain for the compounding of the prescriptions of duly qualified medical practioners, shall in like manner be deemed to be qualified to keep open shop for the sale of medicines and compounding of prescriptions in Ireland, and shall not be subject for so doing to any prosecution or penalty, notwithstanding any enactment to the contrary in the Apothecaries' Act of Ireland of 1791 (31 Geo. 3, cap. xxxiv.).

3. Moreover, that every person duly registered by the Apothecaries' Hall of Ireland as qualified to keep open shop in Ireland for the compounding of prescriptions, shall, in like manner, be deemed to be qualified to keep open shop for the compounding of prescriptions in Great Britain, and shall not be subject to any penalty for so doing, notwithstanding any enactment to the contrary in the Pharmacy Acts of Great Britain hereinbefore enumerated.

Poisoning by Bichromate of Potash.

The *Times* quotes the following from an American source:—Messrs. Murray and Connor, two actors connected with the John Murray troupe, were playing *Ten Nights in a Bar-room* at Portland, Maine, on the 16th ult., and through the alleged negligence of the property man came very near losing their lives. In the scene where the revellers are clustered about the bar, Mr. Murray and Mr. Connor clinked their goblets and emptied them of a pale yellow liquid, resembling whisky in colour. Almost immediately Mr. Murray hastened from the stage, apparently in great agony, and Mr. Connor fell upon the floor in convulsions. The curtain came down with a rush, and the manager announced that the performance could not go on because some of the actors had accidently taken poison. It seems the property man hired some show bottles from the City Hotel for the bar-room scene in the play, the water in one of which was coloured with bichromate of potash and the other with red cochineal. He used the water in these bottles without changing it. Those of the actors who drank from the bottle the contents of which were coloured with cochineal escaped unharmed. The two men suffered great agony all night, but on the following morning they were recovered sufficiently to proceed to Biddeford with the other members of the company.

Review.

The Birth of Chemistry. By G. F. Rodwell, F.R.A.S., F.C.S. With numerous illustrations.

This is one of Macmillan's 'Nature Series.' The author says, "I have endeavoured in the following pages to trace the rise and early development of a very old science, mainly that we may mark the attitude of thought which actuated the scientific mind in bygone times . . .;" but the practical tendency of the work is to show that chemistry as a science is not very old—that a few chemical facts have been known from a very remote period, but that little progress was made in extending this knowledge, and none in deducing any sound principles for the explanation of the phenomena observed, until a comparatively recent date. The very limited knowledge of chemistry possessed by the ancients is represented to have consisted of an acquaintance with some of the metals—at most seven—the means of working them, of producing glass, and of making and applying colours for painting and dyeing. Chemical knowledge had hardly progressed beyond this point when the absurd doctrine of transmutation became so firmly ingrafted in the minds of those who devoted themselves to chemical investigation, that their efforts were all directed to the discovery of facts consistent with the popular doctrine, instead of carefully observing and arranging the results of experiments, and endeavouring to discover the means of connecting these, and of explaining them by reference to some general laws. Much of the work is necessarily devoted to the history of the alchemists and a notice of their published works, many of which purport to be of great antiquity, but most of these are ascribed by the author to no earlier date than the eleventh century. The clearing of the mystery by which the claims and pretensions of this class of writers has been surrounded forms a leading feature in the work, and we are thus brought to the seventeenth century before we find any marked evidence of the approaching birth of chemistry. The author says, "The time when the foundation stone was laid is too remote to be even suggested; the basis of the edifice is sunk deep in Eastern soil; the walls were slowly and laboriously raised during the middle ages, and were completed by Lavoisier, Black, and Priestley; the men of our day are working at the roof."

The work is well written and illustrated, and cannot fail to be entertaining and instructive to those who are desirous of acquiring a knowledge of the early history of chemistry.

BOOKS RECEIVED.

A Treatise on Food and Dietetics, Physiologically and Therapeutically Considered. By F. W. Pavy, M.D., F.R.S., etc., London: J. and A. Churchill, 1874 From the Publishers.

Qualitative Chemical Analysis and Laboratory Practice. By T. E. Thorpe, Ph. D., F.R.S.E. and M. M. Pattison Muir, F.R.S.E. (Text Books of Science.) London: Longmans. 1874. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 4th April, 1874, Mr. James Hore Allen, Pharmaceutical Chemist, of Union Street, Torquay. Mr. Allen had been a Member of the Pharmaceutical Society since 1859.

On the 31st March, 1874, Mr. John Lovering Cotton, Pharmaceutical Chemist, of London Road, Liverpool.

On the 19th December, 1873, Mr. Dennis Grundy, Chemist and Druggist, of Bury.

On the 25th January, 1874, Mr. James Foster, Chemist and Druggist, of Bradford. Yorkshire.

On the 27th February, 1874, Mrs. Ann Watson, Chemist and Druggist, of Annfield Plain, Gateshead-on-Tyne.

On the 3rd March, 1874, Mr. Robert Mitchell Welcher, Chemist and Druggist, of Chatteris, Cambridge.

On the 6th March, 1874, Mr. James Kellett, Chemist and Druggist, of Wigan.

On the 18th March, 1874, Mr. Robert Gordon Nichol, Chemist and Druggist, of Lauder, N.B.

On the 27th March, 1874, Mr. Henry William Coles, Chemist and Druggist, of Poplar, London.

On the 31st March, 1874, Mr. Samuel Birdwhistle, of Oldham Road, Manchester.

On the 5th April, 1874, Mr. Thomas Younger, Chemist and Druggist, of Brampton, Cumberland.

Notes and Queries.

[391]. LOTION FOR MANGE.—Beasley (1857) gives Mr. Guest's recipe (p. 787) as Clater's for red mange, but with twice as much $HgCl_2$, and a difference in the S of 1·60 and 3·80. I have used Clater's satisfactorily for the destruction of parasites on dogs. But read Mayhew on 'Dogs and their Management' (Routledge), p. 229: "Receipts for the cure of mange are all nonsense, unless we can imagine that one physic is good for various disorders." We are, however, picked up with this on p. 231: "The unguent which I have employed, and with such success as emboldens me to recommend it, is composed of:—

Ung. Resini (*sic*)	As much as you please to take.
Sulph. Sub. . .	A sufficiency to make the resin ointment very thick.
Ol. Junip. . .	Enough to make the unguent of a proper consistency, but not too thin."

This refreshes one. There is also a refresher at p. 84. Every chemist should read it, and then forgive the author for the sake of his chapter on distemper. By-the-bye, Mr. Guest should add a few drops of Sp. Terebinth. to save the dog from licking off the lotion. A fruitful source of so-called mange in dogs is bad "greaves"; in other words, bad food often causes eczematous eruptions. Let me suggest the use of anvil chippings, boiled in the drinking water for hard-worked hounds, as a preventive of a lot of the evils dog's hair is heir to. Of course, any chemist will know why (*malgré*, p. 84.) Has anybody tried storax for mange?—L.

[393]. INEXHAUSTIBLE SMELLING SALTS.—I am in want of a good formula for *inexhaustible* smelling salts. If any of your correspondents will kindly furnish me with one I shall feel greatly obliged.—Jas. Doubell.

[*** We cannot do better than refer our correspondent to a paper read by Mr. Allchin, at an Evening Meeting in 1861 (Pharm. Journ. [2] vol. ii., p. 543). Mr. Allchin's method is based upon the conversion of sesquicarbonate of ammonia into neutral carbonate, previous to placing it in the smelling bottle, by the addition of the necessary quantity of strong aqueous solution of ammonia (sp. gr. ·880). Forty avoirdupois ounces of the sesquicarbonate are broken into small pieces the size of a filbert, placed in an air-tight jar, and 20 fluid ounces of the solution of ammonia, previously perfumed, poured over it. The jar is then carefully closed and allowed to stand for two or three weeks, until the mixture becomes hard; but to prevent it setting too closely it must be stirred with a stiff spatula every other day during the first week. Afterwards it is kept in well-stoppered bottles containing one to two pounds each.—Ed. Ph. J.]

The March Examinations.

Sir,—The Secretary of the South London School of Chemistry and Pharmacy asks us to explain, in reply to the letters of Messrs. Gilders and Pickard, that the advertisement to which exception has been taken, should not have appeared after the recent Examinations.

Mr. Baxter sent an altered form of announcement; but through some indistinctness in his instructions, or misconception on our part with regard to them, the *old* form of advertisement was inserted.

J. & A. Churchill.

11, *New Burlington Street, London, W.*
April 13th, 1874.

Cocculus Indicus.

Sir,—Permit me to give the results of my inquiries on the above subject.

In the art of calico-printing (I am informed by a machine printer) "Oclus Indiberries," as they are called by the workpeople, are largely employed in the production of a yellow colouring matter, hundreds of tons being used for this purpose.

These berries are about the size of peas, generally of a yellowish-green colour (a few are black), wrinkled, and sometimes have the stalks attached. They are occasionally used by the workmen for fish-poisoning.

The berries are imported in hair bags, which are much prized for carpets by the workpeople.

I have no doubt that the above are a species of cocculus, probably in an unripe state; if so the large quantity imported to this country is readily accounted for.

Hoping this may assist somewhat in removing the odium attaching to the brewer of *malt liquors*.

"Brunswick."

April 6th, 1874.

"*Mac.*"—See the report of the papers on materials for suppositories, and the discussion thereon at the Evening Meetings of the Pharmaceutical Society last year, in vol. iii., pp. 715 and 781; also the new suppositories in the additions to the Pharmacopœia.

"*Inquirens.*"—(1) Herbaria sent in for competition must consist of specimens of indigenous wild plants only. (2) No candidate is allowed to compete unless he is an associate or a registered apprentice or student of the society, or if his age exceed twenty-one years.

J. W. is referred to the rule respecting anonymous communications.

"*Pharmacopola.*"—In conformity with your note we have forwarded the manuscript enclosed to the publishers, who conduct all business connected with our advertisements, and will inform you as to the charge.

C.L.M.—(1) 'How Crops Grow,' published by Macmillan and Co. (2) We cannot say what the Board of Examiners think of the system you refer to, and we are not sufficiently acquainted with it ourselves to be able to advise.

Communications, Letters, etc., have been received from Mr. Wanklyn, Mr. Armstrong, Secretary of the Quekett Club, Mr. J. Young, Mr. Broad, Mr. G. Carroll, Mr. Jackson, Mr. Rimmington, Mr. Mee, Mr. W. Pickard, Hon. Secretary of the Bristol Association, J. F., W. H.

The following journals have been received:—The 'British Medical Journal,' April 11; the 'Medical Times and Gazette,' April 11; the 'Lancet,' April 11; the 'London Medical Record,' April 11; 'Medical Press and Circular,' April 11; 'Nature,' April 11; 'Chemical News,' April 11; 'Gardeners' Chronicle,' April 11; the 'Grocer,' April 11; 'Journal of the Society of Arts,' April 11; 'Grocery News,' April 11; 'Produce Market Review,' April 11; 'Practical Magazine,' for April.

A SUGGESTED IMPROVEMENT IN THE PREPARATIONS KNOWN AS "SYRUPS OF PHOSPHATES."

BY JOHN MORRIS BROAD, JUN.

It occurred to me some time since that an improvement might be made in those most unsatisfactory preparations, the "Syrups of the Phosphates," though the condition of the dispensing chemists was greatly improved by the boon conferred on them by that well-known and appreciated paper by Mr. Carteighe, published in the PHARMACEUTICAL JOURNAL of March 25th, 1871. I am indebted to him for his most valuable formulæ.

My idea is to substitute glycerine and water, equal parts by measure, for syrup, which I find will help to keep the phosphates in a better condition with less phosphoric acid: the taste is far preferable to the syrups, and, in a therapeutical point of view, it may be beneficial. Being half water, it is thinner, and a nicer form. The cost of preparing is about the same. I find it answer equally well with iodide and bromide of iron. The following are, I think, the best formulæ :—

Glycerine of Phosphate of Iron.

Phosphate of Iron	16 grs.
Phosphoric Acid (Syrupy), sp. gr. 1·5 .	1 fl. drm.
Glycerine and Water, eq. pt. ad . .	fl. ℥ij.

Rub the phosphate of iron down with a little water and glycerine, add the acid, and filter into the rest of glycerine and water.

Glycerine of Phosphate of Manganese.

Phosphate of Manganese	16 grs.
Syrupy Phosphoric Acid, sp. gr. 1·5 .	fl. ℥j.
Glycerine and Water, eq. pt. ad . . .	fl. ℥ij.

Rub the phosphate of manganese down with a little glycerine and water, add the acid, and filter into the rest of the glycerine and water.

Glycerine of Phosphates of Iron and Manganese.

Phosphate of Iron	12 grs.
„ „ Manganese	8 grs.
Syrupy Phosphoric Acid, sp. gr. 1·5 .	fl. ℥j.
Glycerine and Water, eq. pt. ad . . .	fl. ℥ij.

Rub the phosphates of iron and manganese with a little glycerine and water, add the acid, and filter into the rest of the glycerine and water.

Glycerine of Phosphates of Iron and Lime.

Phosphate of Iron	grs. 16
„ „ Lime	grs. 32
Syrupy Phosphoric Acid, sp. gr. 1·5 .	fl. ℥j.
Glycerine and Water, eq. pt. ad . . .	fl. ℥ij.

Rub down the phosphates of iron and lime with a little glycerine and water, add the acid, and filter into the rest of the glycerine and water.

Glycerine of Phosphate of Zinc.

Phosphate of Zinc	grs. 32
Syrupy Phosphoric Acid, sp. gr. 1·5 .	♏ 50
Glycerine and Water, eq. pt. ad . . .	fl. ℥ij.

Rub down the phosphate of zinc with a little glycerine and water, add the acid, and filter into the rest of the glycerine and water.

Glycerine of Phosphate of Quinine.

Phosphate of Quinine	grs. 16
Syrupy Phosphoric Acid, sp. gr. 1·5 .	♏ 20
Glycerine and Water, eq. pt. ad . . .	fl. ℥ij

Rub down the phosphate of quinine with a little glycerine and water, add the acid, and filter into the rest of the glycerine and water.

Glycerine of Phosphates of Iron and Quinine.

Phosphate of Iron.	grs. 32
„ „ Quinine	grs. 16
Syrupy Phosphoric Acid, sp. gr. 1·5 .	♏ 70
Glycerine and Water, eq. pt. ad . . .	fl. ℥ij

Rub down the phosphates of iron and quinine with a little glycerine and water, add the acid, and filter into the rest of the glycerine and water.

Glycerine of Phosphates of Quinine, Iron, and Strychnine.

Phosphate of Iron	grs. 32
„ „ Quinine	grs. 16
Strychnia (in crystals)	gr. ½
Syrupy Phosphoric Acid, sp. gr. 1·5 .	♏ 70
Glycerine and Water, eq. pt. ad . . .	fl. ℥ij

Rub down the phosphates of iron and quinine, with the strychnia, with a little glycerine and water, add the acid, and filter into the rest of the glycerine and water.

Glycerine of Phosphates of Iron and Strychnine.

Phosphate of Iron	grs. 32
Strychnia (in crystals)	gr. ½
Syrupy Phosphoric Acid, sp. gr. 1·5 .	♏ 70
Glycerine and Water, eq. pt. ad . . .	fl. ℥ij

Rub down the phosphate of iron and the strychnia with a little glycerine and water, add the acid, and filter into the rest of the glycerine and water.

A preparation which I made according to one of these formulæ more than two months ago remains unchanged.

Rise House, Hornsey Rise, N.

THE TASTELESS IRON COMBINATIONS.

BY E. RUTTER.

Having been some years connected with the drug trade in London and still taking some interest in British Pharmacy, I notice that at the meeting of the Society last month, the tasteless iron combinations introduced by Mr. Creuse, of Brooklyn, U.S., were somewhat warmly advocated and proposed for adoption in the British Pharmacopœia. I think English pharmacists would do well to look into the matter a little more closely before sanctioning preparations, the chemical composition of which does not answer, as I believe, to the names given them. These salts were, and are still to some extent, popular in the United States; and I was at one time somewhat extensively engaged in the preparation, more especially of the chloride iodide and pyrophosphate, the last having been for some time official in the U.S. Pharmacopœia, and in extended use. Believing that there was some doubt connected with the composition of these preparations, which it was desirable in the interests of pharmacy to clear up, I undertook some experiments on the subject, and the results obtained were published in the American Journal of Pharmacy, of December last. The theory of double decomposition has been advanced, but Mr. Creuse has shown, that in that case only two molecules of the alkaline citrate would be necessary for every molecule of the ferric salt, whereas it is found that invariably four molecules are requisite for the production of the characteristic change of colour. The result of experiments has led me to suppose that the reactions may be formulated as follows :—

$$Fe_2'''Cl_6 + 4(K_3C_6H_5O_7) = 2(Fe'''K_32C_6H_5O_7) + 6\,KCl.$$

$$Fe_2'''I_6 + 4(K_3C_6H_5O_7) = 2(Fe'''K_32C_6H_5O_7) + 6KI.$$

$$Fe_4'''3P_2O_7 + (8\,K_3C_6H_5O_7) = 4(Fe'''K_32C_6H_5O_7) + 3K_4P_2O_7$$

And in like manner with the ferric phosphates, arseniates, and sulphates. The potassium salt may also be replaced by sodium, ammonium, or even magnesium. My reasons for arriving at this conclusion are as follows:—On treating the solution of the iodide with strong alcohol, the double citrate of iron and potassium, being totally insoluble, separates out as an amorphous green mass, and the alcoholic solution being evaporated gives all the reactions of the potassium iodide. The sulphate may be proceeded with in a similar way, but the potassium sulphate, being almost insoluble in strong alcohol, can only be washed out mechanically. Further, on mixing solutions of ferric citrate and potassium citrate, taking care to use exactly equivalent proportions, a liquid results identical in appearance with the so-called tasteless iron combinations, and being evidently a double citrate of potassium and iron, with the formula $K_3Fe'' 2C_6H_5O_7$. The amorphous form of these citrates precludes an exact analysis, but there can be no doubt that these tasteless iron preparations are merely a double citrate of iron and potassium, ammonium, sodium, or magnesium, mechanically mixed with the by-products of decomposition, alkaline chlorides, iodides, or pyrophosphates, as the case may be. Whether it is advisable that preparations, the actual composition of which is so far from being expressed by the names given them, should be included under those names in a National Pharmacopœia, I leave for better pharmacists than myself to decide.

JABORANDI, A NEW DRUG FROM BRAZIL.*

Pilocarpus pinnatus, Linn.

Dr. Coutinho, of Pernambuco, has recently brought under the notice of the French faculty a substance called by the Brazilians "jaborandi," which he describes as an energetic diaphoretic and sialogogue. It consists of the leaves and small branches of a shrub that grows in the interior of some of the northern provinces of Brazil. The leaves resemble those of the bay; they have no smell until gently bruised, when they exhale a slightly aromatic odour. The taste is rather acrid, without being bitter, and does not recall that of any other plant used in medicine and known to the author.

Dr. Coutinho forwarded some specimens to Professor Gubler, who, besides verifying their therapeutic effect, sought to ascertain their botanical origin. The names of "jaborandi," "iaborandi," and "jamborandi" appear to be generic terms popularly used in Brazil to designate plants that are stimulants, sudorifics, sialogogues, and consequently alexipharmics and alexiterics. According to Mérat and Delens the first word is applied solely to a species of *Gratiola, G. monneria,* which has become the type of the genus *Monneria* of Brown, whilst the "iaborandi" include all the species of peppers, a group remarkable for their excitant properties. The principal of the latter is the *Piper nodosum,* Mart., the acrid and sialogogue root of which, bruised, is applied to poisoned wounds and bad ulcers. The roots of the *Piper citrifolium, P. reticulatum,* and of a fourth species, which also bears the name of "iaborandi," are used for the same purposes, and are reputed stimulants, sternutatories and sialogogues. These properties appear to resemble those of the plant sent by Dr. Coutinho, but there the analogy ceases; in its botanical characters it is entirely different.

The specimens of "jaborandi" sent by Dr. Coutinho consist principally of leaves, with a small quantity of slender branchlets. The leaves are impari-pinnate, and are sometimes more than three decimetres long. Upon many of them there are as many as eight or ten leaflets ten to twelve centimetres long by three to four centimetres at their broadest part. The leaflets are nearly opposite, oval, elongated or ellipsoid, obtuse and even retuse at the apex, slightly unequal at the base, and sometimes incurved laterally. They are glabrous, shining, ordinarily thick, particularly brittle in the dry state, shortly petiolate or even nearly sessile. The petiolules are cylindrical, scarcely thickened at the point of insertion upon the common petiole. The rachis itself is enlarged at its base, straight, rounded beneath, slightly channelled above. Altogether, these characters were sufficient to show that the plant was not one to which the name "jaborandi" has hitherto been applied by authors; but, in the absence of the floral organs and fruit, it appeared difficult to determine the genus to which it belonged. Fortunately, by comparing it with the Brazilian plants in his herbarium, Professor Baillon was able to identify it with a Rutaceous species, *Pinocarpus pinnatus,* Lem., received from the province of St. Paul in Brazil.

The method of employing this drug, as described by Dr. Coutinho, is very simple. The leaves and small branchlets are bruised, and from four to six grams are infused in a cup of hot water. Upon drinking this quantity the effects are remarkable. The patient has to retire promptly to bed and cover himself well, and ten minutes afterwards he is seized by sweatings that continue four or five hours to such an extent that it is necessary frequently to change the linen during that time. There is also an abundant salivary and bronchial secretion, so that the patient can scarcely speak without his mouth being filled with the liquid. The quantity excreted is stated to equal a litre or more.

In their descriptions of sudorifics therapeutists have stated that the action attributed to those substances is due to heat. But the action of the jaborandi, although assisted by is not dependent upon heat, and it is a powerful sudorific even when taken cold.

Dr. Gubler has administered this drug a great number of times in the Beaujon hospital, and fully supports all that has been said of it by Dr. Coutinho as an incomparable diaphoretic and sialogogue. In one or two cases the profuse secretion was accompanied by diarrhœa. He considers that it will be used with advantage in a great number of morbid states, differing much among themselves in nature and gravity, but presenting the common necessity for stimulating the secretory action of the skin and salivary glands; since probably the leaves contain one or more principles capable of stimulating them directly during elimination. Dr. Gubler thinks that this Brazilian plant forwarded by Dr. Coutinho will be the first indisputable example of a diaphoretic truly worthy of the name; that is to say, a medicine having the power of provoking directly by an elective action the secretion of perspiration.

* From the *Répertoire de Pharmacie,* vol. ii., p. 171.

A NEW METHOD FOR THE DETECTION OF ALUM IN BREAD.

BY EDWARD LAWRANCE CLEAVER.

The Adulteration Act of 1872 has caused the detection and estimation of alum in bread to become almost a daily operation to the analyst; and as the varying results obtained by different chemists from identical samples seem to prove that a good process is not in general use, I have endeavoured to devise a *short* and *satisfactory* means by which the alum can be estimated.

The best process at present published, is that modification proposed by Mr. Crookes in the *Chemical News* (vol. iii, No. 70); but this, although it leaves nothing to be desired on the score of accuracy, requires a considerable time for its execution, and from the number of filtrations and subsequent washings, is liable to be inaccurate in the hands of any but a careful and skilful manipulator.

The method I have adopted is based on Esilman's process of estimating alumina in mineral phosphates by means of hyposulphite of sodium. (*Chemical News*, vol. xxviii., No. 72.) A slightly acid solution of an aluminium salt in the presence of excess of a phosphate and hyposulphite of sodium, is decomposed, the radical which was combined with the aluminium uniting with the sodium of the hyposulphite, sulphurous acid being set free, whilst the aluminium is completely precipitated as phosphate of aluminium together with free sulphur, and on ignition pure phosphate of aluminium remains.

It will be seen from this that the hyposulphite of sodium merely plays the part of a neutralizer of the acid, much in the same way as acetate of sodium acts in the preparation of phosphate of iron.

The details of the process are as follows :—

Take 1250 grains of bread, ignite in a platinum dish until fumes cease to arise, and powder the coke-like mass thus obtained. Treat this with 4 c. c. of sulphuric acid and 10 c. c. of water, cover with a glass to avoid loss by spurting, and set aside till action has ceased. Evaporate until fumes of sulphuric acid begin to be evolved, and when cold add water and boil for 15 minutes. Transfer the mass to a graduated measure and when cold make up to 125 c. c. Filter through an unmoistened filter until the filtrate measures 100 c. c. This liquid will contain the alumina from 1000 grains of bread. Add to the liquid 16 c. c. of a ten per cent. solution of ammonia (or sufficient to nearly neutralize the acid present without causing a precipitate) and a solution of about 20 grammes of hyposulphite of sodium. Set aside for about 15 minutes to allow of the deoxidation of any iron that may be present, and then boil for half an hour. Set aside for some hours, filter, wash the precipitate until the filtrate no longer precipitates with nitrate of barium, dry, incinerate in a *porcelain* crucible and weigh the resulting phosphate of aluminium, 245 parts of which are equal to 907 parts of ammonia alum or 940 of potash alum. The advantages of this process are its simplicity, and the short time in which it can be performed; the details are very few and can be carried out by any one with a slight knowledge of practical chemistry.

A few examples are appended, to show the correctness of the results.

1000 grains of bread mixed with ·105 gramme ammonia alum, gave ·029 gramme of phosphate of aluminium equal to ·105 gramme alum.

1000 grains of bread mixed with ·109 gramme ammonia alum, gave ·030 gramme phosphate of aluminium equal to ·111 gramme alum.

1000 grains of bread mixed with ·211 gramme ammonia alum, gave ·058 gramme phosphate of aluminium equal to ·215 gramme ammonia alum.

ANALYTICAL AND TOXICOLOGICAL INVESTIGATION OF CARBOLIC ACID.*

BY E. JACQUEMIN.

The employment of carbolic acid in therapeutics, and especially as a disinfectant, and the numerous cases of poisoning by it inadvertently, give an importance to its analytical and toxicological history. The author examines the various methods proposed for the detection of its presence, and suggests in each case certain modifications. It has been recommended to distil liquid or solid organic matters—urine, blood, or organs rich in blood—with a little sulphuric or phosphoric acid. If the distillate presents the characteristic odour it is to be shaken with ether, the decanted liquor left to evaporate spontaneously, and the residue tested with the usual reagents.

When no information exists respecting the cause of the accident under investigation, the author recommends the method published by M. Dragendorff, of Dorpat. The matter, after perfect division, is suspended in sufficient distilled water to render the mass very fluid; ten parts of dilute sulphuric acid are then added to one hundred parts of the mixture, and the whole allowed to digest for several hours at 50° C.; then expressed, and again treated with an equal quantity of acidulated distilled water. The liquors, mixed and filtered, are evaporated to a slightly syrupy consistence; to the residue is added three or four times its volume of alcohol, which is allowed to digest for twenty-four hours, filtered, and the filter washed with 70° alcohol. The alcoholic liquor being distilled leaves in the retort an aqueous liquor, which is filtered after cooling into a large flask, where it is agitated at the ordinary temperature with rectified petroleum spirit, boiling at 50° C. The petroleum having been decanted, the treatment is repeated, and the petroleum is afterwards left to evaporate in a certain number of watch-glasses.

The odour of the residue, and the property of blanching the skin, and of precipitating albumen and gelatine, belongs equally to creasote and to the cresylic phenol, as also does that of colouring blue a deal shaving exposed to the air after being plunged in hydrochloric acid. Some caution, however, is necessary in using this latter test, as M. Ritter states that he has seen a chip of deal coloured blue or green by the action of hydrochloric acid alone. Bromine water, which precipitates carbolic acid yellowish-white from very dilute solutions, is a delicate test; but although the precipitate which is obtained very slowly in dilute solutions takes a crystalline structure, the reaction is rather a complementary than a characteristic one. Neither is the conversion of carbolic acid into picric acid by nitric acid a characteristic test, although a very delicate one, for other substances yield a similar result. The property possessed by the ferric salts of colouring carbolic acid blue is a characteristic reaction, and sufficiently delicate when the phenol has been separated in the manner indicated above; for, according to Dragendorff, ferric sulphate colours lilac a solution of half a milligram to the cubic centimetre.

The reaction discovered by the author, which is the object of his paper, depends upon the extreme facility with which carbolic acid can be converted into erythrophenate of soda, a blue salt possessing a very considerable colouring power. He has found that upon adding to carbolic acid an equal weight of aniline and then of hypochlorite

---

* Abstract of a paper read at the Lyons meeting of the French Association for the Advancement of Science, in August, 1873 (*Répertoire de Pharmacie*, vol. ii., p. 429.)

of soda, a deep blue solution of erythrophenate of soda is produced, remarkable for the purity and persistence of its colour. This blue colour is changed to red under the influencc of acids, in consequence of the setting free of the erythrophenic acid, the blue reappearing when the acid is saturated by an alkali. The same result is obtained with hypochlorite of lime, but less clearly, a slight turbidity being produced. A single drop of carbolic acid, treated with a single drop of aniline, and afterwards with hypochlorite of soda, gives a very deep blue liquid. If the same quantity be added to two litres of water, after a minute the blue colour begins to appear, and so increases in intensity in an hour or two that after further dilution with two fresh litres of water the colour is still marked. This the author estimates as being equal to about 1 part in 66,000. The extreme delicacy of this test has enabled the author to simplify the methods of proceeding for the detection of carbolic acid, especially as the presence of organic matters, such as alcohol, soap, fatty matters, etc., provided they are colourless, does not interfere with the working of the test.

Detection of Carbolic Acid in Blood.—In a case where it might be necessary that the blood of a patient treated internally or externally with carbolic acid, should be examined for its presence, the author recommends that 100 grams of the blood be allowed to run from the vein into a warm tared capsule, and mixed well with an equal quantity of water containing two per cent. of sulphuric acid. But if thc blood be received in a coagulated state, it is necessary to rub it up in a porcelain mortar with a little sand to break up the fibrinous network, and afterwards mix it with the acid. After an hour's contact it is thrown upon moistened calico to strain; the albumenoid matters that pass through first cling to the bottom of the vessel, and allow of the decantation of the greater part of the liquid. To this is added its own volume of 95° alcohol, and it is again filtered. When about 30 c.c. have been collected, the acidity is neutralized by carbonate of soda; by means of a glass rod a fraction of a drop of aniline is added, and finally, the solution of hypochlorite of soda. If carbolic acid be present, the liquid, upon being shaken quickly, becomes grcen, passing to greenish blue.

In operating upon the heart, lungs, liver, or other organs or muscular tissue, about 100 grams should be cut up as small as possible, and the division completed by trituration in a mortar with clean sand. The process is commenced as in the previous case, but the residue left on the strainer is pressed, and then afresh treated with half the previous weight of acidulated water. After an hour's contact it is again strained, pressed, and the combined liquors added to their volume of 90° alcohol, allowed to stand several hours, and filtered through paper in the afternoon. The next day the alcoholic liquid is evaporated in a watcr-bath in a retort furnished with a receiver; and if, after the alcohol has passed over, the liquid be a little turbid, it is filtered into a stoppered flask.

If the preliminary test show the presence of carbolic acid, ether is poured into the flask, well shaken, and after separation the ethereal layer is decanted, and thc operation repeatcd with a fresh quantity of ether. Thc spontaneous evaporation of the ether leaves the carbolic acid in a concentrated state that allows of testing by all the known reagents, and the preservation of a portion of a drop to be used if necessary in evidence. If, however, the liquor be acid, it is necessary to saturate with carbonate of soda in order to be able to produce the blue reaction of erythrophenate of soda.

If the preliminary experiment give a negative result, the author recommends that ether be replaced by a petroleum spirit, boiling at 60°, or, still failing, that benzine be used.

Detection of Carbolic Acid in Urine.—About 200 grams of urine are treated with 4 grams of sulphuric acid, previously diluted with 16 grams of water, and maintained during one hour at a temperature of 50° C. When cool an equal volume of alcohol is added, and after standing some time the mixture is filtered and treated as indicated above.

Detection of Carbolic Acid in Milk.—200 grams of milk, after the addition of the dilute sulphuric acid, as above, are heated and kept at a temperature near to boiling until the casein has entirely separated. The liquid is allowed to cool, filtered, treated with alcohol, etc., as in the foregoing.

The author had occasion tc examine the milk of a cow which, having been severely wounded at pasture, had the wound dressed with carbolic acid. He states that a single drop of aniline and the hypochlorite added directly to the milk was sufficient to produce thc blue colouration of erythrophenate of soda in the course of one minute.

POISONING BY VANILLA-ICE.

BY DR. L. ROSENTHAL.*

(*Concluded from p.* 838.)

I come now to the question: Wherein lies the source of poisoning by the use of vanilla-ice? We may here reasonably take three possibilities into consideration. The symptoms may be caused: 1, by cold; 2, by the materials constituting the frozen substance; 3, by other injurious substances accidentally introduced.

Regarding ice as such, we know well that its use may bc followed by gastric catarrh and other slight stomach disorders, but it is not known that symptoms resembling those of cholera follow its use. Further, the following fact is opposed to this idea. Symptoms like those which I have already described have never yet becn observed to follow thc use of fruit-ices; and among cream ices it is, as far as our knowledge extends, only vanilla-ice that has produced symptoms of poisoning.

I here beg leave to remark, in passing, that fruit-ice is prepared with sugar and the acid of lemons, to which the desired fruit-juice is added; while, in the preparation of cream-ice, eggs and cream are used, and the flavour is given by adding vanilla, chocolate, etc. Besides these, the various kinds of cream-ice are boiled before being introduced into the freezing vessel, which is not the case with fruit-ice.

While we must exclude the cold mixture as such from suspicion as the cause of the severe symptoms of poisoning, we succeed no better when we take into consideration the materials accidentally introduced into the ice. The most careful chemical examinations have given thc following results. Most frequently (as in our case) traces of lead are found, now and then more or less iron, and in two cases there were not inconsiderable quantities of tin. As we may exclude the lead and iron (the former on account of its small quantity) from suspicion as the causes of illness, there remains only the tin; and, in fact, Green, who made a chemical examination of the ice which led to poisoning in Altona, has expressed the opinion that the tin combines with the lactic acid formed from the cream, forming a lactate of tin, which acts as a poison on the organism. The experiments, however, which Maurer of Erlangen has made with tin on animals have shown thc complete harmlessness of this metal. I will finally remark on this subject that in our case the vessels used in the preparation of the ice were found to bc in a faultless and thoroughly clean condition. The ingredients werc boiled in well-tinned copper vessels, and the freezing was carried on in clean porcelain cylinders.

With regard to the materials used in the preparation of the ice, I have already mentioned the milk. Whether eggs can give rise to symptoms of poisoning is unknown to me; and thus we come to the only remaining possibility, that the poisonous agent is contained in the vanilla-pods. Up to the present time we cannot furnish certain evidence

---

* Read before the Berlin Medical Society. (*Berliner Klinische Wochenschrift*, March 9, 1874. From the *London Medical Record* for March 25.)

on this point. The idea is opposed by the fact that, though vanilla is extensively used in the preparation of tea and chocolate, as well as of sauces and soups, which only differ from vanilla-ice in containing greater quantity of milk and in being of a higher temperature, the use of these has never been observed to be followed by symptoms of poisoning. We cannot regard any of the substitutes for vanilla, such as balsam of Peru and storax, as the vehicles of the poison, since in all the known cases it was really vanilla that was used in the preparation of the ice, and neither Peruvian balsam nor storax can be reckoned among poisons.

I must, on the other hand, mention a circumstance which, in my opinion, gives incontestable evidence that the poison is contained in the vanilla-pods. Cases of poisoning by vanilla-ice occurred in a confectioner's shop in Altona. The proprietor of the shop was in consequence obliged to give up his business; the vanilla-pods in his store went into the possession of a confectioner in Bergen —and the ice made with these pods proved to be poisonous.

I now hold, with many others, the opinion that the symptoms of poisoning produced by vanilla-ice must be placed to the account of the vanilla-pods; but the endeavours to ascertain the poisonous agent have hitherto been in vain. Martius believed that he had found it in the crystals covering the pods, since he observed that the pods gathered in the East Indies were covered with crystals of a different shape from those on the pods imported from Mexico. In our case the pods had no crystals at all. Schroff, who had occupied himself with the subject most thoroughly, has put forth three hypotheses, of which he holds the first to be most probable. "In Columbia," he says (*Lehrbuch der Pharmacognosie*, 2nd ed., 1869), "the pods are greased with the fatty oil from the seeds of the *Anacardium occidentale* (cashew-nut) and dried in the sun. As a very acrid juice is contained between the endocarp and ectocarp of this fruit, it is possible that, in preparing the oil from the seeds without sufficient care, this, and the vanilla-pods over which it is rubbed, may become contaminated with the acrid juice; and that in this way the occasional occurrence of poisoning, after the use of vanilla-ice may be explained in these cases, where no other injurious condition can be ascertained." In another place (*Wiener Medizinische Wochenschrift*, No 82, 1863), he says that experiments on rabbits with cardol prepared from this oil have shown that it is capable of producing the symptoms observed in patients.

Setting aside the fact that other observers make no mention of the rubbing of vanilla pods with the cashew-nut oil, Schroff does not show that the cardol used in the experiments was derived from vanilla-pods. Thus his hypothesis loses probability; and Dr. Schädler has been informed that there was no cardol in the vanilla-pods obtained from the Vienna *café*.

The second hypothesis which Schroff put forth, and to which he himself attached little weight, is the following. In the vanilla-fruits, on careful microscopic examination, there are found in the parenchymatous cells of the mesocarp packets of sharp-pointed needle-shaped crystals, which were very large in the vanilla used in preparing the ice in question; and, according to Soubeiran, they act like nettles on the skin. These must act as mechanical irritants; but in the ice examined they were always in a broken-up condition.

Finally, whether any of the fatty acids formed under certain circumstances may be the cause of the poisoning, must remain undecided—as yet, there is no proof of such a cause.

In conclusion, while I thank those who have assisted me by contributing facts and by searching through the literature of the subject, I must guard myself against being supposed to advance a new hypothesis. I abstain from this the more, as the necessary knowledge is wanting to me. But there is one thing to which I may direct attention. Not to mention that the various kinds of vanilla differ much in quality, I have found it stated by Schroff alone that the pods are gathered when ripe. All other authors state that they are gathered in the unripe state, and prepared in many ways for use. I here add what Henkel (*Handbuch der Pharmacognosie*, Tübingen, 1867) says, from Von Müller's travels in Mexico. He first describes vanilla as the dried unripe capsules of the *Vanilla planifolia;* then gives the following account of its preparation. "The Indians of Misantla collect the vanilla in the mountains and forests of Quilates; the fresh capsules contain an acrid viscous juice, which protects them against insects. The Indians, who only betake themselves to the forests for eight days at the time of the gathering, often sell the raw fruit to the colonists, who then prepare and dry them, and tie them in bundles for sale. In Misantla, the most usual way of drying the vanilla is to spread the shrivelled yellow fruit on linen in the sun for some hours. When the pods are sufficiently heated they are wrapped in woollen cloths, where they soon assume a dark copper colour; they are then exposed to the sun from morning to evening until they are dry. When drying in the sun is prevented by continued rain, artificial heat is employed; frames are made of reed or bamboo, which are suspended by cords at the four corners and covered with woollen cloths, on which the capsules are spread. These frames are swung over a fire which does not smoke, until the pods are dried. . . . In the State of Oaxaca the natives dry the vanilla by piercing the capsules all over with needles, so as to allow the escape of the viscous juice."

Flückiger (*Lehrbuch der Pharmacognosie des Pflanzenreichs*, Berlin, 1867), expresses himself in a similar way, though not with so much detail. "In the second year, the fruit buds ripen into an entirely non-aromatic pod-shaded, fleshy capsule, with a viscous milky juice, and opening longitudinally in two unequal valves. It is not allowed to become fully ripe, but is collected when its green colour is beginning to pass into brown, and is dried, according to some accounts, in a very elaborate manner, inasmuch as it is subjected to heat either exposed, or wrapped in woollen cloths; under this treatment it ripens, and first develops the aroma and the favourite dark-brown colour of the commercial fruit."

From these statements, it is difficult to imagine that in some of the pods—and, as far as we know, it is only individual pods that are poisonous—the process of artificial ripening is not complete, and that it is the unripe pods which produce the symptoms? I content myself with having called attention to this question. May those who are more skilful decide it!

[The reading of Dr. Rosenthal's paper was followed by a discussion, a report of which is given in the *Berliner Klinische Wochenschrift* for December 22, 1873.]

Dr. B. Fränkel said that, as his name had been mentioned, he would give fuller information on the cases of poisoning observed in his family. Several persons were taken ill, nearly in the proportion in which they had partaken of a certain dish. The symptoms were those of vanilla-poisoning, such as had just been described by Dr. Rosenthal. One person alone of the household, who did not eat any portion of the dish, remained unaffected. The dish in question was a warm farinaceous compound, to which vanilla was added in preparation. It was made in a porcelain vessel, and was so simple in composition that the illness could only be attributed to the vanilla. He had given to Dr. Liebreich, for examination, some vanilla-pods, obtained from the same dealer, and taken from the same packet as those which produced the poisoning.

Dr. Veit said that, in the nights of August 28 and 29, he observed a case of poisoning with vanilla-ice. He took special notice of the fact, because a female friend of the patient (a woman) who had eaten of the same ice, was taken ill with similar symptoms. The symptoms were those of cholera, but the gastric pain was of longer duration, and recovery slower.

Dr. Kalischer on the same night saw a similar case of

illness in a lady who had eaten some ice in the Vienna *café*. One of her children also ate of the ice, but was not ill.

Dr. Henoch said he ate some vanilla-ice, obtained from one of the first confectioners in Berlin, and four hours later was taken ill. His evacuations were colourless, and resembled those of cholera. He had no pain in the stomach or bowels, a circumstance which spoke against metallic poisoning. In the same night, a young girl and fourteen other persons of the same party were taken ill with similar symptoms; they had all eaten vanilla-ice. Those who ate other ices were not attacked. On applying to the confectioner, he was assured that vanilla-pods of the same kind had been used for some months without producing poisoning. The pods shown to him were abundantly covered with crystals. It was remarkable that the symptoms were specially severe in those persons who had eaten the portions of ice nearest to the containing vessel; especially the servants, who scraped it to obtain the portions of ice that adhered to it. This circumstance appeared to indicate metallic poisoning.

THE ANNIVERSARY DINNER.

It has been decided that the Annual Dinner in connection with the presence in London of many members of the Pharmaceutical Society, to attend the Annual Meeting, shall take place, as last year, at the Crystal Palace, on Tuesday, the 19th May.

On Wednesday evening next, at eight o'clock, a meeting of the Stewards will be held at 17, Bloomsbury Square, to appoint a Committee, and make other necessary arrangements. The Secretaries will be glad if gentlemen interested in the gathering will accept this notice as a sufficient invitation to be present.

The following is a list of the Stewards, from all of whom tickets for the Dinner can be obtained :—

Atherton, John Henry	...Long Row, Nottingham.
Atkins, S. R.	...Salisbury.
Attfield, Professor ...	...17, Bloomsbury Square, W.C.
Baiss, A.	...102, Leadenhall Street, E.C.
Baldock, John Henry...	...3, High Street, South Norwood, S.E.
Barker, W. R.	...143, New Bond Street, W.
Barnes, J. B.	...1, Trevor Terrace, Knightsbridge, S.W.
Barron, Frederick ...	...2, Bush Lane, Cannon Street, E.C.
Baynes, James	...24, Waterworks Street, Hull.
Bell, R. E.	...161, East Street, Walworth, S.E.
Bentley, Professor ...	...17, Bloomsbury Square, W.C.
Betty, S. C.	...6, Park Street, Camden Town, N.W.
Bird, Augustus	...Wood Lane, Shepherd's Bush, W.
Bottle, Alexander ...	...37, Townwall Street, Dover.
Bourdas, Isaiah	...7, Pont Street, Belgrave Square, S.W.
Bremridge, Elias... ...	...17, Bloomsbury Square, W.C.
Broad, John...	...Rise House, Hornsey Rise, N.
Brown, William Scott	...113, Market Street, Manchester.
Burbidge, Thomas ...	...16, Coleman Street, E.C.
Butt, E. Northway ...	...13, Curzon Street, Mayfair, W.

Tickets for the dinner may be obtained up to Thursday, May 14th, from any of the Stewards, or from the Honorary Secretaries, Messrs. RICHARD BREMRIDGE and MICHAEL CARTEIGHE, 17, Bloomsbury Square, W.C. In order to make the necessary arrangements and prevent discomfort, members and their friends are requested to make application for their tickets *at once*.

NOTE ON THE PREPARATION OF EXTRACT OF KRAMERIA.*

* Abstract of a paper in *L'Union Pharmaceutique*, xv. 66.

BY M. CASTEUIL PATTESON.

Two years since, the author, wishing to prepare some extract of krameria and having only some large roots difficult to powder, he had them dried. This process however not being carefully conducted, when the roots were percolated after maceration in water, the liquid obtained instead of being a fine red colour was of a dull yellow. Having read that the addition of sugar increased the product, he treated his drug with sugared water and applied heat. He was surprised to find that under the influence of the sugar the red colour quickly appeared, and he obtained a product consisting of equal parts of extract of krameria and of sugar, and perfectly soluble. The extract of krameria so obtained was found to be convenient as a pill mass, and could be brought to a hard consistence in a stove. In this form it preserves perfectly. Some that the author prepared two years since gives at the present time a perfectly limpid solution. The warmth of the hand is sufficient to soften the mass, and in case of need exposure to the vapour of water for a few minutes will reduce it to a suitable consistence for making pills. The author states that the pills are quickly made, do not alter in shape, contain no objectionable matter, and dissolve perfectly in the juices. Some further experiments have led him to propose a fluid extract in which the menstruum consists of glycerine, sugar, and water; but this is possibly open to the objection appertaining to the use of glycerine in the preparation of astringents, referred to in the discussion at the Bradford meeting of the Conference (*ante*, p. 336).

The Pharmaceutical Journal.

SATURDAY, APRIL 25, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DRUGGISTS AND THE SALE OF ALCOHOL.

THE well-known paradoxical utterance that "extremes meet" has been verified in our literary exchanges received during the last few days. On the one hand, the *Good Templar*, asserting that in the Pharmacy Acts the "Permissive Bill" is already passed, calls upon the Council of the Pharmaceutical Society to place Alcohol amongst the poisons in Schedule A. On the other, the New York *Druggists' Circular* contains sundry protests against the fact that the women engaged in the whiskey war, in initiating the movement in a fresh district, advertise their intention of carrying on the crusade against the *druggists and saloon keepers.*

The *Good Templar* informs its readers that "the "political end and object of the temperance reforma- "tion in Great Britain at this moment, whether "recognized or not, is, in the first place and before all "else, simply to convince a certain number of scientific "men composing the Council of this Society that "they ought to pass a particular resolution." Absurd as such a proposition may appear, it is one that is put forward "soberly" in the official organ of a numerous body, and it is therefore quite possible that it will be brought in some way under the consideration of the Council which will shortly be elected by our Society. But is the temperance millennium to be brought about by labelling every bottle of alcoholic liquor "poison," the registration of the sale, and of the purpose for which it is required—from which it would appear that alcohol is to be classed among the poisons in part 1—and the transfer of the liquor trade from the publican to the pharmacist? Simple as is the faith shown in the deterrent efficacy of a name, and flattering as is the confidence exhibited towards the members of our honourable calling, pharmacists are hardly the men to subscribe to a creed that has been exploded at least since Romeo's time, or to believe that, if they were willing to accept the suggested transfer, the public would be likely to sanction it.

Some two years since, when a declaration respecting alcohol, largely signed by influential members of the medical profession, was put forth, an opinion was expressed in these columns that British pharmacists would be found ready and willing to second any efforts to limit the improper administration of alcohol under the guise of medicine; and that opinion has been supported in our own experience by the fact that, on more than one occasion, our advice has been asked as to the propriety of dispensing certain prescriptions that appeared more suggestive of dram-drinking than doctoring. Still there is no doubt that under various designations what are really stimulants are asked for and supplied by druggists, and it is not probable that the demand would be decreased by the introduction of such a term as "pick-me-up poison."

In some parts of the United States, however, a state of affairs is described as existing that goes much further towards the *Good Templar* proposition of combining the alcohol traffic with pharmacy, and with a resulting deterioration of the interests of the latter. Two causes seem particularly to be operating in this direction: one that the druggist is compelled to pay a tax of twenty-five dollars for a liquor license, which induces him in a few cases to set up a "gin mill" in his establishment in order to recoup himself; another, that the passage of a "local option law" in some districts has induced "some few unprincipled apothecaries" to carry on, in connection with physicians of the same stamp, an illegal trade in liquor, supposing that if they are detected they can hide themselves behind the physician who gave the prescription. In this, however, they would appear to be mistaken; for a judge, in sentencing some offending druggists, said that although a druggist might be fortified by the prescription of the most eminent physician, yet he is not justified in selling to persons of known intemperate habits, or where he knows the liquor will be used as a beverage.

Amongst the minor consequent inconveniences that have arisen to perplex American pharmacists, is a crop of terms in Latin far from Ciceronian. The *Druggists' Circular*, in replying to some queries of a correspondent says, "We are afraid that the temperance crusade in your State has caused such a sudden increase in the number of patients applying to their doctors for stimulant prescriptions that some physicians have had no time to burnish up their stock of Latin." We agree with our contemporary in thinking that a doctor is excusable in this instance: the Latin language had no words for distilled liquors, these having been unknown during the Augustan period; and it is not easy to coin in a hurry readily intelligible Latin expressions, even for the chief ingredients of the various forms of alcoholic stimulants for which America is famous. Although the British Pharmacopœia recognizes "egg-nog" under the name of "*Mistura Spiritus Vini Gallici*," many a good scholar would feel sorely puzzled to write prescriptions for a "sherry cobbler," a "cock tail," a "gum tickler," or an "eye opener."

On the whole, we think we may venture to assure our well-intentioned temperance friends that the pharmacists of Great Britain are averse to any closer connection with the sale of alcohol, either in the form preached for in England or prayed against in America.

THE COLLEGE OF PRECEPTORS AND MIDDLE-CLASS EDUCATION.

Of the many deputations by which the Government have been besieged during its yet brief term of office, one which waited on the Duke of Richmond last week to express the views of the College of Preceptors upon the subject of secondary education was not the least important. The opinion of the members of the College, as set forth in an address issued by them, is that the education of the upper and middle classes is at present very unsatisfactory ; and this is an opinion that will be endorsed by many parents who have found that time and money have been wasted in the effort to secure a good education for their children. Elementary education has now been placed under the supervision of the State, but the advancement of a higher class of education has been left mainly to the schoolmasters and mistresses, who, though numbering among them many possessed of great attainments, have as a body no recognized status. It is now proposed that the College of Preceptors should have such an extension of its charter, as would place it, with regard to the registration of teachers, on the same footing as the Inns of Court in respect to law, and the College of Physicians and Surgeons to medicine. This authority for examining and registering teachers, the College believes, would not only be a great advantage to those engaged in teaching, but would supply a machinery by which the scholastic profession would perhaps be more effectively influenced than by direct legislation. Some little uncertainty seems to exist as to whether the examination and registration should be optional or compulsory ; some speakers wishing for an optional registration, which should confer the sole right to use a certain title but not be essential to practice as a teacher, similar to what is enjoyed by surgeons !

Of course the Duke of Richmond promised to give the subject a most careful consideration, to which it is clearly entitled as another indication of the beneficial influence which is at length being brought to bear upon Middle-Class Education.

AMENDMENT OF THE ADULTERATION OF FOOD ACT.

The session of Parliament has not been allowed to advance very far without signs that the Adulteration Act will furnish a topic for discussion. On Thursday, April 16th, Mr. Mundella inquired of the secretary of the Local Government Board, what steps were being taken to prevent the *importation* of adulterated articles of food into this country, and to relieve honest traders from liability to conviction for the sale of articles adulterated by the foreign producer and on which customs duties have been paid. In reply, Mr. Sclater-Booth stated that any proceedings for the purpose of preventing the importation of adulterated articles of food, must under the existing law be taken by *local authorities* and not by the Government. He added that many memorials had been received, complaining of the hardships inflicted upon retail dealers by the operation of the Act, and the Government had therefore determined to ask the House to appoint a select committee to inquire into the subject.

PAYMENT OF ANNUAL SUBSCRIPTIONS.

It may be useful to remind some of our readers that the time for payment of the annual subscription to the Pharmaceutical Society, due on January 1st, expires on the last day of this month, after which time the names of Members, Associates, and Apprentices or Students of the Society, who have not paid their subscriptions, are omitted from the respective Registers. Under the new Bye-law, which is now in force, the Council will be unable to restore the names of such persons, except upon payment of the subscription for the then current year, and a sum not less than the amount of half of one year's subscription, nor exceeding five guineas, as for and in commutation of arrears of subscription.

APPOINTMENTS OF ANALYSTS.

Mr. Edward Lawrance Cleaver, Pharmaceutical Chemist and Assistant Demonstrator in the Laboratories of the School of Pharmacy, Bloomsbury Square, has been appointed Analyst under the provisions of the Adulteration Act, 1872, for the parish of St. Mary Abbott's, Kensington. The appointment has received the sanction of the Local Government Board.

We are glad also to learn that some objections which had been raised by the Local Government Board to the appointment of Mr. Joseph Young, Pharmaceutical Chemist, of Leicester, as Joint Public Analyst for the Borough of Leicester and the Counties of Leicester and Rutland, have been removed upon consideration of that gentleman's testimonials, and his appointment has now been confirmed.

COCCULUS INDICUS.

A paragraph quoted by the *British Medical Journal* from the *Hospitals Tidende*, and headed "Poisoning by Picrotoxin," appeared at first sight to promise definite evidence respecting the alleged use of the berries containing this bitter principle for the adulteration of beer. A Danish medical practitioner relates that he and three friends, a quarter of an hour after drinking a small glass each of "English ale" with their supper, were attacked with pain in the stomach and frontal headache, followed by violent vomiting and profuse diarrhœa, and other disagreeable symptoms. It is stated that an examination of the ale remaining in the bottle from which the guests drank, and others, revealed the presence of colchicine ; but what method was used for its detection, and why the case is called one of poisoning by picrotoxin, does not appear. A report of the analysis, however, is promised in a pharmaceutical journal. Meanwhile, it is consoling to our *amor patriæ* to learn that the "English ale" was imported into Denmark in bulk and bottled in that country.

THE ANNIVERSARY DINNER.

The attention of those interested in this gathering is directed to an announcement on a previous page that a meeting of the Stewards will be held at 17, Bloomsbury Square, on Wednesday evening next, at eight o'clock, to appoint a Committee, and make other necessary arrangements.

Transactions of the Pharmaceutical Society.

BOTANICAL PRIZE FOR 1875.

A Silver Council Medal is offered for the best Herbarium, collected in any part of the United Kingdom between the first day of May, 1874, and the first day of June, 1875; and should there be more than one collection possessing such an amount of merit as to entitle the collector to reward, a second prize, consisting of a Bronze Medal, and also Certificates of Honour and Merit, will be given at the discretion of the Council. In the event of none of the collections possessing such an amount of merit as to warrant the Council in awarding Medals or Certificates, none will be given.

The collections to consist of British Flowering Plants and Ferns, obtained in a wild state, and arranged according to the Natural System; the collections to be accompanied by lists, arranged according to the same system, with the species numbered.

The collector to follow some work on British Botany (such as that of Babington, Hooker, or Bentham), and to state the work which he adopts. The name of each plant, its habitat and the date of collection, to be stated on the paper on which it is preserved.

Each collection to be accompanied by a note, containing a declaration, signed by the collector, and certified by his employer, or a Pharmaceutical Chemist to whom the collector is known, to the following effect:—The plants which accompany this note were collected by myself, from wild plants, between the first day of May, 1874, and the first day of June, 1875, and were named and arranged without any assistance but that derived from books.

In estimating the merits of the collections, not only will the number of species be taken into account, but also their rarity or otherwise, and the manner in which they are preserved; and should a specimen be wrongly named, it will be erased from the list.

The collections to be forwarded to the Secretary of the Pharmaceutical Society, 17, Bloomsbury Square, on or before the first day of July, 1875, indorsed "Herbarium for Competition for the Botanical Prizes." After the announcement of the award, they will be retained one month, under the care of the Curator of the Museum, for the inspection of persons connected with the Society, and then returned to the collectors, if required.

No candidate will be allowed to compete, unless he be an Associate, Registered Apprentice, or Student of the Society, or if his age exceed twenty-one years.

NORTH BRITISH BRANCH, EDINBURGH.

The sixth and last meeting of the present session was held in the Society's Rooms, St. Giles's Street, on Thursday evening, 16th current, at half-past eight o'clock, Mr. J. R. Young, President, in the chair.

On taking the chair, Mr. Young intimated that the Secretary had received information of the sudden and unexpected illness of Mr. Sadler, of the Royal Botanic Gardens, who had arranged to read two papers to the Society—one on the "History and Structure of certain Edible and Poisonous Fungi," and the other on "Eucalyptus Globulus." The President was sure all present would sympathize with Mr. Sadler's condition, and exceedingly regret the cause which would prevent him fulfilling his kind promise in appearing before them this evening.

Mr. Young then addressed those present as follows:—

"This, as you are aware, is the last meeting of the session, and I may be permitted very briefly to say that on the whole the meetings throughout have been well attended; that we have, as in former sessions, been indebted in great measure for their success to those gentlemen who have so kindly addressed us, but that we have still to lament that so little has been done by those more immediately connected with the business—many of whom, did they but interest themselves a little more in the work of the Society, might feel disposed to contribute to some extent in making these meetings more practical and interesting than they hitherto have been. At the first meeting, in December, Mr. Gilmour, our Vice-President, gave an exceedingly interesting lecture on the polariscope. Mr. Gilmour was placed at considerable disadvantage, in having to conduct his experiments with very indifferent assistance; but, nevertheless, he succeeded in explaining satisfactorily the wonderful effects of polarized light, and in throwing upon the screen a great variety of very beautiful illustrations, which were highly appreciated by those present. The Society will look forward to Mr. Gilmour's future contributions with much interest. In January, Dr. Macadam was kind enough to address us on the collection and examination of potable waters. As the water question has been a subject of much discussion in Edinburgh for many years, and as it was well known that the Doctor had been largely engaged in supplying materials for that discussion, much interest was evinced, and those who had the pleasure of hearing the address were able to realize how much was necessary in regard to the proper collection, and what care was requisite in the examination before giving a detailed analysis of any water. In February, Professor Archer lectured "On the Use and Abuse of Food," when he urged very strongly the importance of right views on the subject, and the hope that at no distant day there would be a course of lectures in every university in Europe in connection with it. In March, Dr. McKendrick, Assistant Professor of Physiology in the University, gave an address on the "Chemistry of Certain Physiological Processes which take place in Digestion, Nutrition, and Excretion." From the numerous diagrams and the variety of illustrations, most carefully conducted, with which this lecture abounded, the greatest pleasure and profit was derived, and the meeting testified its approbation very effectively during its delivery. In April, Dr. Macadam was again kind enough to lecture "On the Quality of Milk supplied to Towns." Some prosecutions under the Food Adulteration Act had taken place in various parts of the country, and very conflicting views were held in reference to a proper standard for genuine milk, and it is hoped that the contributions of Dr. Macadam and others on this very important matter may lead to such a result that the public may be supplied with genuine milk, and that honest dealers in the commodity may be sufficiently protected. The library during the session has been increased to a considerable extent, more especially by the valuable donations of Messrs. Brown and Baildon, which have added very materially to its efficiency and value, and it is pleasing to know that it has been made use of to a considerable extent by those for whom it was intended.

"The museum has been enhanced by donations from Messrs. Howards and Son, Professor Maclagan, and more especially by Mr. Jamie, of Singapore, who, through Mr. Baildon, his former employer here, has sent the most valuable contribution which has yet been made to the museum. Descriptive papers in reference to this presentation are given in the PHARMACEUTICAL JOURNAL of April 4th, and one cannot read these without feeling his heart warm towards Mr. Jamie for the kind and generous manner in which he has acted in making this presentation.

"In connection with the examinations, it may be mentioned that the President of the Society, Mr. Hills, with that liberality for which he is so conspicuous, has during the session given funded property yielding £5 per annum to the North British Branch for the purpose of presenting a prize of books to the young man who stood highest in marks at each minor examination in Edinburgh; and the examiners have already had the pleasure of thus applying this endowment. It is hoped that this prize may have the effect on our candidates that the generous donor intended, and that a healthy stimulus will be introduced, resulting in a desire not merely to pass the

examining Board, but to pass in such a manner that this prize may fall to their lot. In regard to the examinations it would, perhaps, be out of place that I should make much allusion to them on this occasion, but there can be no doubt that the dread of such is already evincing a marked influence in our business arrangements. Assistants are not more plentiful, and those that are procurable, are not, in my experience, better or even safer than men in the olden time; while the influx of apprentices is not so great as to warrant the hope that better times are in store. It appears to me right and reasonable that a chemist should be an educated person, that he should be an examined person, that he should have served an apprenticeship, and that, if practicable, he should have had the benefit of attending lectures on various subjects; but this latter point I would not press too far, as it is consistent with my own knowledge that in several instances parties have appeared at our examining Board, and taken honours in the major examination, who never attended a single class. You may call it "cram" if you will, but their knowledge of the various subjects of examination was honestly and fairly tested, and the result was as I have stated, the whole merit being due to steady persevering industry on their part; and in the face of such successful efforts, it appears to me that any hard and fast line in reference to compulsory attendance on any course of lectures would, in present circumstances, be detrimental to the interests of the business generally. The examinations are, in my humble judgment, sufficiently stringent for the next ten years; and I cannot but feel that a great hardship is about to be inflicted on the mass of our young men by the regulations which come into operation in October.

"Urge education by all means, give facilities for such wherever it is practicable; but it appears to me a mistake to make the test of admission to the Society such that none but those who are skilled analytical chemists have much chance of meeting its requirements.

"Some additions to the Pharmacopœia have been made under the direction of the General Council, and it will be expected that we shall have these in readiness in due course.

"In the Journal for April 4th, a very full account of these is given in a paper read by Mr. C. Umney at an evening meeting in Bloomsbury Square. Most of the preparations have been more or less used for some time past; but there are one or two changes in nomenclature and in composition, which may give rise to many unpleasant complaints causing worry and annoyance to a conscientious chemist. Pulvis Glycyrrhizæ Compositus for example, as sold in Edinburgh, has been prepared invariably according to the formula of the Prussian Pharmacopœia. This contains sulphur and fennel seed powder. The new preparation omits both; so that, unless medical men are very careful in prescribing, there will be a constant succession of doubts and fears as to the preparation wanted. Then nothing is more common than that the preparation of bismuth presently most in use is ordered as oxide of bismuth; and now we have a new preparation bearing that name evidently with the desire of superseding the subnitrate. There are many consumers of medicine, and these the best customers of the Pharmaceutical Chemist, who watch very jealously the appearance, and nicely judge the taste, of the articles they use; and changes such as these give rise to much discomfort to all parties.

"Our apartments here having in some respects been found unsuitable, the Council are glad to intimate that, when they had almost given up the hope of securing more eligible premises on reasonable terms, they were offered such through the kindness of Mr. Mackay on the first flat of 119, George Street. The suite of rooms there are in process of being obtained, and it is hoped that at the opening of next session they will be in such condition as will permit the work of the Society to be carried on in a more efficient manner and with greater comfort than heretofore.

"And now, gentlemen, as this is the concluding meeting of the session, and my retirement from this chair will speedily take place, let me say how grateful I feel for the kindness which has been invariably shown to me. Circumstances have prevented me discharging the duties so fully as I could have desired, but so far as I have been able I have had much pleasure in endeavouring to advance the interests of the Society. You have given me every encouragement, and from the honorary secretary I have derived such assistance as leads me to assure my successor that he need have no fear but that he will find the office in all respects an agreeable one."

As there was abundance of time, in consequence of Mr. Sadler's unavoidable absence, Mr. Mackay, at the President's request, proceeded to make a few remarks in reference to some of the subjects referred to in the valedictory address. He went very fully into the examinations. Alluding to the system at present followed, he spoke of the change about to be introduced on the 1st of October. While quite in favour of increased education and a fair knowledge of the various departments required by the Board, he much feared, unless greater facilities were given for study among the young men, both in town and country, that the stringency of altered chemical and botanical examinations might press so heavily against the candidates that, great as the percentage of rejections had been, they were very likely to be increased. This he very much regretted, because the difficulty of getting young men to come into the business was daily increasing, while of the very best of those already engaged in it some were gradually leaving and finding employment in other spheres. He could not help comparing those requirements with the small remuneration which was offered by town and country chemists to young men who had passed the standard, to fit them for the Government Register. Mr. Mackay then brought before the meeting the recent proposal to establish scholarships in connection with the parent Society. He would be glad to hear the opinion of some now present on this subject. For his own part he did not think it was at all desirable that the funds of the Society should be so spent, nor did he think the large sum proposed to be spent annually for this purpose would be found a successful investment.

Mr. Baildon quite coincided with the views which had been so well expressed by Mr. Mackay, and thought it would be a very unwise thing indeed for the Society to institute the proposed scholarships. He also feared that they were somewhat premature in making the changes in the minor examination, which he understood would really come into operation on the 1st of October.

Mr. Ainslie, while quite agreeing to all that had been said regarding the scholarships, still thought that it might be advisable to compel attendance on certain courses of lectures, even though it entailed the necessity of young men coming from a distance to larger towns, where they might have the benefit of attending the teaching of those capable of giving instructions in materia medica and kindred subjects.

Mr. Gilmour also quite agreed in all that had been said regarding scholarships, and would personally much regret to see them established as had been recently proposed by Mr. Schacht. He rather thought the time was coming when young men would require to visit certain centres to study before passing their examinations, and he would like to see the funds of the Society expended to a certain extent in establishing courses of lectures to which the pharmaceutical students would be admitted free of charge.

Messrs. Blanshard, Finlayson, and Baildon, jun., all spoke against the establishment of scholarships, and were also averse to compelling attendance at a course of lectures.

Mr. Mackay, in replying to Mr. Ainslie's and Mr. Gilmour's remarks, thought it would be a very difficult thing indeed to get young men to come from a distance to large centres, with the view to study and attend courses of lectures, and fancied every object would be attained by

apprentices being obliged to attend prelections on materia medica, botany, and chemistry when this was possible, and where no such opportunity offered that masters should be bound to give time for the pupil to read and study the different subjects on which they would be afterwards examined.

Mr. Mackay then moved a hearty vote of thanks to Mr. Young, who, as had been stated, occupied the chair for the last time this session at a scientific meeting. He felt that the Society was deeply indebted to him for the warm interest he had all along taken in its affairs, and hoped that though for a time retiring from his present high position, he would long be spared to assist in conducting the affairs of the Branch here, in a manner which would prove serviceable not only to the present but more particularly to the rising members of the pharmaceutical profession.

This was carried with loud acclamation.

The Secretary then intimated that as Dr. Frazer had left Edinburgh for an appointment in England, Dr. William Craig, C.M., would lecture during the summer on materia medica, and had kindly agreed to admit students of pharmacy on very liberal terms. Any wishing to obtain tickets might apply to him, at 119, George Street, on or after Tuesday next. Dr. Craig had authorized him to state that as this was to be his first course, all the tickets issued would be perpetual.

The meeting then adjourned.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

At the monthly evening meeting, held on the 11th of March, a lecture on "Colour," experimentally illustrated, was delivered by Thomas Wills, Esq., F.C.S., of the Royal Naval College, Greenwich.

The seventh and concluding meeting of the session took place on the 10th instant; Mr. G. F. Schacht presided. Professor Redwood gave a discourse on "Pharmacy—Past, Present, and Prospective."

A Sketch of Pharmacy: Past, Present, and Prospective.

BY PROFESSOR REDWOOD.

I propose in this lecture to direct your attention to some points connected with the rise and early development of pharmacy, as an occupation distinct and separate from the practice of medicine; to trace its progress to the present time; to point out what I conceive to be the critical nature of its present position, and to indulge in a few speculations with regard to the future.

All our published accounts agree in representing the first rise of pharmacy to have occurred among the Arabs, and its earliest cultivation to have taken place in Spain during the dominion of the Arabs in that country. We read of the existence of a class of men devoted to the collection, preservation, and dispensing of medicines, among the Arabs, prior to the twelfth century. Laws were enacted for regulating the exercise of this business in Spain, in Sicily, and elsewhere, at an early period, and these were subsequently extended to France and Germany.

The richness of the Arabian territory and commerce in vegetable products possessing medicinal properties, the nomadic character of some of the Arab tribes, and their commercial intercourse with many nations, no doubt promoted the encouragement of the study and practice of medicine among them; for there is no better passport for travellers among half civilized people than a knowledge of the means of treating human ailments, and relieving the sufferings of disease.

During the 13th, 14th, and 15th centuries, apothecaries' shops or dispensaries were established in most of the large cities in France and Germany, and these in the first instance were often supported at the public expense. But nothing of that sort existed as yet in England.

So late as the beginning of the 16th century, the preparation and dispensing of medicines in this country was exclusively in the hands of the physicians, who generally kept assistants as the apothecaries do now, for the purpose of preparing the medicines they prescribed. In process of time some of these assistants commenced business on their own account as apothecaries, while at the same time the physicians began to relinquish the practice of supplying medicines to their patients, and sent their prescriptions, or bills as they were called, to be dispensed by the apothecaries.

But although pharmacy had not at this time been separated from the practice of medicine in this country, excepting to the small extent to which a few physicians' assistants had established themselves as dispensing apothecaries, it is obvious that both the physicians and the apothecaries must have obtained the drugs they used in preparing their medicines through some regular commercial channel; and the question naturally arises, How, and by whom was the commerce of drugs conducted? We find an answer to this question in a small work, entitled "Short answers to Tentamen Medicinale," published in 1704, where it is stated that at the beginning of the 17th century, "what drugs and medicines were then in use were sold in common by the grocers; and as for the preparing and compounding of them, *that* the physicians principally took charge of themselves."

There is reason to believe, however, that the grocers dealt only in such drugs as came from abroad; many of which, being imported with articles of grocery, and some of them, such as spices, being used in the preparation of food as well as medicine, naturally passed through their hands, at a time when there were no special dealers in drugs.

After some time those grocers who had devoted most attention to drugs, confined themselves principally to that department of commerce, and from being drug-grocers took the name of druggists.

But there was still another class of dealers in drugs, namely, the simplers or herbalists, who collected and supplied the indigenous vegetable substances used in medicine.

The connection of the grocers of those days with the commerce of drugs, and also the origin of the class of dealers who were first called druggists, are clearly indicated by the manner in which the grocers and apothecaries became associated, just as the barbers and surgeons had been.

In the beginning of the 17th century (1606), the grocers of London were incorporated into a company with the then existing apothecaries, of whom there were but few; and soon afterwards, in 1617, when the number of apothecaries had no doubt increased, that partnership was dissolved and a new company, the Apothecaries' Company, formed, by adding to the apothecaries a few of those grocers who were best acquainted with drugs, and thus making up the number to 114. This number corresponded with that of the physicians then practising in London, so that there was a dispensing apothecary for every physician.

The incorporated apothecaries, to whom the dispensing of medicines was transferred by the physicians, became a prosperous body. In 1623 the company opened an establishment in Blackfriars for preparing and compounding the medicines used by its members. This was commenced on a small scale, but in 1671 it acquired a much more important character by the addition of a chemical laboratory, which afforded the necessary means for the production of chemical as well as galenical medicines. The establishment still exists as the Apothecaries' Hall of London, where medicines are supplied, wholesale and retail, as they were 200 years ago, but with this difference, that it is now a dispensing establishment, which it was not then. The addition of the dispensing department has been made within my recollection.

By the end of the 17th century the number of apothecaries had increased from 114 to nearly 1000 ; and as they had now united prescribing with dispensing, they became formidable rivals of the physicians.

This rivalry is supposed to have originated an important undertaking by the physicians, who, finding that their former dispensing assistants, instead of adhering to their legitimate duties, were now competing with them for the medical treatment of patients, were anxious to provide some other means of getting their prescriptions dispensed than by sending them to the apothecaries.

Accordingly, the leading physicians of London, including the President, Censors, most of the elects, and other members of the College, subscribed a fund for, and otherwise promoted, the establishment of dispensaries ; ostensibly for supplying cheap and good medicines to the poor, but practically, as it appeared, for dispensing generally the prescriptions supplied by the physicians to their patients. There were three of these dispensaries established in London, and they were looked upon as rival establishments to those of the apothecaries. Much acrimonious controversy took place between the physicians and apothecaries respecting these dispensaries, and with reference to the practice which the apothecaries now freely indulged in of prescribing and visiting patients. Each party accused the other of engaging in occupations which did not properly belong to it—the apothecaries were accused of interfering with the legitimate province of the physicians, and the physicians of practically engaging in trade.

At this time—rather less than two hundred years ago—no such body of men as that which has since arisen, with the occupation and title of chemist and druggist, existed. There were the simplers, or herbalists, who collected and supplied indigenous medicinal plants ; the drug-grocers and druggists, who dealt in drugs as imported ; the chemists, or alchemists, who made and supplied such chemicals as were then used in medicine ; the apothecaries, who, from having been the physicians' assistants, made a fair start on their own account as dealers in drugs and compounders and dispensers of medicines, but who, imitating their late employers in giving advice and visiting patients, became the rivals of those who should have been their patrons ; then there were physicians who still supplied their own medicines, and there were also many, and these an increasing number, who, having relinquished that practice, were interested in having suitable provision made for the dispensing of their prescriptions.

It may be well here to consider what was the nature of the medicines principally prescribed in those days.

Until the 16th century chemistry had scarcely contributed anything to medicine. As a science, indeed, chemistry had not yet come into existence, yet there were certain results obtained in the arts through chemical agencies, and a limited number of chemical products were used in medicine.

But nearly all the medicines on which reliance was placed were natural products derived from the animal, vegetable, or mineral kingdoms, but chiefly from the two former ; and these were prepared and compounded according to a system of profuse complication, which obscured if it did not obstruct the action of the individual agents employed.

We may judge of the pharmacy of the 16th and 17th centuries by referring to the early editions of the London Pharmacopœia, which commenced in 1618, and to the Dispensatories which preceded and accompanied that work.

We find here a very profuse Materia Medica. The London Pharmacopœia, for instance, contained no less than 1700 vegetable, 240 animal, and 260 mineral substances in the list of what we may call the crude drugs ordered. From these were prepared simple and compound powders, simple and compound waters, decoctions, vinegars, syrups, honeys, oxymels, lohochs, candies, conserves,. electuaries, pills, troches, oils, ointments, and plasters.

The class of electuaries appear to have comprised the preparations that were considered the most important. One of these, entitled "*Antidotus magna Matthioli adversus venena et pestem*," contained more than 150 ingredients, consisting of animal, vegetable, and mineral substances.

Among the electuaries we find the celebrated *Mithridatum Damocratis*, *Theriaca Andromachi*, and *Philonium Persicum* and *Londinense*, with a host of other complex mixtures bearing the high-sounding names of *Athanasia Mithridatum*, *Benedicta Laxativa*, *Caryocostinum*, *Diacorum*, *Diastyrion*, *Diacatholicon*, and I don't know how many more Dia's.

Now, although there was but little science, there was a good deal of labour involved in the preparation of these medicines, and it is no wonder that the physicians desired to be relieved of the work, and yet to see adequate provision made for having their "*prescriptions faithfully prepared.*"

Some of the drug-grocers, if they had been acquainted with medical Latin, might perhaps have been induced, from their knowledge of drugs, to undertake the compounding and dispensing of such medicines as were then principally ordered ; but there were symptoms of an approaching change in the nature of the remedies that would ere long be prescribed. Efforts had for some time been made to introduce a new class of medicines the production of which involved the exercise of chemical art.

In the 15th and 16th centuries, two great reformers, Basil Valentine and Paracelsus, had been trying to bring about a revolution in the practice of medicine, by substituting chemical remedies for the complex mixtures of animal and vegetable substances which had previously been used, and which were distinguished as Galenicals.

This was the commencement of a new era in pharmacy. For ages the chemical art had been cultivated almost exclusively with a view to the realization of two great objects of human ambition,—the discovery of the means of acquiring wealth, and of prolonging life ;—but hitherto nothing had come of it but the increased poverty and premature death of those who practised the art.

With a zeal and energy deserving of better success, but with a perverseness of purpose which entirely frustrated the attainment of the objects sought, the alchemists of the middle ages endeavoured to unlock the secrets of nature with a key of their own forging, instead of seeking nature's key by a course of inductive research.

It is difficult to say when the extraordinary infatuation of those alchemists commenced. Some of their followers have endeavoured to trace the belief in transmutation and the search for the philosopher's stone and elixir of life through a period extending to remote antiquity, commencing with the perhaps mythical *Hermes Trismegistus*, who is said to have lived 2000 years before Christ. But it is probable that most, if not all, of the writings on which the claims to this great antiquity for the doctrines of alchemy were founded, have no earlier origin or better authority than the Monks of the middle ages.

The earliest works on chemistry we have, that can be relied on as authentic, are those of Geber, an Arab, who lived in the 8th, and part of the 9th, century. He alludes to the seven metals, *gold*, *silver*, *mercury*, *copper*, *tin*, *iron*, and *lead*, which were known from a very early date. He regarded all these except *mercury* as compounds of *mercury* with *sulphur* in different proportions. Gold and silver he considered the most perfect metals, into which the others could be converted by purifying their constituents and uniting them in different proportions. He describes the production of *nitric acid* and *aqua regia*, *caustic potash* and *sal ammoniac*, *corrosive sublimate*, *red precipitate*, and *milk of sulphur*. In fact all the chemistry that was known for many centuries afterwards was known to Geber. The alchemists who followed him, instead of extending chemical knowledge, confined their efforts almost exclusively to the search after the means of producing gold and a panacea for all diseases, including that of old age.

Albertus Magnus, Raymond Lully, and Roger Bacon, were alchemists of the 12th and 13th centuries. Even in the 15th century the belief in the power of alchemy was such, that a law was passed in this country in 1404 prohibiting the making of gold and silver, from a fear of the power it would give to those who practised the art. Half a century later, Henry VI, in a more liberal spirit, granted patents for the discovery of the philosopher's stone, which was to turn base metals into gold ; in fact the king was well advised, for the patents enriched *his coffers* much more than those of the pretended discoverers.

Faith in the power of the alchemists was now evidently on the wane. Basil Valentine and Paracelsus were satisfied to study the effects of the baser metals, and to treat diseases with these and other chemical substances. Valentine was the great champion of antimony, which was afterwards alternately vaunted as a blessing or condemned as a curse through two centuries or more. In his '*Currus Triumphalis Antimonii*' Valentine includes antimony as one of the wonders of the world ; but it was soon afterwards condemned as a dangerous poison, and in 1566 a decree of the French Parliament prohibited its use in medicine. In 1609 a physician in Paris was expelled from the faculty for administering it, but in 1637 antimonial wine was admitted into the '*Antidotarium*,' the work referred to by French pharmacists prior to the publication of the Codex. It was much employed about 1650, although many medical men still considered it a poison and strongly objected to its use. In 1666 the French doctors assembled, to the number of 102, to decide upon the merits of antimony, and 92 voted in its favour ; upon which its use was authorized by the Parliament.

Among the forms in which antimony was used as a remedial agent were those of pills and cups, made of metallic antimony, alloyed with a little tin, the alloy being probably intended to promote, or, at any rate, having the effect of promoting, a galvanic and more powerful chemical action in contact with acid wine, or the contents of the stomach. There is an interesting specimen of an ancient *antimony cup* in the Museum of Practical Geology, in Jermyn Street, London, of which I exhibit an enlarged drawing. Wine allowed to stand for a few hours in one of these cups dissolved some of the metal, and acquired, or was supposed to acquire, the property referred to in the German inscription, which says—

Thou art a wonder of Nature,
And to all men a certain cure.

Antimony cups, and the everlasting pill of antimony, were convenient forms for administration at a time when the use of antimonial preparations was prohibited by law.

Calomel was not introduced into medical practice until the beginning of the 17th century, shortly before the publication of the first London Pharmacopœia, in which there were two processes given for its preparation—one by sublimation and another by precipitation. It was but very slowly that chemical medicines were adopted, but still they were gradually increasing and it became necessary to provide for their production. The drug-grocers were quite unequal to this duty, which was performed by a distinct class, who called themselves chemists, and who, in the 17th century as far as we can judge, were strongly tinctured with the spirit and doctrines of the Hermetic or secret art of alchemy. An advertisement or prospectus of a chemical establishment in London, in 1686, runs as follows :—

"Gaza Chymica.

"A magazine or storehouse of choice chymical medicines, faithfully prepared in my laboratory, at the sign of Hermes Trismegistus, in Watlin Street, London, by me, George Wilson, Phylo-Chym."

It was the common practice, about the period we are referring to, for establishments of this kind to have special signs over the door, as public houses have now. The sign of George Wilson's establishment was *Hermes Trismegistus*, the celebrated oracle of the alchemists, whose effigy we have here, as found in the Temple of Pseleis. The chemical art, as practised by the alchemists, was often called the *Hermetic*, or *secret art*, profound secrecy having been enjoined upon those engaged in the search after the philosopher's stone. Important products were often sealed with the seal of Hermes, as it was called, which was supposed to render the secret of their production inviolable ; and hence superstitious value was attached to substances bearing this seal—a value often required to compensate for intrinsic worthlessness. We retain some vestiges of this practice in the *Terra Lemnia* and *Terra Sigillata*, or *sealed earth*, which is still ordered in the Paris Codex, and we continue to use the term *Hermetically sealed* to represent the most complete cutting off of communication with the outer world that we can effect, as by the fusion of the open end of a glass tube.

An establishment somewhat similar to that of the Gaza Chymica of George Wilson existed at an early period in the Poultry, with the sign of *Bell and the Dragon* over the door. The late Mr. Richard Phillips, whose name is so intimately associated with the London Pharmacopœia, was, I believe, originally connected with this house.

But perhaps the most celebrated of the houses of this class was that which was established in Southampton Street, Covent Garden, in 1680, by Ambrose Godfrey Hanckwitz, the German assistant of the Hon. Robert Boyle, an eminent philosopher and chemist of the 17th century. Mr. Boyle's laboratory was situated at the back of Southampton Street, and here the first practically successful processes for the manufacture, on a commercial scale, of ether and phosphorus were conducted by Godfrey Hanckwitz, who shortly afterwards opened a shop, with the sign of *The Phœnix*, in an adjoining house in Southampton Street, which became celebrated as that of Godfrey and Cooke, the name of Hanckwitz having been dropped and that of Godfrey used.

An original advertisement of this house serves to throw light upon the state of pharmacy at the latter end of the 17th and beginning the 18th century. It runs thus—

"Ambrose Godfrey Hanckwitz, Chemist in London, Southampton Street, Covent Garden, continues faithfully to prepare all sorts of remedies, chemical and galenic. He hopes that his friends will continue their favours. Good cordials can be procured at his establishment, as well as Royal English drops, and other articles, such as Powders of Kent, Zell, and Contrajerva, Cordial red powder, Gaskoins powder, with and without bezoar, English smelling salts, true Glaubers salt, Epsom salt, and volatile salt of ammonia, stronger than the former. Human skull and hartshorn, essence of Ambergris, volatile essence of lavender, musk and citron, essence of viper, essence for the hair, vulnerary balsam, commendeur, balsam for apoplexy, red spirit of purgative cochliaria, spirit of white cochliaria, and others. Honey water, lavender water of two kinds, Queen of Hungary water, orange-flower water, and arquebusade.

"For the information of the curious, he is the only one in London who makes inflammable phosphorus which can be preserved in water. Phosphorus of Bolognian stone, flowers of phosphorus, black phosphorus, and that made with acid oil, and other varieties. All unadulterated. Every description of good drugs he sells, wholesale and retail.

"Solid phosphorus, wholesale, 50*s*. an ounce, and retail £3, sterling, the ounce."

Now, these are the earliest records we have of the existence of establishments of this kind in England, and observe that in neither of these cases is there any reference made to the dispensing of physicians' prescriptions. The chemists as well as the druggists were mere dealers in medicines and certain articles of perfumery, both simple and compound. The dispensing of medicines from prescriptions was as yet confined to the apothecaries, whose special duty it was, or ought to have been ; to the dispensaries, which had been established and were still supported by the physicians ; and to those physicians who continued to send out their own medicines.

It is interesting to trace the first appearance of a class of men professing to deal in chemical medicines—men who, like Mr. Godfrey, had laboratories with chemical furnaces and the means of conducting all sorts of chemical processes. Few men, in those days, were so favourably circumstanced in this respect as Mr. Godfrey, who had the advantage of commencing his career in the service of a distinguished and wealthy philosopher, by whom he was supplied with anything required for carrying out the scientific objects which he and his patron had in view. The interesting account published some years ago by Mr. Joseph Ince, explains the circumstances under which Godfrey commenced the building of furnaces and setting up of stills in Maiden lane, a narrow turning out of Southampton street, Covent Garden; where English smelling salts as well as phosphorus and ether were practically produced, and where Mr. Boyle received his scientific friends to witness the "marvellous lumen" as the newly discovered phosphorus was called. Here Godfrey and his successors continued to make smelling salts, for which they were celebrated, until, aristocratic London having migrated westward, they were fain to follow in the train; and Robert Boyle's laboratory, with its furnaces, after passing through an ignominious transformation into a potato warehouse, at length wholly disappeared, and is now, *Phœnix-like*, in the act of rising from its ashes as a *Catholic chapel*.

The Gaza Chymica in Watlin street, the chemical laboratory and shop in Southampton street, and the physicians' dispensaries in Warwick lane, at the back of Newgate, in St. Peter's Alley, Cornhill, and in St. Martin's lane, Westminster, appear to have started nearly at the same time, or at any rate they were all simultaneously in existence at the end of the 17th and beginning of the 18th century. I have no knowledge of the exact time at which the physicians gave up their dispensaries; but it has been suggested that their doing so in the 18th century, caused the assistants who had been previously employed in those establishments to commence business as chemists and druggists, and to engage as such in the dispensing of medicines, an occupation to which they had been thoroughly trained.

Several important changes occurred through the 18th century in connection with the practice of medicine and pharmacy. At the commencement of this century the elements of an improved organization were discernible among the means provided, but as yet but imperfectly developed, for the administration of medicine. The more prominent appearance of men professing a knowledge of chemistry, among those who dealt in medicines, was a significant fact. Those who previously, from being druggrocers, had adopted the title of druggist, now assumed the more comprehensive title of chemist and druggist. Improvements were effected in the London Pharmacopœia which indicated an advancement in the qualifications, not only of those who were practising medicine but of those also who produced medicinal compounds, galenical as well as chemical, and by whom improved processes were devised and introduced. The first step towards a really scientific improvement in the Pharmacopœia was taken in preparing the edition of 1721, when the botanical names of the plants yielding articles of the 'Materia Medica' were given. This was followed by further and more extensive improvements in the edition of 1746. A better system of prescribing than had previously prevailed was now beginning to be adopted. The College, in their preface to the Pharmacopœia of 1746, say:—

"It were certainly a disgrace and just reproach if pharmacy should any longer abound with those inartificial and irregular mixtures, which the ignorance of the first ages introduced and the perpetual fear and jealousies of poisons enforced; against which the ancients endlessly busied themselves in the search of antidotes, which for the most part they superstitiously and dotingly derived from oracles, dreams, and astrological fancies; and, vainly hoping to frame compositions that might singly prevail against every species of poison, they amassed together whatever they had imagined to be endowed with alexipharmic powers. By this procedure the simplicity of physic was lost, and a wantonness in mixing, enlarging, and accumulating, took place which has continued even to our times."

We could say nothing more to the purpose than this, even in the present day, after the experience of another century and a quarter. Important changes were made in the formulæ inserted in the Pharmacopœia of 1746, and these may be said to have originated and formed the bases of the preparations which have chiefly been used in medicine from that day to the present. Two of the old complex formulæ, however, were retained, namely, those for Confectio Damocratis or Mithridate, and Theriaca Andromachi, or Venice treacle. These preparations were still important items in the stock of every dispensing establishment, and we cannot say much against the London College of Physicians of 1746 for retaining those formulæ when we find that the existing French Codex, published in 1866, has a formula for the same *Theriaca* with 59 *ingredients*, including *dried vipers*, *agaric* and *Terra Sigillata*.

In 1723, increased powers were given to the College of Physicians to examine the medicines sold by apothecaries and others, and to destroy such as were found to be adulterated or otherwise defective.

In 1748, increased powers were also given to the Apothecaries' Company, who were empowered by charter to examine and license those who should practise as apothecaries in and within seven miles of London; and this license was understood to apply to the sale of compound medicines and the preparation of physicians' prescriptions, so that the apothecaries under this charter claimed the exclusive right to practise pharmacy, that is to compound and dispense medicines in London—a claim, however, which they failed to substantiate against the rapidly increasing class of chemists and druggists.

The apothecaries and chemists were now beginning to tread on each other's toes, and many complaints were expressed, especially by the former.

An association of apothecaries was formed in 1793 for the purpose of investigating the cause of evils which were said to exist, and from reports published by this association we are enabled to ascertain some of the facts of the case.

We are told that the druggists were a body of men unknown to the world until about the end of the 17th century; that towards the end of the 18th century those who called themselves chemists and druggists had encroached upon the province of the apothecaries, by vending pharmaceutical preparations and dispensing physician's prescriptions, for which they were very imperfectly qualified.

The association instituted inquiries throughout the country, and found that in many towns the number of chemists and druggists had increased four-fold in ten or twelve years. They declared this spread of a new class of traders, usurping the functions of the apothecaries, to be a "morbific infection—that it began at the capital as a central point, but diffused its deadly breath from thence to all the larger cities and towns throughout the kingdom. Nor stopped the contagion here: from the larger cities and towns it was beheld propagating itself to smaller cities and towns; till, at length, so general was the disease, that there was scarcely to be found a village or hamlet without a village or hamlet druggist, and if the sale of medicines and the giving of advice was not sufficient to support the vendor, he added to his own occupation the sale of mops, brooms, bacon, butter, and a thousand such articles besides."

An attempt was made to induce the legislature to stop this infectious disease, but it failed. The promoters of the movement, the apothecaries, were themselves no better qualified for the duties they were undertaking as medical practitioners than were the druggists as pharmacists.

The requirements of the public called both classes into

existence, and it remained for the process of "natural selection" to develop the characters of the respective species. After a contest of many years, *the Apothecaries' Act of* 1815 defined the qualifications of one class, and *the Pharmacy Acts of* 1851 *and* 1868 settled those of the other class.

Now, the question I wish to ask here is this, What progress has pharmacy made in the last century, and to whom are we indebted for it? That pharmacy has advanced, that better and more reliable forms of medicine are used now than was formerly the case, that the art exercised in their production is more highly cultivated, and that science is more successfully applied in guiding the exercise of the art, are, I think, facts beyond dispute.

In the improvements thus effected, the tendency has been to simplify the composition of remedial agents, and at the same time to obtain them in a more definite and concentrated state. By the application of chemistry the active constituents of natural products have been isolated, and new and active chemical compounds have been produced, which are among the most valuable of the agents employed by the physician in the treatment of disease.

It cannot, I think, be said that it is to the apothecaries we are indebted for these improvements. We are indebted to them for much of the prosperity which has marked the past career of the body to which we belong, but I must say they have done little towards advancing the art and science of pharmacy.

We have benefited from the profuse system of medicine-taking which resulted from the practice of paying the doctor in the price of his physic, and which induced people to think that it was necessary to attack a disease with a battery of physic bottles, just as we should attack a town with a battery of guns; but that system has had its day, and like many false systems it has produced a revulsion from which we are now suffering to some extent.

We cannot even say that it is wholly or chiefly to the chemists and druggists that we are indebted for the improvements of the past century in pharmacy. Mostly we are indebted to their representatives abroad, to those who although called apothecaries, have retained the true type of the pharmacist; and to a considerable extent also we are indebted to distinguished members of the highest branch of the medical profession,—to men who, like Sir Robert Christison, Dr. Pereira, and Anthony Todd Thomson, have cultivated the art of pharmacy, *con amore*, and have enriched our knowledge of medicines with the results of their investigations and labours.

By these means the pharmacy of this country has, I venture to say, been put on a footing of at least equality with that of any other country. You may, perhaps, think I am rather inconsistent in saying this, after giving so much of the credit for past improvements to our continental brethren; but the fact is that much of the improvement I have alluded to had been effected before our pharmacists had been trained, and were prepared, to perform their share of the work; and the principal credit therefore to which they are entitled is for recognizing, appreciating, and adopting the results of the good work done by others, and sifting out from among it that which is worthless and ought to be discarded.

But are we satisfied—have we reason to be satisfied,—with our position and prospects?

Our position is very different from that of the pharmacists, whatever they were then called, of a hundred, and still more of those of two hundred, years ago. The art of pharmacy no longer consists, as it did then, in beating some thousand or more of natural products to powder in a mortar, and then mixing them in various forms, to be administered to unfortunate patients, morning, noon, and night, as if it were their natural food.

The drug-grinder, the wholesale druggist, and the manufacturing chemist, have relieved the pharmacist of that and other parts of the duties involved in the preparation of medicines; but at the same time they have relieved him of some of the profits of his occupation, and the changes to which I have alluded, in the nature of the medicines used and the mode of using them, have still further operated in the same direction.

If we compare the pharmacy of this with that of past centuries, we may say of them that the pharmacy of the 18th century,—that of the old-fashioned apothecary,—was represented by draughts and mixtures, clysters and boluses, administered "*ad plenum et ad nauseam*," with returns and profits, nevertheless, that make our mouth water;—while the pharmacy of the 19th century, is that of the chemist, represented by active proximate principles, concentrated drops, and varnished pills, administered *ad minimum*, with returns and profits in proportion.

And now, if I may venture to speculate with reference to the future, and to suggest a pharmacy for the next century, I would say, Let us seek to give it a new character, in which neither the repulsiveness of the old nor the great concentration of more modern forms of medicine shall prevail.

The course we have hitherto pursued has been right as far as it goes, and we have not yet got to the end of it. We are patiently pursuing the analytical system, and physiologists are testing the effects of isolated agents individually and separately. All this is important and necessary, but it is but the stepping-stone, as I believe, to what will be the result of the final application of the knowledge we are thus acquiring. Nature does not work with isolated agents. All her results are produced by a concurrence of forces, and often by indirect means.

Now, do we sufficiently consult nature with reference to medicinal agents,—that is, as to the forms in which they are administered? We take great pains to consult her about our food, and find that our labours in that direction are not thrown away. Is it not perfectly true that the nutritive value of food is increased by the manner in which it is prepared?—not by isolating its constituents, but by judiciously combining them,—not by simplifying, but by complicating its composition, appealing and ever appealing to nature for her appreciation of results as expressed by all our senses? Thus we attain to perfection, or as near it as we can, in the preparation of food, and why not also—at least as far as the application of the principle is concerned—in the preparation of medicines? If it be the right principle in dietetics, why is it not so in therapeutics? Can we fix upon the exact point where one ends and the other begins, or show that the mode of action in one case is essentially different from that of the other?

I am not assuming that we should be able to make medicine absolutely attractive, but merely contending that we should make it as little repulsive as possible; and when we have attained to this result we may hope to find the use of medicines become popular again, and the pursuit of pharmacy worth following.

And now, in conclusion, allow me to refer again to three emblems which appear to have been used—and two of them frequently used—by those engaged in the practice of pharmacy.

In the first place we have—

Hermes Trismegistus, the oracle of the alchemists, and the emblem of the *Secret Art*, in which *ignorance is shrouded in obscurity*. This has been the emblem of some of our ancestors, but it must not be ours.

Then, in the next place, we have—

Bell and the Dragon—the dragon that destroys the last vestiges of the evil influences of the Hermetic art, and the bell, that with open mouth proclaims the means of alleviating the sufferings of disease. This rightly follows the preceding emblem, and its adoption has, in many instances, been fairly and fully justified.

And lastly, we have *the Phœnix*, which has been more generally used than either of the others; which represents not inappropriately the pharmacy of the present time and may, I hope, be still more appropriately adopted hereafter as the emblem of a system of pharmacy rising from the ashes of that which, being secret, deceptive, and worthless, has

been destroyed and replaced, like the laboratory of old Ambrose Godfrey, by an institution truly Catholic in its character, diffusing its blessings and benefits to all men, not excepting its ministers.

At the conclusion of the lecture, after a hearty vote of thanks had been accorded to Dr. Redwood, the chairman announced that Mr. Thomas Hyde Hills, the President of the Pharmaceutical Society, had been so kind as to place in the hands of the Council a sum of money which he desired should be expended in providing prizes for the pupils of the Association. Mr. Schacht, in acknowledging, on behalf of the Association, Mr. Hills' generosity, which seemed, he said, to be exercised on every possible occasion, remarked that it was especially gratifying on account of the testimony it afforded that their efforts in Bristol were viewed with interest and sympathy by those far removed from them. That would not fail to be an encouragement to them in the future. There probably would be no occasion to avail themselves of Mr. Hills' gift that session—then nearly at an end—inasmuch as the Council had already, as they were aware, provided for a scheme of prizes which at that period it would be desirable not to disturb; but the Council would take care, when new arrangements came to be made, that the best possible use should be made of the money entrusted to them. Meanwhile he would, with their consent, ask Professor Redwood to convey to Mr. Hills their very hearty thanks for his kind thought of them.

The President's remarks met with a cordial response, and a very satisfactory and successful course of monthly evening meetings was brought to a close.

LIVERPOOL CHEMISTS' ASSOCIATION.

The twelfth General Meeting of this Association was held at the Royal Institution, on Thursday evening, April 9th, 1874.

The following gentlemen were elected members of the Association: Messrs. John Horn, junior, and R. P. Sorty.

Mr. Abraham made mention of the death of Mr. Deane, of Clapham.

The following donations were announced: The current Nos. of the Pharmaceutical Journal; Transactions of the Historic Society of Lancashire and Cheshire; Annual Report, 1871, of the Board of Regents of the Smithoonian Institution; 2 copies of the additions to the British Pharmacopœia of 1867, and specimens having relation thereto, from Messrs. Evans, Sons, and Co., per Mr. Mason.

Mr. A. H. Mason, F.C.S., introduced the discussion for the evening, viz., on "Some notes on the 1874 additions to the British Pharmacopœia of 1867," in which he described the chemical and pharmaceutical preparations which have recently been made officinal.

In the discussion that followed the reading of this paper, Dr. Charles Symes said that not more frequently than once in 10 years is it thought desirable to publish a new edition of the Pharmacopœia; but during the interim a number of new remedies are introduced, and some of them have at least the merit of deserving an extended trial. In order that such trials might be made in a satisfactory manner, it was desirable that there should be some recognized standard of strength and character; and he was pleased when he understood that the Medical Council had decided to publish an appendix, a kind of secondary list, intermediately between the editions of the Pharmacopœia. He did not expect to find anything *very* new in the work, as that would frustrate its object. He simply expected to find that many remedial agents with which from almost daily use they had become familiar, and which, either from their non-existence or want of importance in 1867, were not included in the Pharmacopœia of that date, would now be brought forward in a definite form. He thought also that what had been written and said as to their merits, and the best manner of preparing the same, would receive due consideration. But the result was the meagre list before them, of which at least one-third was destined to speedy oblivion. It opens with Acetic Ether as an *internal* remedy, rarely prescribed *as such* in this country, and areca nut, which, though familiar as an anthelmintic for dogs, is a stranger in prescriptions. Injectio morphiæ hypodermica—a solution of acetate of morphia—why the acetate, if that salt is not sufficiently definite to admit of its being used in simple solution, especially as the united testimony of medical men and pharmacists go to prove that a solution of the sulphate is at once the most efficient and permanent preparation. Time alone could prove whether liquor magnesiæ citras will keep, if prepared *precisely according to the formula given*; Dr. Symes thought not. His experience went to show that about the worst form for pepsine possible had been chosen as regards its medicinal value, and the process for its preparation was exceeding crude, and the product disgusting. Pulvis glycyrrhizæ comp. had become popular with practitioner and patient, as *Prussian liquorice powder*; why not have adopted the Prussian formula? the one adopted is not even the ghost of it. He had already seen more than one prescription bearing the word *Prussian* underlined when ordering this remedy. Soap suppositories had too frequently proved a failure to have any right to introduction into even a tertiary list; the addition of glycerine might prevent them from hardening to the extent they otherwise would do, but in his opinion they were usurpers.

Then tinct. aurantii recentis was to be prepared with *rectified spirit*, which did not admit of a reason, much less an argument. Finally, this small book, with all its imperfections, is no secondary list—but essentially a part of our pharmacopœia—and, Dr. Symes presumes, stamped with its full authority.

Mr. John Abraham then made some remarks on the subject, and was to have read a paper on "Commercial Pepsine and its relation to the Pepsine of the Pharmacopœia," but Mr. Mason's paper having taken up so much time, it was thought advisable to postpone it to the next meeting; and after a vote of thanks had been presented to Mr. Mason for his paper, the meeting terminated.

MANCHESTER CHEMISTS' ASSISTANT'S ASSOCIATION.

The last ordinary meeting of the session of the above was held April 13th, 1874, the President in the chair. Mr. L. Siebold (Lecturer to the Manchester School of Pharmacy) delivered a most interesting and explanatory lecture on the "Constitution of Organic Bases," with particular reference to the artificial alkaloids, concluding with brief reference to organic analysis. A most hearty vote of thanks was accorded the lecturer for his kindness in being present and for delivering so instructive a lecture. Mr. Siebold thanked the students for the attention they had given, and stated that he always felt a vast amount of pleasure in being amongst them, remarking that it would have been very difficult some twenty years ago to have called together such a number of young men to listen to a lecture on Organic Chemistry, but he was now glad to find that such a state of indifference belonged to the past.

CHEMISTS AND DRUGGISTS' ASSOCIATION OF IRELAND.

The Pharmacy Bill for Ireland.

A special meeting of the Chemists and Druggists' Association of Ireland, was held at the Society's rooms, Molesworth street, on Monday evening, April 20th, for the purpose of considering the Pharmacy Bill proposed by the College of Physicians, Mr. E. M. Hodgson, President, in the chair.

The chairman said that the meeting was called for the purpose of considering how the interests of the trade would be affected by the proposed bill, and whether it

would be to their interest, as a body, to accept the bill as proposed, or to aid the Apothecaries' Hall in passing a measure prepared by them for a similar purpose. He believed the Apothecaries' Bill would best meet their views. Considerable discussion took place, Mr. Holmes urging the extension of the English Pharmacy Act to Ireland. Professor Tichborne strongly urged co-operation with the Apothecaries' Company, believing their bill would best suit the interests of the Society. It was ultimately agreed that a deputation should wait on the Apothecaries' Company to discuss the matter. The following deputation was proposed :—

Mr. Hodgson, President ; Mr. Hayes, Hon. Sec. ; Mr. Goodwin, Treasurer ; Mr. Grindly, and Mr. Simpson.

Mr. Simpson proposed the addition of the following names :—

Mr. L. Erson, J.P., and Mr. J. T. Holmes, which was agreed to.

HULL CHEMISTS' ASSOCIATION.

Mr. Henry J. Parson, the teacher of the Chemistry and Materia Medica classes in connection with the above Association, writes to say that the last paragraph referring to his report on p. 842, should read as follows :—"In the latter (Materia Medica) the competitors failed to obtain sufficient marks for the prize. He was pleased with Mr. Padley's work, who competed for the Junior Chemistry prize, and recommended him as deserving some reward."

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

The Juries Bill.

On Wednesday last, April 22, Mr. Lopes proposed the second reading of his bill for the reform of the jury system, which, he explained, was substantially the same as the one introduced by the late Government. The main provisions of the measure comprised the increase of the area of choice, the creation of a lodger qualification both for common and special juries, the extension of the liability to serve from 60 up to the age of 65 years, and that all summonses should pass through the post, to avoid bringing the summoning officer in contact with the juryman. Further, it proposed to retain twelve as the number of the jury in criminal cases, but that seven should be the number in civil cases, to be increased to twelve at the instance of either of the parties concerned. Moreover, it would continue the unanimous verdict, the necessity for which would be enhanced by the reduction in the number of the jury, assimilate the qualification in places with limited jurisdiction to that in counties, and, in case of the death or sudden illness of any member or members of a panel, authorize the presiding judge to go on with the trial, provided that where the jury numbered twelve it was not reduced below nine, or if seven was not reduced below five. Lastly, as to payment, the special juror would be paid the guinea for every case he tried, as at present, and the common juror 5*s*.

Mr. Young gave a general support to the bill, but intimated that in committee he should move the omission of the clause requiring unanimity, and the substitution of a majority clause.

Mr. Gregory thought that the present number of twelve ought to be generally retained, in which opinion Mr. Watkin Williams concurred ; but Sir J. Eardley Wilmot, on the other hand, had come to the conclusion that in civil cases the smaller number might fairly be tried, whilst he would adhere to twelve in criminal cases.

Sir H. James hoped that the Government would accept this amongst the other legacies left them by their predecessors in office.

The Attorney-General hoped to be able, before the Bill went into committee, to state whether he could adopt it as a Government measure ; at any rate, he should be prepared to give every assistance in his power to make it as perfect as possible.

Mr. Russell Gurney (Recorder) assented to the principle of taking the verdict of a majority in civil cases, the judge to have power to grant a new trial if dissatisfied with the verdict. As to the reduction in the number, he did not see that it was desirable in all cases to retain the number of twelve ; for the jury had not the same opportunity of consulting together, and a reduced number would impart increased sense of responsibility.

Mr. Secretary Cross tendered to Mr. Lopes the thanks of the Government for the pains he had taken with the subject, and the care with which the bill had been drawn. He hoped to see it in its present or amended shape passed into law this session. The bill was thereupon read a second time.

The Pharmaceutical Society *v.* T. Clarkson.

In this case, brought in the Sheffield County Court to recover a penalty of £5 incurred by using the name of "druggist" contrary to the provisions of the Pharmacy Act, the defendant's attorneys, prior to the day appointed for the trial, paid into Court the £5 sued for, and the costs.

Poisoning by Aconite.

On Thursday, April 16, an adjourned inquest was held by Mr. Wm. Codd, Coroner for the Northern Division of the County of Essex, at Elmstead, to inquire into the circumstances attending the death of Henry Gilbert, a labourer, aged 51, who died after taking some medicine supplied to him by Mr. Webster, a medical botanist, of East Hill, Colchester. On a previous occasion Mr. Squire, surgeon, of Wyvenhoe, stated that after a *post-mortem* examination he was unable satisfactorily to account for the death, and the inquiry was adjourned to allow time for an analysis of the contents of the stomach to be made.

The Coroner having received from Mr. Squire Dr. Tidy's report of the analysis, he read it to the jury as follows :—

"Report on the Analysis of Viscera received from Police-Constable Joyce, March 27th, 1874, at the Laboratory of the London Medical College. Also a bottle of mixture, labelled '*The Mixture: one tablespoonful to be taken an hour after every meal. W. P. Webster, Medical Dispensary, Colchester.*'

"The bottle and jars were securely sealed—the seals unbroken.

"I have carefully examined the mixture. The two principal ingredients were aconite and camphor. I am of opinion that there was sufficient aconite in the whole bottle to produce dangerous results, although I am unable to say that the amount of aconite in the dose ordered on the bottle (a tablespoonful) would be likely to cause death.

"I carefully examined the several viscera. There was nothing in the *post-mortem* appearances that need be specially noted, excepting the heart, which was large and excessively dilated. There were, moreover, evident signs of extensive valvular disease.

"I carefully examined the stomach for both mineral and vegetable poisons, and I found present a trace of aconite.

"I am of opinion that a very small dose of aconite may cause death under the circumstances of the extensive heart disease that existed, but I scarcely think that the dose taken would have proved fatal in an ordinary case, or in a person of fair general health.

"I consider, therefore, death was due in this case to heart disease, accelerated by the aconite taken.

"C. Meymott Tidy, M.B., M.A.

"Lecturer on Chemistry and Professor of Medical Jurisprudence at the London Hospital; Medical Officer of Health for Islington; Public Analyst for the City of London, etc.

"*The Laboratory, London Hospital,*
"*10th April*, 1874."

The Coroner added that there was no doubt, as Dr. Tidy said, sufficient aconite in the whole bottle to produce dangerous results, but no man would be foolish enough to take a pint or a bottle of medicine for a dose. The question for the jury now to consider was whether, after this report, they thought it desirable to further prolong the inquiry. It seemed to him to be perfectly clear that the death of deceased was not due to an overdose of aconite. He would remind them that on the morning in question the poor fellow had walked eight or nine miles to his daughter's home, and on his arrival there he complained of feeling very bad. Then, the *post-mortem* examination revealed the fact that he had an enlarged heart, with extensive valvular disease. It followed, as a matter of course, that he was suffering from his heart; and it was therefore quite within the range of possibility that he might have died from that attack without the intervention of aconite, although not quite so soon. They must also bear in mind that, according to the statement deceased made to his daughter, he must have taken the medicine not later than half-past two o'clock, probably before, because at twenty minutes to three he returned to her and said he had been to Mr. Webster's for some medicine, and had taken a glass of it. At five o'clock he got into the carrier's cart, and then he complained of the symptoms which had been described (tingling of the flesh, swelling of the body, and vertigo); so that two hours and a half must have elapsed from the time of his taking the medicine till the symptoms showed themselves. It followed, therefore, that the dose could not have been very strong. He did not know whether the jury wished to hear any further evidence—he was ready to hear it if they wished—but he could not see, under the circumstances, that they would be any nearer the result than they were now. They could hear what Mr. Webster had to say, if that gentleman wished to be examined.

The Coroner (to Mr. Squire): Are you of the same opinion as Dr. Tidy as to the cause of death?

Mr. Squire: I am of the same opinion—that death resulted from the aconite acting upon a diseased and weakened, and dilated heart.

The Coroner: You are of the same opinion as Dr. Tidy?

Mr. Squire: Yes, I don't say an overdose.

The Coroner: Of course not.

A strong opinion was expressed by some of the jury that aconite ought not to have been administered without first ascertaining the patient's condition. It was urged, however, on behalf of Mr. Webster, that if deceased had been a sickly-looking man there would have been something in the point; but it was not to be supposed that a doctor examined every apparently strong and healthy man who went and asked for something for a cough or cold.

The Foreman asked how long Mr. Webster had been in practice, whether he had ever prescribed aconite before, and whether it had ever before been attended with serious consequences.

Mr. Webster said he had used it every day for the last five or six years.

After a long discussion the jury, upon retiring, failed to agree in a verdict; nine wishing to give a verdict in accordance with the medical testimony, and three one that death occurred from natural causes, without mentioning the use of aconite. Eventually the jury were discharged without giving a verdict.

Alleged Adulteration of Milk.

At the Greenwich Police Court, on Saturday, April 19th, Mr. Daniel Phillips, farmer and dairyman, of Lewisham, appeared to an adjourned summons, at the instance of the Lewisham Board of Works, charging him with selling, or causing to be sold, milk adulterated with water.—Mr. Edwards attended to prosecute, and Mr. Pook appeared for the defendant.—The case was first heard on the 21st ult., when a certificate from Dr. Heisch, Chemical Professor at the Middlesex Hospital, was produced, to the effect that a sample of milk, not being disputed as having been purchased of defendant's servant, was found upon analysis, to have had an admixture of over 25 per cent. of water. Upon this evidence the case had been adjourned in order that Dr. Heisch might personally attend as a witness, so as to admit of a cross-examination taking place as to the date the analysis was commenced and completed; it being shown in evidence that the milk analysed was purchased between three and four on the afternoon of the 24th February, when it was placed in a bottle and sealed, and delivered to Dr. Heisch the next day, his certificate not being dated till the 4th March. The contention was that unless the analysis of milk is commenced within six hours after being taken from the cow the test is uncertain; the defendant, who was examined as a witness in another case, stating that he had then a bottle, into which milk was drawn direct from the cow by himself and sealed. This milk had been standing in a place of rest twelve days, and there was at least 20 per cent. of whey or water perceptible, the rest being curds.

Dr. Heisch now attended, and before giving evidence said he had, on the previous evening, received a subpœna from the office of the defendant's solicitors, and, seeing it related to the present case, he took it for granted that it required his attendance, and had not read it. He was not, therefore, aware he was required to bring his books containing entries of the analysis then under investigation. He then stated that the milk upon which his certificate was based was handed to him at a quarter to five in the afternoon of the 25th of February, and that he then commenced the analysis, the different tests and results of which he detailed. He obtained the residuum from the milk on the 26th of February, and the analysis was completed certainly not later than the morning of the 27th. In making these analyses it was usual to arrive at a conclusion as to the extent of adulteration on an average of tests of good milk, but the conclusion arrived at in this case was taken on an average of the worst forms of milk that could be analysed, and he found it had been very much diluted with water, certainly fully 25 per cent.

Professor Attfield was called, and said he had heard the evidence of Dr. Heisch, and concurred in the conclusions he had stated. In answer to questions, he stated that there was no difficulty in the analysis of milk to tell the component parts of milks that contain water from that known as water coming "from the cow with the iron tail," nor was there any difficulty in analysing milk that had been taken from the cow thirty-six hours, unless placed in a warm place and it had become very bad. He had analysed milk ten days after its being taken from the cow, and had found no change in it, but in others of ten days the milk was so bad it could not be analysed.

Mr. Pook said the defendant was the owner of 400 cows; and, holding many contracts, his character was of the greatest importance. It was true he had before been fined for a like offence—the adulteration being stated to be 8 per cent., but that, it was contended, was pure milk. He was prepared to call scientific witnesses, who would give evidence in the defendant's favour, among whom he mentioned the chief of the chemical laboratory department of St. Thomas's Hospital.

Mr. Balguy said this evidence would take up a great deal of time, and it was determined to again adjourn the case for a fortnight, to devote time specially to it.—*Standard.*

Review.

SKIN DISEASES: an Inquiry into their Parasitic Origin and Connection with Eye Affections; also the FUNGOID OR GERM THEORY OF CHOLERA. By JABEZ HOGG. London: Baillière, Tindal, and Cox. 1873.

The first impression produced on the reader of Mr. Hogg's treatise is an unfavourable one. His method is confused, his style not only inelegant but inaccurate, and his generalizations premature. He has been, however, at pains so obvious in collecting his materials, that the candid reviewer gives him the benefit and himself the trouble of a second perusal, with the result, we are sorry to say, of a confirmation of the first impression.

Having inured himself to such phrases as "the more deeper seated parts of the body" (p. 6); "the several functions of the skin *and which* are five-fold" (p. 9)—"the *dermis* or corium" (p. 10)—derma being the proper word, *vide* Dunglison's Lexicon; "the *quantative* and qualitative errors of the chemical composition of the different structures of the body" (p. 18.), etc., etc.—in other words, having got over the *stile*, we come to Mr. Hogg's theory, which is, as far as we can gather, the following: "there exists but one essential organism, a fungus whose spores find a soil common alike to the surface and the more secluded parts of the human or animal body; variations in skin diseases, associated with a parasitic growth, are due to differences in the constitution of the person affected; consequently it is neither correct nor desirable to separate and classify them as 'parasitic diseases of the skin.'" In other words, while the parasitic fungus is in all cases the same, the skin diseases it is associated with vary according to the constitution of the patient. This is a very old theory indeed; but its antiquity has neither given it acceptance nor prevented its being announced as a discovery by Mr. Jabez Hogg. The primordial identity of matter has been maintained by many philosophers—Huxley, with his protoplasm, being among the latest. The modification of matter in the individual, according as subjective conditions vary, was a truism almost as soon as it was truth.

"What," Mr. Hogg asks (p. 106), "has positively been made out with regard to the fungoid bodies in the production of disease? The most carefully conducted examinations have as yet produced only negative results. That most common form of disease in which fungoid bodies are found—Leptothrix—is known to arise from a neglected condition of the mouth and teeth, and is readily cured by a proper use of the tooth brush." This is a fair specimen of the looseness of Mr. Hogg's mode of reasoning and writing. He omits to tell us in what "a neglected condition of the mouth and teeth" consists. He seems to regard it, indeed, as a primary disease.

In the next page he tells us that fen-ague may be traced to accumulated and decaying animal matter. We had thought that the disease had been conclusively traced by M. Léon Colin, of the Val-de-grâce, to a telluric poisoning (*intoxication tellurique*), due to the absence of that vegetable matter which is the appropriate pabulum of the vegetative energy of the soil. But *n'importe*. The amount of enlightenment the reader has to get from Mr. Hogg's "Fungoid theory of disease" may be inferred from the following sentence, the last but two in his treatise: "If any one is determined to furnish a formula for cholera, he may take bad air, bad water, sewer emanations, floating stinks, *germs if you please*, bad ventilation, with perhaps a dozen or two more evils, which are all more or less concerned in originating the disease." Mr. Hogg subscribes to the maxim that "definition is dangerous" and makes his own elastic accordingly.

Obituary.

Notice has been received of the death of the following:—

On the 13th April, 1874, Mr. James Hodge Byles, Pharmaceutical Chemist, of Hackney Road, London. Mr. Byles had been a member of the Pharmaceutical Society since 1842.

On the 19th February, 1874, Mr. David Howell, Chemist, at Camarthen, after a long and painful illness, aged 45 years. He served his apprenticeship to Mr. R. M. Davies, in the same town, with whom he lived some years afterwards as assistant. He then removed to Northampton, where he lived about two years with Messrs. Jeyes and Co.; after that he was several years in London, an assistant in the Apothecaries' Hall, and subsequently with Messrs. Savory and Moore. He also spent many years in Piccadilly, Manchester, first as assistant to Mr. Dymond, and afterwards to Mr. Pyne. He was also in business on his own account at Manchester for a short time, but failing health caused him to relinquish it and he took a voyage across the Atlantic in the hope of obtaining renewed health, but this was only realized in a small degree. He was of a kind, genial disposition, and was much esteemed.

On the 14th April, 1874, Mr. Edward Lister, Chemist and Druggist, of Cowbridge. A local paper says of him "The deceased gentleman, who died at the advanced age of 75, had carried on an extensive business for upwards of half a century in this town, and his loss will be deeply felt, not only by his nearest friends, but by those with whom he came in contact in his business capacity. The deceased gentlemen was by marriage related the Llewellyns, and nearly related to Lord Ribblesdale. He leaves one son, the Rev. E. Lister, of Newport, Mon., surviving."

On the 15th January, 1874, Mr. Edward Postill, Chemist and Druggist, of York.

On the 9th April, 1874, Mr. Samuel Pinder, Chemist and Druggist, of Laxton, Notts.

On the 21st April, 1874, Mr. John Croston, Chemist and Druggist, of Atherton, Lancashire.

Notes and Queries.

[391]. OINTMENT FOR MANGE.—If *L.* had occasion to try the ointment he refers to upon a dog, he would find it highly successful, in the following proportions:—

℞	Cer. Resinæ	℥j
	Flor. Sulph.	℥ss
	Ol. Junip.	℥iij

M.

I have seen it used in numerous cases with complete success, and I may add it is "refreshing not only to one," but to any mangy dog.

Hydrarg. sulph. flor. gr. iij may be given internally at the same time with advantage.—H.

[394]. PILL COATING.—*H. M. D.* would be glad if any one would kindly inform him of the best way to coat pills with a tasteless, pearly white coating. Treating with a saturated solution of *spent* Tolu in S.V.R., and afterwards roll in powdered French chalk has been tried, but not with good result. The pills by that process are contaminated by the odour and taste of the balsam; neither are they of the desired whiteness.—H. M. DAVIES, *Pontypool.*

JACOBI'S FOOD FOR INFANTS.—The following formula for a food for infants, recommended by Dr. Jacobi of New York, is quoted by the *British Medical Journal* from the *Ohio Clinic*. "Crack a teaspoonful of barley in a common coffee mill, then boil it fifteen minutes in a gill of water, adding a pinch of salt. Then strain, and, for a young child, add half as much cow's milk as

you have barley water, sweeten lightly with sugar, and whilst tepid feed from a nursing bottle. If the bowels be costive use oatmeal in the place of barley.

SOLUBILITY OF SUCCINIC ACID IN WATER.—M. E. Bourgoin, in a communication to the French Acadamy of Sciences (*Compt. Rend.*, lxxviii. 195), has recently reported the results of a series of experiments on the amount of pure succinic acid soluble in water at various temperatures. The method adopted up to 50° C. was to heat purified commercial succinic acid in distilled water by means of a water bath; allow the solution to cool slowly to the temperature desired, shake, and then test the acidity with baryta water. For temperatures above 50° the water was evaporated, and the residue weighed. The following were the quantities held in solution by 100 parts of water at different temperatures:—0° C., 2·88 parts; 8°·5 C., 4·22 parts; 14°·5 C., 5·14 parts; 27° C., 8·44 parts; 35°·5 C., 12·29 parts; 40°·5 C., 15·37 parts; 48° C., 20·28 parts; 78° C., 60·775 parts; boiling, 120·86 parts. Beyond 50° C., therefore, the solubility increases rapidly with the temperature.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Late Henry Deane.

Sir,—Is any movement likely to be made by the Chemists and Druggists, or by the Council, to secure for the Society some permanent remembrance of this distinguished pharmacist and honest man, in the shape of a portrait in oil, bust, scholarship, or in any other form? If so, I shall be glad, with many others with whom I have conversed, to subscribe towards raising a fund for the purpose.

FOUNDER.

The Benevolent Fund.

Sir,—I have read with great interest the correspondence relating to the Benevolent Fund. I quite agree with those who wish to have a good funded capital, and I also agree with those who wish to relieve as much distress as possible; consequently I think a good plan will be, in addition to my usual subscription of 10*s.* 6*d.*, to give a donation of like amount, the first to be funded, the second to be spent during the year. If others will follow my suggestion, I think the fund will derive more benefit than from any scheme which I have seen proposed.

THOMAS DAINES.

King William's Town, Cape Colony.
March 9th, 1874.

[*** We believe that for some years past benevolent members of the trade have volunteered subscriptions by which a fund has been placed in the hands of the Secretary for application by him in urgent cases.—ED. PH. J.]

The Analysis of Milk.

Sir,—Dr. Macadam, whose paper on milk you have published, affords an example of a kind of procedure which is not altogether unknown., viz., the putting forward of a set of experiments, and representing them as establishing the reverse of that which they really do.

Dr. Macadam has analysed 44 samples of milk, obtained from three dairies, and announces, as one of the results of his work, that the "Solids not fat" range from 8·74 per cent. to 11·23 per cent.

But on inspecting his figures it appears that the 8·74 stands quite alone, and that the high result also stands nearly alone. Inasmuch as these extremes are unsupported, and are not verified, they can only be looked upon as errors of experiment.

Rejecting the three extreme results—viz., 8·74, 11·23, and 10·79, as requiring confirmation, Dr. Macadam's work stands thus: he has analysed 41 samples of milk—sometimes the whole milk, and sometimes a fractional part of the milking—and finds, according to his analysis, the "solids not fat" ranging from 8·94 to 10·22. This result is obviously compatible with the real range being 9·3 to 10·0 (which is my proposition).

Should Dr. Macadam object to his single, unsupported, and unverified 8·74 being set down as an error of experiment, let him consider whether, if he had made 44 analyses of the same sample of milk, he would not most probably have at least once got a similar low result.

J. ALFRED WANKLYN.

117, *Charlotte Street, Fitzroy Square, W.*
April 14th, 1874.

Cocculus Indicus.

Sir,—Having noticed for some time the discussion carried on in your Journal in reference to Cocculus Indicus, and what became of it, I will, with your permission, take this opportunity of thanking your correspondent "Brunswick" for informing your readers of the ultimate destination of the large quantities of Cocculus imported, and thus relieving the brewers from the odium cast upon them in this matter. As a brewer I think I may safely venture to assert, without fear of contradiction, that not a single wholesale brewer in the country uses Cocculus Indicus *or any other adulterant.* There are those who use salt to precipitate the tannic acid contained in the hop, but this cannot come under the term adulteration.

It is the retail brewer, the keeper of the low public-house, who occasionally resorts to such practices, but this class of brewer is fast becoming extinct. The brewer who brews on a large scale, who has a properly constructed "brewing plant," and who practically and *scientifically* understands his business and gives it his attention, has no occasion to use anything else but good malt and good hops to ensure good ale.

T. B. ALLKINS,
Pharmaceutical Chemist.

Midland Brewery, Tamworth.

W. S. Wardle.—Apply by letter to Professor Bentley, 17, Bloomsbury Square.

"*Chemicus.*"—Mr. F. C. Hills, Manufacturing Chemist, Deptford, S.E., is the largest manufacturer in London. There are others at Birmingham.

J. B.—(1) American quinine is not imported. (2) About 50*s.* per oz. for large quantity. (3) Useless for pharmaceutical purposes; might be used in the arts as a flux.

"*Hydrargyrum.*"—PHARM. JOURN. [3] vol. iii., pp. 141 and 582, and the present volume, p. 79.

C. Warrior.—There is no law at present to prevent a registered chemist and druggist doing so.

W. H.—Dissolve the hypophosphite of soda in a portion of the water, and add the phosphoric acid to this solution. Mix the hydrochloric acid with the perchloride of iron, and dilute with the remainder of the water. On then mixing the two solutions the least precipitation of hypophosphite of iron will take place that is possible; but, of course, much will precipitate from such a mixture. Add the spirit of chloroform last.

J. F.—We have no doubt that the preparations are of the character you suppose.

C. P.—The graduates referred to have *no* legal statutory qualification.

S. E. Pritchard.—*Luzula sylvatica.*

W. A. W.—Your safest course would be to put the question to the authorities of the Inland Revenue Department.

"*Fair Play.*"—As a matter of expediency we do not share your opinions with regard to the evil you refer to, and as you will find on reference to the Journal of April 11th, we are disposed to think that it must be dealt with otherwise than by litigation. As regards one of the advertisements that you enclose, it is somewhat satisfactory to note that as it has appeared several times in the daily papers it does not seem to have met with very ready response.

"*Inquirer.*"—We imagine the preparations in question are seldom what they profess to be, and should not be used to produce the officinal infusions.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Gallais and Co., J. E. Moore, Evan Evans, Pickard, C. R. Blackett, Dr. De Vrij, Botanist, 806.

ANALYSIS OF SOME CINCHONA BARKS CULTIVATED AT OOTACAMUND.

BY DR. J. E. DE VRIJ.

In the PHARMACEUTICAL JOURNAL for September 6th, 1873, I published the results of my analysis of a part of the 25 samples of bark sent to me by Mr. McIvor. This number has since been increased to 30; and as the analysis of all of them has recently been terminated by me, I publish now the results.

Since the publication of that paper I have ascertained that Dr. Hesse is right, when he states that there exists no *bitartrate* of cinchonidine, and that the compound separated from a solution of a salt of cinchonidine, by bitartrate of sodium, is nothing else but a *neutral* tartrate of cinchonidine. Therefore I have given up the use of bitartrate of sodium to ascertain the quantity of cinchonidine, and use in its stead the Rochelle salt. This non-existence of a bitartrate of cinchonidine is a curious fact, as the well-defined bitartrates of quinine, quinidine, and cinchonine really exist and have been prepared by me.

No. 8.—Red bark; Deva Shola plantation. About 6000 feet elevation. A. Original bark, 8 years old.

48·8 grammes of dry bark yielded 5·3 grammes of mixed alkaloids = 10·86 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{14·6}{0·8634}$; l = 100 mm.; $a° = 5°$ ↖, was $[a]j = 84°·5$ ↖.

4·959 grammes of mixed alkaloids treated with ether yielded 1·692 grammes of alkaloids soluble in ether = 3·705 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·4}{0·67}$; $l = 100$ mm.; $a° = 6°$ ↖, was $[a]j = 111°$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{17·7}{1·232}$; l = 100 mm.; $a° = 3°$ ↖, was $[a]j = 43°·1$ ↖.

1·016 grammes of alkaloids soluble in ether yielded 0·385 gramme of herapathite = 0·2175 gramme of quinine = 0·793 per cent.

B. renewed bark 24 months old.

49 grammes of dry bark yielded 5·096 grammes of mixed alkaloids=10·4 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{15·9}{0·85}$; l=100 mm.; $a° = 4°$ ↖, was $[a]j = 78°$ ↖.

4·484 grammes of mixed alkaloids treated with ether yielded 3·3 grammes of alkaloids soluble in ether = 7·654 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·6}{0·797}$; $l = 100$ mm.; $a° = 10°$ ↖, was $[a]j = 158°$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{12·8}{0·4298}$; l = 100 mm.; $a° = 5°$ ↗, was $[a]j = 148°·9$ ↗.

2·535 grammes of alkaloids soluble in ether yielded 2·728 grammes of herapathite = 1·5413 grammes of quinine = 4·653 per cent.

The results of the analysis of these two barks taken from the *same* tree are very interesting. Whilst the amount of mixed alkaloids in both barks is nearly the same, the amount of quinine in the renewed bark is so much greater that this fact deserves peculiar attention; for if it should prove to be a general rule that the renewed bark of *C. succirubra* is so much richer in quinine than the original bark, then the millions of trees of *C. succirubra* actually growing in British India could be adapted to produce large quantities of bark fit for the manufacture of quinine.

No. 9.—Renewed red bark, 20 months old. Neddiwattum plantation. Elevation about 6200 feet.

50 grammes of dry bark yielded 4·577 grammes of mixed alkaloids = 9·154 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{15}{0·805}$; l= 100 mm.; $a° = 4°·2$ ↖ was $[a]j = 78°·2$ ↖.

3·971 grammes of mixed alkaloids treated with ether yielded 2·476 grammes of alkaloids soluble in ether = 5·707 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·1}{0·728}$; $l = 100$ mm.; $a° = 8°·3$ ↖, was $[a]j = 137°·9$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{12·6}{0·483}$; l= 100 mm.; $a° = 3°$ ↗, was $[a]j = 78°·2$ ↗.

1·791 grammes of alkaloids soluble in ether yielded 1·58 grammes of herapathite = 0·8644 gramme of quinine = 2·75 per cent.

No. 20.—Red bark, 10 years old, mossed. Neddiwattum—

50 grammes of dry bark yielded 5·335 grammes of alkaloids = 10·67 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·5}{0·604}$; l=100 mm.; $a° = 2°$ ↖, was $[a]j = 41°·3$ ↖.

4·805 grammes of mixed alkaloids treated with ether yielded 1·415 grammes of alkaloids soluble in ether = 3·1421 per cent. The molecular rotation calculated from the observation $\frac{V}{p} = \frac{13·1}{0·441}$; l= 300 mm.; $a° = 14°$ ↖, was $[a]j = 138°·6$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{13·6}{0·599}$; l = 300 mm.; $a° = 1°$ ↗, was $[a]j = 7°·5$ ↗.

0·976 gramme of alkaloids soluble in ether yielded 0·777 gramme of herapathite = 0·439 gramme of quinine = 1·413 per cent.

No. 21.—Red bark, 8 years old. Neddiwattum—

50 grammes of dry bark yielded 4·348 grammes of alkaloids = 8·696 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·2}{0·757}$; l=100 mm.; $a° = 2°·5$ ↖, was $[a]j = 43°·6$ ↖.

4·154 grammes of mixed alkaloids treated with ether yielded 1·58 grammes of alkaloids soluble in ether = 3·3075 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·4}{0·511}$; l=100 mm.; $a° = 5°·5$ ↖, was $[a]j = 133°·4$ ↖.

1·068 grammes of alkaloids soluble in ether yielded 0·79 gramme of herapathite = 0·4463 gramme of quinine = 1·382 per cent.

No. 22.—Red bark, the same as No. 20, but unmossed.

50 grammes of dry bark yielded 4·088 grammes of mixed alkaloids = 8·176 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·6}{0·696}$; l=100 mm.; $a° = 2°$ ↖, was $[a]j = 36°·2$ ↖.

3·754 grammes of mixed alkaloids treated with ether yielded 1·365 grammes of alkaloids soluble in ether = 2·973 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·5}{0·477}$; l=100 mm.; $a° = 3°$ ↖, was $[a]j = 78°·6$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{12{\cdot}7}{0{\cdot}692}$; $l =$ 100 mm.; $a° = 1°$ ↖, was $[a]j = 18°{\cdot}3$ ↖.

0·903 gramme of alkaloids soluble in ether yielded 0·638 gramme of herapathite = 0·36 gramme of quinine = 1·185 per cent.

No. 23.—Red bark; Deva Shola; renewed bark, 3 years old.

26·8 grammes of dry bark yielded 2·779 grammes of mixed alkaloids = 10·37 per cent. The molecular rotation calculated from the observation $\frac{V}{p} = \frac{15}{0{\cdot}721}$; $l =$ 100 mm.; $a° = 2°$ ↗, was $[a]j = 41°{\cdot}6$ ↗.

This abnormal rotation *to the right* made me suppose that the quantity of cinchonine in this bark exceeded very much that of cinchonidine. The investigation proved that my supposition was right, as I obtained from 1·577 grammes of alkaloids insoluble in ether, by the use of Rochelle salt, 0·383 gramme of tartrate of cinchonidine=0·308 gramme of cinchonidine, and 1·269 gramme of cinchonine. Besides these I found a trace of quinidine.

2·755 grammes of mixed alkaloids treated by ether yielded 1·114 grammes of alkaloids soluble in ether = 4·193 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{20}{1{\cdot}114}$; $l = 100$ mm.; $a° = 7°$ ↖, was $[a]j = 125°{\cdot}7$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{13}{0{\cdot}632}$; $l =$ 100 mm.; $a° = 9°{\cdot}5$ ↗, was $[a]j = 195°{\cdot}4$ ↗.

1·075 grammes of alkaloids soluble in ether yielded 0·918 gramme of herapathite = 0·519 gramme of quinine = 2·024 per cent.

No. 24.—*C. Pahudiana*, original bark, 10 years old. Elevation 7800 feet.

55·8 grammes of dry bark yielded 1·402 grammes of mixed alkaloids = 2·51 per cent. The molecular rotation calculated from the observation $\frac{V}{p} = \frac{15{\cdot}1}{0{\cdot}51}$; $l = 300$ mm.; $a° = 10°$ ↖, was $[a]j = 98°{\cdot}7$ ↖.

1·402 grammes of mixed alkaloids treated with ether yielded 0·58 gramme of alkaloids soluble in ether = 1·038 per cent.

0·58 gramme of alkaloids soluble in ether yielded 0·032 gramme of herapathite = 0·018 gramme of quinine = 0·032 per cent.

No. 25.—*C. Pahudiana*. A. Original bark.

60 grammes of dry bark yielded 1·214 grammes of mixed alkaloids = 2·012 per cent. The molecular rotation calculated from the observation $\frac{V}{p} = \frac{20}{1{\cdot}214}$; $l =$ 100 mm.; $a° = 9$ ↖, was $[a]j = 148{\cdot}2$ ↖.

1·1533 grammes of mixed alkaloids treated with ether yielded 0·756 gramme of alkaloids soluble in ether = 1·324 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12{\cdot}7}{0{\cdot}305}$; $l = 300$ mm.; $a° = 13°$ ↖, was $[a]j = 180°{\cdot}4$ ↖.

0·756 gramme of alkaloids soluble in ether yielded 0·612 gramme of herapathite = 0·346 gramme of quinine = 0·606 per cent.

B. Renewed bark, 2 years old. The renewed bark grew during the first six months under moss, and was later unmossed.

48·7 grammes of dry bark yielded 2·34 grammes of mixed alkaloids = 4·8 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12{\cdot}7}{0{\cdot}545}$; $l = 100$ mm.; $a° = 6°$ ↖, was $[a]j = 139°{\cdot}8$ ↖.

2·286 grammes of mixed alkaloids treated with ether yielded 1·125 grammes of alkaloids soluble in ether = 2·362 per cent. 1·125 grammes of these latter alkaloids yielded 0·66 gramme of herapathite = 0·373 gramme of quinine = 0·783 per cent.

The alkaloids insoluble in ether consisted chiefly of cinchonidine, with a slight trace of cinchonine.

No. 26.—Strong growing seedling Cinchona, dark leaved, from lower part of the stem. Kartairy.

This and the following three barks were taken from two very strong growing varieties of *C. officinalis*. The barks, Nos. 26 and 27, were taken from a tree planted in 1868, which is now 26 feet in height, with a stem of 16 inches in circumference at 1 foot from the ground, and 12 inches in circumference at 15 feet from the ground.

50 grammes of dry bark yielded 5·43 grammes of mixed alkaloids = 10·86 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13}{0{\cdot}631}$; $l = 100$ mm.; $a° = 8°$ ↖, was $[a]j = 164°{\cdot}8$ ↖.

4·644 grammes of mixed alkaloids treated with ether yielded 1·808 grammes of alkaloids soluble in ether = 4·228 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13}{0{\cdot}781}$; $l = 100$ mm.; $a° = 10°{\cdot}5$ ↖, was $[a]j = 174°{\cdot}7$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{13}{0{\cdot}704}$; $l = 100$ mm.; $a° = 9°$ ↖, was $[a]j = 166°{\cdot}1$ ↖.

1·78 grammes of alkaloids soluble in ether yielded 2·081 grammes of herapathite = 1·176 grammes of quinine = 2·804 per cent.

No. 27.—Strong growing seedling Cinchona from upper part of the stem. Kartairy.

50 grammes of dry bark yielded 3·472 grammes of mixed alkaloids = 6·944 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13}{0{\cdot}614}$; $l =$ 100 mm.; $a° = 6°{\cdot}5$ ↖, was $[a]j = 137°{\cdot}6$ ↖.

As this bark and the former have been taken from different parts of the *same* tree, the difference of nearly 4 per cent. in the amount of the alkaloids is very instructive.

3·317 grammes of mixed alkaloids treated with ether yielded 1·072 grammes of alkaloids soluble in ether = 2·244 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{15{\cdot}8}{1{\cdot}072}$; $l = 100$ mm.; $a° = 10°$ ↖, was $[a]j = 147°{\cdot}4$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{14{\cdot}1}{1{\cdot}174}$; $l =$ 100 mm.; $a° = 13°{\cdot}5$ ↖, was $[a]j = 163°{\cdot}8$ ↖.

1·031 grammes of alkaloids soluble in ether yielded 1·035 grammes of herapathite = 0·585 grammes of quinine = 1·273 per cent.

No. 28.—Strong-growing seedling Cinchona from Welbeck; dark leaved.

50 grammes of dry bark yielded 3·367 grammes of mixed alkaloids = 6·734 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13}{0{\cdot}663}$; $l =$ 100 mm.; $a° = 7°$ ↖, was $[a]j = 137°{\cdot}2$ ↖.

3·27 grammes of mixed alkaloids treated with ether

yielded 1·296 grammes of alkaloids soluble in ether = 2°·67 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{20}{1·296}$; $l = 100$ mm.; $a° = 8°·5$ ↖, was $[a]j = 131°·1$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{13}{1·132}$; $l =$ 100 mm.; $a° = 12°·5$ ↖, was $[a]j = 143°·5$↖.

1·264 grammes of alkaloids soluble in ether yielded 1·395 grammes of herapathite = 0·788 gramme of quinine = 1·681 per cent.

No. 29. –Strong-growing seedling Cinchona from Welbeck; light leaved.

50 grammes of dry bark yielded 2·144 grammes of mixed alkaloids = 4·288 per cent. The molecular rotation calculated from the observation $\frac{V}{p} = \frac{13}{0·642}$; $l = 100$ mm.; $a° = 6°·5$ ↖, was $[a]j = 131°·6$ ↖.

2·01 grammes of mixed alkaloids treated with ether yielded 0 975 gramme of alkaloids soluble in ether = 2·08 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{17·4}{0·975}$; $l = 100$ mm.; $a° = 7°.5$↖, was $[a]j = 133°·8$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{13}{0·792}$; $l =$ 100 mm.; $a° = 10°$ ↖, was $[a]j = 164°·1$ ↖.

0·839 gramme of alkaloids soluble in ether yielded 0·589 gramme of herapathite = 0·333 gramme of quinine = 0·825 per cent.

No. 30.—*C. officinalis.* Prunings from Neddiwattum.

50 grammes of dry bark yielded 1·86 grammes of mixed alkaloids = 3·72 per cent. 1·811 grammes of mixed alkaloids treated with ether yielded 1·605 grammes of alkaloids soluble in ether = 3·297 per cent.

The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{17}{1·605}$; $l = 100$ mm.; $a° = 16°·5$ ↖, was $[a]j =$ 180 ↖.

1·495 grammes of alkaloids soluble in ether yielded 2·085 grammes of herapathite = 1·178 grammes of quinine =2·6 per cent.

Although the total amount of alkaloids in these prunings is not high, the relatively large amount of quinine seems to me very striking.

I conclude this series of investigations by putting the results in a tabular form :—

Amount of Mixed Alkaloids and of Quinine contained in several specimens of Cinchona Bark grown under different conditions, by Mr. W. McIvor, at Ootacamund.

100 Parts of Bark, dried at 100° C., contain :—

Number.		Mixed Alkaloids.	Molecular Rotation Lævogyre.	Molecular Rotation Dextrogyre.	Alkaloids soluble in Ether.	Molecular Rotation Lævogyre.	Pure Quinine.	Crystallized Sulphate of Quinine.
C. Succirubra.	8 A	10·86	84°·5		3·705	111° 0	0·793	1·057

NGAI CAMPHOR AND BORNEOL.

BY JOHN MOSS, F.C.S.,

(*Late Demonstrator in the Laboratory of the Pharmaceutical Society.*)

In the Pharmaceutical Journal of a fortnight ago (March 7th, 1874, p. 722) is a most interesting paper by Professor Flückiger, in which that chemist gives in detail the results of his researches on the optical properties of *Ngai* camphor. One of the most interesting of these results was the discovery that an alcoholic solution of the camphor causes sinistral deviation of the polarized ray—a fact which had been previously made the matter of a suggestion by myself.* Professor Attfield, concurring with this suggestion, amplified and illuminated it, using for this purpose a remarkably successful research by Mr. A. Pedler, which resulted in the discovery of one of the two known varieties of valeric acid.

I would now draw attention to another similar case which is probably even more familiar to pharmacists than that of valeric acid, though it does not possess the recommendation (to them) of having been worked out by a Bell scholar,—I mean that of racemic acid. It is well known that ordinary racemic acid, as contained in the juice of certain kinds of grapes, is quite inactive as regards polarized light, yet is capable of being sundered into two other racemic acids, which, whilst they are identical in composition, in specific gravity, and indeed in most other physical properties, differ in these two—their action on polarized light and their crystalline form. One of these racemic acids twists the ray to the right, the other twists it

* Pharmaceutical Journal, March 7th, 1874, p. 722.

to the left. They are accordingly distinguished by the names dextro- and lævo-racemic acid respectively. In the shape of their crystals they correspond as the right hand corresponds to the left, or as an object corresponds to its own reflection in a mirror.

Now Mr. Sydney Plowman has shown* that in ultimate composition Borneol and Ngai camphor are identical, that in ordinary physical properties they are very like each other, and that he was unable to detect by microscopic examination any marked difference in the shape of their crystals. Professor Flückiger has shown in the paper above referred to that the crystals of both belong to the cubical system, confirming in respect of the whole what Mr. Plowman described of a part. He has also shown that these camphors are opposed in optical properties. The relations which obtain thus far are sufficiently significant to be suggestive of others even more intimate ; what these are is indicated by a study of the partly analogous but more completely unravelled case of the racemic acids. It seems to me highly probable that a very careful comparative examination of the crystals of Ngai camphor and of Borneol will result in the discovery that they are related to each other as are the crystals of the two active varieties of racemic acid,—that is, they are left and right handed. More than this, it is well within the bounds of probability that they may be so combined as to give a well-defined crystalline camphor, the alcoholic solution of which shall be inactive. (Of course an alcoholic solution of the two camphors in equal proportions is not at all referred to).

Certain volatile oils obtained from labiate plants, such as rosemary, sage, lavender, etc., yield, on oxidation by nitric acid or by lengthened exposure, camphors belonging to the $C_{10}H_{16}O$ class, which are inactive in alcoholic solution. Is it an unwarrantable "scientific use of the imagination" to suppose that these bodies are compounds such as it has just been suggested may be formed by the union of two optically opposed varieties ? It is at least worth while making the attempt to ascertain if this is the case. Were it found to be so, such a result would point directly to the existence in the above-mentioned oils, of isomerides of $C_{10}H_{16}$ having different optical properties. That many essential oils are made up of isomerides of $C_{10}H_{16}$ is well known, and our chemical knowledge of these bodies is being greatly increased by the classic researches of Dr. C. R. A. Wright.† In such of Dr. Wright's papers as I have at hand, however, no mention is made of any optical examinations of the isomeric terpenes. Such examinations could not fail of throwing considerable light on the mutual relations of these bodies, even if they did not lead to the more utilitarian result of enabling chemists to obtain the costlier essential oils having the composition $C_{10}H_{16}$, from those which are abundant and cheap.

Oil of lemons as it grows old becomes terebinthinate. Is this because oil of lemons is made up of terebenthene itself united with other more easily oxidizable terpenes, so that as the latter resinify and lose their odour, the smell of the former asserts itself ?

300, *Holborn, W.C.*

THE CHARACTERS, PROPERTIES, AND USES OF EUCALYPTUS GLOBULUS AND OTHER SPECIES OF EUCALYPTUS.*

BY PROFESSOR BENTLEY, F.L.S., ETC.

The great and widely spread interest excited by the recent announcements in the daily papers and various journals of the extraordinary influence of plantations of *Eucalyptus globulus* in destroying the malarious character of marshy districts, and thus preventing the fever which is commonly attributed to them, induced Professor Bentley's colleagues on the Council of the Royal Botanic Society of London to invite him to deliver a special lecture to the Fellows and their friends, with the view of making generally known what has been stated in reference to this subject, and, at the same time, to give a sketch of the other properties and uses of this plant and of the species of *Eucalyptus* generally.

The discovery of the influence of *Eucalyptus* trees in destroying or improving the pestilential nature of the climate of marshy districts has been attributed to Sir W. Macarthur, of Camden, Sydney, Australia, who, for this purpose, offered, about the year 1860, to forward seeds of the plant for distribution among the colonists of Algeria and other marshy districts of the world. But Professor Bentley points out that previously to this period—that is, in 1854 (as mentioned by M. Raveret-Wattel† in a report which he published in 1871 in Paris, for *La Société d'Acclimatation*)—M. Ramel had his attention called while in Melbourne by Dr. Ferdinand von Mueller (now Baron Mueller), the Government Botanist for Victoria, to this tree ; and in 1856 M. Ramel sent some seeds to Paris, and subsequently, in 1857 and 1860, forwarded further supplies. M. Ramel not only called attention to the great value of the *Eucalyptus globulus* as a forest tree, but also claimed for it the power of destroying the miasmatic influence of marshy districts. It seems clear, therefore, that it is to M. Ramel, rather than to Sir W. Macarthur, that the discovery of this valuable property of *Eucalyptus globulus* properly belongs.

Subsequently to the above dates, several notices appeared bearing testimony to the febrifugal property of the bark and leaves of this plant when administered internally—among others by M. Pepin, Dr. Carlotti, of Corsica, Dr. Lorinser, of Vienna, Professor Gubler, and Dr. Maclean, of Netley ; and in 1870 Dr. Gimbert, of Cannes, wrote a memoir entitled '*Eucalyptus globulus* : its value in Agriculture, Hygiene, and Medicine ; ' and again in the *Comptes Rendus* for October 6th, 1873, he made a further communication narrating the results of his experiments in Algeria in improving the miasmatic climate by plantations of this tree, and also published a paper in the *Archives générales de Médecine*, entitled "Etude des Applications Thérapeutiques de l'*Eucalyptus globulus*."

The genus *Eucalyptus* belongs to the natural order Myrtaceæ of botanists, the same order to which belong the Myrtle, the Clove-tree, the Pimenta or Allspice, the Cajeput-oil plant, the Pomegranate, and numerous other plants which are well known as ornamental trees or shrubs, or for their timber, or from yielding various valuable medical and economic products. All the *Eucalypti* (of which 135 species are described in the 'Flora Australiensis'), with the exception of a very few and, in some cases, doubtful species, are natives of Australia, where they are commonly known either as "Gum-trees," from yielding what are generally described as gummy or resinous products, or as "Stringy-bark trees," from their rough fibrous bark. Various other local names are also applied to the different species by the colonists in Australia, such as "blue," "red," and "white" gum, peppermint, turpentine, iron-bark, woolly-butt, &c. All the species

* Abstract of a lecture delivered to the Fellows of the Royal Botanic Society of London, by desire of the Council, on March 14th, 1874.

† An abstract of M. Wattel's paper appeared in this Journal in July, 1872, (vol. iii. pp. 22 and 43).

have evergreen leaves, which, like those of certain species of *Acacia* and other trees that are natives of Australia, usually (after the tree has arrived at a few years of age) hang in an oblique or even vertical direction from the branches, and thus give a very peculiar aspect to the forests of Australia by the difference in the light and shade produced by the trees from those of forests generally in other parts of the world. These leaves are commonly studded with internal glands or receptacles of volatile oil, as may be seen by holding them up to the light, when they present a semitransparent dotted appearance. The flowers, which are usually pinkish or white, are frequently very beautiful, so that this character, combined with the beauty and singularity of their foliage, the elegant appearance generally of the species, and the agreeable nature of their odours, renders them favourite objects for culture. The flowers, when of a white colour, much resemble myrtle-blossoms, but are at once distinguished from them by the absence of petals, and by their peculiar calyx, which in the bud state is closed at the top by a little lid, which is thrown off as the flower expands. The fruit, which consists essentially of the hardened somewhat globular or tubular calyx, contains a number of seeds, which, considering the enormous size and height these trees sometimes attain, over 300 feet in altitude and 100 feet in circumference, are extremely minute. Thus, according to Mueller, one ounce of the seed of the Blue Gum-tree (*Eucalyptus globulus*) contains over 10,000 seeds, and a similar weight of another species more than double that number; and thus, from one pound of seeds of the *Eucalyptus globulus* nearly 162,000 plants could be raised.

The *Eucalyptus globulus*, commonly known as the Blue Gum-tree, is a native of Tasmania, where it is more especially found on the damp slopes of valleys with a southern aspect. The foliage presents in a remarkable degree the changing aspect of the species of *Eucalyptus*. Thus in young plants the leaves are of large size, sessile, placed horizontally on the stem and branches, and of a bluish glaucous-white colour; but on plants varying from three to five years old the leaves become narrower, of a bluish-green colour, somewhat scimitar-shaped, and hang vertically or somewhat obliquely on the branches, instead of horizontally. The flowers, which are large and axillary, and nearly sessible, grow singly or in clusters of two or three: before they expand, the flower-bud, covered by the lid or operculum of the calyx, has a rounded form; hence its specific name of *globulus*.

The tree is so rapid in its growth "that any man in twenty years' time could find himself, if he chose, surrounded by a forest of his own planting." It has been further stated recently that in a grove planted only sixteen years, the trees averaged 72 feet in height and 6 feet in girth. M. Raveret Wattel says that a *Eucalyptus* tree of "ten years old ordinarily presents the development of a well-grown oak of a century; and it is not rare to meet in Australia with specimens in their fiftieth year from 160 to nearly 200 feet high, and 50 to 60 feet in circumference at the base."

These statements are also fully confirmed by the growth of the *Eucalyptus* trees in Algeria; and the following extract from a letter received by Mr. Daniel Hanbury from his brother at Mentone, testifies to the same fact:—"In a good soil with a moderate amount of moisture the growth of *Eucalyptus globulus* is astonishingly rapid. In the ground of the Palazzo Orango, 4 miles east of Mentone, there is a specimen which was planted in March, 1869 (that is just five years ago), being then a seedling of about 3 feet high. This tree was measured a few days ago, when it was found to be 48 *feet high*, with a trunk having a *circumference of* 3 *feet* at 3 feet above the ground."

In some cases the Blue Gum-tree has been known to attain the colossal dimensions of 350 feet in height and 100 feet in circumference, rivalling if not exceeding, in these respects the celebrated Californian Coniferous tree the *Sequoia Wellingtonia* (*Wellingtonia gigantea* of Lindley). There is no question that, with the doubtful exception of this tree, it excels in dimensions any tree in the world: and as it rarely sends out a branch until its trunk is 100 feet high, and the wood is remarkable for its hardness and durability, its value as a timber tree is great.

It is now more or less successfully cultivated in various parts of Southern Europe—as France, Spain, Portugal, Greece, and Italy; also in Palestine, various uplands of India; in parts of North and South America; at Natal, and other places in South Africa; in Cuba, St. Helena, Egypt, Corsica, and Algeria. It has also been introduced into New Zealand, and is said to grow tolerably well in sheltered situations in the island of Jersey, and also in some parts of South Devon and elsewhere in the south and west of England; but the plants, except under very exceptional circumstances, are not likely to withstand the winter in this country. It has, however, been stated lately in '*The Times*' that some *Eucalypti* had been grown in the open air at East Grinstead, Sussex, and that they had survived two winters without any protection. Several other instances have also been mentioned of plants having survived the winter in this country; but it is not probable that this species of *Eucalyptus* will ever become naturalized with us. It would probably succeed admirably in the swampy regions of the west coast of Africa.

The first and most important influence which the *Eucalyptus globulus* tree exerts, and that which has brought it more especially into notice, is its power of destroying the malarious agency which is supposed to cause fever in marshy districts; from which circumstance it has been called "the fever destroying tree."

It is in this respect commonly regarded as being serviceable in two ways—first, by the far-spreading roots of this gigantic tree acting like a sponge, as it were, and thus pumping up water and draining the ground; and, secondly, by emitting odorous antiseptic emanations from its leaves. Professor Bentley said that he did not believe, as has been recently stated, that the branches of a solitary *Eucalyptus* tree can have had any effect in neutralizing the malarious influence of a district previously constantly infected by fever; but he does think that the foliage of groves of *Eucalyptus* trees, by diffusing an agreeable, aromatic, camphoraceous, stimulating odour in the surrounding air, would have an appreciable influence in neutralizing marshy miasmas, and thus improving the healthiness of the district. The great influence is, however, in his opinion, produced by the power the roots possess of absorbing water from the soil. It is stated that a *Eucalyptus* tree absorbs as much as ten times its weight of water from the soil.

But whatever be the cause or causes which render a marshy district thus comparatively healthy to what it was before the introduction of the *Eucalyptus* trees into the neighbourhood, the fact is now testified to in various parts of the world. Thus at the Cape, in a very few years, the cultivation of the *Eucalyptus* has completely changed the climatic condition of the unhealthy parts of that colony; in Algeria, where it has been tried on a large scale in a district previously noted for its pestilential air and consequent prevalence of fever, not a single case now occurs, although the trees are not more than nine feet high; and in the neighbourhood of Constantia it is also stated that at another noted fever-spot covered with marsh-water both in winter and summer, in five years the whole district was dried up by 14,000 of these trees, and the inhabitants now enjoy excellent health. In Cuba, marsh diseases are fast disappearing from the unhealthy districts where this tree has been introduced. In the Department of the Var it is also said that a station-house situated at one end of a railway viaduct, so pestilential that the officials could not be kept there longer than a year, is now as healthy as any other place on the line, in consequence of the planting of a few *Eucalyptus* trees.

Among the products obtainable from *Eucalyptus* wood is potash, in which it is particularly rich. Baron von Mueller found that the ashes of these trees "contained a larger proportion of potash than the elm or maple, which

are the trees most esteemed for that purpose in America. The yield from the latter trees is estimated at 10 per cent. of the ashes, while that from the *Eucalyptus* is 21 per cent."

The barks of various species are also now used to some extent in paper-making; those of *E. rostrata*, *E. obliqua*, *E. corymbosa*, and *E. goniocalyx* are amongst those so employed. Good writing-paper has also been made from the bark of *E. obliqua*.

The barks of many species are used extensively for tanning. They owe this property to the presence of similar constituents to those contained in oak-bark and other substances commonly employed in this country and elsewhere for a like purpose.

A number of species of *Eucalyptus* also exude a very astringent substance, which, from its resemblance to the ordinary medicinal kino, both in appearance and properties, is commonly designated as *Eucalyptus*, or *Botany Bay Kino*. This substance, which, when it first exudes, trickles like blood down the bark of the trees in a semi-fluid state, ultimately hardens into dark-red shining masses, which have a very astringent taste. It is employed for similar medicinal purposes as the official kino, and also for tanning and dyeing.

Another substance, called *Eucalyptus* or *Australian Manna*, is also yielded by *E. mannifera*, *E. viminalis*, and probably other species. Two varieties of this manna have been distinguished. One is in small, rounded, opaque, whitish masses, with an agreeable sweet taste. It has a similar action to the ordinary manna in use in this country, and contains somewhat similar constituents. It exudes abundantly during the summer months through punctures or wounds made in the leaves and young bark. As it exudes it hardens, and drops from the leaves on to the ground in pieces sometimes as large as an almond. The flowers also of species of *Eucalyptus* yield a large quantity of honey, and are therefore greatly affected by bees. It is said that Gould "has taken as much as a teaspoonful of honey from the mouth of a bird shot by him whilst it was feeding."

Another very important produce of the *Eucalypti* is the essential oil, which may be obtained in large quantities by aqueous distillation from the leaves. This oil is stored up in the pellucid glands already referred to as contained in the leaves, and readily observed when these are held up to the light by the semi-transparent appearance they then exhibit. These oils are prepared on a very large scale by Mr. Bosisto, of Melbourne, and now form an important article of commerce with this country and elsewhere. Mr. Bosisto alone produces about 1000 lbs. of *Eucalyptus* oils per month. These oils generally have a somewhat camphoraceous smell; but the odour differs in the various species, and the oil obtained from *E. citriodora* has a pleasant citron-like odour.

Some of these oils have been employed, as *Eucalyptus oleosa*, as a solvent for resins in the preparation of varnishes; but they are of far more value for diluting the more delicate essential oils used in perfumery. The oils of *E. amygdalina*, *E. globulus*, and *E. citriodora* are thus more especially employed. Most of these *Eucalyptus* oils are of a yellowish colour, although some have a bluish tint; by redistillation the oil may be obtained nearly colourless.

From the quantity of oil contained in the leaves, they yield, when burned, a very large proportion of gas; and it is said that one of the towns in the gold-regions was for a long time lighted by gas extracted from this source.

The febrifugal properties of the bark and leaves of *Eucalyptus globulus* have been testified to by many practitioners—as M. Pepin, Dr. Carlotti, Dr. Lorinser, Professor Gubler, Dr. Keller, Dr. Maclean, and more especially of late years by Dr. Gimbert. It is said to be a valuable remedy, and more especially in intermittent fevers and bronchitis.

Probably some of the exaggerated statements that have been made in reference to the efficacy of *Eucalyptus* bark and leaves in fevers have arisen under the mistaken idea that the bark contained an alkaloid resembling, if not identical with, quinine, the well-known alkaloid of Cinchona-barks. But the experiments of Mr. Broughton, the government chemist of Ootacamund, entirely disprove this; for upon careful examination of the bark and leaves, Mr. Broughton states that neither quinine nor the other alkaloids of Cinchona-bark, as quinidine, cinchonine, or cinchonidine, exist in the plant in any proportion. What properties the plant possesses would appear, therefore, so far as known at present, to be due essentially to the presence of eucalyptol, the principal constituent of *Eucalyptus* oil. From the testimony of numerous medical practitioners in various parts of the world, and from its popular reputation in fevers in Australia, it can scarcely be doubted that it does possess anti-periodic properties, although these are far less important than those of Cinchona-bark.

In making preparations of *Eucalyptus* leaves the narrow leaves should alone be used, as recent investigations by a German physician, Dr. Hermann Œffinger, have shown that these are far more efficacious than the broader leaves found on the younger and faster-growing herbaceous shoots.

Dr. Gimbert has also recently introduced a new method of dressing wounds by using *Eucalyptus* leaves instead of lint. The leaves are simply laid on the wounds; and it is said that their balsamic nature not only cures, but removes all the unpleasant odour. Another way of using *Eucalyptus* leaves is in the form of cigarettes, which are reputed to be efficacious in bronchial and asthmatic affections and in other ways.

HISTORY OF THE PARIS SCHOOL OF PHARMACY.

A short time since, the fact was mentioned that a discussion had taken place in the French legislature respecting the dilapidated and unsafe state of the Paris School of Pharmacy. As it appears probable that, after being used for about three hundred years for purposes more or less connected with instruction in the art of preparing medicines, this building will be shortly abandoned by the School in favour of a more commodious one, the opportunity has been taken to publish a short sketch of its history, past and present, in the pages of *L'Union Pharmaceutique*, from which the following is taken:—

The origin of this establishment is very ancient. Upon the site occupied by it at the present day there formerly stood an hospital, probably founded in the thirteenth century by Marguerite de Provence, widow of Louis IX., which, in the following century, belonged to Guillaume de Chanac, bishop of Paris and patriarch of Alexandria. In 1559 the building was in the occupation of a Pierre Galand, when by a parliamentary decree it was allotted to the lodging and treatment of paupers suffering from venereal maladies. So reconstituted, the establishment took the name of the Hôpital de Lourcine.

Afterwards, Nicolas Houel, a grocer, born in Paris in 1520, conceived the idea of establishing a charitable institution where orphans might be instructed in the apothecaries' art, whose mission it should be to administer medicines to the respectable poor. An edict of Henry III., dated 9th October, 1576, approved of this foundation, and of the formation of a garden of simples. Nicolas Houel applied for a portion of the building called the Hôtel de Tournelles, then abandoned, in order to put his project into execution. A commission appointed to consider his application accorded to him the Maison des Enfants-Rouges, in the Marais, and the new institution was installed and remained there until 1578. In that year, in consequence of difficulties met with by the founder, he asked to be allowed to transfer his establishment to the house in the rue de Lourcine, the buildings of which were in a very bad state. A decree of the parliament, dated 2nd of January, 1579, authorized the transfer, which was carried out in the following April. The establishment bore the name of "Maison de la Charité Chrétienne."

Some waste ground belonging to the house, the greater part of which belongs to the School of Pharmacy at the present day, was planted with trees, and on another portion of it Nicolas Houel raised a house at his own expense, which was on one occasion ruined by an inundation of the Bièvre. The inclosure was continued to the rue de l'Arbalète, and eventually Houel formed there, on the model of the garden at Padua, a botanic garden, which was the first that had existed in France. Nicolas Houel died in 1587. Nine years afterwards Henry IV. changed the destination of the establishment, which he appropriated to soldiers of all grades wounded in his service, and it thus became the first germ of the Hôtel des Invalides.

These invalids were in their turn transferred by an order of Louis XIII. to the Bicêtre, and the house of Christian charity thus vacated was occupied by various communities of women, the property being handed over to the Order of Saint Lazarus. From them it soon passed into the hands of the Bishop of Paris, who granted it to the Hôtel Dieu. Finally, by two decrees of parliament, issued in 1624 and 1625, the lands were granted to the Corporation of Apothecaries, who were charged to carry out the foundation of Nicolas Houel. Shortly afterwards, this corporation augmented the original land by the purchase of two large gardens in the rue de l'Arbalète. In 1629 it also built there a large house, which now forms the principal portion of the building of the School of Pharmacy.

This establishment at first went by the name of the "Jardin des Apothicaires." This, by order of the King in 1777, was changed to "Collége de Pharmacie," and to "École Gratuité de Pharmacie," by a decree of the Executive Directory, dated 3 floréal an iv. (22nd April, 1797). Finally the law of the 21 germinal an xi. (10th April, 1804), having established in France three schools, that of Paris, which was only a continuation of the previous school, entered into possession of the ground and buildings situated in the rue de l'Arbalète. This possession was confirmed by a decree of the Government a few months later.

At that time the school of pharmacy managed its own affairs, under the authority of the Minister of the Interior. This arrangement was continued until September, 1841, when, by a royal ordonnance, the schools of pharmacy were placed under the the same *régime* as the universities. In its earlier days the real estate of the school remained the same as when it was received from the apothecaries. It received its first augmentation in 1821 by the acquisition, for the sum of 9,000 francs, of an enclosed garden. In 1844, a neighbouring house, of which, however, possession was not obtained until 1853, was purchased for 20,000 francs. In 1857, part of the original land, abutting upon the rue de Lourcine, was exchanged for some land situated in the rue de l'Arbalète more convenient to the school. Such are some of the principal events in the history of the École Supérieure de Pharmacie, from its foundation in 1578 until the present time."

The buildings of the School of Pharmacy are now unfortunately falling into ruins, and it has become necessary to shore them up on all sides. They have, moreover, become insufficient, and it is under consideration to transfer the school to new premises, which might be built upon ground situated between the Observatory and the Luxembourg. An iron gate, opening upon the rue de l'Arbalète, gives access to a rather small court-yard, where may be seen, on each side of the steps facing the entry, the statues in bronze of Vauquelin and Parmentier. The school contains two amphitheatres, of which the larger would not seat more than 280. But there are 500 students. The same insufficiency occurs in the laboratories, which are six in number: of these, one will accommodate 50 students; the other five, more recently constructed, would not accommodate more than 20 each. So that only 150 students can be employed at the same time in manipulation, and this occasions a great loss of time.

The "salle des actes," where the examinations are passed, is well arranged, and contains a collection of portraits of all the professors who have successively taught in the school. Some of these portraits are remarkable works of art.

The chemical, physical, zoological, and natural history collections, as well as the library, are complete in relation to the teaching imparted in the school. Beyond this, they contain nothing particularly remarkable. They are open every day from 11 a.m. until 4 p.m.

The botanic garden also requires some augmentation. It is intended shortly to establish, upon government land close by, two temporary laboratories, built of wood, of which one is to be devoted specially to botany.

There are nine "chairs" connected with the school: (1) botany, (2) organic chemistry, (3) inorganic chemistry, (4) materia medica, (5) pharmaceutical chemistry, (6) Galenic pharmacy, (7) physics, (8) zoology, and (9) natural history of medicaments.

The staff consists of nine professors, eight assistant professors, a responsible secretary, a superintendent of practical chemistry and pharmacy, four lecture demonstrators, three demonstrators of the practical course, a librarian, and other officials, numbering in all thirty-five persons. The functions of director of the school are exercised by one of the professors.

During the four "trimestres" of the scholastic year 1872-73, there were 1382 entries. During the same time the number of examinations was 1664. The cost of the terms and examinations for the diploma of pharmacien of the first-class is 1390 francs; that for the terms and examinations for the diploma of pharmacien of the second class, 660 francs.

In 1872 the receipts of the École Supérieure de Pharmacie of Paris amounted to 238,790 francs. The expenditure during the same time, including the cost of the staff, was only 174,875 francs 76 centimes, leaving a balance of 63,914 francs 24 centimes.

Amongst the remarkable persons who have passed through this school may be mentioned Parmentier, Vauquelin, Robiquet, Pelouze, Pelletier, and Caventou, the latter two of whom first prepared the sulphate of quinine. At the present day the staff of the school is constituted as follows:—

Director.—M. Chatin.

Honorary Director.—M. Bussy.

Administrators.—MM. Chatin, Berthelot, and Planchon.

Honorary Professor.—M. Caventou.

Professors.—Botany, M. Chatin; Organic Chemistry, M. Berthelot; Zoology, M. Milne-Edwards; Physics, M. Buignet; Galenic Pharmacy, M. Chevallier; Natural History of Medicaments, M. Planchon; Toxicology, M. Bouis; Pharmaceutical Chemistry, M. Baudrimont. The chair of Inorganic Chemistry is at present vacant.

Delegates from the Faculty of Medicine.—MM. Bouchardat and Gavarret.

Assistant Professors.—MM. Soubeiran, Riche, Bourgoin, Jungfleisch, Le Roux, Marchand, Gustave Bouchardat, and Joannès Chatin.

Secretary.—M. Chapelle.

OZONE.*

BY DR. ANDREWS.

Soon after the discovery of ozone, Schönbein having observed that the air of the country frequently coloured a delicate ozone test-paper in the same manner as ozone itself, inferred that ozone is a normal constituent of our atmosphere. He concluded that the amount of this body present in the air is different in different localities, and in the same locality at different times, and with great boldness

* Abstract of an address delivered before the Royal Society of Edinburgh, December 22nd, 1873, and printed in *Nature*.

he attempted to connect its presence or absence with the prevalence or rarity of certain catarrhal affections. A new field for investigation was thus opened up, which has been assiduously cultivated by a large and zealous band of observers. Before referring, however, to their labours, it will be necessary briefly to allude to the present state of our knowledge regarding the existence of ozone in the atmosphere.

Schönbein always maintained that ozone is a constituent of atmospheric air, and his various papers on this subject would, if collected, fill a large volume. In his last memoir he observes that the active substance in the air acts in a parallel manner on iodide of potassium and suboxide of thallium papers, although more slowly on the latter; and that the thallium paper, which has been coloured brown by the air, behaves towards reagents in the same manner as that which has been exposed to artificial ozone. From these facts he infers that the active substance in the air is neither peroxide of nitrogen nor sulphuretted hydrogen. He further states that the atmosphere never contains free nitric acid, although nitrate of ammonium in small quantities is frequently present; and that neither chlorine nor bromine can be present in the free state in air, on account of their affinity for hydrogen. Houzeau also maintained that the existence of ozone in the air was proved by the alkaline reaction of iodide of potassium paper, which had been decomposed by exposure to the atmosphere. Although experiments and arguments of this kind were sufficient to give probability to the view that the active substance in the atmosphere which produces these reactions is ozone, they were at the same time far from conclusive; and some of the ablest chemists in Europe accordingly considered the question doubtful, while others attributed the effects observed to the presence of oxidizing agents altogether different from ozone. I will only cite on this point the opinion of M. Frémy, whose researches in conjunction with M. Becquerel on ozone have already been referred to. "Without denying," he remarked at a meeting of the Academy of Sciences in 1865, "the importance of the indications given by the paper of M. Schönbein, or by that of M. Houzeau, I do not find that these reactions demonstrate with sufficient certainty the existence of atmospheric ozone. I am of opinion that the presence of ozone in the air must be established anew by incontestible experiments."

In 1867 I made a set of experiments which I had contemplated some years before, for the purpose, if possible, of finally settling this important question. These experiments have since been successfully repeated by Dr. C. Fox.

The identity of the active body in the atmosphere with ozone we may now assume to be established beyond dispute, and the accuracy of Schönbein's views on this subject to be fully confirmed. To determine, however, the actual amount of ozone in the atmosphere is a problem of surpassing difficulty, on account of the extremely small proportion in which it exists, even when at a maximum. Its presence can be easily discovered by any of the ordinary iodised starch papers, or even more readily by white bibulous paper which has been moistened with a dilute solution of iodide of potassium, and allowed to dry spontaneously in a dark room. If a slip of this paper be exposed for five minutes to a current of air, which will be often supplied by the wind, or may be produced by walking briskly, it will be found to have acquired a delicate red tint, if ozone be present even in the smallest quantities. The tint will be best observed by comparing the slip after exposure with another slip of the same paper which has not been exposed. The action of the diffused light of day on the paper is rarely perceptible after so short an exposure, but this source of error can be easily avoided by enclosing the paper in a hollow cylinder of wood.

Although, with the experimental resources now at our command, we can scarcely venture even to estimate the actual amount of ozone at any time present in the atmosphere, yet it may be possible, as Schönbein long ago proposed, by applying a chromatic scale to the indications of the test papers, to ascertain approximately its relative amount in different localities, and its variations in the same locality. Such estimates must, however, be most uncertain, since the shades of colour produced on test-paper hardly admit of being defined by numbers; and in this particular case they are liable to a special source of error, as there can be little doubt that a large but unknown part of the ozone in the air which comes into contact with the paper is catalytically destroyed, and produces no chemical effect whatever. At the same time the ozonometer, especially when used with an aspirator, does unquestionably give indications of value regarding the ozone states of the atmosphere; and till more accurate methods are devised these observations ought certainly to be continued.

Ozone is rarely found in the air of large towns, unless in a suburb when the wind is blowing from the country; and it is only under the rarest and most exceptional conditions that it is found in the air of the largest and best ventilated apartments. It is, in fact, rapidly destroyed by smoke and other impurities which are present in the air of localities where large bodies of men have fixed their habitation, and I have often observed this destructive action extending to a distance of one or two miles from a manufacturing town, even in fine and bright weather.

Ozone is rarely, if ever, absent in fine weather from the air of the country, and it is more abundant, on the whole, in the air of the mountain than of the plain. It is also said to occur in larger quantity near the sea than in inland districts. It has been found to an unusual amount after thunderstorms—a fact which is favourable to the view that the presence of ozone in the atmosphere is due to the action of the free electricity of the latter on the oxygen of the air. The amount of ozone in the air is greater, according to some observers, in winter than in summer, in spring than in autumn; according to others, it is greater in spring and summer than in autumn and winter. As regards the influence of day and night, the observations do not all tell the same tale. Ozone has usually been found more abundantly in the air at night than by day, but some careful observers have found the reverse of this statement to be true.

Schönbein was the first who attempted to connect the fluctuations of atmospheric ozone with the prevalence or absence of epidemic disease; and since this suggestion was first published, numerous observations have been made in different countries with the view of ascertaining whether there is really any connection between the indications of the ozonometer and the health of a district. It has been asserted, for example, as the result of observation, that an outbreak of cholera is accompanied by a marked diminution of atmospheric ozone; but this statement has been disproved by later and more trustworthy observations. On the whole, I think it may be safely asserted that no connection has yet been proved to exist between the amount of ozone in the atmosphere and the occurrence of epidemic or other forms of disease.

The permanent absence of ozone from the air of a locality may, however, be regarded as a proof that we are breathing, if I may venture to use the phrase, adulterated air. Its absence from the air of towns, and of large rooms even in the country, is probably the chief cause of the difference which everyone feels when he breathes the air of a town, or of an apartment, however spacious, and afterwards inhales the fresh or ozone-containing air of the open country. It is, indeed, highly probable that many of the most important actions, by which the products of vegetable and animal waste are removed by oxidation from the air, are due to the action of ozone, and could not be effected by ordinary or inactive oxygen. If the amount of ozone in the atmosphere appear too small to produce such large results, we must remember that, from its powerful affinities, ozone is being continually used up, and must, therefore, be constantly renewed.

The physiological action of ozone on the animal system is a subject of interest, and I am able to state the general results of two independent inquiries—one conducted a few years ago, by Dr. Redfern, in Queen's College, Belfast, the other recently communicated to this Society by Mr. Dewar and Dr. McKendrick. Dr. Redfern's experiments have not been published, but he has kindly supplied me with the following note on the subject :—"The general results," he says, "I obtained from about forty experiments conducted from May to September, 1857, to find the effects of oxygen and ozone on different animals, are as follows :—The respiration for a very short time of oxygen, containing about $\frac{1}{240}$th part of ozone, is certainly fatal to all animals. The same gas, when passed over peroxide of manganese and freed from ozone, is comparatively harmless, even when respired for long periods. Respiration of such a mixture of ozone for thirty seconds kills small animals, some dying after respiring it only fifteen seconds ; whilst similar animals will live in good health for months after respiring oxygen alone for thirty-seven hours, the carbonic acid being removed during the experiment. Death is not due to the closure of the glottis, for it occurs when a large opening has been made in the trachea. Ozone causes death by producing intense congestion of the lungs with emphysema, and distension of the right side of the heart with fluid or coagulated blood, frequently attended by convulsions. If ozone be respired in a dilute form, the animals become drowsy and die quietly from coma ; the condition of the lungs and heart being the same, except that the emphysema is less marked. Animals which have respired oxygen for more than twelve hours will now and then die suddenly from the formation of coagula in the heart, even after they have appeared in good health for some days."

The following are the conclusions which Mr. Dewar and Dr. McKendrick have deduced from their researches : Inhalation of an atmosphere highly charged with ozone diminishes the number of respirations per minute, and reduces the cardiac pulsations in strength, the temperature of the animal being at the same time lowered from 3° to 5° C. After death the blood is found to be in a venous condition. Neither the capillary circulation nor the reflex activity of the spinal cord is appreciably affected. The same remark applies to the contractility and work-power of the muscles. Ozone acts on the coloured and colourless corpuscles of the frog like carbonic acid. Ciliary action is not affected by ozonized air or oxygen, but if the layer of liquid be very thin, the cilia are readily destroyed.

The thermal changes which accompany many of the reactions of ozone are well marked, and their investigation, which has been undertaken by Mr. Dewar, promises to yield a valuable addition to our thermo-chemical knowledge.

A PLEA FOR WILD PLANTS.*

There is a prejudice against the Umbelliferæ : they are poisonous (witness Æthusa, Hemlock, &c.); they are merely culinary plants (Angelica, Celery, Fennel, Carrot, Parsnip, Parsley, &c.); they are a difficult tribe to know. If yon ask the young student for a name, you are put off with "It is one of the Umbelliferæ," and the veteran shelters himself with the excuse that his botany has got rusty, or the plant is not in a fit state to name. I am convinced that a thorough acquaintance with this class of plants, acquired when the memory is retentive of knowledge, would make all plants with conspicuous flowers quite easy to the young botanist, and be a good preparation for the study of the grasses — a class sadly overlooked. It is such an advantage to master one confusing family at the beginning, and not to put off all difficulties to the end.

There is perhaps no tribe of herbaceous plants that supplies us with such a variety of foliage for so many months in the year. In January we find the fresh young leaves of *Chærophyllum sylvestre* (Cow Parsley) months before any Fern unrolls its young fronds, and when, with the exception of that persistent flowerer, Chickweed, there is positively nothing in flower. Soon the little *Draba verna* (Whitlowgrass) bristles on the tops of walls; *Mercurialis perennis* (Dog's Mercury) and *Lamium purpureum* (Red Dead Nettle), with its tops of soft purple bloom, give interest to the hedge bottoms, but the *Chærophyllum* is first. It is no small recommendation that this class of plants affects the outskirts of towns, waste places, and rubbishy corners, unpromising ground for the collector; or is found under trees where, with the exception of a carpet of Wordsworth's favourite Celandine (*Ranunculus Ficaria*), nothing flowers.

It must be owned it requires a positive conviction that the plant wished for is there, before plunging in the height of summer growths above one's ankles into Nettles, and up to one's waist among umbelliferous plants, Thistles, and intolerably hooking burrs ; but now (April) one sees where one is going — Nettles and grey stars of Thistles are equally harmless and close to the ground, this last seemingly retaining for itself a larger share of air and moisture on its hoary, greedy leaves; and the various clumps of *Scandix odorata*, *Conium maculatum* (Hemlock), and *Chærophyllum*, are then in the perfection of freshness. It is very improving to learn to distinguish them in their young state before the tell-tale bags at the base of the leaf-stalks of *Heracleum Sphondylium* (Cow Parsnip) are developed, or the spotted stems of the Hemlock, or the concave flower-head of *Daucus Carota* (Bird's Nest), or the edible roots of *Bunium Bulbocastanum* (Pig-nut) are formed, and before the long-beaked seeds of *Scandix Pecten-Veneris* (Venus' Comb) serve to identify the plant.

Most unenviably difficult to please must those be who are not attracted by the groups seen now : young plants of *Scandix odorata*, with white variegation at the base of each pair of light green decompound leaves, associated with the simple dark green Lily of the Valley-like leaf of *Allium ursinum* (Garlic), or the halberd-shaped *Arum maculatum* (Lords and Ladies) ; the little gold Celandine forming a groundwork under the scraggy trees, with an occasional flower almost entirely white. On the other hand, by the sandy margin of the river is again the Myrrh, making foliage for the pinkish club flowers of *Tussilago Petasites* (Butterbur), as yet devoid of its huge rhubarb-like leaves; then in a dry, exposed spot, is a patch of closely-fitting *Scandix Anthriscus* (small Hemlock Chervil); and under a hedge this same most beautiful of the Umbelliferæ, represented by fine plumy plants of brightest green and finest division, is dotted through a large mass of *Lamium purpureum*, which has now lost much of the soft velvet bloom of its tops, but is in profuse flower; its bright orange anthers and delicately spotted throat are well worth noticing.

Not far off the stronger-growing *L. album* is plentiful. I always think plants of the class Didynamia should be held downwards ; the upper whorl of the White Dead Nettle has its anthers still black, the lower story of which being longer exposed, are yellow, both most attractively dotting the white upper lip. *Ægopodium Podagraria* (Gout Weed) is everywhere. It is probably the least interesting of all the Umbelliferæ, and is a fearful pest in the garden (N.B. Let not a variegation hobby induce any one to admit the variegated form into a border) ; still, its smooth, uncut bright leaves are pleasant to look upon, especially as I saw it, with the cut leaves of *Tanacetum vulgare* (Tansy), and *Potentilla anserina* (Silver Weed) and small seedlings of Cow Parsnip.

Through a bramble-covered bank, thinly leaved, one can at present see the fresh tufts of *Hypericum pulchrum* (St. John's Wort), the blue-green *Antirrhinum Linaria* (Yellow Toad Flax), the delicate shoots of *Viccia cracca*, showing its first tiny tendrils; *Geranium Robertianum* (herb Robert), *G. dissectum*, and *G. molle*, all three with

* From the *Gardeners' Chronicle* for April 25.

red stalks and crowns; and how beautiful are the leaves of *G. molle* when held between you and the sunlight, so thickly clothed with soft down they look as if frosted. How different is this plant in such a position, with shelter and loose soil, its footstalks some 5 inches long, and in the hard, open field, laid down in grass seeds; then this Geranium fits closely to the ground, and spreads out star fashion, like *Semper vivum montanum*. There are patches of seedling Umbelliferæ that one almost takes for *Thalictrum minus* or *Adoxa Moschatellina*, only one is surprised to find this particular patch without flowers. One is never weary of admiring the little green Moschatel with its four-sided head of flowers, and a fifth at top, that being the first always to expand. The beautiful foliage of *Fumaria officinalis* (Fumitory), the pointed leaves of *Achillea* (well-named *Millefolium*), *Lathyrus pratensis* (Yellow Vetchling), *Stellaria Holostea* (Stichwort), *Vaillantia cruciata* (Mugweed), and *Galium Aparine* (Cleavers) —these four last-named plants have not yet begun to climb up by anything they can lay hold of to support their weak stems. The *Galium* is not so adhesive as in summer. *Tormentilla Myosotis*, *Sherardia arvensis* (Field Madder), Epilobium, &c.—all will be choked up by summer time with the mass of Bramble arches treacherously rooted firm at the tips, and ready to trip up an intruder. Such a trip-up, however, is not to be regretted if it gives one a hint how to propagate some select garden variety, troublesome or hopeless, by cuttings, grafting, or seed.

So pleasant is it to recognize one's old friends in their first spring freshness, and so varied and beautiful in foliage are many of the plants here named, that one hardly values as one ought the first white tops of *Erysimum Alliaria* (Jack by the Hedge), or the half-opened pink *Lychnis dioica* (Campion), or the first pair of flowers on *Veronica Chamædrys*, *V. agrestis* and *V. arvensis*. *V. Beccabunga* is not in flower, and is still temptingly like Watercresses, but there is one *Viola canina* and a flower of *Glechoma hederacea* (Ground Ivy), and the little wild Strawberry.

Broom in a sunny spot has a few blossoms, but one admires the pale green leaf-buds regularly set on the dark green stems like beads; the brown velvet Whin buds are in a mass of flower, and so is the leafless Sloe. The early *Tussilago farfara* is now in cottony leaf and full erect Dandelion-like seed; just here and there a bright yellow flower is left, and a few are nodding, not yet ripe enough to stand erect on their scaly stalks. *Draba verna* is also in seed.

A thicket of *Salix Helix* is a most beautiful object, there is such variety in the different stages of its male and female flowers—soft lilac catkins ticked with scarlet, gold, and black up their slender length, according to the time the anthers have come out. *Salix Caprea* also is still in beauty—the Saugh of Scotland, and Palm Willow of England; but handsome as are its catkins, and earliest of all, they are not to compare in beauty with those of *S. Helix*, or the large soft grey flowers of *S. purpurea*, which so strikingly catch the eye on the fine purple-barked twigs. But I will not trench on the Willows, a tribe of trees far more confusing to the botanist than even the Umbelliferæ are to the amateur. It would be a well-spent spring if a score or two were mastered: three hundred, I am told, are in cultivation in Nottinghamshire.

I must bring to a close these notes on the commonest weeds gathered up in a walk on very common ground, but I was so forcibly struck by the fact how much more one saw now, when all plants are on a level, so to speak, and have a fair start, than in summer. They are spread out like a mass before one, and very good is it to probe one's memory and take note of one's ignorance, marking those plants (you must know them) which you do not recognize at present, and returning in summer to identify them, being prepared to find them a new lot of Umbelliferæ to puzzle over, and such plants as *Symphytum*, *Epilobium*, *Doronicum*, *Digitalis Rumex*, and grasses choking up the weaker growers seen with such interest now.

A great charm of the Umbelliferæ is that all the season through there are young seedlings coming on; thus you have beautiful fresh leaves. It has always struck me this family would make a good addition or substitute for what in Covent Garden parlance is vaguely called Fern, and the small leaves of even the larger growers can be used intact. I cannot bear to see the waste and destruction of the perfect fronds of such-like Ferns as *Aspidium Filix-mas* and *Asplenium Filix-fœmina*, the tips of which are alone used for certain decorative purposes. Might it not answer to sow seed of umbelliferous plants in bare places, and under trees (rookeries) where grass has been tried and failed? It would insure a beautiful green undergrowth at the barest time, from January to April. It is easy to cut over the flower-stems if they are an objection, but seeding should be encouraged for a year or two to secure a succession of young plants; and in the openest spots plants of *Heracleum giganteum*, &c., would have a grand appearance.

Of the numerous garden varieties suitable as leaf plants, I shall make some remarks later on in the year, when I can prove from memoranda that beautiful foliage can be gathered every week in the year from this family alone.

As a conclusion to this paper on Common Weeds, let me recommend an uncommon winter and spring nosegay, and one from which the amateur will learn much, and that at present has daily growing interest. Have a bunch of twigs of all the forest trees you can get in a jug of water in your room, and simply watch their buds swelling, bursting, unfolding and expanding their leaves and flowers. I am in the practice of cutting off a handful of such twigs monthly, keeping each month's supply by themselves; and most interesting is it patiently to watch and compare their various and varied progresses from the end of January to April. It would take a long paper to note all one sees with the naked and, alas! ignorant eye, but it is a capital plan by which to learn a little of the different ways in which the leaves are packed and folded inside their numerous coverings—from the thick leathery scolloped outmost scales of the Walnut, or sticky ones of Horse Chestnut and Poplar, to the softest smooth ones lying closest to the tender leaves. Pleasant is it to stand under a bursting Sycamore or Horse Chestnut, and almost hear the cracking of the large buds, and be covered with the pretty pink bud-coverings of the one, and be stuck over with the resinous husks of the other; but more improving is it to have the buds under your eye from day to day. By this means one realizes (so far) the wondrous rapidity of growth in spring. We are all acquainted with, and talk freely of, the rush of the arctic summer at the Poles, and of the tropical growths after the rainy season in the torrid zone; but of the amazing bound that takes place under our own eyes every spring we live, we are grossly ignorant.

I have simply not been believed, and by country friends, too, when exhibiting the gross young shoot of a Horse Chestnut, and from a later tree a similar bud, out of which this marvellous growth of shoot (above a foot in length) and pairs of leaves has issued. Still more startling is it to observe the commencement of the new bud for next year at the base of the new-born leaf, not above a fortnight or so old, as these few days are sufficient for this huge leap into active life. To the amateur only seeing is believing in such a case. I will not add another word at present, but hope, for their own sakes, some may gather themselves a tree nosegay, and this very spring be a little less ignorant of "common things"—*i.e.*, of wonders that may never be understood, possibly, by them, but which, nevertheless, any, even the faintest, approach to them, enlarges the mind and heart, for then there must be deep and humble admiration of the amazing workings of Nature, obedient to the Great Creator.

The Pharmaceutical Journal.

SATURDAY, MAY 2, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACY IN IRELAND.

THE course of the Irish Pharmacy Bill which we published a fortnight since, bids fair to be far from smooth. The circular sent out by the College of Physicians, putting forward the reasons which had induced that body to introduce a Bill to amend the laws affecting the practice of Pharmacy in Ireland, has been promptly responded to by the Governor and Company of the Apothecaries' Hall of Ireland. It now seems evident that there is little ground for adhering to the hope we ventured to express that the Apothecaries' Company would not be altogether adverse to the Bill. In the circular that body has issued in reply to the College of Physicians it is stated that, after careful consideration of the Bill and its several provisions, it has been decided to object to it, and that a sense of public duty constrains the Company to make known the reasons for doing so.

These reasons are somewhat voluminous, and they do not appear to leave much room for anticipating cordial co-operation on the part of the Irish apothecaries, in the endeavour to remedy an evil which is severely felt in many cases by the public, as well as by members of the drug trade, and the existence of which is admitted by the Apothecaries' Company.

In the first place, the College of Physicians' Bill is objected to because when the English Pharmacy Bill was before Parliament, in 1868, a similar proposition was rejected by the House of Commons on the ground that there was a difference between the two parts of the kingdom; for while in Ireland for nearly a century every person who practised pharmacy had been compelled to attend a prolonged course of study, and undergo a strict examination prior to his doing so, any person in England or Scotland might keep open shop for that purpose, however unqualified. Hence it was held that the provisions of the Bill being throughout intended for Great Britain, they could not be extended to Ireland.

This certainly seems but a slender reason for objecting altogether to the present extension of the Pharmacy Act (1868) to Ireland, although we can well understand the difference above referred to might be successfully urged against the application of the Act to Ireland at that time. In the interval, the conditions under which the practice of pharmacy may be carried on in Great Britain have been vastly amended, and indeed, assimilated to those which have long obtained in Ireland, with this important difference, however, that here the course of study and the examination required are specially and properly adapted to secure competent knowledge and skill on the part of pharmacists, without imposing upon them the expenditure of time and money in studies that are of no kind of utility to them in their after career as compounders of medicine.

Another reason for objecting to the proposed Bill is, that it would subvert the rightful control over pharmacy exercised by the Irish Apothecaries' Company. In regard to this we have no desire to say anything in disparagement of the mode in which the Company discharges its duty in regard to pharmaceutical qualification, so far as the discharge of that duty extends; but we may at least point out that it falls short of present requirements. This is admitted by the Apothecaries' Company, as we showed in a recent article on the subject, and we fail to perceive why that body should object to a mode of supplying the want it acknowledges, which would afford facilities for competent pharmacists carrying on business in Ireland as they now do in other parts of the kingdom.

The next objection, however, appears to afford some clue to the real ground of opposition to the proposed Bill on the part of the Apothecaries' Company, for it is urged that by Clause 2 there would be introduced into Ireland a number of English "chemists and druggists," who are on the English register, but who never passed through the course of study or examination required for pharmaceutical chemists under the Pharmacy Acts, and with reference to several of whom it is pointed out that an eminent member of the Pharmaceutical Committee of the House of Commons is reported to have said in 1868 that many persons under the name of druggists were entrusted with the selling and compounding of poisons who were utterly ignorant of the nature of those poisons, and of the general effect of drugs. The Apothecaries' Company, in its circular, openly expresses the fear that "such is the class that the Bill of the College of Physicians would most probably introduce into Ireland as compounders of prescriptions for the public."

If there were any reasonable ground for such a fear we should not hesitate to share with the Apothecaries' Company its objection to the proposed measure; but we believe that is not the case necessarily. So far as the object of the Apothecaries' Company is to secure competency on the part of pharmacists, it would entirely command the sympathy of the Pharmaceutical Society, and, we may safely add, that of the entire pharmaceutical body in this country.

It may perhaps be inferred from the way in which the last-mentioned objection is stated by the Apothecaries' Company that nothing less than the Major qualification of the Pharmaceutical Society is looked upon as the requisite indication of fitness for the practice of pharmacy, and such a view will, we are sure, find many adherents among ourselves.

The third clause of the Bill is objected to because the licence of the Irish Hall is already a legally recognized medical qualification throughout the Queen's dominions, entitling the holder of it to practise both pharmacy and medicine.

Lastly, the especial reason why the company objects to the proposed Bill of the College of Physicians is that it has a Pharmacy Bill of its own which does not disturb vested rights—one drafted by consent of Government a few years since,* which it is considered provides amply for the pharmaceutical wants of the public, and has the approval of the Associations of the Licentiate Apothecaries and of the Chemists and Druggists of Ireland.

THE ADULTERATION OF FOOD ACT.

On Monday night Mr. Sclater-Booth nominated the following members of the House of Commons as a Select Committee on the Adulteration of Food Act, 1872:—Mr. Clare Reed, Mr. Muntz, Mr. Welby, Sir Charles Dilke, Mr. Peek, Mr. Colman, Mr. Carpenter Garnier, Mr. Alexander Brown, Viscount Barrington, Mr. Backhouse, Mr. Heygate, Mr. Mundella, Mr. Sandford, Dr. Brady, and Mr. Benyon.

LEGACY TO THE PARIS SCHOOL OF PHARMACY.

The director of the École Supérieure de Pharmacie of Paris has been authorized to accept, in the name of the State, and under the clauses and conditions laid down by the testator, a legacy to the School, by M. Leroze, of the sum of 10,000 francs. This money is to be devoted to the foundation of an annual prize for the best memoir upon qualitative and quantitative analysis.

ALTERATION IN PHOSPHORETTED RESIN.

At the March meeting of the Philadelphia College of Pharmacy, Dr. W. H. Pile showed a sample of phosphoretted resin which, from exposure to sunlight, had become changed in colour to a beautiful red. He also exhibited a sample of an emulsion made with phosphoretted resin, and a tube containing a mixture of alcohol and the resin, showing that the phosphorus had separated as a fine precipitate.

We are glad to learn that M. Masson has published a verbatim report of the important discussion in the French Academy of Medicine upon the questions referred to it by the Minister of War, relative to the future position of pharmacists in the French army. The pamphlet is entitled, "Discussion sur les Rapports à Établir entre la Médecine et la Pharmacie dans l'Armée, en réponse aux Questions posées par M. le Ministre de la Guerre." Some months since we gave a *résumé* from this interesting discussion, in which the interests of pharmacy were defended by such men as Dumas, Poggiale, Bussy and Gobley. Should the time ever come for the English pharmacist to put forward a claim to a similar position in the public service, powerful support for his arguments will be found in the pages of this *brochure*.

* See Pharm. Journ., i. 405.

THE NEXT EVENING MEETING.

On Wednesday next, May 6th, an extra Evening Meeting of the Pharmaceutical Society will be held, to afford an opportunity for discussing the "Additions to the Pharmacopœia," and the paper on this subject read by Mr. Umney at the last meeting. The Chair will be taken at half-past Eight o'clock precisely, and the discussion will be opened by a short paper by Mr. E. Smith, of Torquay.

THE JURIES BILL.

The consideration of the Juries Bill in Committee of the House of Commons has been postponed until Tuesday next, May 5th.

AN APOTHECARIES' OATH.

From an interesting work on the handicrafts of Paris, by M. Desmaze, which is shortly to be published, the *Répertoire de Pharmacie* produces two excerpts, relics of the middle ages, the one being the oath then taken by the apothecaries, the other that taken by the midwives. The following is a free translation of the apothecaries' oath, from which, although mainly of a negative character, it will be seen that his duties closely resembled those of the pharmacist of the present day:—

"I take to witness, before all, God the Creator of the Universe, in three persons, that during the whole of my life I will observe that which follows:—

"I will live and die in the Christian faith. I will honour my parents. I will honour the physicians and masters under whom I have studied. I will never say anything that shall be injurious to the seniors of our order, or to others. I will adorn with my best the dignity of the art, and I will not reveal its secrets. I will do nothing imprudently nor through hope of gain. In acute sickness I will not give purgatives without the order of the physician. I will not touch the secret parts, except to apply remedies to them. I will keep the secrets of the patients. I will administer no poison, neither will I allow it to be administered, even to my enemies. I will not give an abortive remedy, even to provoke the expulsion of a fœtus, except upon the order of a physician. I will not alter the prescriptions of physicians. I will never substitute one remedy for another without their knowledge. I will discourage the fatal practice of empirics. I will refuse to no person my legitimate assistance. I will not keep in my pharmacy stale or badly prepared medicaments.

"In making and observing these rules, may God assist me. *Ainsi soit-il!*"

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

April 15th, 16th, 17th, 22nd, 23rd, and 24th, 1874.

Present (15th and 22nd)—Messrs. Allchin, Barnes, Benger, Carteighe, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

(16th)—Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Martindale, Schweitzer, Southall, Taylor, and Umney.

(17th)—Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Taylor, and Umney.

(23rd)—Messrs. Allchin, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

(24th)—Messrs. Allchin, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Taylor, and Umney.

Dr. Greenhow was present on the 22nd and 24th on behalf of the Privy Council.

MAJOR EXAMINATION.

Eight candidates were examined. *One* failed. The following *seven* passed, and were declared duly qualified to be registered as Pharmaceutical Chemists:—

*Richmond, Robert, jun.	Leighton Buzzard.
Walsh, Albert	Richmond.
Carter, Arthur Joseph	London.
Willan, Robert	Ulverston.
Chamberlain, Arthur Garratt	Leicester.
Jones, Rees Thomas	London.
Polley, John	Chester.

MINOR EXAMINATION.

One hundred and fifty-eight candidates were examined. *One hundred and sixteen* failed. The following *forty-two* passed, and were declared qualified to be registered as Chemists and Druggists:—

	*Marsh, Edward Robert	Oakham.
	Thomas, William	London.
	Harvey, William Sutton	Margate.
Equal.	Gilbert, Sydney	Exeter.
Equal.	Spencer, Joseph	West Bromwich.
	Boultbee, Charles Edward	Norwich.
	Davies, Frederick	Chester.
Equal.	Crowden, Francis	Keswick.
Equal.	Kirk, John Robert	Leeds.
Equal.	Shakespeare, Alfred William	Leicester.
	Lowe, Arthur	Lynn.
Equal.	Atkinson, Henry B.	York.
Equal.	Fawthrop, Thomas	Ryde.
	Lilley, John Henry	Staveley.
Equal.	Spence, John	North Shields.
Equal.	Wood, Henry Thomas Gibbons	Hull.
Equal.	Hewett, William Herbert	Basingstoke.
Equal.	Marsh, William Henry	Norwich.
	Pitchford, William	Newton Abbot.
Equal.	Broughton, Thomas	Salford.
Equal.	Procter, Robert	Kidderminster.
	Willan, William	Preston.
Equal.	Naylor, Wm. Arthur Harrison	Manchester.
Equal.	Patridge, William Ford	Wisbeach.
Equal.	Rayson, John Thomas	Swineshead.
	Walmsley, Robert	Clitheroe.
	Blunt, George	Upton-on-Severn.
Equal.	Jones, William	Bagillt.
Equal.	Pearson, Walter	Hull.
Equal.	Woodland, John	Rochester.
Equal.	Woods, Richard	Cirencester.
Equal.	Partington, John James	Macclesfield.
Equal.	Stratford, Alfred Joseph	Kilsby.
	Smith, Charles Albert	Gosport.
Equal.	Parker, Robert Henry	Barnstaple.
Equal.	Patman, Francis Thomas	Whitehaven.
	Osborne, George Cooch	Nottingham.
	James, Isaac Rowland	Aberystwith.
	Owles, Arthur	Bungay.
Equal.	Hindle, William	Lowestoft.
Equal.	Jones, Thomas Glynne	Llanidloes.
	Francis, Charles	Winchester.

The above names are arranged in order of merit.

* Passed with Honours.

PRELIMINARY EXAMINATION.

The following is the result of the Preliminary Examination, held on the 13th ultimo :—

ENGLAND AND WALES.

Three hundred and fifty-five candidates presented themselves for examination, of whom *one hundred and eighty-six* failed. The following *one hundred and sixty-nine* passed, and have been duly registered as Apprentices or Students :—

FIRST DIVISION.

	Hubbard, Henry Joseph	Norwich.
	Stead, Thomas Gomersall	Chesterfield.
	Dawson, John William	Burgh-le-Marsh.
	Stevens, J. Jesse William	Strood.
	Holden, John	Burnley.
Equal. Equal.	Agars, John Charlton	South Shields.
Equal. Equal.	Tanner, Herbert	Wendlebury.
Equal.	Loney, Thomas Slade	London.
Equal.	Newth, Francis Henry	Southampton.
	Oliver, Henry C. Hewitt	Maidstone.
	Bainbridge, Arthur	Birkenhead.
Equal. Equal.	Campling, William James	Northampton.
Equal. Equal.	Jenkins, John	Haverfordwest.
Equal.	Cooper, David	Church.
Equal.	Davison, Thomas Grey	West Hartlepool.
	Nathan, Lewis Bernard	Jersey.
	Hart, Thomas	Darlington.
Equal.	Hudson, William	Sunderland.
Equal.	Mason, William Brandwood	Bolton.
Equal.	Phethean, James	Bolton.
Equal.	Quick, William Thomas	Chelsea.
	Eggett, Edmund Cater	Lynn.
Equal.	Duckett, John James	Preston.
Equal.	Parkin, George Anthony	Ripon.
Equal.	Silvers, William Brightin	Camberwell.
	Pollard, Alfred	Sherborne.
Equal.	Dewhurst, Thomas	Preston.
Equal.	Purser, Thomas	Stratford-on-Avon.
	Cooper, William Harry	Bridgnorth.
Equal.	Bevis, Walter	Newport (I. of W.)
Equal.	Booth, Thomas	Bolton.
Equal.	Morris, George Harris	Bristol.
	Tucker, Robert William	Totnes.
	Davies, Hugh	Machynlleth.
	Clarke, Isabella S.	London.
Equal.	Bulman, George	Keswick.
Equal.	Colley, Alfred James	Coventry.
Equal.	Waring, Edwin Scholey	Greetland.

SECOND DIVISION.

	Leithead, Robert	Sunderland.
Equal.	Jackson, William John	Lytham.
Equal.	Knight, Thomas	Nottingham.
	Creer, George	Castletown, I. of Man.
	Railton, William	Penrith.
Equal.	Chipperfield, Edmund	Southampton.

SCOTLAND.

Forty-two candidates presented themselves for examination; of these *sixteen* failed. The following *twenty-six* passed, and have been duly registered:—

FIRST DIVISION.

MacEwan, Peter	Lochee.
Boa, Peter	Stranraer.
Glover, William Kensit	Aberdeen.
Jones, Frederic	Annan.
Picken, James Alexander	Brechin.
Buchanan, James	Glasgow.
Watt, James	Haddington.
Scott, Charles	Fraserburgh.
Keith, John	Forres.
Walker, William	Aberdeen.
Hutcheon, William	Montrose.

SECOND DIVISION.

	Fisher, Alexander Bowman	Greenock.
	Marsden, John	Banff.
Equal.	Kinross, William Malloch	Edinburgh.
Equal.	Moore, Frank Philip	Aberdeen.
	Anderson, James	Fraserburgh.
	Maconachie, Andrew Wyllie	Glasgow.
	Lee, Henry	Fraserburgh.
	Cruickshank, John	Aberdeen.
	Macdonald, John	Edinburgh.
	Wilson, Peter B.	Aberdeen.
	Keith, Sydney	Perth.

Anderson, James .....Dundee.
Davidson, Peter.....Insch.
Roy, Alexander.....Crieff.
Hay, Alexander .....Insch.

The following was received in lieu of the Society's Examination:—

Certificate of the College of Preceptors.

Porter, John Thomas ....Coalville.

The questions for examination were as follows:—

Time allowed: Three hours.

LATIN.

N.B.—Candidates are not required to translate more than two paragraphs, and are recommended to select either Nos. 1 *and* 2 *or Nos.* 3 *and* 4.

1. Ita ancipiti prœlio diu atque acriter pugnatum est. Diutius quum nostrorum impetus sustinere non possent; alteri se, ut cœperant in montem receperunt, alteri ad impedimenta et carros suos se contulerunt.

2. Nihilo secius Cæsar, ut ante constituerat, duas acies hostem propulsare, tertiam opus perficere jussit. Munitis castris, duas ibi legiones reliquit, et partem auxiliorum; quatuor reliquas in castra majora reduxit.

3. Misce. Fiat haustus, quartâ quâque horâ sumendus, donec paroxysmi non discrucient, instillando alternis vicibus, si diarrhœa adfuerit, tincturæ opii guttas duas vel tres.

4. Calci, aquæ pauxillo prius resolutæ, reliquam aquam affunde, et simul agita; tum protinus vas contege et sepone per horas tres; dein liquorem cum calce superstite in vasis vitreis obturatis serva, et, ubi utendum est, ex limpido liquore sume.

5. State the genitive singular of "pater, caput, genu, os, and corpus."

6. Give the infinitive perfect, and supine of "do, misceo, video, dico, vivo, cedo, fero, possum."

7. What case do the following prepositions take "ab, ad, ante, ex, post, propter, cum, pro?"

8. Parse "Pueri discendo fiunt docti."

ARITHMETIC.

9. Divide 1·69, by 1·3 by ·13, and also by ·013, and prove the truth of each result by fractions.

10. How much water must be added to a cask containing 60 gallons of gin at 12*s.* 6*d.* a gallon, to reduce the price to 8*s.* a gallon?

11. Reduce 3qrs. 4lbs. to the fraction of 2cwt.; and three-fifths of a guinea to the fraction of £1.

12. If the carriage of 1cwt. 3qrs. 21lbs. for 52¼ miles come to 17*s.* 5*d.*, what will be the charge of 2½ tons if carried 46½ miles?

13. Find the total value of 43 articles at £4 6*s.* 8*d.* each, 57 at £11 8*s.* 6*d.* each, and 4 at £13 15*s.* 4*d.* each. What is gained or lost by selling them at the rate of 3 for £28.

ENGLISH.

14. State the past tense and past participle of:—
"bear, strike, burst, bind, and choose."

15. Parse the following:—
"The last of all the bards was he,
"Who sang of ancient chivalry."

16. Write about 20 lines on *one* only of the following subjects:—
Courage,
Beauty,
War.

The following is a list of the Towns at which the Examinations were held, with the numbers of Candidates annexed:—

Provincial Transactions.

BRIGHTON ASSOCIATION OF PHARMACY.

At a meeting of this Association on Friday, April 17th, the Chair having been taken by the President, Mr. W. D. Savage ;—a paper was read by Mr. T. Haffenden entitled "A few notes on Hippocrates." Mr. Haffenden commenced by giving an account of medicine before Hippocrates' time, tracing the progress of the art from Egyptian science and philosophy, and showing the intimate connection between religion and science in the fact that there were priest-physicians, called Asclepiades, who practised their art in the Asclepions or Colleges of Health, to which invalids resorted in those days as they do to the spas and hospitals in the present time. The office of priest-physician descended from father to son, and it was in one of these temples, the asclepion of Cos, that Hippocrates was born and educated. A list of contemporaries was read, showing that Hippocrates lived at a very remarkable period of Grecian history. He practised homœopathy and allopathy, and paid great attention to "*Diet*," looking upon roasting, boiling, diluting, as merely medicinal modes of preparing food for absorption into the body, really as the origin of medicine. A copy of an oath was also read, showing that there was in his day a corporate body of practitioners, bound by oath, and having regular instructors in the art. Extracts were also given from the Materia Medica of Hippocrates' time, showing that his contemporaries were familiar with many remedies in common use at the present time.

The Chairman drew attention to the fact that Hippocrates employed only vegetable substances as medicines, so that they had to thank the alchemists for a knowledge of chemicals. He also stated that as *post mortem* examinations were in the time of Hippocrates prohibited by law, he could have known very little about the anatomy of the human body, nor was he acquainted with the circulation of the blood, or of the existence of the nervous system, etc.

A lively discussion then ensued, and the meeting concluded by passing a hearty vote of thanks to Mr. Haffenden for his paper and to the Chairman for presiding.

HALIFAX CHEMISTS AND DRUGGISTS' ASSOCIATION.

April 23rd, 1874. Mr. Jessop, president, in the chair. The chief topics which occupied the attention of the meeting, were the Juries Bill and the Adulteration Act. With respect to the first subject, great satisfaction was expressed at the Bill having passed a second reading, and that there was a possibility that, before long, registered chemists and druggists would share, with their pharmaceutical brethren, exemption from jury service. With regard to the Adulteration of Food Act, the following resolution, on the motion of Mr. Dyer, seconded by Mr. Brierley, was carried :—"This Meeting records its satisfaction at the fact of the Government appointing a Commission to inquire into the working of the Adulteration Act, and trusts the Council of the Pharmaceutical Society will take such steps in the interests of the trade as may be deemed advisable ; more especially with respect to the retail dealer being held responsible for the faults and shortcomings of the wholesale dealer and manufacturer."

A copy of this resolution was ordered to be forwarded to the Registrar of the Pharmaceutical Society.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, April 16th, 1874. Dr. Odling, F.R.S., president, in the chair. The minutes of the previous meeting having been read and confirmed, Messrs. J. Smyth, Howard Barrett, H. L. Greville, T. M. Nishigaiva, G. H. Beckett, and A. J. Greenaway, were formally admitted Fellows of the Society.

The first paper 'On Aqua Regia and the Nitrosyl Chlorides' was read by the author, Dr. A. W. Tilden, who was induced to undertake this research in hopes of being able to obtain nitroso-compounds by the action of nitrosyl chloride, NOCl, on organic bodies. As no process existed for the preparation of this substance in quantity, the author devised the following :—The gases evolved on gently heating aqua regia were dried by calcium chloride, and then passed into concentrated sulphuric acid to saturation. The product, when exposed to a low temperature, deposits crystals having the composition $NOHSO_4$. These melt at 85° to 87°, and possess the characters of the ordinary sulphuric acid chamber crystals. Attempts to obtain a dinitrosyl sulphate $(NO)_2SO_4$, were unsuccessful ; on mixing either the crystals or the sulphuric acid saturated with the aqua regia gases with dry sodium chloride, and gently heating, nitrosyl monochloride is at first given off —$NOHSO_4 + NaCl = NaHSO_4 + NOCl$. When this has ceased, the application of a stronger heat causes the evolution of torrents of hydrochloric acid. The pure nitrosyl chloride thus obtained is an orange-yellow gas, which may be condensed to a mobile liquid of a deep orange colour, boiling at − 8°. It attacks platinum and gold, but only very slowly. The existence of the remarkable dichloride, $NOCl_2$, which, according to Gay-Lussac, occurs among the products of the decomposition of nitric acid by hydrochloric acid, seemed doubtful, as no compound having any analogy with it is known, except the vanadyl dichloride, $VOCl_2$, of Roscoe. The author endeavoured to prepare this substance by fractionally distilling nitrosyl monochloride saturated with chlorine, but no definite compound could be obtained ; a similar result ensued on examining the liquid produced by condensing the gases from aqua regia : from this it would appear that the monochloride is the only definite nitrosyl compound obtainable from aqua regia, the reaction being $HNO_3 + 3HCl = NOCl + Cl_2 + 2H_2O$. Gay-Lussac's dichloride was probably a solution of chlorine in the monochloride. The action of nitrosyl sulphate on potassium bromide does not give nitrosyl bromide but nitric oxide and a dark liquid which could not be distilled without the evolution of the same gas. It was not further examined.

The president, in thanking Dr. Tilden, said that the subject of which he had treated was one of very great interest to chemists, and the results he had obtained satisfactorily proved the existence of the compound NOCl, which, if he remembered rightly, Gay-Lussac had passed over with very slight notice, his attention being directed to the mixed body which he supposed to be the dichloride. This compound, whose existence Dr. Tilden had shown to be more than problematical, would be the legitimate analogue of nitric peroxide.

In reply to a question of the president, Dr. Tilden said that Roscoe's vanadyl dichloride was a green crystallizable body of definite composition, but, as it did not seem to be volatile, there was no means of determining its molecular weight.

Dr. C. R. A. Wright then read a paper on 'Isomeric Terpenes and their Derivatives ; Part IV.'—1. 'On Cajeput Oil,' by C. R. A. Wright, D. Sc., and T. Lambert. By carefully fractioning oil of cajeput, an oil, cajeputol, was obtained, boiling between 176° and 179°, and having the composition $C_{10}H_{18}O$, isomeric with the citronellol described in Part III. Like the latter, it combines with two equivalents of bromine, forming the compound $C_{10}H_{18}Br_2O$, which, when heated, splits up into cymene, hydrobromic acid, and water—

$$C_{10}H_{18}Br_2O = C_{10}H_{14} + 2HBr + H_2O.$$

This cymene, when purified, boiled at 176° to 177°, and, on oxidation, yielded terephthalic acid free from isophthalic acid, so that it is identical with that obtained from the other terpene derivatives.

2. 'Action of Pentasulphide of Phosphorus on Terpenes and their derivatives,' by Dr. C. R. A. Wright. On treating

cajeputol with its own weight of the pentasulphide, a vigorous reaction takes place, and a hydrocarbon distils over, which appears to be a mixture of cymene and a terpene, the former predominating. As it seemed probable that the cymene might result from the action of the pentasulphide on the terpene—$C_{10}H_{16}+S=C_{10}H_{14}+H_2S$, the terpene from turpentine oil, boiling at 159°, and hesperidene, boiling at 178°, were digested with an equal weight of phosphorus pentasulphide, when a continuous evolution of sulphuretted hydrogen took place, and much of the hydrocarbon was resinified, but about 30 to 40 per cent. distilled over, consisting almost entirely of cymene. It would seem that the class of bodies known as terpenes, and their derivatives of the form $C_{10}H_{16}O$ and $C_{10}H_{18}O$, are closely connected with cymene, so that this hydrocarbon may be regarded as the central form of matter from which these classes of substances are derived, by operations similar in character for all members of a given class, but differing apparently in the extent to which energy is involved in each operation respectively.

The president said the society was much indebted to Dr. Wright for the continuation of his investigations of the ten-carbon bodies. It was curious that the vegetable kingdom should yield such a vast supply and so great a variety of the ten-carbon bodies, and not other benzene derivatives containing C_9, C_7, etc. He believed that other bodies existed, having the same percentage composition as the terpenes, but only half the vapour density, so that they might be considered as five-carbon bodies ; he would like to ask whether any relation had been made out between these and the ten-carbon bodies.

Dr. Wright replied that this subject had been but little examined. It was a curious fact that, although we could obtain the polymerides from the C_{10} bodies, we could not perform the inverse operation, and unpolymerize them, so to speak,—that is, convert C_{15} or C_{20} compounds into C_{10} bodies.

The meeting was then adjourned until Thursday, May 7th, when there will be papers 'On the Constitution of Urea,' by Dr. D. Tommasi ; 'Researches on the Action of the Copper Zinc Couple on Organic Bodies : Part VII., On the Chlorides of Ethylene and Ethylidene,' by Dr. J. H. Gladstone and Mr. A. Tribe ; and 'On a Mineral from New Caledonia,' by Mr. A. Liversedge.

SOCIETY OF ARTS.

Cocoa and its Manufacture.*

BY JOHN HOLM, F.R.C.S., EDINBURGH.

(*Concluded from page* 846.)

Any Adulteration Act, to be successful in working, and that does not, while protecting the public against fraud, commit injustice against the trader, must be very comprehensive ; for it is impossible to put, in a few short clauses, the power of dealing with all the various substances we use as food, especially those of a mixed character, such as cocoa, condensed milk, etc. It appears to me that the difficulty would best be met by appending, in the form of a schedule to the present or an amended Act, a list of the various mixed foods we take, and of what they should consist ; but such a schedule could only be successfully compiled after an examination by a commission of the House, of practical as well as scientific men.

As regards the manufacture of cocoa, I most indignantly deny that the admixture of sugar and farina are adulterants in any sense. They are, as I have shown, necessary to make the article of commerce known as soluble cocoa, which, from being the form in which it is generally used, is known simply as cocoa. The public is but little acquainted with the raw nut, which, as I have said, is almost useless as a food without considerable preparation. Those, however, who like the unmixed forms of cocoa, obtain them at the shops by asking for them under their appropriate names. They are the raw and roasted and flaked nuts, and roasted, ground, and flaked cocoa nibs. These forms of cocoa have been accessible to the public almost since its introduction in this country, but have never been largely used on account of the time and trouble required to prepare beverages from them, the unsatisfactory nature of the result, and the wastefulness attending such a mode of use. We have seen that the only way to reduce cocoa into an elegant powder is either by admixture or abstraction ; and in the earliest record we have of the use of cocoa as a food in any form, that it has been always prepared with other substances ; the instinct of the Indian leading him to the same result as that attained by civilized man. This necessity has not only been fully recognized and sanctioned by high scientific authority, but also by Act of Parliament (3rd Geo. IV., c. 53) passed in the year 1822, to regulate, amongst other things, the manufacture and sale of cocoa. It is therein provided that it shall be lawful to manufacture "Cocoa Paste, Broma, and other Mixtures and Preparations of Cocoa with Sugar and Arrowroot Flour, or other Farinaceous Powders ; such Arrowroot Flour, or other Farinaceous Powder not being baked, scorched, roasted, or otherwise disguised or altered from its natural state, except by being mixed with cocoa as aforesaid." The latter provision is an instance of how favourably some of these old Acts compare with much of the over-hasty legislation of the present day, in the care with which they were prepared ; for it takes in the whole question of cocoa adulteration, and while not, on the one hand, prohibiting its preparation with other substances, yet guarding against a fictitious appearance of strength being produced in fraud of the consumer.

In the interests of honest cocoa manufacturers it is highly desirable that this clause should be incorporated in any future legislation, and a further enactment be made requiring a specification of the different ingredients employed. The proportions in which these are mixed it would not be just to require, as in this constitutes the difference of one manufacturer's preparation from another, and any such statement is quite unnecessary if the consumer is protected against deception, as he will then be able to judge fully the quality of his cocoa, and will refuse to take those preparations in which the admixture of sugar and farina is pushed to excess. Amongst the numerous eminent scientific men who have given their sanction to this mode of preparation, I will only name Drs. Pereira, Johnston, and Ure, and Messrs. Tomlinson, Brande, and Cooley, all Fellows of the Royal Society. The testimony of Drs. Normandy and Letheby is also of great value. The former states that "the preparation known as cocoa powder or chocolate powder, when genuine, consists only of cocoa nibs, sugar, and arrowroot," and states that the "butter of cocoa is thereby rendered emulsive and more digestible." Dr. Letheby states that cocoa and chocolate owe their chief value, as food, to the fat they contain," and further states "it is necessary to reduce it with some easily digestible substance." Johnston, in his "Chemistry of Common Life," states "that the presence of the cocoa-butter justifies also, as fitting it better for most stomachs, the practice of mixing the cocoa with sugar and farina," and says, "both practices are skilful chemical adjustments." The testimony of Dr. Ure is perhaps the most important of all, he having been appointed by Government to inquire into the manufacture of cocoa for the navy in the year 1842. The reason of his appointment was, that the cocoa as then made at the Deptford Victualling Yard was found to produce a spurious form of dysentery amongst the men. Dr. Ure soon discovered that this arose from the practice of grinding the whole nut, husk and nib, in a coarse and ineffective manner. He therefore conducted a series of experiments, which led him to recommend to the Lords of the Admirality the preparation of a chocolate combined with sugar and farina, but freed from the husks. This form is still used, and its value is shown by the fact that the virtues of navy cocoa are proverbial. That

* Reprinted from the *Journal of the Society of Arts.*

Dr. Ure should have arrived quite independently at conclusions so similar to those formed by Mr. Dunn so many years previously, is a source of satisfaction to that gentleman's representatives. The opinion is of the greater value from the fact that he is the only chemist of eminence who has studied this question with a view to practical results.

These facts show conclusively how unjust and unwise it is to asert that manufactured cocoas prepared with sugar and farina are adulterated articles, and it surely was never the intention of the legislature—even of the dozen members who passed the Bill—to annihilate a large industry supplying the public with so valuable a food in the best, and, indeed, as far as the poor are concerned, in the only way it can be rendered available for consumption.

The cocoa powders prepared without admixture, but which have a large proportion of the fat extracted, are deteriorated in value by such treatment, are not readily prepared, and are so expensive as to be beyond the reach of all but the wealthy classes. Yet this mode of preparation is justifiable, and in certain cases even desirable; the consumer being aware of the kind of preparation he is buying. The objection has been made to the use of sugar and farina that they are of less value than the cocoa with which they are admixed. This is perfectly true, but would also be an objection to almost every mixed article of food; and the effect of competition gives the full benefit in the difference of their price to the consumer, except in the cases where disguising adulterants are employed. The addition of sugar and farina to cocoa has also been objected to on the ground that, being carbonaceous elements, they are added to a substance which already contains them in excess. This would be a very valid objection were we condemned to exist on cocoa only; but as it is only one of many foods, it falls through. The necessity also exists of taking the carbonaceous elements in each of their different forms, and the presence of the cocoa-butter does not render them less necessary in the form of starch or sugar. The fact is, the deductions of mere theoretical chemistry have been pushed too far, as applied to the food of man. I do not wish, however, to disparage such investigations, or to deny their beneficial results when brought to aid the observations of the practical physiologist, and when kept in proper subordination. But it is undeniable that the instincts of man are a far safer guide as to the foods he requires, than mere chemical dogmas, founded on abstruse considerations, which vary from time to time. Reliance on these has, on more than one occasion, produced painful results in our workhouses and public institutions; and but recently Mr. Brudenell Carter, F.R.C.S., pointed out in how great a degree the recent epidemics of ophthalmia which have scourged our schools were due to insufficient dietaries, prepared, however, on the most abstruse chemical principles. He says that in the matter of food supply even the street Arab is in a better condition than some of these poor children.

The popularizing of cocoa as a food was greatly aided by the reduction of the duties on the raw material. Until the year 1832 the duty on cocoa was 6*d.* per lb.; it was then reduced to 2*d.*, and in 1842 to 1*d.* per lb. on that produced by our own colonies. A larger duty was levied on foreign produce for a time, but later on was wisely taken off and the duties equalized. The duty is now 1*d.* per lb. on all raw, and 2*d.* per lb. on all manufactured cocoa imported.

From these causes in combination, the consumption of raw cocoa has risen, as shown by the following tables, from 276,321 lbs. in 1820, to 8,311,023 lbs. in 1872, an increase equal to nearly thirty-threefold in about half a century.

AMOUNT OF COCOA DUTY PAID FOR HOME CONSUMPTION.

Year.	No. of lbs.	Year.	No. of lbs.
1820	276,321	1860	4,583,124
1830	425,382	1870	6,943,102
1835	1,084,170	1871	7,333,988
1840	2,645,470	1872	7,853,165
1850	3,080,641	1873	8,311,023

CONSUMPTION OF COCOA PER HEAD IN GREAT BRITAIN (W. HOYLE).

Year.	lbs.	Year.	lbs.
1841	0·08	1868	0·17
1842	0·07	1869	0·19
1843	0·08	1870	0·20
1844	0·09	1871	0·23
1845	0·09	1872	0·23

So great a result is not only gratifying as a mere matter of commercial statistics, but in a higher degree as showing the wide and extending appreciation and use of so valuable a food.

In reference to the foregoing lecture we have received the following letter from Messrs. CADBURY BROTHERS:—

THE COCOA QUESTION.

In the paper recently read before the Society of Arts by Mr. Holm, we are surprised to find that he reiterated the same arguments as to the *necessity* for adding starches to cocoa.

These mixtures are no doubt wholesome, provided they are thoroughly boiled, otherwise (as was clearly shown by Mr. Bartlett, who spoke on Mr. Holm's paper) they are not digestible; this being frequently the cause of "soluble cocoa" disagreeing with delicate and dyspeptic persons.

But there are much more important subjects involved in this portion of the question. Cocoa, as Mr. Holm himself showed, contains about 20 per cent. of albuminoid constituents, and he adds, "These are classed amongst the nitrogenous principles of food, *and their presence renders cocoa one of the richest flesh-formers we have.*"

It will therefore be seen that every pound of starch or sugar added (both being heat-givers and not containing any nitrogenous element) will reduce its value as food in the same ratio.

The most important constituent of cocoa—that which constitutes its stimulating and refreshing element—is theobromine, or the alkaloid principle, on which Mr. Holm remarks:—"In regard to these alkaloids, it is interesting to note that throughout the world the instinct of man has led him to seek some substance which contains one of these principles, which owe their value to the specific influence they exert on the nervous system, stimulating it and checking waste of tissue."

It will again be seen that the proportion of this important constituent is reduced in exact ratio to the amount of starch and sugar added.

It would be as sensible to add starch to tea and coffee as to add it to cocoa, except for the plea that such addition renders cocoa more easily miscible.

Progress in science and mechanism has rendered this antiquated plea unnecessary, for by expressing the *excess* of butter from the cocoa, as we do in preparing our cocoa essence, the necessity of adding starch is dispensed with, and consequently the proportion of nitrogenous and alkaloid principles is *considerably increased* instead of being diminished.

The abstraction of a portion of the butter renders cocoa easily miscible, and is not only much more valuable in a dietetic point of view, but is far more refreshing and delicious in flavour and aroma.

The assertion that has been made that the extraction of the butter from cocoa "is analogous to the abstracting of cream from milk" is incorrect in *fact* and in the *idea it conveys*, because the whole of the butter is never abstracted in the manufacture of genuine soluble cocoa. The addition of starch to attain the same result (viz., suspension in the cup), reduces the proportion of cocoa-butter to the same extent as by the extraction of the butter:—

Cocoa Essence contains:

Cocoa-butter	19·22
Albumen and other component parts of Cocoa	80·78
Total . . .	100·000

The Best Homœopathic Cocoa contains:

Starch and Sugar added	53·00
Cocoa-butter	20·15
Albumen and other component parts of Cocoa	26·85
Total . . .	100·000

The proportion of cocoa-butter given in these tables are from Dr. Muter's analyses.

Cocoa-butter is both nourishing and wholesome, but owing to the large proportion (50 per cent.) that cocoa contains, the addition of starch renders it an emulsion that may fairly be compared to melted butter, which is likely to disagree with many constitutions, and cannot be *refreshing* as a beverage should be.

Parliamentary and Law Proceedings.

Conviction for Illegal Sale of Poison.

At a magistrates' meeting held at Stradbrooke, Suffolk, on April 23rd, James Thurston, member of the College of Veterinary Surgeons, living at Fressingfield, was charged with selling a certain poison, to wit, strychnia, in the form of vermin-killer, the said James Thurston not being on the register of the Pharmaceutical Society of Great Britain.

The case arose in consequence of an attempt to poison by means of vermin-killer, which came on for trial at Norwich Assizes, in March last. The prisoner was a domestic servant, living at Harleston, in Norfolk, and having an illegitimate child out at nurse at Fressingfield, in Suffolk. She asked a boy to purchase a packet of vermin-killer at Thurston's, and he was supplied with a threepenny packet, without any questions being asked or any register of the sale being made. Having obtained the poison the woman put it into some cakes, and sent them by a carrier to her child out at nurse. The child had a portion of a cake given to it, but was immediately sick, and got rid of the poison. Some children of the nurse also had some, but spat it out on the floor. A portion was also given to a little dog in the room, and being swallowed, death resulted very speedily.

The circumstances being so suspicious, some of the cake was sent to Mr. Francis Sutton, analyst for the county of Norfolk, who found strychnia in considerable quantity.

When Mr. Sutton gave his evidence before the magistrates he learned how the poison had been obtained and at once suggested that the police should purchase some, and prosecute the seller of the vermin-killer.

This is the short history of the case, and the result of the prosecution for illegal sale was as follows :—

Superintendent Ward deposed that he went to defendant's place of business on the 7th February, and bought a threepenny packet of vermin-killer, the envelope of which he produced. He took the packet to Mr. Sutton on the 11th February ; and Mr. Sutton gave as the result of the analysis that it contained 20 per cent. of strychnia, the remainder being starch with a little colouring matter.

Mr. Francis Sutton was then called, and deposed that he received the packet from Superintendent Ward, and found the contents to be as he had stated.

The defendant was then asked what explanation he had to make ; when he stated that he relied upon his being a member of the College of Veterinary Surgeons, which in his opinion entitled him to act as though he were on the register, and alluded to Section 16 of the Act for the grounds of his exemption. The chairman, however, immediately pointed out that this did not affect his position in the slightest. Mr. Sutton also, as a member of the Council of the Pharmaceutical Society, tendered evidence to the same effect ; whereupon the chairman summed up by stating that he believed the defendant had acted innocently in vending the poison, and, taking into account his good character and respectable position, the magistrates had determined to fine him in the merely nominal sum of 6*d.*, which they thought would suffice, as the costs were very heavy ; but they trusted it would be a warning to all others illegally dealing in poisons, seeing how narrow an escape many people had received in the present instance.

The costs, £4 6*s.* 6*d.*, and fine, 6*d.*, were immediately paid.

Supposed Poisoning by Phosphorus.

On Monday, April 27th, an inquest was held before the Liverpool borough coroner, on the body of Mary Collier (32), who died at the Royal Southern Hospital from the effects of poison. The deceased suffered severely from a swollen and ulcerated leg, and on Wednesday obtained admission to the Royal Southern Hospital. On the following day she told one of the nurses that she had taken poison. This information was conveyed to Dr. Hughes, senior house-surgeon, but on his questioning the patient, she denied having taken anything of the kind, and he observed no symptoms to lead him to attach any weight to her statement. On Friday morning, however, she vomited, and died the same day. A *post-mortem* examination was made, but there were no traces of poisoning. It was stated that the deceased said she had taken phosphorus paste. The immediate cause of death was asphyxia, caused by a spasm. The jury, after hearing the evidence, returned a verdict that the deceased died from asphyxia, the result of a spasm caused by poison ; but that under what circumstances the poison was taken there was no evidence to show.—*Liverpool Daily Post.*

Prosecutions under the Adulteration Act.

Adulteration of Milk.

On Wednesday, April 22nd, Bank Horrocks, milk dealer, attended at the Manchester City Police Court, before Mr. Headlam, charged with selling adulterated milk. The prosecution was the first of the kind that had taken place in Manchester.

James M'Intee, provision and milk dealer, said he had entered into an arrrangement with the defendant for a supply of milk, not milk and water, and on the average he had been accustomed to take from him six or seven quarts a day. On Sunday, the 12th of April, the defendant called at witness's shop, and proceeded to supply him with his usual quantity of milk. The defendant had a small can in his left hand, and when about to fill this can from a larger can in the cart, witness went forward and seized the small can and found it to contain about half a gallon of a white mixture. Witness, followed by the defendant. took the mixture into the shop, and on the defendant being asked what he had to say he remarked "It is pure water." Witness replied, "There is something more than that here," when the defendant again said, "It is a drop of pure water." Subsequently Horrocks remarked, "I admit I have done it ; I don't deny it ; but they all do it, but if you will give me 3d. a dozen more, I will supply you with pure milk." Several complaints had been made to witness respecting the quality of the defendant's milk. The contents of the small can witness took to the nuisance office.

Mr. J. Wrigley, an official of the nuisance department, of the Corporation, proved having received from the last witness a bottle containing a portion of the contents of the small milk can. The bottle and contents were taken to the analyst of the Corporation.

Mr. C. Estcourt, the analyst, said he had examined the liquid in the bottle, and had found that 93 parts of it were water, the rest was milk which had evidently been the rinsings of the can.

Mr. Cobbett for the defence said the specific charge against the defendant was that he had adulterated a certain article of food. That charge was not proved, because the milk he was selling had not actually been supplied. He had been actually prevented from committing the very offence he was now charged with.

Mr. Headlam said the contents of the small can were

about to be supplied by the defendant, and that was sufficient to prove the sale. The point would be overruled.

Mr. Cobbett said the defendant was the first person who had been proceeded against for this offence in Manchester, and he hoped the bench would deal with the case in a light manner. It was a very notorious fact that there was no milk sold in Manchester that was not adulterated with water, and in this case the defendant plainly told M'Intee that the milk was mixed with water.

Mr. Headlam said this was the first case in Manchester, or else the fine would have been very heavy. As it was the defendant would be fined £5 and costs.—*Manchester Courier.*

The Secrets of the "Family Jam" Trade.

At the same sitting of the Court, Messrs. Stower and Company, jam and pickle merchants, Liverpool, were summoned for selling adulterated black currant jam.

Mr. Bennett (M'Culloch and Co., Brunswick Street) said that in February he bought a quantity of jam from the defendant, but so much dissatisfaction was expressed with it that he (witness) took it to the nuisance office. The order for the jam was given to the defendant on 'Change in Manchester.

The defendant said the witness was told that Messrs. Stower had several sorts of jam for sale. The jam sold to witness was not the best quality, and the best price was not paid for it.

Witness: Nothing was said about price.

Mr. Headlam (to witness): Did you say anything about wishing to buy "Family Jam?"

Witness: No; but the defendant said that what he was selling me was pure fruit—black currant.

Mr. C. Estcourt, analyst to the corporation, said the pot of jam called "Superior family jam," which he examined, contained over 25 per cent. of adulterated matter, which he believed to be parsnips. Taking the actual percentage he should say there was 25 per cent. of real black currant, and over 25 per cent. of adulteration. The matter used for adulteration was not of an injurious character.

Defendant: Are you sure the adulterated matter is composed of parsnips?

Witness: It is not apple.

Defendant: I have a letter here from the maker of the jam, in which he says that he will defy any analyst in the world to say that the jam is made with parsnips. He says it is apple.

Witness: It is not apple, because it would be too dear.

Defendant: Our firm have nothing to do with it. We simply buy the jam. It is invoiced to us, and then we sell it. We buy the jam for 5*s.* a dozen, and we sold it to Mr. Bennett for 6*s.* 4*d.* a dozen, and we have to pay the carriage from London.

Mr. Headlam: But you are not charged with that. The alleged offence is that you did not say that the jam was made of something else beside black currants.

Defendant: Every grocer knows that jam labelled "family jam" is not of the best quality. The words "black currants" were only put in to let the public know what the principal flavour of the jam was.

Mr. Headlam: I shall impose a fine of 20*s.* and costs, and recollect that when you sell this "Family jam" again, you tell the purchaser that it is not made solely of black currants.—*Manchester Courier.*

Alleged Adulteration of Butter.

The first case tried at Sittingbourne Local Petty Sessions under this Act elicited a point of considerable difficulty. Mr. Benjamin Nutt Rayner, grocer, was summoned for selling butter, which, according to the analysis of Dr. Tidy, one of the county analysts, was adulterated with about 21·5 per cent. of water, and a large admixture of fats other than butter. The defendant stated that a period of fourteen weeks had elapsed between the taking of the sample and his being served with the summons showing the result of the analysis. The butter was Lepelletier's Normandy, of the third quality. He had had a sample, from the same firkin from which the inspector took the butter complained of, analysed by Professor Wanklyn, and the result of the analysis was that the butter was not adulterated. Besides, it was preposterous to imagine that a pound of butter contained three ounces and a half of water; it could not be kept together. Under these circumstances the Bench ordered the butter in question to be re-analysed.—*Grocer.*

Pharmaceutical Qualifications.

Sir,—Amidst the existing controversy with regard to the subjects and mode of the Pharmaceutical Examinations one thing seems to be overlooked, viz., the qualifications required by *employers* in their assistants.

I suppose that the advertising columns of the Journal may be taken as a fitting index for ascertaining what those requirements are; so, taking last week's issue, I find under the heading of "Assistants wanted," thirty-four employers advertising, one third of whom seem to be more solicitous about the *height* of applicants than about anything else (salary always excepted). Those gentlemen apparently measure a man by his inches, setting at nought the assertion contained in Dr. Watts' lines:—

"I must be measured by my soul,
The *mind's* the standard of the man."

To those in quest of employment in such situations, I imagine that the services of the author of the following advertisement, extracted from a weekly newspaper, would be found much more valuable than the assistance of any number of professors or "crammers."

"To Short Persons.—Remarks on a method of Increasing the Height and Improving the Figure, with 250 authenticated testimonials and reports of results. Sent post free on receipt of a directed envelope."

I suppress the address, as I have no notion of favouring our friend with an advertisement gratis. It may perhaps in the course of time become a question for the consideration of the Council "What is the standard of height for a chemist and druggist?" should this *gigantic* demand continue.

CORTEX RHAMNI FRANGULÆ.

BY H. C. BAILDON.

When, in August, 1871, at the Pharmaceutical Conference held in Edinburgh,* I brought under the notice of its members this bark, as likely to prove a valuable addition to our Materia Medica, I could only give as my authority for its virtues the Dutch gentleman who first introduced it to my notice. Since then I have been applied to by various pharmacists throughout the country for supplies of it. Among the first of those to obtain it was Mr. Richard W. Giles, of Clifton: indeed, I think he has had three different quantities; and, being anxious to ascertain whether his experience of the action of the bark corresponded with my own, which was in all respects very favourable, I wrote to him in March last, and I now quote from his reply, having obtained his permission to do so.

"I have had less experience of the *Rhamnus frangula* under my own observation than you have happily met with in the case of your relative.

"I think that I once took it experimentally, and found that it produced precisely the action attributed to it in your paper, read to the Conference in Edinburgh, viz., a natural movement of the bowels without drastic action. I have recommended it very steadily when occasion has offered, and the consequence appears to be that the few cases who require habitual laxatives and make a trial of the *Rhamnus* stick to it pertinaciously. Some surgeons who have tried it tell me that it has answered in counteracting habitual constipation in a marvellous manner, when everything else seemed to lose its power.

"It appears to have tonic and aromatic qualities which stimulate the muscular action of the bowels, as distinguished from the cathartic effects produced by irritating purgatives through the influx of serum into the bowels, which latter action must necessarily be attended with debilitating effects. I feel that the *Rhamnus* fills up all that was wanted in purgatives in our Materia Medica, which is now copious in that class of medicines, including aloes, colocynth (extract) and senna (syrup if well made). I entirely agree with your opinion, that it should be included in the Pharmacopœia, and will willingly support your suggestion to that effect; but with you the honour of its introduction should rest."

The case alluded to by me in my letter to Mr. Giles was one of long standing indigestion accompanied with severe headaches, both of which yielded to the action of the bark.

As my stock of the bark was nearly exhausted, I wrote to Mr. Baruchson, the gentleman referred to, for a further quantity. In his reply he says, "I am glad you have taken pains to make this valuable medicine known. I have often reproached myself for not having made long ago an effort, and to benefit thereby suffering humanity. I wrote about eighteen months ago to the *Lancet* (I think it was that periodical), but received no reply. I do not think that I should now be living if I had not got this substitute for the drastic purgatives, and even the milder ones I used to take. The bark has the same effect on me now as it had twenty years ago."

I brought the *Rhamnus frangula* under the notice of Professor Redwood, but unfortunately too late for its introduction into the additions to the British Pharmacopœia recently published. In his reply the Professor says, "You certainly seem to have made a strong claim on behalf of the *Rhamnus frangula*. I have made a note of it for further consideration."

I believe it is already admitted into several, if not all, the European Pharmacopœias. I have the Pharmacopœa Germanica now before me, where it is thus described:—"A quilled bark, about one millimetre in thickness, grey or brownish-grey externally, with small white warty protuberances, which are generally lengthened transversely. . . . The bark of the younger trunks and the larger branches of the indigenous shrub are gathered in the spring."

This kind only should be used, as the bark taken from the thick part of the trunk is altogether different, and the decoction made from it is nauseous to the taste, whereas that made from the quill bark is singularly pleasant, with a slight almond or prussic acid flavour—no small advantage to those for whom it may be prescribed.

I hope this communication will have the effect of calling the notice of the faculty and of pharmacists generally to this valuable medicine; possessing, as it does, properties peculiar to itself, and which are not found in senna and other drastic purgatives, which it ought to supersede, at least to a considerable extent.

* See PHARMACEUTICAL JOURNAL, 3rd series, vol. ii., page 152.

IMPROVED FORMULA FOR CHARTA SINAPIS.

BY A. W. GERRARD,

Dispenser and Teacher of Pharmacy to University College Hospital.

The formula given in the "Additions to the Pharmacopœia" for the preparation of mustard paper is unsatisfactory and expensive. The proportion of solution of gutta-percha necessary to render the ounce of mustard ordered sufficiently fluid for coating is ten drachms. This would contain more than a drachm of gutta-percha, which, when it is applied to the paper and the chloroform has evaporated, gives the surface of the mustard a glossy, varnished appearance. In fact, the gutta-percha acts as a varnish, much retarding the absorption of moisture and the development of the essential oil upon which the activity of the paper depends. Another objection to gutta-percha is its insufficient adhesive power, for the coating cracks and peels from the paper after but slight handling.

With the object of remedying these objections, I made trial of a solution of india-rubber in benzol as a menstruum; for I judged from its physical properties much less of this than of gutta-percha would be required to keep the particles of mustard cohesive, and at the same time the action would be retarded only to a minimum degree. I found it well answered my intention. After several experiments to determine the most suitable proportions, I have adopted the following:—

Take of

Caoutchouc	1 part.
Benzol	49 parts.
Black Mustard, in powder, a sufficiency.	

Dissolve the caoutchouc in the benzol; then stir in the mustard till of a proper consistence for spreading on paper.

In this, as also the B. P. form, the presence of the fixed oil in the mustard gives the back of the paper a greasy appearance. Moreover, its removal, which might be effected either by pressure or by percolation

with benzol, would be an advantage, not only as removing the cause of this greasiness, but it would render the mustard more active.

Papers spread with a mixture made according to the form I have here given, have a dull, smooth surface, and the mustard adheres well together, although it contains only one-fourth as much india-rubber as the British Pharmacopœia formula does gutta-percha. The above preparation readily absorbs water and develops its activity. A piece applied to the arm gave evidence of its presence in less than two minutes, whilst a piece of the B. P. preparation required seven minutes, its full effect being comparatively slight. An estimate of the cost of the two forms shows that a Charta Sinapis prepared as suggested above could be made for one-eighth the expense of the B. P. preparation.

AILANTHUS GLANDULOSA AS A REMEDY FOR DYSENTERY.*

In a recent issue of the *Archives de Médecine Navale* is published an official note, addressed by Dr. Robert, who is the medical chief of the naval division of China and Japan, to the inspector-general of the health service in the French navy, calling attention to a drug used by Chinese physicians in the treatment of dysentery. It consists of the root bark of the *Ailanthus glandulosa*, Desf., a plant belonging to the natural order Simarubaceæ, very common in the North of China and less so in Japan. It is also frequently cultivated in France and Italy for the purposes of shade, whilst its leaves have been used as food for silkworms.

The bark of the root is the only part employed. It is white when fresh, resembling mallow root, but it acquires a greyish tint in drying. It is fibrous and loose in texture, and is almost without smell. An infusion of this bark however exhales a slightly nauseous odour, and possesses an excessive bitterness resembling that of sulphate of quinine. The Chinese physicians employ the root in the fresh state only; but Dr. Robert, having been compelled to use some that had become dry, found no sensible difference in its action in the two states.

For administration, 50 grams weight of the fresh root is cut into very small pieces and triturated with 75 grams of hot water for a few minutes in a mortar, in order to soften the bark, and then strained. A tea-spoonful of this strong infusion is administered as a dose morning and evening, alone or in a cup of tea. Taken in this form, it provokes vomiting. The medicine is administered in this manner during three days, the patient being kept upon full diet. After that time the ailanthus is omitted and the diet is altered to broths until health is restored. If after eight days' treatment the patient is not cured, the Chinese physicians recommence the use of the ailanthus; but Dr. Robert states that he has not met with a single case in which this resumption has been necessary, although he has had under his notice some where the disease had lasted several months as well as others of more recent origin.

The principal symptoms which follow the administration of the ailanthus are said to be nausea, and sometimes vomiting, followed by a temporary lowering of the pulse. The disappearance of blood from the evacuations commences on the first day and is complete on the second; the colic ceases a little later. The effect of the drug upon the colour of the evacuations is variable. Dr. Robert sums up by expressing his opinion that the administration of the *Ailanthus glandulosa*, as witnessed by him in China and Japan, gave superior results to that of ipecacuanha, astringents, alone or combined with opiates, or calomel. The remedy, he says, is only known to a portion of the Chinese physicians, a circumstance which he attributes to their custom of preserving the secrets of their practice.

Dr. Robert states that the root of *Ailanthus glandulosa* is not usually to be obtained in the Chinese pharmacies; but that in the dialect spoken at Shangai it is called "hiang" or "siang-tcham," and in the mandarin dialect spoken at Pekin and Tiensin, it is named "tchau-tchoun," which latter agrees with the name attributed to it by Dr. F. Porter Smith in his 'Contributions to the Materia Medica and Natural History of China' (p. 6). The latter writer points out that the *Pen Ts'au* includes *Ailanthus fœtida* or *glandulosa* with *Cedrela odorata* and other trees distinguished by their odour, under the common name "Chun-chu." He further remarks that "this species of *Ailanthus* grows all over China, and is met with on the walls of Pekin. The leaves are used to feed silkworms, and in times of scarcity are used as a vegetable, though much less agreeable than the young leaves of the *Cedrela*. They are said to be slightly deleterious, and are used as astringent, anthelmintic, and deobstruent remedies. They are given in diseases of the lungs, dysuria, tabes infantum, menstrual disease, spermatorrhœa, and fluxes in general; and a wash is made to promote the growth of the hair and to wash scabious eruptions and ulcers. In most of these cases the bark both of the tree and the root is used, having precisely the same properties. The bark of the mangrove tree is sometimes adulterated with this inferior substitute." But he does not mention its use in dysentery.

In the non-officinal portion of the Pharmacopœia of India, the *Ailanthus Malabarica*, D.C., a large tree of Ceylon, Malabar, and Concan, is mentioned as yielding an aromatic gum-resinous substance, known by the Tamul name of matti-pawl, which is used medicinally, especially in dysenteric cases and as incense. Dr. Gibson regards it as a good stimulant in bronchitic affections. The bark is rough and very thick, with a pleasant and slightly bitter taste; it is studded with bright garnet-looking grains, apparently of a resinous nature, but not burning like resin or dissolving either in spirit or water. A specimen of the extract prepared from this bark may be seen in the Museum of the Pharmaceutical Society.

The bark of another species of *Ailanthus*, *A. excelsa* is mentioned as being used by the natives in dyspectic complaints, and esteemed as a powerful febrifuge. This bark was the subject of an exhaustive treatise by Mr. Narayan Daji, read before the Grant College Medical Society of Bombay, in which its properties were attributed to the presence of ailanthic acid. The paper was published in the present series of the PHARMACEUTICAL JOURNAL, vol. i., p. 154.

* Abstract of a paper in the *Répertoire de Pharmacie*, vol. ii. p. 237.

NOTE ON SYR. FERRI PHOSPHATIS.

BY C. R. BLACKETT,

Vice-President of the Pharmaceutical Society of Victoria.

During the course of some experimental researches upon syr. ferri phosphatis, instituted through having

to prepare a paper for one of the evening meetings of the Pharmaceutical Society of Victoria, I found, as others before me have done, no method by which this preparation could be kept for any length of time without manifesting change of colour, accompanied by a deposit of oxy-ferric phosphate. It occurred to me that a solution of ferrous phosphate might be made that would keep indefinitely; on trying the experiment I found that I had a successful result. It may seem contrary to the generally received opinion, but I find that sugar, instead of being the preservative agent, is really the opposite as far as this particular preparation is concerned.

To prepare a liquor ferri phosphatis I suggest the following method. Proceed as ordered in the Pharmacopœia, but take the acid. phosph. dil. 5½ oz. and evaporate to 2 oz. (in a platinum dish if available), then add the well-washed ferrous phosphate, just as it remains upon the filter without pressing, add water (distilled) to make it up to 2 fl. ounces and 5 drs., dissolve and filter. This quantity of solution is of such a strength that it is, on making up to 12 ounces with simple syrup, exactly equal to the B. P. syr. ferri phosph. ℥j ♏xxij with syrup to one fluid ounce.

The same principle may be applied to the preparation of a liq. ferri phosphatis c. quiniâ et strychniâ to still greater advantage, as this syrup is more prone to change and darkens more. To make a solution so that ℥ij + ℥vj syrup should be equal to Easton's syrup, take:

Acid. phosph. dil. ℥x, evaporate to 4 fl. ounces, then add the usual proportions of ferrous phosphate, quinia and strychnia. Make up to 6 ounces, and filter. To make 24 fluid ounces with simple syrup.

Those pharmacists who do not consume very large quantities of these syrups will find it very convenient to keep ready these solutions. The syrups can thus be dispensed uniform in composition, colour, and taste. I venture to think that a liquor ferri phosphatis might advantageously be introduced into the Pharmacopœia.

THE PRESERVATION OF HERBS, ROOTS, BARKS, ETC., FOR PHARMACEUTICAL USES.

Mr. Hugo Dwyer, writing in the Chicago *Pharmacist*, speaks very favourably of some samples of herbs, roots, etc., submitted for his inspection, which had been grown at Niles, Michigan, and dried there by the "Alden process of pneumatic evaporation." The principal advantage claimed for this process is that it leaves the herbs in a comparatively unaltered condition, no injurious chemical change taking place during the drying. At the same time, it is stated that they resemble in appearance the finest qualities of dried herbs. It is asserted that whilst in the ordinary processes of drying the decay of the plants commences even before the evaporation, and continues during the whole of the operation until all the essential flavours which constitute the charm of freshness are lost, the pneumatic evaporation operates so rapidly as to leave no time for the exhalation of the flavouring essences or the deterioration of colour or structure by decay. Another important merit attributed to this process is the uniform quality of the botanical materials it supplies for pharmaceutical operations.

The process is described as follows:—"The principal part of the apparatus consists of a vertical chamber or shaft, 25 feet high and 5 feet square, containing a series of frames one above the other, 4½ inches apart, covered with netting, and moved upward all together by endless chains. The heating apparatus, consisting of a steam coil, is placed under this chamber, from which currents of air, heated to any required temperature, pass up through and around the herbs. On each frame is spread about 20 pounds of the material. The lowest frame is first placed in the chamber directly over the heat, at the bottom of the shaft, where it remains from three to six minutes. It is then moved up 4½ inches, and another frame of herbs is placed beneath it. At regular intervals the whole series of frames are moved upward 4½ inches, and a fresh frame is put on beneath them until they are all in, 50 in number, containing about 1,000 pounds. At this time, the shaft being full, one frame is taken off at the top and one is put in at the bottom, at intervals varying with the article treated. The water contained in the herb is seized by the ascending air, and passes with it up, through, and around it;—the moisture is taken gradually from the herb, enveloping it to the last in a cloud of vapour. The pores of the herb are thus kept open, free for the circulation and exit of vapour until all the free water is removed; the remainder (a small per centage) being held as hydrate."

Mr. Dwyer was at first inclined to believe that the heat used would destroy any volatile principle contained in the drug, but he is now firmly convinced that such is not the case, as a sample of peach leaves shown him tasted quite as strongly of hydrocyanic acid as any fresh leaf he had ever tasted. He thinks that if a volatile principle so delicate and so liable to be injured by heat is not so injured there need be but little fear of the others, such as those contained in the herbs of the mint family. The degree of heat used is from 80° to 110° Fahr., and with articles containing volatile principle never higher than blood heat.

THE RECTIFICATION OF ALCOHOL BY MEANS OF LIME.*

BY CHARLES BULLOCK.

The process usually employed to obtain absolute alcohol, is distillation of the spirit from quick lime.

The practical result of the process will appear from the following operation.

Fifteen gallons of alcohol. sp. gr. ·82361 at 60° F. = 93 per cent, was poured upon seventy pounds of well-burned lime (previously broken into small pieces), in a still, heated by a steam jacket. The still was then made tight, and heated to about 120°; after standing three days, a worm was attached and distillation commenced, protecting the distillate from the air. Each gallon was collected in a separate vessel, the heat being gradually increased as was necessary to cause the alcohol to pass over slowly.

Ten gallons was all that could be made to pass over by steam heat. Water was then added to the lime in the still, and most of the alcohol recovered as dilute alcohol.

The ten gallons of strong alcohol thus obtained was returned to a still with twenty-five pounds of quick lime, and the operation, as above, repeated. Eight gallons of alcohol was obtained, separated as before in fractional portions of one gallon.

The specific gravity of the several portions taken on a balance with the one thousand grain bottle, temperature at 60° F. is shown in the following summary:

Gallon.	First Distillation.	Second Distillation.
1st.	·80170	·80978
2nd.	·79756	·79700
3rd.	·69610	·79461
4th.	·79762	·79516
5th.	·80040	·79458
6th.	·79593	·79410
7th.	·79782	·79425
8th.	·79632	·79615
9th.	·79706	
10th.	·79780	
Mean	·79783	·79695

The density of absolute alcohol varies somewhat with

* From the *American Journal of Pharmacy* for April.

different authorities; Drinkwater and Fowne give ·79381, Tralles, ·7939, and Gay-Lussac, ·7947; taking the mean of these authorities, we have ·79413.

It will be seen, on reference to the figures given above, that the sixth gallon of the second distillation alone is absolute, according to this mean standard, and that the mean of the 3rd, 4th, 5th, 6th, and 7th gallon of the second distillation is ·79425, being within the figures given by Gay-Lussac.

It will be noticed that the weakest alcohol distills over first, which would lead to the supposition of an affinity of the lime for the stronger portion of alcohol, or else water having a greater disposition to vaporize in an atmosphere of alcohol vapour.

The distillates all contain lime, which does not separate on standing; the stronger the alcohol the greater appears to be the amount of lime present. Redistillation from over-dry tartaric acid removes the lime (Gmelin), and renders the alcohol perfectly clear.

THE SELECT COMMITTEE ON THE ADULTERATION ACT.

The select committee, appointed to inquire into the subject of adulteration, commenced its sittings on Monday last, Mr. Clare S. Read in the chair; and there was a full attendance of members. The subject did not seem to attract much public attention, and there were none of the large manufacturers present, although several principals of tea firms were in attendance. The evidence taken on Monday chiefly related to the subject of tea, all the witnesses concurring in their evidence to the effect that the colouring of green tea with gypsum and Prussian blue could not be considered an adulteration, as it was not in any way injurious, was not fraudulently done to increase weight or bulk, but had been done from time immemorial in order to suit the taste of the English public. One of the witnesses, Mr. Owen, an officer of the Local Government Board, gave some evidence as to the appointment and qualifications of public analysts. After referring to past legislation upon adulteration, and the provisions thereby made for the analysis of goods, he stated that in the metropolis the number of analysts appointed was about forty. In some cases, medical officers of health had been appointed; in others, persons practising as analysts on their own account; and in others, professors of chemistry at the different hospitals had been appointed to discharge the duties incident to the position. He also pointed out that there are different modes of paying the analysts thus appointed. In some cases they are paid by a fixed salary, the minimum being £50, and the maximum £150; while there are cases where the remuneration is partly by salary and partly by fees. In addition, there is one class where the payment is made entirely by fees; and Mr. Owen also pointed out the peculiar fact that, in one town, the analyst was paid according to a scale which varied for articles or commodities analysed. The Local Government Board, before giving their sanction to the appointment of analysts, sent out a form of queries as to their eligibility and the qualifications they possessed for the office. It was essential that they should possess competent chemical, medical, and microscopical knowledge. He believed that in some cases the question whether the analysts possessed such qualifications had been raised, and that there had been some discrepancies in analysis. Referring next to the country, he mentioned that the appointments of analysts in the counties numbered thirty-four, and the number in the boroughs was twenty-six. Of course, there were a very large number of boroughs and some counties where analysts had not been appointed; and the Local Government Board had not put their compulsory power into force with regard to the non-appointment of these officials. In some cases a considerable difficulty had been experienced in getting a competent person appointed as analyst, who lived in the district where his services were required; and, in consequence of this difficulty, persons at a distance had frequently been appointed. Dr. Tidy, he mentioned, residing in London, was analyst for Essex, Kent, and Sussex. The result of this was that when any samples were procured for analysis, the inspector who bought them was obliged to attend the analyst when the analysis was made; and thus some trouble was necessitated in that way. If the analysts were required to attend at any public courts, in support of any prosecutions, they received an additional fee; and he had not heard of any complaints from the analysts as to their remuneration being inadequate or niggardly. With regard to the question, whether the system of paying by salary only, or that of paying by a smaller salary and fees, or that where the remuneration consisted exclusively of fees, was the best, he could not offer any decisive opinion. It was somewhat difficult to judge, as it was also whether an analyst possessed the necessary qualifications. A medical man might not possess a very complete knowledge of chemistry, while a chemist might be also deficient. As to the medical and microscopical knowledge, however, there did not seem to be so much difficulty as with regard to the chemical knowledge. The item of expense had, perhaps, been an obstruction in small towns to the appointment of analysts. Again, if there were tradesmen in the local Town Council, they doubtless would not be too greatly desirous that such officers should be appointed.

The Committee then adjourned.

PHARMACY IN IRELAND.

A deputation from the Chemists and Druggists' Society of Ireland waited by appointment on the Governor and Company of the Apothecaries' Hall, on Friday, May 1st. The deputation consisted of Messrs. E. M. Hodgson, President; J. Goodwin, Treasurer; W. Hayes, Secretary; L. Erson, J. P., J. Grindley, J. T. Holmes, and R. Simpson. The object of the deputation was to request the Apothecaries' Company to form with them a joint deputation to wait on the College of Physicians, to discuss the provisions of the new Pharmacy Bill. The Apothecaries' Company, however, at once declined having any communication with the College of Physicians; and complained of the want of courtesy of that body, in introducing a Pharmacy Bill without either consulting them or advising them of their intention. Dr. Leet then informed the deputation that he had forwarded their Bill to the Attorney-General, together with their objections to the Bill of the College of Physicians. It transpired, however, that since the Bill had been agreed to by the Chemists and Druggists' Association, some alterations had been made by the Apothecaries' Company without either consulting the Association or apprizing them of the fact.

A long conversation then took place on the subject of the Examinations. In reply to a question from Mr. Holmes, Dr. Collins said they would entertain no lower qualification than that of the major examination of the Pharmaceutical Society. Mr. Holmes urged that an examination of so high a standard as the Major of the Pharmaceutical Society was utterly unnecessary for a proper fulfilment of the duties of a pharmacist. Dr. Collins replied that it was their determination to keep up the standard of pharmaceutical education. Mr. Simpson pointed out that, under the English Pharmacy Act, it was not necessary to pass the Major examination to carry on the business of pharmacist; that the Minor examination was all the law required; if that is considered qualification enough for England he thought it should also be considered qualification enough for Ireland. Dr. Leet said that when he received a reply from the Attorney-General he would communicate with the Association of Chemists and Druggists, and the deputation withdrew.

The Pharmaceutical Journal.

SATURDAY, MAY 9, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PHARMACY OF THE PHARMACOPŒIA.

ON reference to the report of the proceedings at the Evening Meeting of the Society, last Wednesday, it will be seen that they were more animated than is commonly the case with adjourned discussions. Not, indeed, that there was, properly speaking, much discussion upon the merits or demerits of the various preparations included among the Additions to the Pharmacopœia, for the obvious inutility of such discussion in regard to formulæ which have now acquired the force of law was generally recognized. The main point to which attention was directed had reference more especially to the way in which a Pharmacopœia may be most satisfactorily framed, and to the mode in which the practical experience of pharmacists may be most serviceably turned to account in determining the formulæ to be adopted for new remedies, or the alterations to be made in established preparations.

It was contended that the work of deciding how certain medicines should be prepared is essentially the business of the pharmacist, and that inasmuch as his assistance in this respect is desirable, in order to give full effect to the intentions of the medical practitioners, there should be a larger and more official co-operation of pharmacists with medical men than has hitherto obtained in the preparation of the Pharmacopœia of this country.

We do not hesitate to declare our opinion that this seems at once a well founded and a modest aspiration on the part of British pharmacists, one which is justified no less by the example of other countries than it is in the nature of things. So much indeed is this the case that we can only regard Professor REDWOOD'S opposition to the suggestions of Mr. CARTEIGHE and Mr. SMITH as having been based on the misapprehension that they involved some kind of disparagement of the services he has rendered in the preparation of our Pharmacopœia and its Additions. But, in reality, the argument that pharmacists should have some more prominent part in that work does not in the least involve such an implication, and we regard it as very unfortunate that, for the reason we have indicated, or for any other, such a marked personal tone should have been given to the reply to that argument.

In one respect, however, Professor REDWOOD'S remarks served to indicate that there is on the part of the members of the Pharmacopœia Committee a disposition to recognize the capability of pharmacists to be serviceable in the carrying out of the work entrusted to that body; and it is gratifying to find that this is the case not only in sentiment but in practice, since we learn that the four-and-twenty proof copies of the Additions were sent out to members of the Medical Council especially for the purpose of being put into the hands of their pharmaceutical friends, with the view of getting all the advice and assistance possible.

We repeat that it is as gratifying to learn that this was really done as it is natural to expect that it would not be omitted by a body so constituted as the Medical Council. But we do not think that this is merely a reason to "rest and be thankful." We regard it as evidence that there has been some progress in the pharmaceutical body, and we are fain to adopt it as being an adequate ground for asking the question whether that pharmaceutical progress has not advanced so far that the advice and assistance desired by the Medical Council may be asked officially of the entire body, through the medium of the Pharmaceutical Society, instead of being sought only from those with whom the members of that Council may chance to be acquainted.

It is to this end that we understand the more serious part of Mr. SMITH'S remarks to be directed, and this, to our apprehension, was also the purport of Mr. CARTEIGHE'S argument. We hope yet to see Professor REDWOOD prominent in promoting such combined action between the representatives of the medical profession and of pharmacy.

MASSACHUSETTS COLLEGE OF PHARMACY.

ON the 22nd of April the "Annual Commencement" of the Massachusetts College of Pharmacy was held in the City of Boston, with an "Order of Exercises," in which the musical performances of the Germania band were interjected between the annual report, conferring of degrees, and professors' addresses, and other more serious business.

From a prospectus of the College, issued with the invitation, we take the following particulars respecting the qualifications for graduation; premising that although pharmacy has not yet become the subject of special legislation in all the American States, such Pharmacy Acts as have been passed prescribe as a qualification for keeping an open pharmacy, and in some for acting as an assistant, the passing of a special examination in the respective State or city, or the possession of a diploma such as is here referred to. It will be seen that the tendency in the United States is to raise a more stringent standard than that which has been thought by some to be too high in Great Britain.

Every person upon whom the degree of "Graduate in Pharmacy" of this College is conferred must be of good moral character and twenty-one years of age. He must have attended two courses of lectures; one course, at least, being in the Massachusetts College,

and the other in a recognized college of pharmacy or medicine, where the same subjects are taught. He must furnish satisfactory evidence of having served an apprenticeship of at least four years with a qualificd pharmacist. Finally, he must produce an original dissertation, written with neatness and accuracy, upon some subject of pharmacy, materia medica, chemistry, or one of the branches of science closely connected therewith, and he must also be recommended in writing by the professors.

Only such students as may have served their time in "dispensing stores" can obtain the degree of graduate in pharmacy; medical students and others are allowed to attend the lectures, but are ineligible for the degree. The reason given for this distinction is that the art of dispensing medicines can only be properly learned by long practice at the dispensing counter, and that lectures, however good, are only valuable aids to practical instruction, but utterly fail to make a good dispenser in the absence of careful practical training under the supervision of a competent preceptor.

There are three series of lectures—pharmacy, chemistry, and materia medica and botany—and the fee for each series is fifteen dollars. The diploma fee is ten dollars.

THE GROWTH OF CINCHONAS.

Some idea of the rate of growth of Cinchonas in India may be gathered from a Report of the Assistant Conservator of Forests in Tinnivelly. He says "While engaged in examining the Surveyar and Lower Oollar plantations, I also paid a visit to the block of Cinchona trees planted in the heart of the Pappanasam forests in the year 1866, by Mr. Macgregor, the sub-collector. Something less than one fourth of an acre of forest was cleared and planted with two kinds of cinchona, the *Cinchona succirubra* and *C. Condaminea*." Of the former, at the time of the visit, now about two years since, "there were 62 alive, the largest measuring 19¼ feet in height and 11½ inches in girth, the smallest 14½ feet in height and 4½ inches in girth, and an average tree 17 feet in height and 7 inches in girth. Of the latter species there were 32 plants alive, the largest measuring 25 feet in height and 11 inches in girth, while there was another which measured only 21⅓ feet in height but 13 inches in girth; the smallest was 20 feet in height and 7 inches in girth, and an average tree 22¼ feet in height and 12 inches in girth." No attention had been paid to these trees for two years previous to the visit, and they are described as having had some of their branches broken off and otherwise ill used.

SCHOOL OF PHARMACY.

It will be seen, by reference to the advertisement of the School of Pharmacy of the Pharmaceutical Society of Great Britain, that Professor Bentley will commence his course of Lectures on Systematic and Practical Botany at the Royal Botanic Society's Gardens in the Regent's Park, on Saturday morning, May 16th, at Eight o'clock.

At the General Monthly Meeting of members of the Royal Institution on Monday last, it was announced that the managers had appointed John Hall Gladstone, Ph.D., F.R.S., Fullerian Professor of Chemistry.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, May 6th, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Baynes, Betty, Frazer, Greenish, Hampson, Mackay, Owen, Radley, Robbins, Sandford, Savage, Schacht, Shaw, Sutton, Urwick, and Williams.

The minutes of the previous meeting were read and confirmed.

The North British Branch.

Mr. Mackay explained the circumstances under which the North British Branch had felt it necessary to take immediate action with regard to securing more commodious premises. He drew attention to the statement which had appeared in the Pharmaceutical Journal of Feb. 7th, as made by himself, to the effect that the North British Branch had, for some time past, felt that they were paying too high a rent for the accommodation they possessed, which was not sufficient for their purposes; that they had now a prospect of receiving eight cases of specimens, for which they had no room; that he had given notice to terminate the lease in May; and that they were looking out for more suitable premises, as to which he would again communicate with the Council. He thought, without going farther into detail, that was a sufficient explanation of the reason for seeking fresh premises; and he had only to add that the reason why the offer of the new rooms was not communicated to the Council was that if they had taken time to do so, they would inevitably have lost the chance of getting them on anything like such advantageous terms. He now begged leave to submit plans showing the accommodation afforded respectively by the two sets of rooms; from which it appeared that in the new rooms there would be half as much more floor area, and also wall space. There was a large front room, to be used as a museum and examination room; another suitable for a library, reading, and waiting-room, and another which could be well adapted for a laboratory and dispensing-room. The proposed arrangements were, of course, all subject to the approval of the Council, but he might add that Dr. Maclagan, the Government visitor in Edinburgh, had expressed himself very much pleased with the plans suggested, and had offered to render any assistance in his power. He should be glad to know if the Council approved generally of the proposed arrangements, and if they would authorize him to obtain the requisite plans and estimates. The rent of these new rooms would be £75 per annum, as against £85, the present rent.

Mr. Williams explained that his principal reason for bringing forward this matter at the last Council meeting, was the statement made by one of the gentlemen who recently attended as a deputation from the North British Board of Examiners, that in the new premises there would not be accommodation for conducting the examinations, especially in practical chemistry. He thought Mr. Mackay would easily understand his astonishment at the proposed change on hearing such a statement, and why he felt it his duty to mention the matter to the Council. The explanation now given by Mr. Mackay was perfectly satisfactory, and he had no doubt the Council would also give their approval.

Mr. Mackay expressed his surprise at the statement quoted by Mr. Williams, which the plans he had now submitted most effectually disposed of.

Mr. Hampson said the explanation was no doubt satisfactory with regard to the change being made, but he thought the Council had some slight reason to complain of its being carried out without communication with them. He did not consider the reason which had been given, that in all probability the premises might have been lost, was a sufficient answer.

Mr. SAVAGE, on the contrary, thought the Edinburgh Board had acted very wisely in the course they had adopted. He wished to know, however, if there would be two rents payable for any time.

Mr. MACKAY said they would enter on the new premises on the same day on which they left the old ones, so that there would be no double rent.

Mr. BAYNES was glad the North British Branch had had the courage to set aside red tape routine under the circumstances, which he considered fully justified them.

Mr. WILLIAMS said there was one point he desired to mention before parting with this question. Another statement made by the deputation from the North British Board of Examiners was that there was a deficiency of specimens and appliances for conducting the examinations in Edinburgh; this he said at the time was chargeable solely to the North British Branch, because the Council were desirous of doing everything necessary to ensure efficiency in the examinations. He wished now to reiterate the same statement, and he hoped there would be no hesitation on the part of the North British Branch in making their wants known.

It was then resolved unanimously.

"That this Council approves of the change of premises of the North British Branch, and requests the Honorary Secretary to procure estimates for the necessary specimens, fittings, &c., and submit them to the Council at the meeting in June."

THE LATE MR. HENRY DEANE.

The PRESIDENT said: I have to call the attention of the Council to the fact that since the last meeting we have lost, as you are all aware, one of our most distinguished, most accomplished, and most amiable pharmacists. Mr. Deane was a member of the Council almost from the commencement of the Society's existence; he was also a member of the Board of Examiners, and, in all the operations of the Society, nobody took greater interest than Mr. Deane. He was a kind and warm friend, and a most amiable and straightforward man—I think I may say he was one of God's noblest works. I beg to move, therefore,

"That the Council deeply regret the loss they have sustained in Mr. Henry Deane, who was for so many years a member and one of the most active supporters of the Pharmaceutical Society; and that a letter be addressed to Mrs. Deane, expressing the great sympathy felt by the Council and the Board of Examiners for her in her great affliction."

The VICE-PRESIDENT, in seconding the motion, said he might reiterate all which the President had said with reference to the late Mr. Deane. It had been his privilege to know him, in connection with the Society, for many years, and it had been his painful privilege to witness the last scene of his career on earth. On Good Friday, the day before he died, he had spent some hours in Mr. Deane's society, most agreeably, the recollection of which would form a red-letter day in his existence. He had always highly esteemed Mr. Deane, as did everybody who knew him.

The resolution was passed unanimously, and the President, Vice-President, and Mr. Sandford were appointed a committee to draw up and send the letter to Mrs. Deane.

ELECTION OF HONORARY MEMBERS.

Robert Bentley, M.R.C.S., F.L.S.; and Frederick Porter Smith, M.B., M.R.C.S., L.S.A.; were elected Honorary and Corresponding Members of the Society.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma, stamped with the seal of the Society:—

Carter, Arthur Joseph.
Chamberlain, Arthur Garratt.
Jones, Rees Thomas.
Polley, John.
Richmond, Robert, jun.
Walsh, Albert.
Willan, Robert.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

Carter, Arthur Joseph	London.
Hetherington, Martin Luther	London.
Jones, Rees Thomas	Hirwain.
Modlen, Robert	Harrow-on-the-Hill.
Polley, John	London.
Richmond, Robert, jun.	Leighton Buzzard.
Senior, William Furber	Doncaster.
Thompson, Lawrence Joseph	Thirsk.
Walsh, Albert	London.
Willan, Robert	Barrow-in-Furness.
Williams, William Francis	Chepstow.

Chemists and Druggists.

Brown, Andrew Henry	Shanklin, I. of W.
Dorman, James	Stranraer.
John, William David	Cardiff.
Porter, John	Coalville.
Sargent, George West	Kensington.
Sharp, John Charles	Musselburgh.

ASSOCIATES.

The following, having passed their respective examinations, and being in business on their own account, were elected "Associates in Business" of the Society.

Minor.

Butterworth, Henry	London.
Collins, Martin Austin	Bradford, Yorks.
Flinders, Matthew Tom	London.
George, John	Kidderminster.
Haller, Frederick William	Boston.
Herd, Henry Wilson	Ambleside.
Kershaw, Joseph Henry	Glossop
Laverack, William Henry	Malton
Luke, Tom	Bacup.
Nicholls, Theophilus	London.
Peake, Arthur	Earlestown.
Sharrah, Richard	Rochester.
Smithies, William Edward	Elland.
Smyth, Arthur William	Yoxford.
Stephenson, Frederick	Edinburgh.
Tucker, Robert Lewis	Bristol.
Usher, John	Newcastle-on-Tyne.
Woods, Richard	Jersey.

Modified.

Ball, Samuel	Sutton, Chester.
Bannister, Theophilus Mayo	Burnley.
Boorman, Charles John	Malvern Link.
Cavell, John	Long Sutton.
Embleton, Bradley	London.
Furniss, Thomas	Liverpool.
Hobbes, Alfred Edward	Milton-next-Sitting-bourne.
Hughes, John Edward	Bath.
Hughes, John Henry	Southampton.
James, James Thomas	London.
Lowther, Maslyn Kelsey	Hull.
Nugent, George Thomas	Brighton.
Richardson, Alexander	Newcastle-on-Tyne.
Stewart, William Henry	London.
Swain, James	Roehampton.
Targett, Charles George	Weymouth.
Turner, Henry Prosser	Lydney.

The following, having passed their respective examinations, were elected "Associates" of the Society.

Minor.

Atkinson, Henry Bacon .....York.
Black, William Jones ... .Bangor.
Blunt, George ....Upton-on-Severn.
Broughton, Thomas ... .Salford.

Several members who had neglected to pay their subscriptions within the time specified by the bye-law, were restored to their former status, subject to the payment of the subscription for the current year and a fine of half the same amount.

LIBRARY, MUSEUM, AND LABORATORY.

The report of this Committee was read, the main feature of which was the draft annual report, the consideration and revision of which occupied the Council for several hours. It also mentioned a report from the curator of the museum, that he had received about one hundred specimens of medicinal plants in the green state for the herbarium. Professor Attfield had reported that 76 students had entered the laboratory since the commencement of the session, and that 39 were now at work. It had also been reported that the attendance books of the lectures showed that 26 students were now attending Professor Redwood's class, and 27 Professor Bentley's. The Committee recommended the purchase of five copies of 'The Additions to the Pharmacopœia' for the library. The report was received and adopted.

FINANCE.

The report of this Committee, recommending the payment of sundry accounts, was received and adopted. The auditors' report was also adopted and ordered to be printed.

BENEVOLENT FUND.

The Committee recommended the following grants of

money:—£10 to the orphan daughter of a late member at Southampton, being the seventh grant; £15 to a chemist and druggist at Croydon; £10 to a chemist and druggist at Wells, Norfolk. They also recommended that the name of William Atherton, of Liverpool, be placed on the list of approved candidates for an annuity. Other applications were deferred for further consideration and inquiry, and the report and recommendations of the Committee were received and adopted.

Parliamentary.

This Committee had held three meetings during the past month. The Committee reported that proceedings had been taken against Thomas Clarkson, of Sheffield, for infringement of the provisions of the Pharmacy Act, and that the penalty and costs had been recovered from him.

Some correspondence was read with reference to the Select Committee of the House of Commons, recently appointed to consider the working of the Adulteration Act; and the Committee recommended that the Society should endeavour to secure a hearing before the Select Committee of the House of Commons with reference to this measure, to show the difficulty under which druggists labour with reference to drugs coming into England in an impure condition, the impossibility of obtaining some of them without admixture of foreign matters, and the difficulty of detecting such admixture. They considered the question of guilty knowledge one of the most important points to be insisted upon. They also considered that prosecutions for the sale of impure drugs and chemicals involved the necessity of a technical knowledge not generally possessed by local authorities; and they suggested the desirability of one or more central boards being appointed, to which appeals should be made by inspectors for authority to take proceedings. With reference to the Juries Bill, Mr. Mackay had communicated to the Committee letters which he had received from the Lord Advocate, Earl Dalkeith, and Mr. Duncan McLaren, M.P. for Edinburgh; that from the Lord Advocate stating that he would take steps to secure that whatever rule was adopted in England with regard to the exemption from jury service of chemists and druggists should be extended to Scotland. A prescription containing poison, not duly labelled with the name and address of the compounder had been placed before the Committee, who had requested the Secretary to write to the offender, calling his attention to the provisions of the Pharmacy Act on the subject.

At the suggestion of Mr. Mackay, the President was requested to write to Earl Dalkeith, the Lord Advocate, and Mr. McLaren, thanking them for their promise to endeavour to secure the extension to Scotland of the exemptions with regard to serving on juries enjoyed by pharmacists in England.

Mr. Williams suggested that, as there were so many matters dealt with in this report, some of them had better be referred back to the Parliamentary Committee for further consideration.

Mr. Hampson asked what would be the scope of the proposed central board. It appeared to him the object of such a board should be that if two conflicting analyses were made, as had more than once happened, an appeal could be made to this board for an independent analysis, which should be accepted as final. Of course, the members should be well paid, and be of undisputed authority.

Mr. Greenish did not think it was possible to constitute such a board.

Mr. Urwick thought the central board referred to in the report was of quite a different character, and was desired rather as an authority whose consent should be required before local inspectors took proceedings.

Mr. Williams thought this matter had better be further considered by the Committee.

It was then resolved—

"That the recommendations of the Parliamentary Committee with respect to the amendment of the Adulteration Act be received; and that the Committee be requested to put themselves in communication with those gentlemen whom they may think it right to put forward for examination by the Select Committee of the House of Commons, and to take such other measures from time to time as may be required."

It was also resolved that the President should be requested to communicate with the Chairman of the Select Committee of the House of Commons appointed to consider the Adulteration Act.

The Committee further reported that the President had laid before them some correspondence which he had received from the Cororer of Lincoln, between himself and the President of the Medical Council, suggesting the insertion of chloral hydrate in Part 2 of Schedule A to the Pharmacy Act, 1868.

The Secretary read two letters, which had been received from the Chemists' Association at Hull and Halifax respectively, each containing a copy of a resolution which had been passed, expressing satisfaction at the appointment of the Committee to inquire into the working of the Adulteration Act; and expressing a hope that the Society would take such steps as might be necessary to protect the interests of the trade, especially with regard to retail dealers being made responsible for the faults of wholesale dealers and manufacturers.

A special meeting of this Committee was then appointed for Friday, the 8th inst., at 3 o'clock.

Additional Scholarships.

The report of this Committee, recommending that a paragraph, bearing upon this subject, should be inserted in the annual report of the Council, so as to bring the matter before the General Meeting, was read and adopted.

Report of Board of Examiners.

The Board of Examiners for England and Wales reported the result of their examinations as follows:—

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	8	7	1
Minor	158	42	116
Modified	34	19	15
Preliminary	355	169	186
	555	237	318

Certificates received in lieu of the Preliminary Examinations:—

College of Preceptors	3
University of Cambridge	1
University of Oxford	2

The Board of Examiners for Scotland reported that they examined 42 preliminary, passed 26—16 failed.

The Secretary reported that a letter had been received from the Secretary of the Royal Botanic Society, granting the usual privilege to the students in Professor Bentley's class to attend the Society's gardens.

The Congress at St. Petersburg.

Mr. Hampson asked if it was necessary to send an immediate reply to the communication from the International Pharmaceutical Conference, or whether it would be in time at the next meeting.

Mr. Greenish said he had, on the previous day, received from the Secretary an invitation in German, which he had translated, and it appeared therein that they requested the names of the representatives to be communicated before the 15th of July. The question was accordingly deferred till the next meeting.

Erratum.

Greenish, Thomas	12	Sandford, George Webb	13	Williams, John	13

Number of Council Meetings during the year, 14.

PHARMACEUTICAL MEETING.

Wednesday, May 6, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed, the following donations were announced, and the thanks of the Society awarded to the donors :—

To the Library :—Durham University Calendar, 1874, from the University; Guy's Hospital Reports, vol. xix., 3rd series, from the Hospital; London University Calendar, 1874, from the University; Proceedings of the Literary and Philosophical Society of Manchester, vols. viii.—x., and Memoirs, vol. iv. 3rd series, from the Society; Gondard's 'Étude sur les Acides Oxyphénylsulfureux et les Oxyphénylsulfites,' Roucher's 'De l'Autorité et de la Responsabilité Médicales dans l'Armée,' Verne's 'Étude sur le Boldo,' and Bouchardat's 'De la Mannite et de ses Éthers,' from Dr. J. L. Soubeiran.

To the Museum :—A Specimen of Persian Stick Opium, from Mr. J. Wood; Liquid Chloride of Nitrosyl, from Dr. Tilden; Arrows tipped with Curari Poison, from the Executors of the late Mr. T. N. R. Morson; A Specimen of the Root of *Richardsonia scabra*, from Mr. D. Hanbury; A curiously formed Crystal of Bromide of Potassium, from Mr. T. Hudson; a Specimen of the Stem of *Chondodendron tomentosum*, from Mr. A. H. Squire, and of the Stem and Root, from Messrs. Corbyn and Co.; a Specimen of an Adulterant of Opium, from Mr. Romans; and a Specimen of *Tulipa sylvestris* for the Herbarium, from Mr. Corder.

Adulterated Opium.

Mr. Gostling, a student in the laboratories, read the following note :—

A few days ago, Mr. Romans, Chemist, of Wrotham, Kent, sent to Professor Attfield a contribution to the Museum collection of opium adulterants, in the form of a lump of what appeared to be earthy matter, which had recently been found in a piece of opium. The piece of opium weighed 28 ounces, the lump of "dirt" 2½ ozs.—or nearly ten per cent. of the opium. I find the adulterant to consist of silicious, aluminous, ferruginous, and calcareous matter, with a little oil and a small quantity of other organic matter. The lump furnished 3 per cent. of moisture, about 5 per cent. of oil, 26 per cent. of other organic and volatile matter, and 66 per cent. of ash. It is evidently a lump of clayey earth; no doubt the first that came to the hand of the person who buried it in the piece of opium. From long soaking in the opium it has apparently absorbed some of the moisture or juice of the opium, hence its "organic matter:" otherwise it is simply clay-earth.

Additions to the Pharmacopœia.

The discussion on Mr. Umney's paper on the Additions to the Pharmacopœia, adjourned from the last evening meeting (see before, p. 789), was then resumed by the reading of the following note, written by Mr. E. Smith, of Torquay :—

"Any attempt to criticize the recent addendum to the Pharmacopœia savours very much of the principle involved in locking the stable door after the horse has been stolen; for no matter how valuable or otherwise any particular preparation may be shown to be, the formulæ have all the force of law, in fact, have already become *the law*, so far as pharmacy is concerned.

"It has been known for a long time past that the General Medical Council contemplated the issuing of an addendum to the British Pharmacopœia which, it was supposed, would include all those medicines and preparations which had, since the publication of the 1867 Pharmacopœia, been brought into general use, and which had to a greater or less extent acquired the sanction of the medical profession. Whether such an addendum was really necessary, especially when issued as the present one has been, so short a time before the next decennial edition of the British Pharmacopœia, may well be doubted. It is, of course, eminently desirable to ensure uniformity in the strength of medicines whenever possible; but it is very questionable whether this is of so very supreme importance, in the comparatively few medicines of any value that are introduced and accepted in the course of the decade, as to necessitate the publication of a supplementary authorized Pharmacopœia. For, in the first place, the current medical and pharmaceutical journals generally indicate with sufficient exactness the general characters and doses of new preparations; and again, prescribers not unfrequently indicate the strength when there are known to be material differences of composition in medicines of like name.

"The doubt as to the unwisdom of issuing the present addendum becomes a certainty when the contents are examined. There is not a single 'medicine or preparation' that could not have waited—without any detriment to the world—until the next edition of the British Pharmacopœia, whilst the information to be derived from further experience of the value of some of the 'new preparations' would probably have secured for them a more appropriate position.

"If it were not now too late to comment, one would naturally ask, Why introduce such a wretched form for Tinctura Quiniæ Ammoniata? A much more agreeable and aromatic, and I think a much more universal one, is simply the solution of a grain of quinine in a fluid drachm of sal volatile. Then, again, syrup of chloral. The great majority of chloral takers have become so accustomed to a more grateful syrup, that the thin, mawkish, miserable syrup of the addendum has little chance of popularity, either amongst prescribers or patients.

"As for pepsine, the form involuntarily carries one back to primitive times. Scrape the stomach with a blunt knife indeed! Well, I should dearly like to see the Medical Council at this work! Some of them would most likely prefer a week's hard labour at Millbank to a day's stomach scraping with a blunt knife! I have had some little experience of pepsine making, and if I were asked to point out *the least desirable* method, I should have little hesitation in fixing upon the addendum process.

"Liquor Magnesiæ Citratis is out of place in a Pharmacopœia; it would be more at home in a volume dedicated to 'Domestic Receipts.' It may have been introduced to fill up a corner, and possibly in the next addendum, if ever we are blessed with another, we may find 'Nettle beer and Lancashire pop!' Who knows? Tinctura Aurantii Recentis is a desperate attempt at fancy pharmacy. Mrs. Jones' flummery may be all the better for it, but in the more serious matter of every day pharmacy one is at a loss to discover how, in any essential particular, the new tincture is better than the old.

"The contrast between the primitive simplicity of the pepsine formula, the dandy elegance of the new orange tincture, and the insipid crudeness of our new chloral friend, would be supremely ridiculous were it not for the harrassing position most pharmacists will be placed in. Some friend may peradventure suggest that there is some good in the addendum, that all is not bad, or doubtful, or childish, or what not. True, Tinctura Laricis is good, and so are Succi Belladonnæ and Hyoscyami, and one or two others; but, notwithstanding these, does not the prefatory announcement, printed on the very first page, cut the throat of the addendum most completely?

"Is it not there stated that 'several new medicines and new preparations having been introduced and established since the Pharmacopœia was published in 1867, the Council have thought it desirable to supply the requisite information concerning them?'

"Does not this statement directly, indirectly, or inferentially indicate that the best established, the most popular amongst physicians, the most commonly employed extra-pharmacopœial preparations, might be without doubt found in the addendum? Where, then, are Parrish's syrup and Easton's syrup, almost as commonly prescribed as Aqua Destillata or Mistura Camphoræ? where Nepenthe

and Chlorodyne ; where Tinctura Actææ Racemosæ ; or Pruni Virginianæ, or syrup of the same ; the two latter quite as frequently prescribed as Tinctura Laricis ? Has the Medical Council never heard of the utility of Syrupus Ipecacuanhæ and its superiority over the old Vinum ? But enough of this. Surely a more ricketty, weakly bantling, one more innocent of the least possible *raison d'être*, never was suffered to exist.

"I had nearly suggested its withdrawal, but there is really nothing of any moment to withdraw. Left to itself—in spite of its eminent parentage—its early atrophied condition leaves but little hope that the thing can survive, except as an amusing and instructive lesson, or as a remarkable illustration of the old fable of the mountain and the mouse.

"The time has long since passed when any Council composed of medical men can frame a Pharmacopœia. All future works of this nature can only be successfully accomplished by a medical council deciding of what preparations and medicines the Pharmacopœia shall consist, whilst *the method* of compounding and preparing is left to a council of practical pharmacists, well versed in such matters."

Mr. M. CARTEIGHE said he was prepared on the last occasion to bring forward one or two matters involving more or less pharmaceutical et[illegible]s, or, rather, his notion of how a Pharmacopœia and the [illegible]ditions or supplements to it should be compiled ; but, owing to the adjournment of the discussion, he had been anticipated by other members, who had naturally thought over the subject in much the same way as himself. He did not claim to criticize the book, because it was unnecessary to do so seriously at a time when it had been issued with legal authority, and was the recognized standard according to which they were bound to prepare their medicines. He considered, therefore, that the proper time for criticism and suggestions would be at a later period, when, perhaps, a new edition of the British Pharmacopœia was in preparation ; because any suggestions now made would probably be lost sight of before the time arrived, for, seeing how long it had taken to produce these few pages, they could not hope to see a new edition of the Pharmacopœia for many years. He would, however, fain express his regret that this little book did not reflect so much credit on its authors as did the original edition, which every one would admit was a decided success, at any rate, when regarded as in some sort a compromise between the Pharmacopœias of three different countries. They must also admit that the main part of that credit was due to one of their own professors, who had laboured long in the cause of Pharmacy and for whom they all had the greatest possible respect. He feared, however, the majority of the members would not be able to view this supplement in the same light ; not that they attributed the difference to any want of skill on the part of the gentleman he had referred to, but to the fact that probably he had had to deal with elements very difficult to manage. Mr. Umney had already covered nearly the whole ground which any fair criticism could be expected to embrace ; and some observations in Mr. Smith's paper as to the necessity for practical pharmacists being called upon to aid in the preparation of any Pharmacopœia, and a similar passage in the *British Medical Journal*, included practically the gist of what he himself wished to say. The last named journal, after giving a *précis* of Mr. Umney's paper, went on thus :—

"Many of the objections urged by Mr. Umney seem to indicate the necessity of giving greater prominence to the element of practical pharmacy in the Pharmacopœia Committee of the Medical Council. This has long been done in other countries, and the adoption of such a course would certainly be advantageous here ; for, though it is true that the decision as to the medicines to be comprised in the Pharmacopœia must always remain with those who have to prescribe their use, still questions as to the best means of preparing them for various purposes call greatly for the aid of the practical pharmacist, who, being daily occupied in such work, is enabled to bring to bear the results of his experience, so as to advantageously promote the objects of the physician. If this were properly done, we should then, perhaps, hear less of complaints that officinal formulæ were inferior to other methods of preparation. The material services which Professor Redwood has already rendered in this direction may, perhaps not without advantage, be supplemented by the aid of other pharmacists."

He regretted that the Medical Council had not thought fit to send copies of this book to a few practical pharmacists, when they issued the proof addendum which by accident got into Mr. Bottle's hands. As it was, it now contained some matters which must be dealt with in a sort of roundabout way, because it would be impossible to follow literally the directions given, of which he would give one or two instances to justify his assertion, though he must repeat his protest against this being the proper time for detailed criticism. With regard to the hypodermic injection of morphia, there might have been some objection to the introduction of sulphate of morphia when the strength was 1 gr. in 6 min., but now it was made so much weaker there was no reason why sulphate of morphia, if not acetate, should not be used. The sulphate formed a very practicable, definite, colourless solution, which acted very well, and would not involve the time and manipulation required by the process now given.* If he rightly understood the necessity for such a preparation, it was that pharmacists, not in London but in the most remote country districts, should be able to prepare it at short notice ; but how would it be possible to carry out this process under such circumstances ? Suppose the life of a patient depended on the prompt injection of such a solution, how could any one prepare it by such a formula ? He considered it a pure waste of time, because there were salts of morphia perfectly definite, which, as far as he could judge, answered as well as the solution of the morphia alkaloid in acetic acid. Why, again, did they omit sulphur and fennel from *Pulvis glycyrrhizæ comp.*, especially when it was being prescribed more frequently than formerly, and almost invariably, as he believed, with a sign indicating that not this formula but the one including sulphur and fennel was to be used ? If pharmacists had been asked to give an opinion on the book before it was published, many would have loyally devoted their time and attention to the various matters contained in it for the benefit of pharmacy. He did not attribute, however, any shortcomings to want of consideration on the part of the editor, but rather to his being overweighted by the other members of the body entrusted with its preparation. Again, take *Liquor magnesiæ citratis ;* on what principle was such a name given to such a compound ? He did not concur in Mr. Smith's condemnation of this compound, which he thought a very useful one ; on the contrary, he was rather astonished it had been omitted so long, and not introduced until some time after the Americans had published the formula in English, though it had been occasionally prescribed for a considerable period under its French designation. He objected to the name, however, especially bearing in mind the recent discussion on the so-called Effervescing Citrate of Magnesia, where the use of names not strictly accurate had been condemned by Professor Redwood and others. The name here given expressed a definite compound, whereas other ingredients were directed to be added ; and when penalties on all kinds of adulteration were being so rigidly enforced, he objected to these definite names being given.

Professor REDWOOD : What do you say to "tincture of rhubarb ?"

Mr. CARTEIGHE said he should object to such a name

* This salt is more soluble than is commonly supposed. A solution of the strength ordered has been made and kept for two or three weeks. See a paper by M. Adrian in vol. iii. of the present series, p. 2.—ED. P. J.

simply, but with the addition of the word "compound" it applied perfectly well. He contended that this case differed only in degree, not in kind, from the citrate of magnesia, of which so much had been said. "Magnesian lemonade" would better represent the preparation. With regard to suppositories, it was entirely a question for medical men whether or not soap would be an irritant. Syrup of chloral had been condemned as a syrup, but he did not think there was much in it; the only question was—why had such a form been introduced under the name of a Syrup? In conclusion, he would say—What had been the history of the Society as connected with the public and the medical profession for the last thirty years? It had often been stated by Presidents of the Society that it was recognized by the public and by the medical profession, but how was its recognition shown in the compilation of this book? It was true, the Society's professor of chemistry and pharmacy had been engaged upon it, but not in his official capacity as connected with the Society, and being only one individual, he was not sufficiently strong; he should have been supported by men engaged in the daily practical work of pharmacy, each of whom would make it a labour of love to work out every process which could be devised, with a view to its insertion in such a book. He thought the time was come when pharmacists should claim—he would not say the right, but the privilege—of assisting in the compilation of such a work. In days gone by, when the lamented Mr. Deane was President, the first Pharmacopœia Committee was formed, and its labours tended greatly to assist the fusion of Pharmacopœias which ultimately took place. Why should not a similar committee be formed when additions were proposed? He asked this, not because pharmacists wanted more work, but in the interests of the medical profession themselves; for what could be more mischievous than to insert formulas in a national book, some of which were practically unworkable? A Pharmacopœia in this country should be compiled by a joint committee of medical men and pharmacists, the latter to be only responsible for the preparation of the medicaments which the former decide on inserting. In asking this, pharmacists were only asking for the same recognition as had been accorded for many years to their brethren in Germany and France, and for a long time in the United States.

Mr. BLAND thought some gentlemen were scarcely disposed to make sufficient allowance for the difficulties which must always attend the preparation of a Pharmacopœia, and reminded the meeting of what had already been said, that it was much easier to criticize processes described than to suggest new ones which should be unassailable. Mr. Smith's note might be amusing, but he thought the censure it contained was scarcely justifiable. At the same time he thought some of the new preparations were superfluous, and others, he thought, would have only an ephemeral existence. For instance, he saw no reason for introducing the *Syrupus chloral* unless for the purpose of giving a definite strength to it, and with regard to *Aqua chloroformi*, all chemists kept at least one alcoholic solution of chloroform, and many two, from which there would be no difficulty at any time in preparing *Aqua chloroformi* by adding sufficient water. The *Tinctura quiniæ ammoniata* could certainly be improved, as suggested by Mr. Smith, whose form was the one he had used for many years. He had never been an advocate for introducing *Tinctura aurantii recentis* into the Pharmacopœia, though he had made it for a long time, and considered it useful for flavouring purposes. He feared it might be confused with the other preparation, made with proof spirit and dried peel. It was, however, quite a mistake to suppose, as some gentlemen seemed to do, that dried orange peel was the same as fresh, minus a certain quantity of water. When freshly-cut peel was exposed to the air, the first thing which took place was a loss by evaporation of a considerable portion of the essential oil; next, by far the larger proportion of the essential oil still left was oxidized into a bitter matter soluble in proof spirit. Hence the fact that tincture made with proof spirit was darker and more bitter the older the orange peel from which it was prepared. He thought the dose of the *Tinctura aurantii recentis* recommended much too large, and would be found objectionable. On the table he had placed a bottle of what he called "artificial orange juice," which he thought would be found a very agreeable flavour. The *Tinctura aurantii recentis* might be added to a ferruginous solution without causing any considerable alteration in colour, which was not the case with the tincture of dried peel. Amongst the corrections at the beginning of the book was one relating to the specific gravity of the *Liquor ferri perchloridi fortior*, which he was glad to see, for he had been for some time misled by the figures given in the Pharmacopœia. He found, however, that authorities were not agreed on this subject; Mr. Squire putting it first at 1·41, afterwards at 1·42; the present correction put it at 1·44, whilst Mr. Umney, some time ago, put it at 1·444. He had prepared considerable quantities of ferrous and ferric chloride in solution, for other than medicinal purposes, and hence had been led to notice certain circumstances which considerably modified the result in preparing the *liquor ferri perchloridi*. In the first place, the hydrochloric acid might be deficient, in which case when the alcohol was added the whole would soon become turbid, owing to a deposit of oxychloride. This could be easily remedied however, by adding a few drops of hydrochloric acid and shaking. A more serious defect was when the tincture, after a short time, acquired a strong ethereal smell; in some cases he had noticed a strong smell of aldehyd, while there was a partial reduction of the iron, so that the addition of a recent solution of red prussiate of potash would give a copious precipitate. This change could invariably be traced to an excess of nitric acid used in preparing the perchloride. In some samples, again, he had found the iron only imperfectly converted, and containing a considerable quantity of ferrous chloride; now this was considerably less soluble in alcohol than the ferric chloride, and in a few days crystallized, but leaving the solution weaker in iron than it should be. The Pharmacopœia process was in the main a good one, but required some little modifications. The hydrochloric acid need not be diluted; and if a mass of crystals were formed which prevented the action of the acid on the remaining part of the iron, the aid of a gentle heat and the addition of a few drops of nitric acid would remedy the difficulty.

Mr. T. H. WILLIAMS (Holloway), said he had tried making the carbolic acid suppositories with soap for several hours, according to the method given in the addendum, but he had completely failed. If he used properly powdered soap, as sent out by the wholesale houses, they could not be made without employing something like hydraulic pressure to form them into the moulds. On the other hand, if he used soap partly dried so that it could be rubbed to a coarse powder in a mortar, they could be made, but if the same kind of soap was used for the Tannin suppositories they acquired a size of about 30 grains, which was very objectionable. Mr. Umney had suggested that perhaps the *Acetum Ipecacuanhæ* did not keep; but he had been in the habit of making it for fifteen years, and found it keep perfectly; and Messrs. Ferris, of Bristol, whose preparation he had imitated, had used it for twenty years and always found it keep remarkably well.

Mr. MARTINDALE said he could scarcely concur in the unqualified condemnation which had been given to the hypodermic injection of morphia by Mr. Carteighe, as he thought it a really good formula, having had considerable experience in such matters; though he thought it was weaker than that generally used, which had one grain to six minims. There might be an advantage, however, in having it more dilute, especially if it had to be used by unskilful persons. He had no doubt that the precipitated pure morphia prepared from the hydrochlorate,

and re-dissolved in acetic acid, formed a more stable solution of acetate of morphia than could be made direct from the acetate. The sulphate required from 20 to 24 parts of water to dissolve it, which would make the solution much weaker, therefore it was objectionable on that score. There was perhaps a little objection to injecting so much as six minims at a time, but he supposed it was safer than using a more concentrated solution. The ordinary commercial acetate, when kept for twelve months, became liable to change in a variety of ways and was much less soluble than when freshly prepared, requiring almost as much water to hold it in solution as the hydrochlorate or sulphate. Some years ago he had given a formula for making the solution direct from pure morphia, in preference to making it from acetate, but the present process had an advantage over his, inasmuch as it required such a slight excess of acetic acid to re-dissolve the precipitated morphia. With regard to the phosphorated oil, he was rather surprised it was directed to be made so weak as one grain in 160 minims; and, as Professor Redwood was so much in favour of introducing the decimal system, it was rather strange he had not given the strength of one in 100. The French Codex had it one grain in 50 minims, but that proportion it was almost impossible to dissolve; one in 100, however, was easily dissolved. With regard to the mode of conducting the process, he had formerly suggested that it was an "unnecessary refinement" to heat the oil to 300° F. He was now prepared to go further and say that it was positively deleterious, because the phosphorated oil so made became much more viscid when kept for some time, in fact almost like castor oil. The next substance to which he wished to call attention was the phosphorus pill mass. He had had considerable experience in making phosphorus pills, it being rather a fashionable remedy lately, but he considered the process now given for making it into a solution in balsam of tolu was objectionable. You could not be certain that you had a perfect solution by such means, as the balsam became hydrated; there was also a difficulty when the wax was added in mixing the ingredients together, as the wax floated on the top of the water, while the phosphoretted resin sank to the bottom. He rather objected to the balsam of tolu being used in any form as a solvent, because phosphorus was not so soluble in it as in other resins he had found. However, having made the pills as directed, it occurred to him that they might not be really soluble, yellow wax requiring a temperature of 140° F. to melt it, that of the body being under 100° F.; and therefore, bearing in mind the old saying, *fiat experimentum in corpore vili*, he had tried them upon himself, taking one in the morning and one in the afternoon. As he expected, he found them both next morning perfectly globular, as slightly acted upon as possible, and not appreciably decreased in weight. He then repeated the process, rubbing the mass up with a little spirit of wine, as suggested; this certainly made it a little more plastic, but not more soluble, and he therefore could not approve of the preparation at all. He thought it would only tend to shake the confidence of medical men in any medicine, if formulæ of this misleading character were given. He further tried some of the advertised kinds of phosphorus pills, and one which was very extensively advertised he found was open to the same objection; it was almost perfectly insoluble. Mr. Gerrard's pills, however, completely disappeared, and he also found them to have much more influence on the system, the breath in particular being more affected; this was slightly affected by the pills prepared as directed in the addendum. In the case of Mr. Gerrard's pills, however, on rubbing the mass in a mortar, the phosphorus became oxidized in such a manner that it possibly might not act as phosphorus when taken. The compound powder of liquorice he thought would lead to a great confusion of names, and that it would have been much better, if such a preparation were needed, to adopt the Prussian formula; with regard to the suppositories, he had not had much experience in making them with soap, but it was not possible to mould them according to the new method with anything like the rapidity which was desirable. He believed that if they were made firm enough they would not be soluble. With regard to *Liquor magnesiæ citratis*, he thought Mr. Carteighe had justly condemned the name; and he did not see why light carbonate of magnesia might not be used as well as the heavy kind, it would be more economical. He was sorry to see the syrup of chloral in the form now produced, without flavour; the *Tinctura aurantii* he found increased 10 per cent., and thought it was better made with weaker spirit. He still held it was useful as a flavouring preparation. The chloroform water, he thought, would be a useful preparation. The *Charta sinapis* he considered a bad imitation of a good article.

Mr. Barnes said he had made phosphorus pills with soap, and found that the phosphorus dissolved uncommonly well.

Mr. Umney then said: I promised on the last occasion of our meeting to make some experiments upon acetic ether, the description of which, as given in the addendum, I then ventured to conjecture was inaccurate. I find that crude acetic ether, prepared by the process there indicated without desiccation by chloride of calcium will have a specific gravity of ·910, and will be much contaminated by acetic acid; also that by the use of chloride of calcium and subsequent distillation the specific gravity is ·895, and the product still contains free acid. Again, that the mere rectification of the crude ether over carbonated alkali as directed in the Codex, distilling a quantity equal in weight to that of the original spirit of wine employed, makes the specific gravity ·899, entirely removes the acid, and leaves by this simple process little to be desired. Finally, crude acetic ether, washed, digested over chloride of calcium and a small quantity of caustic lime, will produce, upon rectification, acetic ether having a specific gravity of ·8956, which I regard as very nearly pure. I am still of opinion that the Addendum is inaccurate.

Mr. Williams said he also had made some careful experiments on acetic ether, being the only chemical in the addendum for which a process was given. He could not agree, however, that the process was altogether a right one, for there was an omission of a most serious nature, namely, that the excess of acid which always accompanied the ether was not removed. He found that this ether, made exactly according to the Pharmacopœia and simply treated with chloride of calcium, had a sp. gr. of ·895; but if it were previously distilled over carbonate of potash, and afterwards, from the large quantity of chloride of calcium he obtained an ether having a sp. gr. of ·880, which was very different from the ·910 mentioned, that difference might be very serious, because they were bound to produce an article to the public when required which would answer the test of the Pharmacopœia. He was aware that Kopp gave ·910 as the sp. gr., but he made the ether in a peculiar manner with a large excess of acetate of soda and took the sp. gr. at zero Cent; whereas it was distinctly ordered in the Pharmacopœia that it should be taken at 62°F. In the last edition of Fowne's Chemistry, by Watts, the gravity was given at ·890, which he believed was correct.

Professor Redwood said very important, interesting, and valuable discussions had taken place on many previous occasions on similar subjects to the one now brought forward, but he must confess to having heard with very great regret much of what had now been stated. He did not know what authority was now exercised over papers read at these evening meetings; but if he had been in a position in which his opinion were asked, as to whether such a paper as that by Mr. Smith should be read, he should have said decidedly not, and he certainly considered it very undesirable that it should be published in the Journal, with the stamp and authority of the Society. However, it had been read, and had been followed by an harangue given by a gentleman occupying a prominent

position in the Society—an harangue not so objectionable as the paper which preceded it, but which he thought, going before the world at large and the medical profession, would not be calculated to elevate the Society and its proceedings in their estimation. The subject of it could hardly be said to be a continuation of that which had been so properly brought forward by Mr. Umney on the previous occasion, for that gentleman's paper was in every respect unobjectionable, and his criticisms had been very welcome, as also had some others which had been given that evening. He objected, however, to the political question, as it was called, being introduced; though in one respect the introduction of this extraneous matter served to explain and to account for the nature of the criticisms which had been offered, for it simply amounted to this—Here is a portion of the Pharmacopœia which we have not had a finger in, and therefore we will object to it. The animus, therefore, was most clearly explained.

Mr. CARTEIGHE: No.

Professor REDWOOD said that was certainly the impression produced on his mind, and when the discussion was published he thought the same impression would be produced on those who read it. Coming, however, to the criticisms themselves, what did they all amount to? Did they amount to anything? He found a difficulty in picking out any portion which really called for any serious answer, certainly any answer beyond what had been already given. Taking the present discussion in connection with that which took place on the former occasion, except what had just been said about acetic ether he did not think there was much left to answer. With regard to this article, he also had had some experience in its preparation, for it was an old and familiar operation with him; and he was quite prepared to defend what was stated in the Addendum with reference to it. He did not say that the specific gravity given was the true specific gravity of acetic ether, because he, like other gentlemen, had not always found precisely the same results following the same process of manipulation. He accordingly referred to some of the best and highest authorities on the subject; and here he must take a slight exception to one part of Mr. Umney's paper, where he referred to some authorities, and stated that Gmelin gave the specific gravity of acetic ether at ·888. The fact was, Gmelin hardly ever gave a fact on his own authority; and on referring to this article he found a number of authorities given, with specific gravities varying from ·866 up to ·932. Referring to different authorities, Thénard gave ·866; Miller and Pereira, ·890; Becker, ·903; Pierre, ·906; Kopp, ·910; the French Codex, ·920; and Gosmon, ·932. There was thus a great range given, and he had taken about the mean of the different results, which happened to be that recognized by Mr. Watts in his 'Dictionary,' given on the authority of Kopp. And he would ask how it happened that the same rule was not applied in this case as with reference to nitrite of amyl, for both might be put on the same footing. There was a difficulty in getting it in a state of absolute purity, and therefore it had been said it was excusable if there were a little deviation from what might ultimately turn out to be the absolute specific gravity. Mr. Umney had allowed in the case of nitrite of amyl a range of 8° or 10°; and why was not the same latitude to be allowed with regard to acetic ether, a preparation which involved the same difficulty? A strong point had been made that the necessity of rectifying it over lime, potash, or some alkali, had not been mentioned; but with reference to acetic ether, as with nitrite of amyl and hydrate of chloral—those being chemical compounds, which necessarily come from the manufacturing chemist—he had not professed to give a detailed process; they were merely outline processes, the details being left to the manufacturer. But taking what was strictly indicated in the Addendum, he maintained that a practically good preparation for all the purposes contemplated might be obtained without the use of either lime or any other alkali. If the distillation were conducted properly and judiciously in the first instance, you could get the result with no more excess of acetic acid than was almost necessarily contingent on preparations of that description. You never got it perfectly neutral in commerce, according to his experience, and if you made it neutral it soon became acid. If you added carbonate of potash to it and left them to stand, it caused a decomposition of the ether, for which there was no occasion. There were at least three methods for making it, of which that given was the best. If the spirit and acid were converted into sulphovinic acid and this were added to a perfectly dry acetate of soda, the acetic ether comes over of itself, without the necessity of applying any artificial heat, so rapidly that the only difficulty was in condensing it, and at a temperature which brought scarcely any appreciable quantity of free acetic acid with it. In that way acetic ether of considerable purity was obtained, as good as is commonly met with in commerce; and this could be further purified by chloride of calcium and rectification, the latter being a comprehensive term. Many remarks had been made of a disparaging nature, indicating that amongst the additions were substances which were unworthy of a place in any Pharmacopœia. That was a matter of opinion; and, judging from what had passed on this and other occasions, if the president were sitting as chairman of a committee, he would find a difficulty in ascertaining which way the opinion inclined with reference to some of the preparations which had been mentioned. He thought there could be no question as to the propriety of introducing acetic ether, which was one of the most agreeable of the compound ethers, and was destined, he believed, to occupy a prominent position in the pharmacy of the future. It contributed greatly to give the peculiar flavour to wines and vinegars, and if wine were to be replaced as a vehicle in medicine by some dilute spirit, this acetic ether would be advantageously used as a flavouring agent. If Mr. Bottle had looked into the copy which by an unfortunate accident had got into his hands, he would have found that acetic acid was intended to form a component part of one of the preparations which at one time was intended to be introduced, but which was subsequently rejected. But to proceed, nitrate of ammonia was now largely used for making nitrous oxide gas, and was therefore introduced. With reference to nitrite of amyl, it was a very powerful and valuable medicinal agent, and it was desirable and necessary that its composition and characters should be defined. With regard to the *Aqua chloroformi* again, it was a matter of opinion whether it ought to have been included or not. Mr. Umney said it was one of the most valuable preparations in the whole list, whilst others said it was not worthy of a place. He had long been of opinion that it was a very elegant and agreeable aqueous vehicle for medicines compatible with it. It was said, however, that spirit of chloroform might be used to make it. So it might, but then either too much or too little might be used. This was a perfectly definite preparation which would keep perfectly well for any length of time. He could say nothing with regard to the areca nut, because he had no experience of it, but on a former occasion, it had been stated on the highest medical authority to be a valuable anthelmintic, and as had been admitted by Mr. Carteighe it was for the profession to decide what medicines should be introduced; he considered therefore it was rather in bad taste to make the sort of disparaging remarks with regard to it which had been offered. With regard to fresh orange, that of course was required for the tincture. Oxide of bismuth he had heard nothing against, and it was one of the most definite preparations of bismuth, and easily obtained in a state of purity. In his opinion it was much preferable to the nitrate or carbonate. With regard to the hypophosphites of lime and soda, he believed all that had been said was in their favour. Hydrate of chloral came next, and was it right that it should be so extensively used as it now was, without having a recognized description of it and a

method of testing it? Next came the liquid extract of liquorice, which was not a matter of great importance, but it was a convenient preparation, and the formula given was that given by Mr. Squire. Gutta percha was simply used in another preparation, and was introduced as such. The yellow oxide of mercury had been recently used in medicine and had been recommended to the Society years ago by Mr. Squire in preference to the less soluble oxide generally employed. Then with regard to the hypodermic injection of morphia, he thought it fully time that this should be introduced, and that it was not right to wait until a new Pharmacopœia came out; in fact this one article alone was in his opinion sufficient to justify the issue of the Addendum, inasmuch as it would be a great advantage and convenience to retail pharmacists throughout the country to have a good practical process as he called it (and Mr. Umney further had said it was the best process) for making this hypodermic solution. It was done with a view to their own convenience and to the interests of the public. Before this came out he had been repeatedly applied to by chemists throughout the country to know how a solution of acetate of morphia could be made capable of being used for this purpose, the attempt to do so by dissolving commercial acetate of morphia having always failed. With regard to larch bark he might say the same as in the case of areca nut, it was for medical men to say what they would prescribe. Next came the solution of citrate of magnesia, and here again was introduced a very efficient, elegant, and agreeable purgative, not before in use in this country. The term citrate of magnesia was justified by its composition, and he entirely disagreed with Mr. Carteighe on this subject. The *Liquor magnesiæ citratis* was precisely what its name indicated, and a better name could not have been adopted. It would have been very objectionable to give such a name as purgative lemonade, or anything of the kind. The whole of the ingredients constituted citrate of magnesia, with the exception of a little flavouring matter. Next came *Oleum phosphoratum*. The formula had long been used on the Continent, and he knew of no better mode of making it. He had made it over and over again, and had not found the oil become viscid, at any rate, not to such an extent as to interfere with its use, even after being kept nearly twelve months. The only object of heating the oil was to drive off the water, though in some samples of oil it also rendered a portion of albuminous matter insoluble and precipitated it, so that if after it had been heated it was filtered, it would be more likely to form a permanent solution of the phosphorus. Then it was said, why make it of the strength? The fact was, as originally proposed, he had made it of the strength suggested, one grain in 100 minims, but he was afterwards called upon to introduce a formula for a phosphorus pill. The physicians decided what they wanted to have, and as they required phosphorus both in the liquid and solid form, he was asked to devise a formula by which it could be administered in both ways. Just at the time a paper was published by Mr. Abraham, jun., of Liverpool, in which he indicated balsam of tolu as a suitable vehicle for phosphorus, and he at once saw there was a manifest advantage in this balsam over any other resin that he knew of, viz., that whether in the solid or liquid state it was heavier than water, so that the solution could be made without any exposure of the phosphorus to the air, thus preventing any oxidation. He contended that this was a perfectly practical process, and the best yet devised for diffusing phosphorus in a form in which it admitted of administration in the solid state. He could only say to Mr. Martindale, if he found any difficulty in effecting a mixture of the wax and the resin to try again, and that if he availed himself of the proper time and temperature, when the wax was just soft, but not fluid, there would be no difficulty in getting the ingredients to unite. The great advantage was that from beginning to end the phosphorus never came in contact with the air, and was thoroughly dissolved or diffused throughout the mass, it did not much matter which. It was said, however, it did not dissolve in the stomach; and if that was the case, some remedy might be found for it, either as suggested by Mr. Gerrard, the addition of a little sugar, or some other method. This could be done at the time of dispensing. If it were done when the pill mass was made it could not be kept without change. According to the formula here given, however, it was perfectly stable for any length of time, and when prescribed could be mixed with any ingredients necessary to render it soluble in the intestines, if such should be required, which he doubted. The process for pepsin had been strongly criticised, and he must say that a more absurd and, indeed, more disgraceful criticism he had never heard uttered by a gentleman desiring to occupy a respectable position. He, also, had made pepsin, perhaps even more extensively than Mr. Smith, and he was prepared to say that that made by the process given in the Pharmacopœia was the only kind he should be prepared to recommend, and the only form in which it could be presented to the medical profession with satisfaction. There had been processes proposed for procuring it in the liquid state, but they were not reliable, and this was the nearest approximation to pure pepsin. Compound scammony pill was the name adopted instead of compound jalap pill, as first suggested, for the pill of jalap and scammony resin, with soap and ginger. Certainly it was a desideratum to have a purgative pill containing no aloes, and no one had proposed a better formula. It had been said that this was not the proper time for making suggestions, but to this he would reply that long ago he had explained as fully as possible what was proposed to be done, and had asked over and over again for the assistance of practical gentlemen in the matter. They did not render it then, and now they said this was not the time to make suggestions, and it was no use asking their opinion. Of course not, and their opinion was not asked, but they came forward and volunteered it, not having given it when it was asked months and months ago. Among compound powders they had *Pulvis elaterii compositus*, to which he believed no exception had been taken, and every practical man who had spoken of it said it was a valuable addition. It had been asked why sulphur and fennel had been left out of the *Pulvis glycyrrhizæ compositus*. He had a note from Dr. Quain, which would explain the reason why. But, it might be asked, why should they be put in; why should they make a useful preparation an offensive one; was there any necessity to make those to whom it was administered a nuisance to all their neighbours? That was the view taken of it by the Medical Council. If sulphur were required it could easily be prescribed; but it was not in accordance with senna as an adjunct, and therefore was omitted. With regard to fennel, some liked it and others did not, and it was felt that those who wanted it could order it, but if introduced it was not so easy to take it out. Nothing had been said against the vegetable juices of belladonna and hyoscyamus, and why should they wait three or four years as suggested, if there were an opportunity of introducing them now? Next came syrup of chloral which had been described as too thin and not flavoured as it should be. He would leave Dr. Quain to answer that, but he might say that it was the medical men who considered it was not desirable in administering half a drachm of chloral to be obliged at the same time to give three or four drachms of sugar, when they found that a solution of hydrate of chloral in a much weaker syrup, would keep perfectly well. The physician ordering it might prescribe what flavour he liked, but many preferred it without flavouring at all. Lastly came the tinctures; one gentlemen had said that the ammoniated tincture of quinia was not aromatic enough, but if that were so, let them add what was required in prescribing it. This was a formula in extensive use already in Edinburgh and elsewhere, and any absence of flavouring could easily be remedied. With regard to the tincture of fresh orange

peel, he must admit that he had fallen into a little error which he must take the responsibility of in the process indicated for making it; but the formula now given was not the original one, as had been pointed out by Mr. Bottle at the previous meeting when drawing attention to the discrepancies between the two copies he produced, though for some reason or other this remark has been kept out of the Journal, either by the reporter, editor, or sub-editor, possibly because it did not tend to support the views of some parties. He must admit that the addition of spirit to make up the quantity was an error, but the fact was that was done in committee about twelve o'clock at night, while considering a great number of suggestions coming from different parts of the country, for the work was not completed without practical pharmacists having been consulted. He was sorry Mr. Carteighe was not consulted, but certainly many others were, twenty-four copies having been sent out to members of the Medical Council, especially for the purpose of being put in the hands of their pharmaceutical friends and getting all the advice and assistance they could. He was sure neither the President nor Mr. Squire, nor many other pharmacists, would say that practical pharmacists had not been consulted, for some of the most eminent had had the work put into their hands with a request that they should suggest any improvements. The result was that at the last meeting the committee had a bundle of letters from various sources, and all the suggestions had been attended to, except where one was answered by the others. He regretted that the tincture of fresh orange peel was a subject which last came under attention; and it was suggested that the wording of the formula should be assimilated to others in the Pharmacopœia, where the quantity was directed to be made up by the further addition of spirit, and in a weak moment he passed it, which he admitted was an error. But it was a slight and very unimportant error, and he was certain that if any twenty gentlemen present set about making it, they would not experience the difficulty mentioned by Mr. Umney, unless they used an hydraulic press in the process. However, that was the only error he admitted from beginning to end of the work; and that being so, he thought he might justly appeal to the meeting for exoneration from the very serious charges which had been urged. In conclusion, he read a note which he had received from Dr. Quain, regretting he was not able to be present that evening, as he certainly should have made some remarks on the observations previously made, because he saw in them too much tendency to consider the Pharmacopœia as intended rather for the use of pharmacists than of physicians. For instance, it was said that the syrup of chloral did not look like a syrup; but who cared what it looked like if it were suitable for prescription? and as it was made previously, 30 grains of chloral were given in 3 drachms of dissolved sugar, which was a most objectionable dose of sugar to be put into the stomach. Comments had also been made on the strength of the hypodermic solution of morphia; but it should be known that $\frac{1}{6}$th of a grain in each minim, as recommended by some pharmacists, was too large a dose for a first injection; hence it was better that $\frac{1}{12}$th grain strength should be made, and two minims used if necessary. The sulphur and fennel were left out of the compound liquorice powder because they were objectionable, and the fluid extract of liquorice, as now ordered, was very far superior to the black stuff melted and diluted, as some persons had suggested.

Mr. Umney said Professor Redwood had not referred to the curd soap. Did he find it soluble in spirit? because he (Mr. Umney) found it insoluble.

Professor Redwood said he found it perfectly soluble. With regard to the suppositories, the new processes were simply given as alternatives. A good deal of discussion had taken place some time ago as to what could be used as a substitute for cocoa butter in making those articles; medical gentlemen recommended soap, and his own opinion went in the same direction. He considered soap an unobjectionable vehicle, though there might be cases in which something else would be preferable. There were also other reasons why curd soap was introduced, which would be more apparent when a new edition of the Pharmacopœia came out.

Dr. Paul begged to say, in reference to one remark of Professor Redwood's, that according to his view of the duty appertaining to the editorial department of the Society's Journal, it was not competent for either the editor, sub-editor, or anyone else, to keep out or introduce into it anything with the object of supporting the views of any particular party. Such an act would be a gross dereliction of duty on the part of an editor, and he would emphatically say that nothing of the kind had taken place. He believed what was inserted in the Journal was simply a faithful report of what had taken place.

Professor Redwood said he had referred to the remarks made by Mr. Bottle on the discrepancies he observed between the two copies which had got into his hands; all of which were reported, except the one instance which would have formed a sort of excuse for the little error which had been referred to with regard to the tincture of fresh orange peel. He had no doubt it arose from some accident.

The President said at that late hour he would not pretend to go into the merits of the discussion which had just taken place, but must say he did not approve of Mr. Smith's paper, and must express his regret at its tone. He felt sure that it must have been written in haste, and that Mr. Smith, on consideration, would not have sent it. For himself, he was for making additions to the Pharmacopœia at any time when necessary, and should like the proposed additions to be brought before the meetings of the Pharmaceutical Society for discussion, in order that the formulæ might be as perfect as possible. That being the last evening of the Session he would call upon all the gentlemen present to do what they could in writing papers during the recess for discussion in the next session, which he was sure would be gratefully accepted by the chairman of the evening.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

On April 27th, 1874, a special meeting of this Association was held, Mr. H. J. Masters in the chair.

The minutes and list of donations having been read by Mr. G. C. Druce, Mr. Masters congratulated those members who had recently passed their examinations.

Discussion then ensued as to the destination and time for the annual botanical ramble. Eventually it was decided to fix May 15th, 1874, for the date, and Bow Brickhill Heath and Woburn Abbey, for its destination. The president said how pleased they would be to see any old members or friends of the Association on the occasion. Those willing to attend were requested to meet at Bletchley station, L.N.W.R., at 8.52 a.m., first sending word to the secretary of their intention to be present.

It was then arranged to have a morning botanical ramble once a fortnight.

The apprentices who intended competing for the Herbarium prize were requested to send in their names at once, as unless three competed no prize would be given.

Mr. G. C. Druce then read a paper on Indigenous Botany, which will be printed in a future number.

The discussion was long and interesting, and, after the usual vote of thanks, the meeting terminated at an unusually late hour; the attendance having been remarkably good.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The fifth ordinary monthly meeting of the session took place at 37, Blackfriars Street, on Tuesday evening,

April 28. It had been announced that, in the absence of any special lecturer for the evening, the meeting would be of a conversational character, and members were invited to introduce any subjects of general interest for discussion. The attendance was, however, small.

A series of dried and mounted indigenous medicinal plants of the British Pharmacopœia, presented to the Association by Messrs. Butler and Mc Culloch, was placed on the table; and a vote of thanks, proposed by Mr. Brown and seconded by Mr. Woolley, was awarded to the donors.

Mr. Benger drew attention to a recent fatal case of poisoning by arseniuretted hydrogen, which had occurred in Messrs. Calvert's Laboratory, and urged the importance of extreme caution in the application of Marsh's test. Mr. Siebold said he had specially cautioned his class on this point when treating of the detection of arsenic.

This being the last meeting of the winter session, arrangements for the summer months were discussed, and it was resolved to open the rooms on Tuesday and Friday evenings only till further notice.

Students could, however, obtain the keys at any time by applying to the Secretary. Mr. Siebold's lectures would conclude about the fourth week in May, and an examination for prizes would then take place in the various classes.

SUNDERLAND CHEMISTS' ASSOCIATION.

The annual meeting of the above Society was held on Wednesday, April 29th, when the following officers were elected for the ensuing year :—

President, Alderman Thompson ; Secretary, Mr. J. J. Nicholson ; Treasurer, Mr. R. Robinson ; Council—Messrs. J. Harrison, C. J. Lord, H. Thompson, Priestly, Mitchinson, Nasbet, Sayer, Sharp, Turnbull, Chapman.

In the course of a discussion which ensued with regard to a proposed scale of prices for dispensing, Mr. J. R. Thompson read the following paper on the subject :—

In considering the question of prices, it is well to remember that it is a subject surrounded with many difficulties. Difference of neighbourhood and difference of style in conducting the pharmacy will necessarily tend to difference of charges. The plan proposed by your committee, of making the size of the vessel containing the medicine determine the price, I think faulty, and extremely artificial. The same remark applies to the division of medicines (for the purpose of charging) into the several classes of mixtures, drops, lotions, injections, gargles, draughts, pills, powders, ointments. It does not seem to be founded on principles either philosophical or commercial. Every dispenser of medicine knows with how much more trouble, and with what an extra expenditure of time, generally, a box of pills is made than a mixture of whatever size. Yet medicine in the form of pills is recommended to be charged at the rate of 1*d.* per dose, while that in the form of mixtures, 2¼*d.* In other words, a less expensive medicine is to be charged more than double one of greater cost. It may, perhaps, be said that the public is more willing to pay for mixtures than for pills. To such a suggestion I would reply that its willingness to do so arises from ignorance of the above facts, and, as a reform is contemplated, it might be well to correct an impression so erroneous. At any rate, it is unworthy an intelligent body of men to bind themselves to a practice so unequal. The use of a private price mark seems to me superfluous, and in some respects objectionable ; superfluous, because there is no reason for hiding from the purchaser that an understanding exists among members of the profession and trade as to the scale of remuneration ; objectionable, as it might facilitate rather than prevent a practice of underselling, which, it is hoped, no member of our body would willingly adopt. Fewer objections, I think, are to be found in the following plan. In dispensing from prescription let the charge be made up of a fee, plus the retail price of the ingredients used. By this method the dispenser will be paid in each case for his professional skill, and also the tradesman for his goods, while the customer will be charged in proportion to what he receives. A not undesirable variation would thus arise in the price of medicines, which would do more to acquire the confidence of the public than one fixed charge for medicine, however different.

LEEDS CHEMISTS' ASSOCIATION.

The sixth monthly meeting of this Association was held in the Library, at the Church Institute, on Wednesday, April 29, 1874, the President, Mr. Freshfield Reynolds in the chair.—The business of the evening was commenced by the Honorary Secretary reading the minutes of the last meeting, which were confirmed.—Mr. Taylor then proposed and Mr. Watson seconded, "That the Honorary Secretary write to the Pharmaceutical Society, tendering their thanks for the PHARMACEUTICAL JOURNAL for the past year."

A paper was then read by Mr. E. Yewdall on the Adulteration Act, and how it affected the chemist and druggist. On the conclusion of the paper a discussion was carried on by several members of the trade. A vote of thanks was then passed to Mr. Yewdall, on the motion of Mr. Payne, seconded by Mr. Hallowell.

HULL CHEMISTS' ASSOCIATION.

At a Committee Meeting of the above Association, held on the 4th inst., the following resolution, proposed by Mr. Earle, and seconded by Mr. Myers, was carried unanimously.

"That the Government having appointed a commission to inquire into the working of the Adulteration Act, this Committee, having in view the annoying and unfair proceedings which have, from time to time, been instituted under the Act, respectfully urges upon the Council of the Pharmaceutical Society the necessity of taking such steps as may be advisable for protecting the fair interests of the trade ; especially with respect to the retailer being held responsible for other than his own acts. That this Committee is further of opinion that the 24th clause of the Pharmacy Act of 1868 is amply sufficient for the protection of the interests of the public in the sale of drugs."

ASSOCIATION OF CHEMISTS AND DRUGGISTS OF IRELAND.

The monthly meeting of the above Association was held in the Society's rooms, Molesworth Street, on Monday, May 4th. Mr. E. M. Hodgson, President, in the chair.

The minutes of the last meeting having been read and confirmed, and several new members proposed, the President said that the principal business of the evening was to hear the report from the deputation which waited on the Apothecaries' Company at the request of the Association. He believed that their position with that Company had been much changed since the last meeting. The main object of the deputation was to ask the Apothecaries' Company to join the Association in a deputation to the College of Physicians, to discuss the proposed Pharmacy Bills. The Apothecaries' Company, however, declined. Dr. Leet informed the deputation that he had forwarded their Bill, as approved by the Association, to the Attorney-General for Ireland ; but it transpired that, according to Dr. Leet's statement, there were some trifling alterations: these alterations had been inserted to please some of the northern apothecaries. On looking into these trifling alterations, he (the President) thought them not trifling, but of vital importance, and that the meeting should discuss those clauses that night.

The Secretary then read the clauses, as in the Bill approved of by the Association of Chemists and Druggists, and then as altered by the Apothecaries' Company. The Apothecaries' Company had taken the liberty of changing clause 3, relating to the constitution of the board of examiners under the Act. In the Bill agreed to by the Society, the board of examiners was to consist of the Governor or Deputy Governor with six members of the Court of the Apothecaries' Hall, and six members to be chosen by

the Association of Chemists and Druggists of Ireland; instead of the latter is inserted—six Apothecaries (not members of the Court of the Hall) chosen from the Apothecaries of Dublin.—This alteration was unanimously objected to, as the examiners under that provision would be the very men whose interest it would be to keep out the chemists and druggists; and it was considered that an examining body so constituted could not have the confidence of the members of that Association.

Mr. O'Brien read correspondence which had taken place between the Apothecaries' Hall and the Association, in 1870, and remarked that they were in no better position now than they were three and a half years ago. He had no faith in the Apothecaries' Company, and did not believe that body had any desire for any alteration in the existing pharmacy laws; he believed the Apothecaries' Company were trifling with them.

Mr. Holmes remarked that if the Apothecaries' Company had forwarded the altered Bill to the Attorney-General, stating that that Bill was agreed to by the Association of Chemists and Druggists of Ireland, they had simply stated what was not true; and he proposed that the Secretary be requested to communicate at once with the Attorney-General, and inform him that the Bill forwarded to him by the Apothecaries' Company had not the approval of that Association, but that the Association would use every means in its power to oppose it (in its present form); a copy of this resolution also to be forwarded to the Secretary of the Apothecaries' Company. The resolution was carried unanimously, and the proceedings terminated.

Parliamentary and Law Proceedings.

Poisoning by Carbolic Acid.

An inquest has been held at Battersea by Mr. Carter, Coroner for East Surrey, upon the body of George Cannon, aged 14, who had poisoned himself by drinking carbolic acid. Evidence was given that the deceased was seen by a child to pour some carbolic acid out of a bottle and drink it. Two hours afterwards his brother, Mr. Matthew Cannon, manager of Beaufoy and Co's chemical works, Battersea, found him lying insensible in the kitchen. His daughter told him that deceased had taken some carbolic acid, and he immediately sent for a doctor. Deceased recovered consciousness and told witness that he had taken half a cupful of carbolic acid, but did not know it was such nasty stuff. Witness tried to ascertain why he had drank it, and deceased replied that he did not know. Witness did not think deceased was aware of the poisonous nature of the fluid. The carbolic acid had been used as a disinfectant (there having been scarlet fever in the house) and had been left in the bedroom with the cork out. Deceased could read the Testament, but, perhaps, could not read the label on the bottle. Deceased said nothing to lead witness to suppose he had taken the acid with a view to poison himself. The lad died about fifteen hours after drinking the poison.

The Coroner remarked that the word "Poison" was not on the label, and suggested that in future enactments it should be ordered that poisonous substances, of whatever nature, have a label with the word "Poison" affixed to them whenever sold to the public. He had had recently several cases before him of poisoning caused by carbolic acid, and in each the bottles were not labelled "Poison."

Mr. Toone Smith, surgeon, said he was called to deceased about three hours after he had taken the poison, and found him in a state of collapse and almost pulseless; the surface of the body was cold, the pupils of the eyes contracted, the lips slightly livid, and a strong odour of carbolic acid pervading the place. He administered an emetic, and mucilaginous and oleaginous drinks. He asked deceased why he had taken the poison, and he replied that he had been in the habit of taking small doses of physic for fun; and witness did not believe, from his manner of answering, that he thought it would cause death.

The Coroner having commented upon the evidence, the jury returned a verdict of "Death by Misadventure."

Charge of Poisoning by a Liniment.

At the Dale Street Police Court, Liverpool, on Monday, April 27th, before Mr. Raffles, Eliza Hales, a girl 14 years of age, was charged with having administered a poisonous substance to the infant child of William Henry Duckett.

It was stated that on Saturday morning the prisoner was employed by Mrs. Duckett to do some housework. There was a bottle containing a liniment marked "poison," on the mantel-piece, and Mrs. Duckett cautioned the prisoner not to have anything to do with it. During the morning Mrs. Duckett alleged that the prisoner had tried to defraud her of a penny. Some time afterwards the baby was heard crying, and on Mrs. Duckett's sister going to see what was the matter, she found the tube of the feeding bottle out of the child's mouth. She tried the tube under the impression that it would not draw, and then discovered that something had been mixed with the milk. She told the prisoner that she must have put something in the bottle, and prisoner denied that she had done so, but said that Mrs. Duckett herself had mixed something with the milk in order to avoid paying the sixpence which the prisoner was to receive for cleaning. An examination subsequently made showed that a portion of the liniment had been mixed with the milk. Nobody had actually seen the prisoner put the liniment in the feeding-bottle, but nobody else was there to do it. The prisoner was remanded, and Mr. Raffles said he would accept two bails of £25 each for her appearance.—*Liverpool Daily Post.*

Chemists and Druggists, and the Adulteration Act. The Sale of Milk of Sulphur.

Mr. Hannay had before him, at Worship-street Police-court, on Tuesday last, two summonses taken out by direction of the authorities of Hackney parish, against two gentlemen carrying on business as chemists and druggists—Mr. Nicholls, of 99, Wick-road, South Hackney, and Mr. Maizey, of 2, Market-road, Cassland-road, South Hackney—charging them with selling, as unadulterated, a certain drug or article usually taken as a medicine, to wit, milk of sulphur, which was adulterated, contrary to the statute. With respect to these, Mr. Watts, the sanitary inspector, said that on behalf of the parish he desired to be allowed to withdraw. Notice of intention to make this application had been given to the defendants.—Mr. Wontner, jun., who appeared for the gentlemen summoned, desired to be heard on their behalf. —Mr. Hannay asked if he objected to the withdrawal, or if he desired to be prosecuted.—Mr. Wontner thought that if the parish, having taken out the summonses, now desired to withdraw, they should at least pay the costs to which they had exposed the defendants. The question, he said, which would be raised in this case had been already decided before Mr. Arnold, at the Westminster Police-court. His clients were not charged with the adulteration but, in fact, with not manufacturing in accordance with the British Pharmacopœia. The decison of Mr. Arnold, given last November, expressed the great hardship to which, in his opinion, the defendants were put, and the authorities appeared anxious to lay down the law that drugs should be manufactured according to the British Pharmacopœia or not at all.—Dr. Tripe, medical officer of health and analyst for the Hackney parish, desired, in the interest of the public, to explain the matter; but Mr. Wontner objected to Dr. Tripe being heard. He thought that a public body like the Hackney Vestry might appear professionally, and at least make up their mind whether they intended to appear or not.—Mr Hannay said that, as the defendants had notice of the intended

withdrawal, he, Mr. Wontner, need not have attended.—Mr. Wontner, while admitting this, said that it was usual to carry out the instructions to attorneys, once given. It was a great hardship on the defendants, after being put to the expense of instructing him, Mr. Wontner, to be told a week afterwards that all that expense and all that trouble was thrown away, because the parish did not intend to proceed.—After some further discussion, Mr. Wontner said that if the parish objected to pay the costs he would make them a present of the amount. At the same time he desired to publicly protest against such hasty proceedings on the part of such public bodies, who desired to hold up the drugs of the British Pharmacopœia as the only good drugs.

Adulteration of Milk.

On Saturday last, at the Greenwich Police Court, Mr. Daniel Phillips, farmer, appeared to an adjourned summons (see before, p. 866), at the instance of the Lewisham District Board of Works, charged with selling milk with an admixture of water. The case had been adjourned because the accuracy of the analysis of the milk, made by Mr. Heisch, of Middlesex Hospital, was disputed; and it was stated that skilled and scientific evidence would be called to show that, unless an analysis of milk was commenced within six hours after being taken from the cow, no analysis could be relied upon.—Mr. Balguy now asked whether this evidence was forthcoming.

Mr. G. Gates said he was the son-in-law of the defendant, and a master at the Merchant Taylors' School. He had taken a sample of the same milk to Professor Barth, analytical examiner to the Royal Academy of Arts, but could not obtain an analysis of it. He knew some little himself about chemistry, and did not believe that any difference could be found between water found in pure milk and water that might form an admixture.

The defendant was put into the witness-box, as was also his clerk, and both deposed to having about a pint and a half of the same milk placed in a bottle, and given to the last witness; and a milk dealer named Robinson also deposed to purchasing 65 gallons of milk daily at defendant's farm, and said he never was complained against.

Mr. Balguy asked if there was any scientific evidence that could be called.

Mr. C. J. Stewart was then tendered as a witness, to give his opinion upon the notes entered in a book by Dr. Heisch, of the analysis in question. He said he was chief assistant to Dr. Bernays, professor of chemistry at St. Thomas's Hospital. Examining the entries, he said he found 8 per cent. of cream, which was a fair amount of cream, and fat normal. The solids were marked 6·46. His opinion, from the notes, was that the analysis was not sufficiently completed.—Mr. Collins, for the prosecution, declined to put any other question to this witness, who answered that both Dr. Heisch and Dr. Attfield were gentlemen of great experience as analysts.—Mr. Balguy said, to his mind, there could be no doubt that where 25 per cent. of water was deposed to have been found, there must have been an admixture of water; and there would be a fine of 5*l.*, and 2*l.* 2s. for two attendances of Dr. Heisch, and 2s. cost of the summons.—*Standard.*

Adulteration of Butter.

George Andrews, West Fields, Barnes, was charged at the Wandsworth Police Court, before Mr. Bridge, with selling butter which proved to be adulterated. The defendant said he was not aware it was adulterated. Mr. Cook, the inspector, said on the 13th inst. he sent to the defendant's for half a pound of butter. The messenger paid 8*d.* for it. The certificate of the analyst was produced, stating that the butter was adulterated with 27 per cent. of water. Mr. Bridge said in making butter there must be water. Mr. Cook: Not to that extent. Mr. Bridge said his notion of making butter was that water had to be squeezed out of it. It was not an adulterated article unless water was put into it. It was simply not squeezed out enough. Under the third section, any person who shall sell any article of food or drink, or any drug, knowing the same to have been mixed with any other substance, with intent to increase its weight or bulk, was liable. The complainant had taken out the summons for selling adulterated butter. Mr. Cook submitted that the mixing of water increased the bulk. Mr. Martin, the usher, said he was in the business for a number of years. Water could not be added after the butter was made. Mr. Bridge said it could not be called adulterated because the water was not squeezed out. He dismissed the summons.

The *Wandsworth and Battersea District Times*, in remarking upon this and other cases, calls attention to the convenience of having an erudite usher in a police court, who is able to assist "his worship" when he fails to grasp the technicalities of a case.

Correspondence.

Pharmaceutical Qualifications.

Sir,—Zaccheus is quite right with regard to his statement respecting applications for assistants. He may derive consolation from an anecdote of Napoleon. The Emperor was trying to reach a book from too high a shelf, when his Secretary interfered, saying, "Laissez moi, Sire; je suis plus grand que vous." The reply was, "Vous voulez dire plus haut."

But there is a much more serious matter. I read in the same number of the Journal an advertisement for a thoroughly competent assistant, *single-handed*. Is not this a case in which the Council might interfere?

Lævo-gyrite.

"*Loudon.*"—(1, 2 and 3). We are not competent to say what are the most practically useful works on these subjects. (4) 'How Crops Grow,' published by Macmillan; (5) Bentham's 'Handbook of the British Flora'; Hooker's 'Student's Flora of the British Isles'; Bentley's 'Manual of Botany.' (6) We know of no preventitive; as a remedy, try dilute solution of ammonia.

"*Figitum.*"—Several papers upon the subject have been published in former volumes of this journal, and a *résumé* of them, with references, was published in vol. i. of the present series, pp. 421 and 481.

"*Botanist.*"—We should recommend you to consult a cabinet-maker.

"*Rosarum.*"—(1) The form is quite correct, and in accordance with the rule followed in other parts of the Pharmacopœia. (2) We cannot supply the information; but possibly it might be obtained by applying to the Registrar.

"*Percontator.*"—(1) See vol. i. of present series, p. 897. (2) Apply at Apothecaries' Hall.

W. Trevaskis and *J. Polley.*—Your communication should have been sent direct to the publishers.

We have received the reports of meetings of the Liverpool Chemists' Association and the Glasgow Chemists and Druggists' Association from the respective Secretaries; but in consequence of the length to which the report of the meetings of the Pharmaceutical Society extend, we have been compelled to defer their publication until next week.

Communications, Letters, etc., have been received from Mr. Southall, Mr. C. Cotterell, "A Dispenser," "A Pharmacist," "Excelsior," "Erin," "Inquirer."

MEDICINAL PEPSINE AND ITS RELATION TO THE PEPSINE OF THE PHARMACOPŒIA.*

BY JOHN ABRAHAM.

We have long been familiar with the name of "Pepsine;" and now we find it in the Additions to the Pharmacopœia, it is incumbent on us to inquire whether the article which we supply is in conformity with the new and legal standard.

Although the medicine to which the name is now authoritatively given cannot be considered a pure proximate principle, it will not be found, I fear, that the commercial article commonly supplied conforms to it.

A reference to the formula will show that it does not contain any starch, but starch is usually present in the commercial preparations.

Pepsine was introduced into medical use in France, and a form for it is given in the French Pharmacopœia. A solution is made by digesting the mucous membrane of the stomachs of animals in water. A precipitate is thrown down by the addition of acetate of lead, and the lead having been separated by means of sulphuretted hydrogen, the solution is supposed to contain the active agent. If this is evaporated to dryness, a gummy mass is obtained, not very suitable, it has been thought, for medicinal use. Starch is therefore previously added, perhaps also some acid, and a dry powder of starch with pepsine, commonly called pepsine, is obtained.

Another article is also in the market, called *Pepsina Porci*. A formula for this was furnished by Dr. Beale, and the method of the Pharmacopœia corresponds to it, but with this difference, that the Pharmacopœia authorizes the use of the stomach of the pig, of the sheep, or of the calf. The glandular stomach of any one of these may be scraped, the fluid rapidly dried at a temperature not exceeding 100° F., and the product called "pepsine." According to Dr. Beale it contains the gastric juice, with much epithelium from the glands and surface of the mucous membrane.

I have no intention of inquiring now which of these preparations is the *best*. I wish simply to call attention to our responsibilities in the matter.

The difference between the two is very apparent when they are looked at through the microscope, as you will see by means of the two instruments and samples on the table.

Sample No. 1 is a preparation made according to the Pharmacopœia, prepared under my own direction; Nos. 2 and 3 are commercial specimens of Pepsina Porci, and they greatly resemble No. 1; Nos. 4 and 5 are specimens of commercial "pepsine." You will see that they are loaded with starch.

You have no need of a microscope to ascertain this. Mix a little with water, boil, and add a drop of solution of iodine, and the blue colour will give an unfailing proof if starch be present.

But there may be no starch and the preparation may look perfecly right, and yet be inert. Nothing but the physiological test—its power to dissolve albumen or animal fibre—can show its value.

Our responsibility, however, remains the same, even should it prove that the active principle diluted with starch is better than the active principle diluted with the mucus with which it is mixed when obtained, as directed in the Pharmacopœia, by scraping the glandular coat of the stomach.

But I think it right to add that not only do the microscopical appearances of the commercial pepsines of the pig correspond to that of the Pharmacopœia, but, so far as my opportunities of examination have extended, they bear best the Pharmacopœia test, which is, their power to dissolve the albumen of the egg.

* Paper read before the Liverpool Chemists' Association.

THE ASH AND EXTRACT OF TEAS.

BY G. W. WIGNER.

(Public Analyst for Greenwich, Plumstead, and Woolwich Districts).

Some months since, Mr. Wanklyn published the average percentages of ash from a few samples of tea, and Mr. A. S. Wilson has since published the analysis of the ash of nine more samples. Having examined the ash of a large number of samples of tea, and in most cases determined the proportions of the ash soluble in water and in acid, I think the results will be of use for comparison.

The determinations of *soluble* ash have been made by boiling in water, filtering, and igniting and weighing the insoluble residue, the latter being afterwards boiled in hydrochloric acid to separate the silica. The aqueous solution has in most cases been titrated for total alkali, which has been calculated as potash.

The 24 samples in the following list were all obtained from original chests, as imported. They vary in price from No. 3 and No. 13, which were sold at 3*s.* per lb., to No. 1, which is stated to have been sold at $1\frac{3}{4}d.$ per lb. in bond. This sample consists entirely of very small broken particles of leaves.

TWENTY-FOUR SAMPLES OF GENUINE TEA, AS IMPORTED.

Number.	NAME OF TEA.	Total Ash.	Ash Soluble in Aqua.	Ash Soluble in Hydrochloric Acid.	Silica.	Alkali in Ash calculated as Potash.
1	Siftings	5.55	3·16	2·14	·25	
2	Gunpowder	5 73	3·08	2·25	·40	
3	Ditto	5·71	3·35	2·16	·20	
4	Ditto	5·72	3·29	2·12	·30	
5	Congou	5·60	2·75	2·52	·33	1·50
6	Ditto	5·58	2·99	2·20	·39	1·65
7	Ditto	5·73	2·67	2·43	·63	1·36
8	Pekoe	5·89	2·86	2·49	·54	1·64
9	Mixed	5·74	2·78	2·36	·60	1·60
10	Congou	5·59	2·91	2·22	·46	1·78
11	Ditto	5·62	3·01	2·16	·45	1·71
12	Ditto	5·49	2·98	2·11	·40	1·42
13	Ditto	5·58	2·86	2·25	·47	1·67
14	Gunpowder	5·92	2·87	2·44	·61	1·79
15	Ditto	5·65	2·85	2·02	·78	1.62
16	Bohea	5·46	3·06	1·96	·41	1·60
17	Black Tea	5·74	3·18	2·36	·20	1·30
18	Ditto	5·68	2·98	2·15	·55	1·72
19	Ditto	5·56	3·02	1·97	·57	1·76
20	Ditto	5·49	2·94	1·90	·64	1·69
21	Ditto	5·54	3·26	2·04	·24	1·36
22	Ditto	5·99	2·81	2·17	·71	1·40
23	Ditto	5·69	3·35	2·13	·16	1·88
24	Ditto	5·53	3·32	2·04	·17	1·60
	Average	5·66	3·01	2·21	·41	1·62

The deviations from the averages are comparatively

small in these samples, the maximum variations being —in total ash, ·33 per cent.; in soluble ash, ·34 per cent.

The next 12 samples are of what would be considered good tea, but as I have not received them from the importers, I cannot say that they are in the same state as reeeived here; several of them were indeed sent to me as "mixed tea."

TWELVE SAMPLES OF TEA FROM RETAIL DEALERS.

Number.	NAME OF TEA.	Total Ash.	Ash Soluble in Aqua.	Ash Soluble in Hydrochloric Acid.	Silica.	Alkali in Ash calculated as Potash.
25	Black	5·31	3·29	1·89	·13	1·83
26	Green	5·23	2·87	2·07	·29	1·93
27	Broken Congou	5·20	3·33	1·70	·17	1·54
28	Mixed	5·48	2·45	2·29	·74	1·51
29	Ditto	5·54	3·22	1·24	·08	1·75
30	Ditto	6·14	2·68	2·78	1·68	1·56
31	Ditto	6·12	2·88	2·71	·53	1·71
32	Ditto	6·07	2·73	2·75	·59	1·71
33	Ditto	6·20	2·70	2·84	·66	1·48
34	Ditto	6·05	2·99	2·21	·85	1·83
35	Black	6·31	3·23	2·37	·74	1·42
36	Ditto	5.60	3·55	1·83	·22	1·75
	Average	5·77	2·99	2·22	·56	1·67

The average of these is rather higher, and the deviations from it are greater. I attribute this to the circumstance that several of the mixed teas contained small proportions of Caper and other heavily-faced teas. The maximum deviation in total ash is ·54 per cent.; in soluble ash, ·56 per cent.

The next four samples are in the same condition as imported, but of exceptional character, high price, and avowedly used only for mixing with other teas. The variations from the average will be seen to be excessive, although the average itself is similar to the other samples.

GENUINE TEA OF EXCEPTIONAL CHARACTER, AS IMPORTED.

Number.	NAME OF TEA.	Total Ash.	Ash Soluble in Aqua.	Ash Soluble in Hydrochloric Acid.	Silica.	Alkali in Ash calculated as Potash.
37	Orange Pekoe	5·11	3·15	1·60	·36	1·88
38	Indian Pekoe	5·61	3·56	1·63	·42	1·75
39	Indian Twankey	5·00	2·34	2·18	·48	1·42
40	Summer Shoots	6·55	2·62	2·99	·94	1·33
	Average	5·57	2·92	2·10	·55	1·59

The average of the 40 samples is as follows :—

Total ash	5·68	per cent.
Ash soluble in water	3·00	„ „
„ „ „ acid	2·20	„ „
Silica	·48	„ „
Alkali in ash, calculated as potash	1·62	„ „

The proportion of alkali in the ash varies from 1·30 to 1·88 per cent.

The iron was only determined in a few cases.

The next list includes 21 samples, all of which are more or less adulterated.

ADULTERATED OR SPURIOUS.

Number.	NAME OF TEA.	Total Ash.	Ash Soluble in Aqua.	Ash Soluble in Hydrochloric Acid.	Silica.	Alkali in Ash, calculated as Potash.
41	Caper	15·42	2·24	3·40	9·78	1·21
42	Ditto	2·13	1·62	5·78	4·73	2·10
43	Ditto	10·11	·76	1·09	8·26	
44	Ditto	17·13	2·43	2·86	1·84	·35
45	Ditto	7·03	3·00	2·64	1·39	
46	Ditto	6 94	2·66	2·61	1·67	1·50
47	Gunpowder (special)	2·94	·47	4 60	37·87	
48	Gunpowder	47·01	2·74	3·38	·89	1·44
49	Ditto	6·53	3·19	2·56	·78	1·57
50	Ditto	8·05	3·08	3·55	1·42	·94

61	Mixture of 40 per cent. Exhausted leaves No. 60, with 60 per cent., Mixed Black Tea	4·64	1·98	2·50	·16	1·15
	21 Samples Average	8·78	2·12	3·00	3·66	9·30

No. 47 is a remarkable specimen. It contains small stones of an average weight of about ·15 grain, fairly uniform in size, mostly wrapped in the leaves and is very heavily faced. It was taken from the top of a chest as imported. Obviously, this sample and No. 43 consist mainly of exhausted leaves re-dried and coloured.

No. 56 contained a very large proportion of exhausted leaves.

Nos. 48 to 53 were all most grossly faced; not with the ordinary slight facing, but with as much colour as could be made to adhere.

No. 54 had been wetted and re-dried.

No. 55 consisted mainly of stalks.

Nos. 57 and 58 contained excessive proportions of stalks.

Nearly all these samples contained leaves which were not tea leaves. Nos. 59 and 60 are ordinary samples of exhausted tea leaves from my own use.

No. 61 is an artificial mixture of exhausted leaves with good mixed tea, to show the effect on the ash.

The averages of this series are of course of very little value, owing to the various classes included in it.

Some of these samples have been extracted with boiling water, and the extract dried and weighed.

These determinations have been made on powdered tea, since it is not practicable to take a small sample (10 grains) fairly from a whole leaf tea. The extract has been dried at 212° and weighed, and then fully ignited and re-weighed.

WEIGHT OF EXTRACT OF TEAS.

Number.	NAME OF TEA.	Aqueous Extract dried at 212°.	Ash of Extract.
1	Siftings	34·40	5·35
3	Gunpowder	43·70	4·30
4	Ditto	34·51	3·25
5	Congou	27·80	3·00
6	Ditto	30·10	4·54
7	Ditto	27·60	3·80
8	Pekoe	35·16	3·86
9	Mixed	23·93	3·65
10	Congou	31·09	4·37
13	Ditto	25·08	3·66
15	Gunpowder	30·54	4·24
17	Black	30·66	4·21
22	Ditto	26·04	3·38
35	Ditto	31·68	4·53
36	Ditto	35·68	6·44
38	Indian Pekoe	41·65	4·60
39	Indian Twankey	39·53	4·93
40	Summer Shoots	38·03	4·98
41	Caper	34·58	4·18
47	Gunpowder (special)	20·35	3·90
52	Ditto	36·70	4·25
53	Hyson	34·70	5·00
56	Congou	27·86	4·80
60	Spent leaves	8·53	1·53
61	Mixture of 40 per cent. exhausted leaves No. 60, with 60 per cent. Mixed Black Tea	23·78	3·43
	Average	31·35	4·16

These results are far from regular, and the determination of extract does not appear to be of much value in judging whether a tea is adulterated.

The mixed black tea in No. 61 sample gave nearly 36 per cent. of extract.

The exhausted leaves are of course very different in result; but when the leaves have been re-gummed the difference is far less, as for instance in sample 56.

It will be seen that No. 47, the *special* gunpowder, gives a full proportion of extract, though it is entirely a spurious tea. Yet there may be special cases in which this determination would be of value.

These adulterated samples must not be viewed as a fair average of commercial samples, since several of them were procured for me at my request by an experienced tea buyer as samples of the worst tea imported.

NOTE ON A SOPHISTICATION OF PAREIRA ROOT.

BY JOHN MOSS, F.C.S.

(Late Demonstrator in the Laboratory of the Pharmaceutical Society.)

It was my intention, at the last evening meeting of the Pharmaceutical Society to have brought before the notice of the members present a sophistication of pareira brava which has not, so far as I know, been previously announced. With this object two specimens had been placed on the table, but the press of other matter crowded out every opportunity of speaking about them.

The specimens were taken from a bale of pareira brava, the contents of which were professedly the root only of *Chondodendron tomentosum*; a cursory inspection, however, was sufficient to show the presence of two totally different structures. One of these, which is hard, heavy, and of a dark brown colour, is plainly the root described by Mr. Daniel Hanbury;* the other, which is lighter in weight, paler in colour, and much less compact in texture, is as evidently a stem—for the majority of pieces are covered with an easily seen bark, the hue of which is variegated by whitish patches of microscopic lichens and occasional green tufts of moss. A comparison of this stem with an authenticated specimen in the museum of the Pharmaceutical Society, leaves no doubt that it is derived from *C. tomentosum*. On the pieces of stem presented by Messrs. Corbyn and Co., the characteristic warts are shown in a marked manner.

The stem is sickly sweet, yet slightly bitter in taste. In the root the bitter taste is very much intensified, and indeed predominates over every other. This difference is best noticed by appropriate comparison of the respective infusions.

The object of this note is to induce pharmacists to examine their stock of pareira, and so prevent the substitution for the root, of the much less active, if not altogether inert, stem. In my opinion, few parcels will be found free from the admixture here described; in the first place, the admixture occurs in original packages, and in the second, it is very unlikely that experience of this kind is confined to one house. I may say in conclusion that two bales, the aggregate contents of which were 137 pounds, gave 73 pounds of stem—over 50 per cent.

CHEMICAL ANALYSIS OF JABORANDI.†

BY M. RABUTEAU.

Some leaves of "jaborandi" which had been received from Dr. Coutinho (see before, p. 850) by M. Rabuteau, have been submitted by him to a chemical and physiological investigation, from the report of which the following particulars are taken:—

The jaborandi leaves have an odour difficult to define, but which recalls to a certain degree that of dry herbs or hay. This odour, which is faint when the leaves are intact, becomes more manifest when the leaves are bruised. The taste also is weak; it is, however, slightly bitter when the leaves are masticated.

Fourteen grams of leaves, reduced to a coarse powder, were submitted to distillation with 200 grams of pure water, the heat being continued until about one-third of the water had passed over. The liquor so obtained exhaled strongly the odour of the leaves, and had a very slight peppery taste; it was colourless and presented a scarcely perceptible turbidity, but no globules could be seen floating on the top. Treated with phosphomolybdic acid, the double iodide of mercury and potassium, or with solution of iodine in iodide of potassium, it did not give any precipitate or turbidity. Consequently the odour of the leaves would appear to be due to a volatile principle, and further, the liquid obtained by distillation does not contain any volatile alkaloid.

The water which had not passed over was separated from the leaves and filtered. It was of a red brown colour, and presented also the odour of the leaves; but it had a bitter taste. It gave no precipitate with either the iodide of mercury and potassium or with solution of iodine in iodide of potassium, showing the absence of any alkaloid. Phosphomolybdic acid, it is true, produced a dirty green turbidity; but vegetable infusions generally are clouded by this reagent, although they may not contain any alkaloid. Further, the application of Stas' test

* PHARM. JOURN., Aug. 2, 1873, p. 81, and Aug. 9, p. 102.

† Abstract of paper in *L'Union Pharmaceutique*, vol. xv. p. 120.

to the liqnor that remained with the leaves in the retort, failed to reveal the presence of any organic base.

Finally, the aqueous liquid which did not distil over was evaporated to dryness. The residue was brown, bitter, and very soluble in water. It was treated with boiling alcohol, which only dissolved a part, and filtered. The alcoholic liquid was bitter, whilst that which remained on the filter was brown, but had no bitterness.

From these experiments, it would appear that the jaborandi leaves have an odour due to a volatile principle which is not analogous to the essential oils contained in aromatic plants. It has a bitter taste, due to a principle soluble in water and in alcohol, which can be separated easily by heating the aqueous extract of the leaves with alcohol. Lastly, the leaves do not appear to contain any alkaloid. The author, however, does not consider the investigation conclusive, in consequence of the small quantity of leaves operated upon.

M. Rabuteau had intended to await a further supply, to study the effects of the bitter substance which he looked upon as the active principle. Meanwhile, having seen M. Gubler's report, which has previously been noticed in these pages, and although he had but eleven leaves, weighing 2·90 grams, at his disposal, whilst from the above results, added to the fact that the leaves when masticated only slightly increased the flow of saliva, he had not much faith in the properties attributed to the drug, he resolved to experiment with them upon his own person. The 2·90 grams were therefore reduced to powder, and, about ten o'clock in the evening, he prepared from them about an ordinary tea-cupful of infusion. This he took when nearly cold, one half alone and the other half with the addition of a little sugar. The sugar, however, was scarcely necessary, since the taste of the infusion was not disagreeable. Ten or fifteen minutes after M. Rabuteau had drank this infusion his forehead became moist, and he went to bed. The sweating came on shortly afterwards, and at the same time an abundant salivation, which continued during nearly two hours. The sweating began to diminish about an hour and a half after the commencement of the experiment, and ceased at nearly the same time as the salivation. The buccal temperature was noted during the experiment, and was found to oscillate between 28·8°C and 37·1°C, the thermometer being placed under the tongue. There was, therefore, scarcely any abnormal heat. Nevertheless the temperature was highest when the effects of the medicine were most active, about three-quarters of an hour after the infusion had been taken. After changing his wet shirt about midnight, the author slept well.

M. Rabuteau states that he has experimented upon himself with a considerable number of medicaments, but has seldom been so surprised as on this occasion; and he agrees with M. Coutinho, that the jaborandi is a powerful and energetic diaphoretic, sialogogue, and sudorific.

The botanical description of "jaborandi" (*Piper jaborandi*), a shrub found in the forests of Brazil, translated from the *Diccionario de Botansia brasileira*, is appended to the paper. It will not, however, be forgotten that M. Baillon is of opinion that the leaves received from Dr. Coutinho do not belong to a Piperaceous plant at all, but to one in the order Rutaceæ, which he identifies as *Pilocarpus pinnatus*, Linn.

THE USE OF SULPHIDE OF SODIUM IN TANNERIES.

One of the earliest processes in the preparation of hides for tanning is the removal of the hair. This is sometimes effected by inducing a slight putrefaction, which loosens the epidermis and renders the hairs easily detachable. But in this country the method usually adopted is to place the hides in a large vat or pit containing milk of lime, in which they are frequently moved so as to allow the lime to act equally on every part. After from sixteen to twenty days the hair is easily removed by a blunt scraper.

In Germany, Austria, and Belgium, however, the trade is reported to have all but abandoned the old methods of unhairing, in favour of one in which sulphide of sodium is the depilatory agent; the sulphide of sodium in a crystalline form being now especially manufactured for the purpose in Germany. The process is modified in various ways to meet the peculiarities of the material operated upon. Sometimes, where it is necessary that the hair should be removed as quickly as possible, as in the case of sole leather, the hides are painted with a paste consisting of one part of crystallized sulphide of sodium and three parts of lime. The hides are covered with damp matting to prevent the drying of the paste, and in fifteen or twenty hours the process is complete, and the hides can be unhaired. In other cases the skins are steeped in a solution of sulphide of sodium (1lb. to 100 quarts), when the time required is two or three days. Where the hides are to be unhaired by hand, it is necessary that they should be first well rinsed in water; and the men employed in the laying on of the paste are usually provided with india-rubber gloves, on account of its corrosive properties.

NOTE ON ERGOT AND ITS PREPARATIONS.*

BY EDWARD R. SQUIBB, M.D.

There is, perhaps, no better example of the unity of pharmacy with practical medicine than is seen in a review of the career of ergot in the 'Materia Medica.' The relation is a closer one than that of interdependence, and the support of a common interest from different bases of support. It is rather the relation of a single cause to a single effect. If knowledge and progress in medicine may be represented by light, then the correlation of electricity, magnetism, and heat in lighting up the universe may not unfairly represent the correlation of pathological research, chemistry, and pharmacy in therapeutics.

From 1807, when Dr. Stearns, of Saratoga County, recalled professional attention to its use in medicine, its history in the 'Materia Medica' is most varied and interesting; and, from a simple parturient and supposed example of a specific effect upon a single organ, it has come to be applied upon a broad general principle, and is already sufficiently studied to extend its utility beyond anything that could have been foreseen. If the influence of pharmacy could be subtracted from this beneficent result, as it cannot be, it is highly probable that the remainder would be comparatively small. The ergot in substance, or by infusion, or by tincture, could have advanced slowly, if at all, to the present state of knowledge in its application. Professor Procter, in a paper published in the Proceedings of the American Pharmaceutical Association in 1857, p. 127, was the first to give uniformity and permanence to any preparation of ergot; thus rendering its systematic and accurate administration practicable by so simple a proceeding as the addition of an acid to preserve it from those changes and uncertainties which, for half a century, had stood in the way of any very accurate investigation of its nicer therapeutic effects. Various investigations, chemical and pharmaceutical, had gradually led to this, but the various extracts, fluid and solid, and the various preparations under the name of ergotin, had all seemed to partake of the perishable nature of the drug in substance, so that the administration could be neither accurate nor uniform. And without this factor of tolerably fixed and known quantities in dosing, effects must always be liable to such confusion and uncertainty as to render the difficulties of accurate investigation almost insurmountable.

Although it may be quite true that when the life of one, or the lives of two human beings depend upon the parturient effects of a dose of ergot, there is no better practice, nor any that is so safe, as the use of fresh ergot in freshly made powder; yet experience has abundantly

* Paper read before the American Pharmaceutical Association at Richmond, Va., September, 1873.

shown that it is upon the age and condition of the ergot, rather than upon its being ergot, that the safety depends, and that this age and condition can rarely be known with that certainty which is necessary when human life depends upon it. Hence it is that the elements of greatest importance in the use of ergot, as indeed of the whole materia medica, are to get the drug in good condition, and then to preserve its activity from change, so that its quantities may be uniform; and this is pharmacy.

Modern investigation and experience have shown that the principal and prominent effect of the administration of ergot to human beings, in adequate quantity, is to cause contraction of the involuntary or unstriped muscular fibre wherever this is found. The gravid uterus being constituted principally of this variety of muscular tissue, this was the organ upon which its effects were first observed, and it was long used as a parturient, both by empirics and by the medical profession, before its more general effects were recognized. One of the most important deposits of unstriped muscular fibre is that which constitutes the middle coat of the arteries; and any agent which causes contraction in this, diminishes the quantity of blood which passes through the vessels and so modifies the nutrition of diseased parts. Hence the uses of ergot in cerebral and spinal congestions, in capillary hemorrhages, in bloody tumours, and especially in tumours and hemorrhagic affections of the uterus, such as fibroids, polypi, etc. As a parturient, a single dose or two is sufficient, and it matters little in what form or how that is given, if the quality be assured and the quantity sufficient. But for many of the other uses it requires to be taken for weeks or months in full and frequent doses, as the only means of keeping up its effects until the cure is established, and hence the prime necessity for a stable and uniform preparation of the drug.

The first requisite to any trustworthy preparation of ergot is, of course, a uniform good quality in the drug, and this is by no means easy to attain. The American market is now overstocked with ergot at extremely low prices. Tons of it might be had at sixteen to eighteen cents per pound, but it is all so small as to render it almost certain that it is from oats, barley or wheat, rather than from rye, while its deficiency in odour and taste, and its uncleanness, forbids the idea of its being trustworthy. Most of it is imported in bags, and thus only by chance can arrive in proper condition. Much of it is contaminated with the seeds of various weeds, and requires much labour in cleaning, as the weed-seeds are often very bitter, and may be poisonous. It is not unfrequently wormy, or bears the marks of having been cleaned from worms and worm-dust to improve the chances of sales and profits. Occasional lots, and these often large lots, look as if they had been washed, and suggest the idea of having been partially exhausted for the making of some of the so-called "ergotins." Hence it may be easily understood that to obtain a uniform supply of good ergot is a very difficult matter, even with the screw of price entirely taken off. Throughout the present crop the writer has paid various prices, from 1·25 dollars down to twenty-two cents, without always being able to get what was desired, though always on the alert in a large market, and always in the presence of far lower prices. Many good authorities state that wheat and oat ergot is as good as that from rye, and some even give the preference to that from wheat; but after many years of pretty close observation, the writer has failed to convince himself that these cheaper varieties are as good. They are certainly very inferior in odour and taste, and it is not an unfair inference, nor without natural analogy, that it finds better conditions for growth in its original and more natural habitat in the paleæ of the rye, where it certainly grows most vigorously.

The existence of one or more active principles in ergot, which may be isolated for therapeutic use, has been very generally believed; and various substances have been extracted and sold under the name of ergotin, those of different makers having different properties and different doses, but all producing some of the effects of ergot, though in very different degrees. After a careful attention to the literature of this subject, and comparing it with the results which seem to have been realized in practice by experience, the writer does not believe that there is an active principle separable from ergot which, in any proper sense, represents the drug. Like senna, rhubarb, and many other drugs, its effects seem to be dependent upon a natural association of its various separable elements. If this be true, there is no such thing as ergotin, and the various substances so called only represent the activity of the drug as they represent more or less perfectly its entire composition. Of course certain of its constituents, such as lignin, starch, fixed oil, gum, etc., are known to be inert, and such being excluded by the choice of a proper menstruum for extracting it, the nearer its preparations come to representing or containing all the remainder of the drug the better. The molecular constitution of the active portion of the drug seems, however, in its natural condition, to be loose, and like a slow fermentation, to be undergoing slow molecular changes, so that by age its peculiar activity is slowly diminished until finally lost. This process of change seems to be arrested by acids, just as many other delicate slow changes are; and whether this be effected by the substitution of a more permanent acid for a less permanent one, in one or more salts, as has been suggested by Professor Procter, but not distinctly proved, or how it is effected, seems as yet unknown. It is, however, well established that the addition of about one per cent. of acetic acid, which is added to the officinal fluid extract of 1860, renders this liquid preparation permanent; at least the writer has known the same preparation to be continuously used as a parturient for six years, without apparent change in activity, though watched closely for such change throughout the time, until the parcel on trial was all used. The ergot in the grain, however well kept, is known to become inactive without known change in appearance, though the sensible properties, such as the odour and taste, may, and probably do, change. Ergot in powder is known to diminish in activity much more rapidly than when in grain, and probably soon becomes inert. The tincture and wine of ergot are believed to change, though more slowly than the ergot in substance, whilst the extracts and so-called "ergotins" are all supposed to change more rapidly than the tincture. Much of this latter, however, is traditional, rather than exact knowledge, and must be presented as such.

There can probably be no better preparation of ergot than the officinal fluid extract of the U. S. Pharmacopœia of 1860.* The formula for this was published by Professor Procter in the Proceedings of this Association in 1859, and the writer has made it continuously by this formula ever since. From this experience in making, which now amounts to many thousands of pounds, and from frequent opportunities of hearing of its activity and its effects, as well as of its permanency, the above statement of its value is made up. When given in frequent large doses for a long time, however, as is required for many of the more modern uses of the drug, it becomes very disagreeable, and occasionally deranges the stomach, producing nausea, loss of appetite, and consequent debility. Occasional intermissions in its use, with other suggestions of care and

* In the last revision of the U. S. Pharmacopœia the formula and process for this fluid extract have been materially changed; first, by the introduction of glycerin, and next by adding the acetic acid to the preparation after the percolation, instead of percolating the drug with an acidulated menstruum. It is difficult to account for these changes in a preparation so well established and so well tried without known complaint. The addition of glycerin may have been to bring it into uniformity with other fluid extracts—a uniformity of very doubtful utility at best—but the change in the use of the acetic acid seems still more objectionable. The present officinal fluid extract will not serve to make the solid extract from.

skill, will often relieve the stomach for a time without material intermission in the effects. It has also been often and much used by hypodermic injection, generally through the integument of the abdomen, in order to relieve the stomach, and it generally acts promptly and energetically when thus used, though in smaller dose; but from being loaded with organic matter, and containing alcohol and a little free acetic acid, it is very apt to produce small abscesses, and thus cause much suffering. Indeed it is by no means well adapted to hypodermic use, and such use of it has always been discouraged by the writer.

(*To be continued.*)

IS PETROLEUM "EXPLOSIVE"?

It may be news to some of our readers that a select committee of the House of Commons has just been sitting, with a view to thoroughly inquire into the subject of "Explosive substances," and at their last sitting petroleum was incidentally mentioned. Sir John Hay was in the Chair, and he shortly examined Major Magendie, government Inspector of Gunpowder Factories, as to the "explosibility" of petroleum. Sir J. Hay said that he noticed that petroleum had not been included amongst explosive substances. He desired to know whether or not there was any necessity for so including it. To this Major Magendie replied, that he was not exactly aware how it was possible to include petroleum in the Act for explosive substances. Practically speaking, it was not an explosive substance, but when the temporary vapour which it gave off became mixed with a certain portion of atmospheric air, then an explosive substance was formed. He further stated that petroleum was much the same as coal-gas, which in itself was not explosive, but became so when combined with atmospheric air; but petroleum was not *per se* an explosive substance at all, and therefore could not more properly be legislated upon as an explosive substance than coal-gas could be legislated upon in a similar manner. Indeed, if explosions which had been attributed to the presence of petroleum were necessarily included in a Bill professedly drawn up for explosive substances, precisely the same argument would apply to steam and compressed air, and even to flour mills, because explosions had been known to occur in the last mentioned establishments. He also pointed out that petroleum was legislated for in a special Act of Parliament, which regulated the trade in the article; as to the sufficiency of this enactment, that of course was another question, but in his opinion that Act was much in advance of the Gunpowder Act. Further he stated, that, in the event of its being shown that the existing legislation as to petroleum was inadequate to the purposes in view, and consequently required amendment, the matter must be dealt with quite independently of such legislation as was deemed necessary for explosive substances, inasmuch as the provisions of the Gunpowder Act would undoubtedly be unfitted in their application to petroleum.

After this expression of opinion from Major Magendie, the subject of petroleum was not again mentioned.

THE ADULTERATION OF MUSTARD AND COCOA.

Our readers are aware that since the present Adulteration Act has come into operation, great attention has been directed to the manufacture of mustard and cocoa; and important evidence was given on the subject before the select committee of the House of Commons, on Monday last. Mr. Colman, the well-known mustard manufacturer, in the course of a long examination, said that there are two processes for the manufacture of mustard, one of which produces pure mustard, and the other, mustard mixture, or what may be termed mustard condiment. The only ingredient which enters into the manufacture of pure mustard is the flower of the white and brown mustard seed; while to make mustard condiment, there is an addition of a little wheaten flour and turmeric, and, if it is desired to produce a very cheap article, some manufacturers use a small proportion of chilies or cayenne. Mr. Colman stated that the object of the manufacturer in mixing wheaten flour is to improve the article, to soften its flavour, to prevent fermentation, and to enable him to utilize a cheap description of seed. According to his experience, perfectly pure mustard does not so well please the public palate as the mustard mixture ordinarily sold. In the manufacture of mustard, he further stated, it is important that there should be a preponderating quantity of brown seed, or else mustard of superior quality cannot be obtained. In consequence of the operation of the Act, his firm adopt the plan of supplying their customers with a printed label stating that there are other ingredients used; but some magistrates held that this was not sufficient, under the Act, to protect the retailer, and that a verbal declaration is necessary. He further testified that the operation of the Act has had a very disturbing influence on the trade, and he contended that mustard should be exempt from the Act altogether, because the quality of the article at present produced could not be improved upon. As to the idea that the retailers adulterated the article, he emphatically denied it, as it would not pay them to pursue such practices. If the Act must apply to mustard at all, a notice-label such as he had mentioned should be sufficient to protect the sale on the part of the retailer. He also mentioned that it is possible to have a chemically pure mustard which is inferior to the best mixed mustard—that is, mustard into the manufacture of which other ingredients have entered.

The next article upon which evidence was taken was cocoa. The first witness examined was Mr. Fry, a well-known cocoa manufacturer. He said that the mixed cocoas are sold as distinct preparations, and have been so sold for a long time. More cocoa is sold prepared with other ingredients than in its pure state; he attributed this to the fact that the manufactured cocoa is more convenient for the use of the public, and, generally speaking, more wholesome. The principal ingredients used are sugar and arrowroot, or sago; and some descriptions are flavoured with aromatic substances, such as vanilla, which is very expensive. One of the chief objects of combining arrowroot and sugar in the manufacture of cocoa, is to render the article soluble, or, as this term had been objected to as not chemically accurate, he would say miscible. "Soluble," however, as applied to cocoa, is used in the popular sense. He also stated that he did not consider the cocoa trade should have been brought under the operation of the Act, because the article is not in any way fraudulently made, but is sold honestly as the article which it really is. He was not particularly desirous of any alteration being made in the law, because in the prosecutions against the retailers for selling cocoa, the decisions of the magistrates had uniformly been in their favour; but if any new Act was to be passed, it was desirable that a notice-label, stating that the article was a mixture, should avoid the liability of the retailer being prosecuted. He also mentioned that these mixed cocoas are largely used by the working classes, and in that respect are more or less valuable as a substitute for intoxicating drinks. Evidence generally corroborative of that given by Mr. Fry, was given by Mr. Holm (of the firm of Dunn and Hewett), who expressed the opinion that the consumption of the prepared cocoas had been slightly checked by the Act, although this did not appear from the Board of Trade returns, as the consumption of eating chocolates had of late greatly increased. He further stated that the cocoa manufacturers are placed in what he termed a middle position; on the one hand they were desirous of protecting the public from fraud, and on the other they were desirous of protecting the retailer from any undue annoyance.

No other evidence was taken upon the subject, and the committee adjourned.

The Pharmaceutical Journal.

SATURDAY, MAY 16, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE THIRTY-THIRD ANNIVERSARY OF THE PHARMACEUTICAL SOCIETY.

THE Report of the Council, which before this time should have reached the hands of all the Members and Associates in Business of the Pharmaceutical Society, will have intimated to them that the meetings in connection with the Thirty-third Anniversary will take place during the coming week. First in importance is the Annual General Meeting, which will be held in the Society's house, Bloomsbury Square, on Wednesday at noon, when the Report will be submitted for approval, and the members present will be afforded an opportunity of expressing their opinions upon the various topics mentioned in it. Although there does not appear to be any subject that will rival in interest those which have given a spice of excitement to the annual meetings of the last two years, the important step taken by the Council with regard to the School of Pharmacy is now submitted for a formal ratification at the hands of the members; whilst their opinion is also sought upon a proposal for the establishment of extra scholarships, made by a gentleman whose name is closely associated with the subject of pharmaceutical education.

Those gentlemen who, on both or either of the previous occasions, visited Sydenham to dine with the members of the Society and their friends, will have gladly noted that this "institution" shows signs of vigorous life. Probably, as the time has now passed for the returns to be made by the Stewards, most of those who wish to be present next Tuesday evening have already secured tickets. Should there be any, however, who have not done so, we are authorized to state that some tickets may still be had by applying *immediately* to the Honorary Secretaries, Messrs. RICHARD BREMRIDGE and MICHAEL CARTEIGHE, 17, Bloomsbury Square.

With regard to the Conversazione, nothing further need be said than that it will be held on Wednesday evening, and that the entertainment at South Kensington promises to be as brilliant as on any previous occasion. For the convenience of intending visitors, however, they are reminded that the officials at South Kensington will not undertake the charge of hats, and that programmes of the music are provided and should be obtained by each visitor upon entering the Museum.

INTERNATIONAL CONGRESS OF PHARMACISTS AT ST. PETERSBURGH.

AT the close of the Third International Pharmaceutical Congress, which was held in Vienna in 1869, it was resolved that the next meeting should take place after the lapse of three years. A committee was appointed to decide upon the place of meeting, and to make the necessary arrangements. But, *l'homme propose et Dieu dispose*. Three years passed away, and 1872 entered into a heritage of ill-feeling between the scientific men of France and Germany, that made it hopeless to expect their co-operation in such an enterprise. However, time, the healer of all ills, has been at work, and the committee has come to the conclusion that this year the deferred Congress may be advantageously held.

As many of our readers are aware, St. Petersburgh is the city chosen for the place of meeting, and the Organization Committee has issued a circular to all the recognized pharmaceutical societies of the different countries, informing them that the Congress will commence on the 13th of August next (1st of August, o. s.), and inviting them to send representatives. The subject was under the consideration of the Council of the Pharmaceutical Society at their meeting last week; but, in consequence of the pressure of more urgent business, a decision as to what course should be taken was deferred until June. In the meantime, however, it may help to give a more concrete form to the speculations of some fortunate pharmacists who are looking forward to a continental ramble in the autumn, as well as prove of interest to others who will have to stay at home, if a few lines are devoted to an epitome of the proposed proceedings of the Congress.

Four questions are at present announced for discussion: (1) How far does the personal responsibility of the Assistant Pharmacist extend, in the exercise of the duties of his calling? (2) How may the Apothecaries' Committee of Revision be most advantageously organized? (3) Is it necessary that a professorship of pharmacy should be held only by a pharmacist? (4) Has not the time come for the institution of an International Pharmacopœia? In the event of any Society wishing to propose other questions for discussion, it is requested that notice be given to the Committee before the 27th of June. At previous Congresses the business has been confined to the discussion of questions similar to the foregoing; but, with the object of making the present gathering as profitable as possible, it is proposed on this occasion, in addition to the ordinary general meetings, to hold two further sittings for the purpose of scientific discussions.

In the transaction of the ordinary business, only deputies from pharmaceutical unions and societies recognized by their respective governments, and holding a written authorization from their Society, can take part and vote. Every such Society has the right to

send a deputy, with the power of voting; if the society consists of more than one hundred members, it has the right to send an additional deputy for each hundred. All members of pharmaceutical societies, however, are invited to attend the sittings, and to take part in the discussion at the scientific meetings. In the discussion, speakers will be allowed to use the German, English, French or Russian languages, and the purport of the various speeches will be translated into the "business language," which will be selected by a vote of the majority.

The programme of the Congress, subject to alteration, extends from Wednesday, August 12th, when there will be a reception of the foreign visitors and a social meeting in the evening, to Tuesday, August 18th, on which day the final sitting of the Congress will be held. The Ordinary Meetings will be held on Thursday the 13th, Saturday the 15th, and Tuesday the 18th; the Scientific Meetings on Friday the 14th and Monday the 17th. Sunday will be devoted to sight-seeing, visiting the various churches, etc., and a trip to Peterhof by steamer in the afternoon. Other visits and excursions are allotted to Friday the 14th and Monday the 17th, and on Saturday the 15th there will be a banquet. During the Congress there will also be an Exhibition of Drugs, Chemicals, etc., to which pharmacists of all nations are earnestly invited to contribute.

In order that the visitors may be lodged during their stay in St. Petersburgh as conveniently and economically as possible, the Organization Committee have entered into an agreement with the proprietor of the Demuth Hotel, Stallhofstrasse, according to which all members of the Congress will be provided by him with rooms at considerably reduced prices. Persons wishing to avail themselves of this arrangement are requested to communicate with the Committee before the 9th of August. During the Congress the office of the Committee will be at the Hôtel Demuth, but previous to the 12th of August it will be in the premises of the Pharmaceutical Society, Wosnessensky Prospect, Haus Schkljarski, Nr. 31, Quart. Nr. 18, and intending visitors are invited to forward any inquiries to that address.

Such are the principal points of interest in connection with the Fourth International Pharmaceutical Congress; and although international congresses have not hitherto attracted the amount of attention from British pharmacists which is perhaps due to them, whilst St. Petersburgh does not lie in the ordinary track of their footsteps, we are not without hope that there will be more than one of our countrymen amongst the visitors privileged to receive the greetings of the white-rosetted organization committee on the arrival of the foreign train in St. Petersburgh on the 12th of August.

Amongst the names included in the list of candidates, selected and recommended by the Council of the Royal Society for election as Fellows, we notice that of Henry Bowman Brady, F.L.S., well known to our readers by his services to the Pharmaceutical Society, and as the late President of the British Pharmaceutical Conference; and that of John Eliot Howard, F.L.S., who is a member of the firm of Messrs. Howard & Sons, of Stratford, and whose researches upon the *Cinchonas* have contributed so much to their successful acclimatization in India and other countries.

On p. 926, will be found a clause in the Metropolitan Buildings and Management Bill,—recently introduced into the House of Commons by the Chairman of the Metropolitan Board of Works,—which relates to the storing of chemicals. The Bill has been referred to the consideration of a Select Committee.

The Corporation of Colchester has appointed Mr. John Wiggin, F.C.S., Pharmaceutical Chemist, Public Analyst for that borough.

ERRATUM.

No. 201, page 881, col. 2, line 3, *for* Patman, Francis Thomas, *read* Patman, Frederick Thomas.

NORTH BRITISH BRANCH, EDINBURGH.

The Annual meeting was held in the Soeiety's rooms, St. Giles street, on Monday, May 11th, at 12 o'cloek. Mr. Young, President, in the Chair. The Secretary read the following:—

Annual Report, May, 1874.

"The Council of the North British Braneh have again as usual to present their Report for the past year.

"They have much pleasure in testifying to the suceess whieh has attended the oecupation of the Soeiety's rooms in St. Giles street. In all departments, whether in referenee to the conduet of examinations, as a museum, library, or as affording opportunities for study, the change has been beneficial, while, when used for evening meetings during the winter, the rooms have been well and fully attended. Sinee they were opened in November, 1872, 1332 visits having been paid; 874 of this number have visited the rooms between 1st January and 31st Deeember, 1873. These visitors were chiefly young men preparing for their different examinations.

"Hitherto the rooms have been found fairly eonvenient for earrying out the examinations of the Soeiety. Having in view, however, the greater stringency in the future of the practieal working in the chemieal department, both in minor and major examinations, as well as the neeessitous eall for inereased aeeommodation in eonnection with museum and library, it was thought advisable that steps should be taken to give up the present rooms, by taking advantage of a break in favour of the Soeiety occurring at Whitsunday first, and thus getting quit of the lease whieh, if not done *now*, would bind the Soeiety in its oeeupation five years longer. Aeeordingly, arrangements have been made, with the eoncurrenee of the London Council, to remove on the 25th May, now approaching, to more eommodious premises in the west end of George Street; and where, in a suite of three apartments, there will be available 50 per eent. more wall and floor space, with every eouvenience for the ereetion of a laboratory and dispensing eounter for the use of the Board of Examiners; while, from the lofty nature of the eeiling, better and more comfortable spaee will be available for the evening seientific meetings.

"A glanee at the weekly journals will show that our evening gatherings have been, both in point of interest and attendanee, a fair average. The Couneil tender their best thanks to those gentlemen who have so kindly taken part in these proeeedings; and special thanks to Mr. Jamie, of Singapore, who, while so far distant from Edinburgh, should yet have so substantially and so handsomely remembered the museum of the Society. In like manner they offer to those who have eontributed to the library, and partieularly notiee the liberal presentation made, during the winter, by Mr. D. R. Brown, of Edinburgh, of so many volumes, a list of whieh was published at the time when they were presented.

"The examinations have been more numerous during last year. The date for the preliminaries are of eourse fixed, being held throughout Great Britain on the first Monday of eaeh quarter, eommencing with January. During 1873, 167 offered themselves for this examination, with a large pereentage of failures. For the Modified, 21 candidates came before the Board, 76 for the Minor, and 10 for the Major, or in all 274. Throughout all these examinations, failures bulk very largely, and it is with mueh regret that the Council have to record this faet.

"The Couneil take this opportunity of again thanking Mr. Hills, the London president, for his liberal gift to the North British Branch, whereby from funded property to the extent of £5 annually they are enabled to bestow a prize of books at the board meetings in Edinburgh, to each eandidate who passes highest in honours in the Minor Examination.

"The diffieulty in connection with the best form of provineial education appears to be as great as ever, while the Council feel that the reeent proposal to establish scholarships at a large annual outlay to the Society is not at all likely to be produetive of satisfactory results. There seems also to be grave objections to centralize the real means of education; beeause the Couneil think it would not be an easy matter for all young men in the country to go to large towns, and there spend time and money to gain a knowledge of the different departments, apart from the routine of the daily shop and counter practice. Some such neeessity may yet eome, but the Couneil think it is too premature to make such a course at present imperative.

"The Supplement to the Pharmacopœia has been published, and must be in the hands of most pharmaceutists by this time. The eontents will therefore tell their own tale; but the Couneil eannot help thinking that in some respeets the additions are a mistake, as likely to lead to eonfusion without any corresponding benefit.

"The Council express a hope that, in the eourse of this session of Parliament, and espeeially now that a eommittee has been appointed, and is already sitting, something may be done to modify the praetical working of the Adulteration Aet: feeling assured that, in its applieation to many artieles, its scope and intention have been very seriously misunderstood.

"A Juries Bill is now going through the House; and the Couneil feel hopeful that steps may be taken to obtain an extension of its operation to Seotland in referenee to the exemption from jury service of all pharmaceutieal ehemists as well as ehemists and druggists. This the Council think might be effeeted in one of two ways, either by the introduction of a speeifie elause in the proposed bill or a short special Aet of Parliament extending the privileges of the bill to Scotland. For many years parties in Seotland have suffered under the anomaly by whieh pharmaceutical chemists, beeause residing in Seotland, fail to partieipate in the boon aeeorded to their brethren in the south; and trust that the present session of Parliament may be able to put this matter on a fair and proper footing. The Couneil understand that their Seeretary has reeently been in eorrespondenee with the members for the city and eounty, as well as with the Lord Advocate for Seotland, on the subjeet; and thus, through the influenee of the latter there is a prospeet of due attention being given to this subject, and with some hope of suecess.

"The Council eannot elose this report without referring to the great loss whieh not only the Society but pharmaey generally has sustained in the death of three very well known and mueh respected members of the Soeiety, Messrs. Meggeson, Morson, and Henry Deane. The grave had scareely closed over the remains of George Meggeson, who died at a very advaneed age, well known and mueh respeeted by all who were privileged to have his aequaintance, when the announcement was made of the deeease of Thomas N. Morson, and within only a few days thereafter, all were startled to know that Henry Deane had also passed away. The Couneil feel that this is neither the time nor place to record all that these two latter well-known men have done for pharmacy, and can therefore only express grief at their removal from this their seene of active labour. As examiners and ehief office bearers in the early days of our Society, they did much to further its true interests; while among seientific eireles at home and abroad their names were widely known and deservedly esteemed.

"In eonelusion, the Council have now to intimate that, as promised last year, a new system of electing members of Council in Edinburgh has this day to be inaugurated. Cireulars have been sent out to all members of the Society, as well as to associates in business throughout Scotland, who, having paid their annual subscriptions previous to the printing of the same, have been asked to vote for 15 out of 23 names submitted; and it will now be for the meeting to ascertain by the voting papers who are to be the members of Council in Edinburgh for the year 1874-75."

After a few remarks from one or two members, Mr. W.

Aitken moved the adoption of the report, which was seconded by Mr. J. Macdonald, and carried unanimously.

The envelopes containing the voting papers were then opened in presence of the meeting, and a committee appointed to examine and sum up the votes. This having been done, the following were declared duly elected as Councillors for 1874-75, as they stood highest on the list. The names are given alphabetically :—W. Ainslie, H. C. Baildon, G. Blanshard, J. Buchanan, D. R. Brown, T. Davison (Glasgow), W. Duncanson (Stirling), D. Frazer (Glasgow), J. Fairlie (Glasgow), W. Gilmour, A. Govan (St. Andrew's), J. Heron, D. Kemp (Portobello), A. Kinninmont (Glasgow), and J. R. Young—in all 15. Mr. Gilmour was then proposed as Chairman and Mr. Kinninmont as Vice-Chairman for 1874-75. Both these appointments, as well as that of Mr. John Mackay as Secretary, were carried unanimously and with acclamation.

The committees were to be settled at the first meeting of the new Council.

Mr. Mackay proposed a vote of thanks to Mr. Young for his conduct in the chair, referring in a special manner to his services to the Society, to which Mr. Young replied, and thus brought the meeting to a close.

Provincial Transactions.

GLASGOW CHEMISTS' ASSOCIATION.

The annual Business Meeting of the Association was held in Anderson's University, on Wednesday, 15th April, at 9 p. m., Mr. John Currie, President, in the Chair.

The minutes of previous meeting having been read and adopted, Mr. Fairlie then, in the name of Messrs. Evans and Company, Liverpool, presented the Association with one of their first class "Pharmacy" microscopes, and it was agreed "that the Secretary be instructed to forward the sincere thanks of the Association to Messrs Evans and Company for their most seasonable present."

Business connected with the Library was then brought forward; when it was resolved that a sub-committee of three be elected to make the necessary arrangements for establishing the Library, but that nothing be finally settled without the sanction of the Council.

The following gentlemen were elected Library Sub-Committee :—Messrs. J. M. Fairlie, Wm. Whyte, and Alexander Kinninmont.

It was also agreed that the Library fund should be banked, and drawn upon as required.

The Secretary then read the following report :—

"The session commenced on the 1st of October, 1873, with an address by the President on 'Education connected with the trade.' On the 29th of the same month we were favoured with a highly interesting lecture by Dr. Wood Smith on 'The Circulation of the Blood.' The attendance of members on this occasion was very good. On November 26th we had a lecture from Dr. Nairne on 'The Brain and Nervous System.' This lecture was illustrated by means of anatomical specimens. We held our fourth meeting on December 24th. The business done consisted in making the necessary arrangements for the annual festival; that being done, the remainder of the evening was devoted to a discussion on 'The Adulteration Act,' Mr. Kinninmont being the chief speaker. The fifth general meeting was held on the 21st of January, 1874, when we were honoured with an exceedingly interesting lecture by Professor Thorpe, on 'The Life and Scientific Works of the late Thomas Graham.' The lecture was profusely illustrated by experiments, and it may truly be said that those members who were absent from that meeting certainly missed a great treat. On the 18th February the evening was mainly devoted to a discussion on Mr. Hunter's motion connected with the Library, and which, as most of the members are aware, has resulted in the collection by subscription of about £40, which the Council trust may be further increased by a grant from the Pharmaceutical Society. The last general meeting was held on the 1st of April, when the Association was favoured with a lecture by Dr. Fergus, on 'Pure Air and Water.' The Doctor showed how, by the aid of 'Nessler's solution,' the presence of sewage in water might be detected, and he also gave the formula for the test solution.

"Your Council are not in a position to say that the present session has been a very remarkable one, but they can say that it will be long remembered on account of its giving birth to the Library; and they feel confident that if we go on accomplishing as much every session as we have done during the last few sessions, we shall in a few years have great reason to congratulate curselves on the progress we have made. Your Council trust that the time is not far distant when the Association may have the pleasure of meeting in a Hall of its own, but although this is 'a consummation devoutly to be wished' still it can only be brought about by the united effort of every member of the Association; and as we all know that to gain the object that we have in view, namely the acquiring a Hall of our own, will be to incur a considerable additional expense, it behoves us to endeavour to add to our list of members; because it is only by so doing that we can carry on the work commenced in connection with the Library to a successful issue, and we know that there are many masters and assistants in the city who do not belong to the Association, and who by a little persuasion might, we think, be induced to join us. My own individual opinion is this, that, until we have the great majority of both the masters and assistants in our ranks, the Association will never be in a thoroughly flourishing condition; and I consider it a sure sign of disease when any Association, either secular or sacred, has to depend for its main support on a few influential members, because I shall ever hold it as truth that forty customers at 1*s.* each show a much securer state of trade than four at 10*s.* or two at 20*s.* each."

The Treasurer, Mr. McKenzie, submitted the financial statement, which showed that there had been an income of upwards of £50, including Library fund.

The report was adopted.

The following report of the Assistants' Branch was then read by its Secretary.

"As secretary of the Junior Section of this Association, I am, with the senior secretary, expected to give a *résumé* of our past year's proceedings.

"As you are aware, this is the first year of our existence as a junior section of this Association; and although the success attending our efforts has not been so great as we anticipated, nor as I think we had a right to expect, still, we must not repine. Most undertakings have a small beginning, and assuredly our beginning has been small enough, whatever our future success may be. However, the Society has reason to congratulate itself on the amount of talent, hitherto undeveloped, with has developed itself during the session in the meetings of the junior section, talent which, had we remained in our former position as one Association without two sections, would have remained undiscovered.

"But other means, as well as the absence of our seniors, combined to bring the assistants out of themselves; by the munificence of one of our members, a master whose name I may not mention, our Council have been able to offer the members of the junior section a prize or prizes for the best papers on trade subjects, subject to such rules and regulations which the donor as donor had a right to lay down.

"Our Council, while not undervaluing the handsome offer, have determined, with the kind permission of the donor, to leave it over for another season; as, considering the smallness of attendance, and the small numbers of papers given, they feel that they could not consistently come to a conclusion. But the gentleman, on being informed of the circumstance, is so pleased with the exertions of the assistants that he has expressed his willingness to give

each of the essayists a volume, which he will accordingly do. The papers given were five in number, the essayists and subjects being as under : Mr. J. Hunter (Modern Relations of Organic and Inorganic Chemistry) ; Mr. J. Foster (Animal Substances as used in Medicine and the Arts); Mr. W. Currie (Iodine); Mr. W. Bray (Mercury and its Preparations); Mr. J. Mc Gunndech (Drugs and Druggists).

"Our attendance has been, as I have said, small; the number on the roll being 26, average attendance scarcely half. But our Council think the reason is not far to seek, and explain it in this way : that on account of the visible declension of the early closing movement, assistants cannot, after closing at nine (minus their tea), come to our meetings, nor can we expect them.

"Let us hope, then, by next season we may resort again to early closing, and then, with time, books, cabinet and microscope at our disposal, I am afraid the Council will have to make a virtue of necessity and look for larger premises."

The election of office-bearers then took place (prior to which the Secretary said that he did not intend to seek re-election), which resulted in the following returns :—

President, Mr. John Currie; Vice-President, Mr. W. Whyte; Secretary, Mr. J. M. Fairlie ; Treasurer, Mr. W. McKenzie ; Council, Messrs. T. Davison, J. A. Clarke, R. Brodie, A. Paterson, G. Garry, J. Jaap, J. Fenwick, A. Paul, D. Frazer, W. Greig, A. Kinninmont, and R. C. Rait ; Auditors, Messrs. R. S. Dun, and J. Fotheringham.

The concluding remarks of the Chairman terminated the proceedings.

LIVERPOOL CHEMISTS' ASSOCIATION.

The thirteenth general meeting of this Association was held on April 24th, 1874, at the Royal Institution. Dr. Charles Symes occupied the Chair.

There was a very fair attendance.

Mr. John Abraham read a paper on "Medicinal Pepsin," which is printed at p. 909.

Mr. James T. Armstrong, F.C.S., read the following paper, sent to the Association by Dr. J. M. Milne, of Glasgow, entitled "Notes on the Analysis of Char : "—

We live in an age of investigation. New theories are being constantly propounded with astonishing assiduity. Fortunately, however, such theories have to undergo the test of severe criticism, under which many of them, remarkable only for their absurdity, are immediately consigned to oblivion.

In no case, perhaps, are criticisms more severe than when the subject under discussion belongs to the domain of chemistry. Here, at least, the theorist must be prepared to have his opinions sifted to the utmost by a host of fellow scientists, who, as a rule, are not too tolerant of any ideas but their own. Probably, after all, it is a good thing that such is the case. Its good results are visible in the high degree of accuracy to which analytical chemistry, for example, has now attained. Even in the so-called "commercial work," the highest degree of accuracy compatible with the limited time usually available for such analyses is demanded, and processes which but a few years ago were considered reliable for practical purposes, are now discarded as erroneous.

Manufactured chemicals of all sorts being usually sold and valued according to the amount of pure substance present, the analytical chemist occasionally finds his results called in question to an extent which becomes extremely annoying. From a commercial point of view, it is of course the seller's interest to have results as high as possible, while the buyer prefers them low. Those analytical processes which are now proved to give results too high, are often still preferred by the seller, while the buyer shows a predilection for those methods which err on the opposite side. Perhaps, therefore, we can scarcely wonder at the existence of what are called "High Chemists" and "Low Chemists," while at the same time we deplore the condition of things which gives rise to them.

The analyst, therefore, who uses only such methods of whose accuracy he is conscientiously convinced, often finds himself in the position of the man who tried to please everyone and pleased no one. It is to be regretted that professional analysts are not more united as to the adoption of various analytical methods. How often do we find processes, considered accurate by one chemist, completely ignored by others. Such a state of matters is by no means satisfactory.

Might not a remedy for this be found in an understanding among analysts, by which only those methods should be employed which are recommended by a majority as standing all the tests available for ascertaining their accuracy ? I make this suggestion, in the hope that attention may be more fully drawn to it by societies such as this. The discrepancies in many of our "commercial analyses of the same sample" is a crying evil, and demand the attention of every chemist who desires to uphold the dignity of our science. The foregoing remarks have recently suggested themselves to me, and although, perhaps, not strictly belonging to the subject under consideration, I do not consider them out of place here.

The application of animal charcoal to the purposes of sugar refining, has rendered its accurate analysis a matter of great importance to the refiner. It is a good thing to know that manufacturers of all kinds are becoming more and more alive to the superiority of chemical knowledge and rigid chemical analyses over the old rule of thumb methods of manipulation which have, in many cases, so long prevailed

The present communication contains the results of a number of careful experiments made on char with the view of testing the accuracy of some statements which have been lately made regarding the determination of some of its constituents—more particularly the presence of soluble organic matter and the estimation of water in new char. The correct determination of the latter ingredient has been a source of no small discussion; and as char is usually sold under a stipulation that it shall not contain over a certain percentage of water, the chemist to whom the question may be referred has of course to contend with the opinions of the buyer and seller. The latter usually considers 212° F. the proper temperature for such a determination, while the former is disposed to insist on a higher one. With such differences of opinion the analyst *ought* to *have nothing* to do. His duty is to make every determination according to the method, or at the temperature, which, from his own observations and those of others, he believes to give the most accurate results. Of course, if a sample is brought to him with the request that he determine the amount of water *at* 212° F., that is quite another question, and is not to be confounded with the actual amount of water in the sample.

Two papers on the above subject have recently appeared in the *Chemical News*, viz., one by Mr. J. L. Paterson (vol. xxvii., p. 111), and a short review of the same by Mr. A. S. Wilson (vol. xxvii., p. 225). A somewhat lengthy discussion on the same subject has also been carried on in the pages of the *Greenock Sugar Trade Review* between Mr. Paterson and Mr. Murphy, of Liverpool.

In one of his replies to Mr. Paterson, Mr. Murphy makes the somewhat startling announcement, that water with which new char has been treated is *strongly alkaline*, and will therefore *dissolve appreciable quantities of organic matter from a paper filter*. He thus accounts for the soluble organic matter found by Mr. Paterson in his experiments. I must confess that I, for one, have yet to learn that the water from new char is *strongly alkaline*—much more that it will *dissolve filter paper*. In order to set aside all doubt on the subject, however, the following experiment was made : 5 grms. of a sample of new char were treated with water, and the liquid filtered without

the use of paper, the neck of the funnel being stopped with recently ignited asbestos. The filtrate, which was quite colourless, and only *very feebly alkaline*, was carefully evaporated to dryness in a weighed platinum basin; the residue dried at 130° C., weighed, and cautiously ignited. The contents of the basin blackened quite perceptibly; and on the ignition being completed and the capsule weighed, the loss was found to be ·112 per cent., a result corresponding very closely with that given by Mr. Paterson in his paper.

Although the moisture in samples of old char. can be correctly determined at 212°F., it is well known that this temperature is quite inadequate for the expulsion of *the whole* of the water from new char. In his instructions for the analysis of bone-black, Fresenius gives 160°C. to 180°C. (320°F. to 356°F.) as the temperature at which the moisture should be estimated. A few years ago, Dr. Wallace, in a paper on "Animal Charcoal" gave it as his opinion that a temperature of not less than 350°F. was necessary. Very recently, J. Walz, writing in the "Zeitschrift für Analytische Chemie, von Dr. C. R. Fresenius, Zwölfter Jahrgang, Zweiter Heft, 1873, states that a temperature of 121°C. (250°F.) for four hours, or a period of 24 hours in the exsiccator, is sufficient to drive off all the moisture from bone-black. Mr. Paterson, however, considers 350°F. much too high, and sufficient to destroy a portion of the organic matter. He considers that five hours in the water bath, at 212°F. is all that is necessary, and asserts that char, during the process of pounding, always loses water. Now, while it is quite possible that long continued grinding in a warm atmosphere may have that effect, it is difficult to understand that a porous substance like charcoal, which retains water somewhat persistently, should lose some of it during the short time necessary for reducing it to powder. On the contrary, we should rather expect a slight increase. That this is really the case, the results of Mr. Wilson's experiments, as well as my own, seem to demonstrate. The following experiments were made with reference to this part of the subject :—

A—(1) A sample of new char was taken, and one half reduced to powder; both were placed in tightly corked bottles : 2 grammes of each were weighed out and kept in the water bath, under precisely similar conditions. The loss of weight was as follows :—

	Unground.	Ground.
After 1 hour	4·67 per cent.	4·92 per cent.
,, 3 hours	4·85 ,, ,,	5·09 ,, ,,
,, 5 ,,	there was no further loss in either case.	

(2) 1·2802 grammes of the same sample was heated in an ordinary air bath, at different temperatures as under :—

	Unground.
At 350°F., for 15 minutes, the loss was	6·11 per cent.
,, 400°F., ,, 10 m. longer, ,, ,, ,,	6·78 ,, ,,
,, 450°F., ,, 10 ,, ,, ,, ,, ,,	6·85 ,, ,,
,, 500°F., ,, 10 ,, ,, ,, ,, ,,	7·36 ,, ,,

(3) 2 grammes of the sample were placed in a platinum boat, and introduced into a glass tube about nine inches long. The tube was then placed in an air bath made for the purpose, and one end attached to an apparatus for drying the air previous to entering the tube. To the other end a weighed Chloride of Calcium tube was attached, and this again was placed in communication with one arm of a Staedler's aspirator, by means of which a uniform and well regulated current of dry air could always be obtained. The air bath was heated by a small Bunsen burner, the temperature being registered by a thermometer passed through the lid. For temperatures not over 350°F., a ⊥ shaped glass tube is useful, the thermometer being passed through a cork; but for higher temperatures a plain tube is to be preferred.

A great number of experiments were made with this apparatus, in order to determine the water by direct weighing, some of the results of which are given below.

Two grammes heated in the air current—

	Unground.	Ground.
At 350° F., for 15 minutes, gave	6·50 p. c.	6·52 p. c.
,, 450° ,, ,, 10 ,, longer, ,,	7·01 ,,	7·07 ,,
,, 500° ,, ,, 10 ,, ,, ,,	7·17 ,,	7·19 ,,

B.—(1) Another sample of new char (foreign) was subjected to the same mode of treatment.

Two grammes of the unground sample, placed in the water bath, lost—

In one hour	3·23 per cent.
,, two hours	3·29 ,, ,,
,, four ,, ...	3·31 ,, ,,
,, five ,, ...	3·38 ,, ,,

After five hours there was no further loss.

(2) The same quantity was placed in the air bath.

At 250° F. for 15 minutes, the loss was	3·92 p.c.
,, 350° ,, ,, 30 ,, longer, ,, ,, ,,	4·51 ,,
,, 450° ,, ,, 30 ,, ,, ,, ,, ,,	5·01 ,,
,, 500° ,, ,, 30 ,, ,, ,, ,, ,,	5·22 ,,

Two grammes heated directly to—

500° F., for 20 minutes, lost	5·43 per cent.
500° F., for 20 minutes longer, ,,	5·08 ,, ,,
500° F., for 10 ,, ,, ,,	5·28 ,, ,,

(3) Two grammes, heated in air current—

At 250° F., for 15 minutes, gave	4·17 per cent.
At 350° F., for 15 minutes longer, gave	4·62 ,, ,,
,, 525° ,, ,, 5 ,, ,, ,,	5·22 ,, ,,
2 grms. at 350° F., for 15 m. gave	4·61 ,, ,,
2 ,, ,, 450° ,, ,, 10 m. longer, ,,	4·81 ,, ,,
2 ,, ,, 500° ,, ,, 5 m. longer, ,,	4·92 ,, ,,
2 ,, ,, 450° ,, ,, 30 m. gave	5·03 ,, ,,
2 ,, ,, 450° ,, ,, 20 m. gave	5·24 ,, ,,
2 ,, ,, 500° ,, ,, 15 m. longer, ,,	5·29 ,, ,,

Two grammes were taken, as before, but in this case the loss of weight was also found by weighing the residue in the boat, which was placed in a glass tube, closed by a cork.

	Gain in $CaCl_2$ tube.	Loss from Residue.
At 500° F., for 10 minutes, . .	5·40 p. c.	6·63 p. c.
,, 500° F., ,, 15 ,, . .	5·47 ,,	—
,, 500° F., ,, 20 ,, . .	5·55 ,,	6·98 ,,
,, 525° F., ,, 5 ,, longer,	5·65 ,,	7·22 ,,
Two grammes—		
At 500° F., for 20 minutes, . .	5·35 ,,	6·03 ,,
,, 500° F., ,, 30 ,, . .	5·37 ,,	6·21 ,,

From an examination of the above results we are justified in concluding—

1st. That the water in a sample of new char is sensibly increased by the process of pounding, instead of being diminished.

2nd. That a temperature of 212° F. is quite inadequate for the determination of the water in such samples.

3rd. That there is a loss on heating in the air bath up to 500° F.; and that, if heated in the air current, there is a gain in the $CaCl_2$ tube up to that temperature, showing that even at 350° F. the water is not completely expelled.

The determination of the water by direct weighing is, of course, to be preferred to the ordinary air bath, which, at the higher temperatures, usually gives too high results. The difference between the gain in the $CaCl_2$ tube and the loss of weight from the residue, shows that the loss is not entirely water. I would recommend heating in the air current for say 30 minutes, as giving reliable results.

Both papers resulted in an animated discussion, and a vote of thanks to the writers brought the meeting to a close.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, May 7th, 1874. Professor Odling, F.R.S., President, in the Chair. After the customary business, four papers were communicated to the Society: the first on "The Action of Ammonia on Phenyl and Cresyl Chloracetamide," was read in French by the author, Dr. D. Tommasi; the second was entitled "Researches on the Action of the Copper Zinc Couple on Organic Bodies: Part VII., on the Chloride of Ethylidene and Ethylene," by J. H. Gladstone, F.R.S., and A. Tribe, F.C.S. The authors find that these two isomerides behave differently when treated with the couple; the latter splitting up into ethylene and chlorine, whilst the former gives zinc chlorethylate, $\left.\begin{matrix}C_2H_5O\\Cl\end{matrix}\right\}Zn$. Mr. Charles E. Groves then read a "Note on the Preparation of Ethyl Chloride and its Homologues." He finds that when hydrochloric acid is passed into a boiling solution of zinc chloride in alcohol, the latter is completely converted into ethyl chloride; other alcohols, such as the methyl and amyl, under similar treatment, yield the corresponding chlorides. The process was shown in action during the reading of the paper. The last communication was a "Note on a new Mineral from New Caledonia," by Mr. A. Liversidge. The meeting finally adjourned until Thursday, May 21st, when there will be a lecture on "The Sewage question, from a Chemical point of view," by W. H. Corfield.

Parliamentary and Law Proceedings.

Proposed Regulations as to the Storing of Chemicals in the Metropolis.

The following clause occurs in the Metropolitan Buildings and Management Bill, which has been introduced into the House of Commons by Colonel Hogg, the Chairman of the Metropolitan Board of Works:—

29. "It shall not be lawful for any person to deliver, receive, or keep any quantity greater than that from time to time prescribed by bye-law of the Board under this Act of any of the following articles, namely—petroleum, phosphorus, mineral oil, turpentine, resin, tar, pitch, paraffin, naphtha, varnish, fireworks, matches, sulphuric acid or other mineral acid, or chemicals of an inflammable nature, into or in any building other than a fire-resisting building, or a cellar, or a room on the basement storey of a building, or a room on the ground storey of a building having a cellar or vault immediately under it, covered with such arching as is required for support of floors in fire-resisting buildings.

"It shall not be lawful for any person to deliver, receive, or keep, any quantity exceeding *half a ton* of saltpetre or nitrate of soda into or in any building other than a building approved by the Board as fit for that purpose; in which case no goods other than saltpetre or nitrate of soda shall be delivered, received, or kept, into or in the same building.

"If any person acts in any manner in contravention of this section, he shall be deemed guilty of an offence against this Act, and shall for every such offence be liable, on summary conviction before a magistrate, to a penalty not exceeding *fifty pounds*, and to a further penalty not exceeding *twenty pounds* for every day on which the offence continues after notice thereof served on him by the Board."

Alleged Improper Use of an Ointment.

At an inquest held at Radcliffe, respecting the death of George Nuttall, a collier, who was severely burnt by an explosion of gas at a colliery, at Ontwood, the widow of the deceased, said that up to the previous Tuesday her husband seemed to be going on very well, but on that day Mr. Chisholm, the assistant to Dr. Sellers, brought some ointment, which he spread on some cloths, and after they were applied to deceased he became very ill, and his agony was such that he begged for the cloths to be taken off. He afterwards became delirious. Some of the ointment got on her hands and blistered them.

James Olive said he assisted to take the cloths off the deceased, and as some of the ointment got on him it blistered his hands also.

Dr. Sellers was then sent for, as was also Mr. Chisholm.

Dr. Sellers said that the ointment was the same as that recommended for burns by Dr. Smith, of Manchester, as well as Dr. Lund. It contained a little carbolic acid, which was put in to keep down the stench from the sores; but that would not produce the effects deposed to by Mrs. Nuttall and Olive. It was largely used in cases of burns at the Manchester Royal Infirmary. The ointment was made up by his assistant.

Mr. Chisholm produced the pot of ointment sent for use in Nuttall's case, and said it was composed of wax, resin, oxide of zinc, and two drachms of carbolic acid. There was nothing in it which would produce blisters on the flesh of a healthy person. The use of such ointment was the proper treatmeat in cases of burns. He had no objection to allow his hand to be covered with it in the presence of the jury. Mr. Dickinson, the Government mine inspector for the district, applied some of the ointment to his finger, but it did not produce any prejudicial effect. In answer to the coroner, Mr. Chisholm said he was quite sure that the ointment was made up according to the proper formula, and that no mistake occurred in compounding it.

After some further evidence the inquest was adjourned, in order to admit of a *post-mortem* examination being made, and the Coroner ordered the medicine and ointment used in the treatment of the deceased to be analysed in the meantime.

Prosecution under the Adulteration Act.

Adulteration of Milk.

Mr. John C. Ford, farmer, Welshampton, Shropshire, was summoned before Mr. Raffles at Liverpool, at the instance of the health committee, for selling adulterated milk. The defendant, it seemed, supplied milk to Mr. Breakell, wholesale milk dealer, Copperas-hill and Pitt-street. On the 15th ult., the inspector of nuisances took a sample of milk from one of the defendant's cans on its arrival at Lime-street station. The sample was analysed by Dr. Browne, borough analyst, who found that it contained seven parts of water to one hundred parts of the poorest milk, and was very deficient in cream. The defendant did not deny the accuracy of Dr. Browne's analysis, but said that he had only just commenced to sell milk, and had confided that part of his business to a manager. There had been no adulteration of the milk within his knowledge; but Mr. Raffles told him this was immaterial.

In answer to Mr. Raffles, Dr. Browne stated that the defendant's milk was 20 per cent. poorer than the average of milk sold in Liverpool; but country milk was, in his opinion, generally poorer than town milk.

Mr. Raffles asked how he accounted for this.

Dr. Browne said that in towns, cows were fed upon richer food than in the counfry—they were mere machines for producing milk. In the country, cows got more watery food than in towns. The defendant's milk was 10 per cent. lower in quality than the poorest country milk he had ever seen.

Mr. Raffles remarked that the case was not so bad as it first appeared; the amount of adulteration did not appear to be large. He could not, however, impose a smaller penalty than 40s. and costs.

Extra costs, making the total costs £2 4s. 6d., were granted.—A summons which had been taken out against Mr. Breakell was now withdrawn.

BOOKS RECEIVED.

THE ORGANIC MATERIA MEDICA OF THE BRITISH PHARMACOPŒIA SYSTEMATICALLY ARRANGED; together with Brief Notices of the Remedies contained in the Indian and United States Pharmacopœias. By W. SOUTHALL, F.L.S. London: J. and A. Churchill. 1874. From the Author.

PROCEEDINGS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION at the Twenty-First Annual Meeting, held at Richmond, Va., September, 1873, also the Constitution and Roll of Members. Philadelphia. 1874.

THE SPECIFIC ACTION OF DRUGS ON THE HEALTHY SYSTEM; an Index to their Therapeutic Value, as Deduced from Experiments on Man and Animals. By ALEXANDER G. BURNESS, M.B., etc., and F. J. MAYOR, M.R.C.V.S. London: Baillière, Tindall and Cox. 1874. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 1st May, Mr. Henry Fowler, Pharmaceutical Chemist, of Great Torrington, Devon. Mr. Fowler had been a member of the Pharmaceutical Society since 1853.

On the 13th March, 1874, Mr. John Griffith Hughes, Chemist and Druggist, of Thornbury, Gloucestershire. Mr. Hughes was a Member of the Pharmaceutical Society.

On the 24th April, 1874, Mr. Capel Thomas Lechmere, Chemist and Druggist, of Fown Hope, Herefordshire.

On the 25th April, 1874, Mr. Charles Quested Baker, Chemist and Druggist, of Margate.

On the 22nd March, 1874, Mr. F. De Carle Smith, Chemist and Druggist, of Norwich.

On the 10th May, 1874, Mr. Joseph Brayton Mossop, Chemist and Druggist, of Longsight, Lancashire.

Notes and Queries.

THE ACID OF BALSAM OF TOLU.—Various statements have been made as to the organic acid obtained when balsam of Tolu is digested in boiling water; it being usually represented to be a mixture of benzoic acid, with more or less cinnamic acid. By treating some specimens of crystallized acid so obtained with a titrated alkaline solution, and making a calculation based upon the respective equivalents of the two acids, M. Carles has come to the conclusion (*L'Union Pharmaceutique*, xv., 82) that it does not consist of a mixture, but is pure cinnamic acid.

CEMENT FOR AFFIXING LABELS TO TIN OR OTHER METALLIC SUBSTANCES.—Mr. E. B. Shuttleworth has found (*Canadian Journ. Pharm.* vii. 306) that the incorporation or trituration of dry wheaten flour with a mixture of tragacanth mucilage and honey improves its tenacity for the above purpose, and causes it to dry more quickly:—

Tragacanth mucilage. . . .	10 parts.
Honey.	10 „
Dry wheaten flour.	1 „

FLUORESCENCE OF THE ACID RESIDUE FROM THE MANUFACTURE OF ETHER.—The extraordinary fluorescent appearance of the sulphuric acid remaining at the close of the operation of making ether is referred to by Mr. E. B. Shuttleworth (*Canad. Journ. Pharm.* vii. 306), as likely to be of interest to those engaged in researches on fluorescence. The fluorescence of this residue is very intense. Viewed by reflected light, the liquid is of a deep green colour and appears to be perfectly opaque; by transmitted light it is brownish red. The degree of fluorescence appears to be influenced by impurities in the alcohol treated by the acid, the intensity increasing with the proportion of impurities present. Methyl compounds, especially, have an intensifying effect.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE ADDITIONS TO THE PHARMACOPŒIA.

Sir,—I am amazed at the excessively irate and personal tone of Dr. Redwood's remarks on Wednesday evening last. The discussion upon the Addendum was, it must be admitted, in the main, adverse to the new work. Dr. Redwood, it seems, attributes some of the criticisms to some sort of animus, or piqued or jealous feeling. When such eminent pharmacists as Mr. Williams says that in the formula for acetic ether, the only chemical in the Addendum, "there was an omission of a serious nature;" when another equally accomplished pharmacist states that "the description of acetic ether in the Addendum is inaccurate;" when Mr. Martindale says of one preparation that the mode of conducting the process is "positively deleterious," and stigmatizes another form as one of a "misleading character;" when another gentleman, Mr. T. H. Williams, had tried for several hours to make carbolic acid suppositories according to the Addendum, and had completely failed; when, in point of fact, every speaker had some objection to raise, or unfavourable comment to make; and when, on the other hand, not a single voice—save Dr. Redwood's—is raised in defence of the Addendum, clearly enough such an unanimous consensus of opinion cannot reasonably be set down to any personal feeling whatever, but must have a much more solid basis than Dr. Redwood would fain believe. That the Medical Council, cognizant of the great value of the Doctor's assistance in the compilation of the British Pharmacopœia, very much relied upon the learned professor to arrange the practical portion of the Addendum is highly probable; and the Doctor, knowing this, possibly feels very much annoyed that the whole thing is not quietly swallowed, without fuss or comment, like a sugarplum, by the whole body of pharmacists.

I see no other explanation of the Doctor's dislike to the criticism and free handling the Addendum has received. Such weakness as that displayed by Dr. Redwood when he asserts that the critics are actuated by "an animus most clearly explained" by their "not having had a finger in it" is almost incredible in one occupying so exalted a position, and would be unpardonable in any one else. If these remarks are in any way intended to apply to me, I give them a *most emphatic denial*. I had neither expectation nor desire to be consulted respecting the contemplated Addendum. This is obviously the *rôle* of those veteran pharmacists whose practical experience is far more extended than mine, and consequently of far greater value. At the same time I shall always reserve to myself the privilege of criticizing, in any way I may think fit, either the Pharmacopœia or its Addendum, notwithstanding Dr. Redwood's somewhat rude insinuation.

And now, just a word as to my note. It was written offhand, and perhaps on that account does not possess that ponderous, somnolent, dreary decorum of language the usages of our evening meetings seem to demand. However, as the wording has in it nothing worse than a vein of banter, plainly to be seen—of course very uncommon, and doubtless to many minds highly improper on such solemn and momentous occasions—I can only express my regret that the same has, very unintentionally, been the cause of so much irritation. ὃ γέγραφα γέγραφα.

Not a single word or phrase was intended by me to disparage the great services rendered by Dr. Redwood; indeed, I hope I have too much respect for a veteran pharmacist, no matter how much I may differ from him, to permit such an idea to enter my mind.

Putting aside the phraseology, the gist of my note was in accordance, I believe, with the views of the most practical

pharmacists. 1st, That the Addendum is not up to the mark, that it contains grave errors, some omissions, and many useless forms. 2nd, That the time has arrived when the abilities of the most accomplished men amongst us, could, with manifest advantage, be made use of in the important matter of compiling a Pharmacopœia.

Dr. Redwood takes special exception to my remarks on the pepsine formula, dubbing them "disgraceful." I see nothing "disgraceful" about them, and, to my mind, they are certainly not a tithe so "disgraceful" as the ill-judged and out-of-temper speech of the Doctor. Turning to page 864 of the present volume of the Journal, Dr. Symes says of this same formula, that "the worst form had been chosen," "the process for its preparation was exceedingly crude, and the product disgusting." This is just what everybody knows, who has had anything to do with pepsine.

EDWARD SMITH.

THE NEW PREMISES OF THE NORTH BRITISH BRANCH.

Sir,—At the last meeting of Council in Bloomsbury Square, Mr. Williams is reported to have said that his reason for bringing forward the matter of the change of rooms contemplated by the North British Branch, was the statement made by one of the gentlemen who formed the late deputation to London, "that in the new premises there would not be accommodation for conducting the examinations, especially in practical chemistry."

The subject was only incidentally alluded to at the meeting in London, and this may explain the cause of misunderstanding; but most certainly any expression of opinion by the deputation, consisting of Mr. Tait and myself, as to unsuitableness of premises, referred to those at present occupied by the North British Branch, and not to the new premises.

The undersigned are quite at a loss to account for the erroneous impression made on the mind of Mr. Williams, and they cannot help expressing regret that such a misunderstanding should have arisen.

WM. GILMOUR.
WILLIAM TAIT.

Edinburgh, 12th May, 1874.

THE REMUNERATION OF ASSISTANTS.

Sir,—The remarks made by Mr. Young in his Presidential address commend themselves not only to the future but the present generation of Chemists. It is a bitter satire that young men should be asked to give an utterly disproportionate amount of time and money to arrive at a position in which they will be badly paid for responsible duties which, from late hours, are made unnecessarily irksome to them. It is very obvious from the paucity of assistants that many young men have and are quitting so beggarly requited an occupation; and the exceedingly limited number of educated lads coming into the business is equally evident. The principals, with very truth, say they cannot afford to pay more; and until they show more respect for themselves than is evinced by the present miserable system of petty charges for skilled labour, and the small-souled jealousy of one another gives place to feelings of a less selfish character, they are not likely to be able to do so, even if all the letters of the alphabet were appended to their names.

With the exception of a small number of men residing in fashionable localities and well-to-do towns, the majority of Chemists live by a trade: and not one hundredth part of the information insisted upon, can or ever will be applied to the trade (for such it is) of Chemist and Druggist. Do we then work to live and keep our families? or is the contemplation of symmetrical rows of extract pots and tincture bottles, containing the choicest results of pharmaceutical skill, sufficient to afford sustenance for the souls and bodies of the Pharmaceutists of the future? I fear this would neither keep the wolf nor tax collector away from the door.

Let some amount of consistency be shown on this education question, or we shall find we have improved the Chemists' Assistant off the face of the earth and be left to drudge alone ourselves.

A PHARMACIST.

THE SALE OF BENZINE.

Sir,—There is a section of the Petroleum Act under which druggists may keep Benzine without a licence, provided it is kept in vessels holding not more than a pint and that the aggregate quantity does not exceed 3 gallons. I took occasion recently to enquire of my Insurance Company if I might keep Benzine, under the above condition, under my policy of "single hazardous" insurance. They replied in the negative, and on a second application refused to allow me to keep even so small a quantity as one dozen two-ounce bottles. So that it appears, wishing to keep Benzine, I must either pay more insurance or render my policy void by violating its conditions; the quantity of Benzine I sell being very small.

Under the above circumstances, I have decided to give up the sale of Benzine and at present sell another article. What have my brother druggists to say on this subject?

CHEMICUS.

[**** In order to avoid the risk of vitiating his policy, we think it would be advisable for "*Chemicus*" to ascertain whether the objections of the Insurance Company to Benzine extend also to the other article,—which is probably a preparation consisting mainly of the light spirit of petroleum.—ED. PH. J.]

"LEGS" *versus* "EXAMINATIONS."

Sir,—I was very glad to see a letter from "Zaccheus" on the above subject, as I have reason to believe there are many pharmacists who would do well to show greater partiality for examined men than for six-footers.

The latter class of gentlemen, knowing that they can always obtain a good situation, with salary to match, are sometimes, and I think very frequently, tempted to defer going through the examinations, until, perhaps, they are little inclined for study; so *they* are not much benefited by this favouritism on the part of men in business.

Talking to an assistant (age about 25) whose chief qualification lay in his having attained the height of 5 feet 11 inches, I presumed to look up and ask him when he intended to get through the "Preliminary, etc." "Oh," he replied, "I shall do all three at once when I want to go into business," giving me at the same time the names of some of the leading London chemists, who, he said, would just as soon engage an unexamined man as an examined one. However, I have not seen his name in the Journal since I spoke to him, and that is two or three years since.

Why is it, too, that chemists having branch businesses will sometimes place in them unqualified gentlemen to take charge of them? Is the only answer to be "legs?"

Perhaps some of our enlightened chemists would take advice from a little fellow, and think on these things.

EXCELSIOR.

X. Y. Z.—(1) Composition and parsing. (2) We do not know. (3) The examination begins and ends on the same day. (4) *Chrysosplenium oppositifolium.*

"*Excelsior.*"—There is no limitation of age until the 31st December, 1874, but after that date no person is to be "admitted to the Major or the Minor Examination who shall not have attained the full age of twenty-one years."

A. B. C.—It may be ordered through most stationers or booksellers.

W. T. Green.—15 to 20 per cent.

"*Inquirer.*"—Benzol is used for this purpose; and the light oil of petroleum, or coal oil, would probably be equally serviceable.

"*Asbestos.*"—No.

J. B.—According to the Calendar, rather more than three hundred.

X.—(1) See the answer to "*Excelsior.*" (2) There is no law at present to prevent him doing so.

A. P. S.—We understand the meaning of the statement is as you suppose.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Wellborn, Mr. J. A. Cope, Mr. A. Wilson, Dr. Macadam, Mr. F. Dicks, "Erin."

THE ANNUAL DINNER.

The Third Annual Dinner of the Members and Friends of the Pharmaceutical Society took place on Tuesday, the 19th, and was in every respect equally successful with its predecessors. The scene of the festivities was, as heretofore, the saloon at the Crystal Palace; and it would indeed be difficult to find a more eligible spot for this annual reunion than the spacious and elegant room at the south end of the Palace at Sydenham. The chair was occupied by Mr. T. HYDE HILLS, President, who was supported on the right and left by Dr. Greenhow and Victor De Meric, Esq., President of the Medical Society, and there were also present Dr. Langdon Down, Professor Redwood, Professor Bentley, Dr. Richardson, Mr. Henry Watts, etc., etc. The number of gentlemen present was 237.

Grace having been said by the Rev. J. Nicholson,

The PRESIDENT then said: As this meeting is for social intercourse and enjoyment, it is not my intention to give many toasts, or to bore you with long speeches. But there are certain toasts which we as Englishmen and Pharmacists feel it our duty, as well as our pleasure, to observe, the first of which is—"The health of Her Majesty our Queen." Her Majesty takes so much interest in everything that elevates and improves the condition and adds to the prosperity of the people, and has so much consideration for the welfare of her subjects, that I feel sure the toast will be received most heartily. Before giving it, I will venture to allude to the marriage of the Queen's second son, His Royal Highness the Duke of Edinburgh, with the only daughter of our Imperial guest, the Emperor of all the Russias, an alliance which I hope will not only be for Her Majesty's comfort and happiness, but also one to promote the advantage and mutual good understanding between the two countries, as well as that of the whole world. The toast is—"Her Majesty our Queen," with three times three.

The toast having been drunk with enthusiasm, the President said the next toast I have the honour to propose is that of "Their Royal Highnesses the Prince and Princess of Wales, their Royal Highnesses the Duke and Duchess of Edinburgh, and the other members of the Royal Family." The Royal Family are much amongst us, doing all they can, and interesting themselves on all occasions for the advancement of science and art, and the education of the people; besides this, they exert themselves in trying to improve the condition of the necessitous and unfortunate, and I am sure you will agree with me that they all fill their respective positions with much credit to themselves and great advantage to the community. I therefore give you the toast—"Their Royal Highnesses the Prince and Princess of Wales, their Royal Highnesses the Duke and Duchess of Edinburgh, and the other members of the Royal Family, wishing them all health, happiness, and prosperity," with three times three.

The Vice-President, Mr. ALEXANDER BOTTLE, proposed the next toast "The Medical Profession." He said no one in the room could hold in higher honour than he did the profession to which they all owed so much; a profession whose members were always with them in time of sickness, and even at the closing scene of all, and whose duties were in his view second in importance to none. Without saying one word in disparagement of the army or the navy, he would claim for the medical profession that its duties were equally onerous and equally well performed. During the last few months they had heard a great deal of the gallant army which had done so much at Coomassie: but did not the medical staff attached to that expedition do as much as either the army or navy? Did not they face yellow fever, and death in all its forms, equally with any other branch of the service? In the House of Peers the Church, the Army, the Navy, and the Law were represented, but where was the Medical profession? Was not that profession equally entitled to be represented in such an assembly? He hoped the day was not far distant, therefore, when members of the medical profession would hold life peerages, at any rate, and take their places side by side with the others he had mentioned.

Mr. VICTOR DE MERIC, in responding, said he could only do so, in the presence of so many other members of the profession, as the representative of one of the oldest medical societies in the metropolis. The speech of Mr. Bottle had aroused a new ambition in his breast, and if the prospect of a peerage was as yet not very near, he could not but feel flattered at the way in which the toast had been proposed and received. It showed the goodwill existing between the two professions, which might indeed be said to go hand in hand, neither being able to go without the other. The medical profession had certain duties to perform, and he hoped they discharged them on the whole with credit to themselves and for the benefit of the public at large, but they would be helpless without the aid of the pharmacist. There had been times in the history of the medical profession when it had been attempted to relieve them from all necessity for seeking the aid of the pharmacist. There was a time when every disease was to be cured by cold water; and there was another time when infinitesimal doses were advocated; and what would have become of pharmacy if rational medicine had not triumphed? Fortunately good sense and reason had triumphed, and both professions still went hand in hand together. He considered it a great honour to the members of the Pharmaceutical Society that they owed their present standing and position before the world entirely to their own voluntary exertions, which could not be said of any of the medical corporations, all of which had been founded by monarchs or governments. In behalf then of his friends and himself, he begged to return his most hearty thanks for the kind manner in which the toast had been received.

Dr. GREENHOW said it was his privilege to propose the toast of the evening—"The Pharmaceutical Society of Great Britain." It was one which deserved to be well received; and, from the position he occupied in relation to it, he was able to confirm, and even to add to, what had been so well said by the preceding speaker. The Pharmaceutical Society was about entering on its thirty-third or thirty-fourth year, and had therefore attained mature age. After many years, during which the Society had endeavoured to raise the calling of the pharmaceutical chemist by means of voluntary examinations, but during which persons were allowed to exercise that calling without any qualification whatever, and the business was, in fact, in many country towns monopolized by grocers, the Government saw fit to entrust to the Society the duty of examining all who should in future commence business as chemists and druggists; and, in order to provide an additional guarantee that this duty should be properly performed, had further seen fit to appoint a Visitor of these examinations, and the choice of the Privy Council had fallen upon himself. He had accepted the appointment with some little hesitation, feeling the position to be a somewhat invidious one, but his experience of the last five years had shown him that his fears were groundless. Not once had he had occasion to express disapproval of any proceedings on the part of the Board of Examiners; on the contrary, they had conducted the examinations in the most admirable manner, not beginning too stringently, but gradually, year by year, improving the examinations, until very shortly they would be everything which could be desired. He had found also that, so far from being looked upon as a spy or an intruder, his visits had been welcomed, his suggestions had been cordially received, and his position had enabled him to form many valuable friendships which he hoped to retain even after his official connection with the Society had ceased. He had often had occasion to remark and admire the wonderful patience and good feeling with which the examiners went on examining men whom they knew would be infallibly plucked. He had for his own part always endeavoured to co-operate with the Society in carrying out the true intent and meaning of the examinations, viz., that every man who undertook these duties, so important to the public and the medical profession, should be properly qualified; and, these duties being practical, he

was glad to see that the examinations also had become more practical. They wanted gentlemen who were perfectly masters of the British Pharmacopœia, conversant with drugs, able to distinguish the genuine from the spurious and the pure from the adulterated; and also able to ascertain, by testing, the nature of chemical substances, and to determine by volumetric analysis the strength of certain solutions which were liable to variation. All these were points which the examiners had borne in mind; and, seeing how well they had begun, he might venture to predict that they would go on well, that there was a great future before the Society, and that the calling would ultimately be raised to a position it had never held before, except in the case of a few princely houses in the metropolis. There always had been men of science, and of eminence, in the pharmaceutical body, men who had taken their place side by side with the first men of science of the day; and he doubted not that this which had hitherto been the exception would hereafter become more frequent. He was heartily glad to see that two gentlemen out of the fifteen selected by the Royal Society for the honour of a fellowship this year were pharmaceutical chemists, a matter of which the whole Pharmaceutical Society might well be proud. In conclusion he begged to couple with the toast the name of the President, Mr. Hills, whose genial and sterling qualities were known to all.

The toast having been drunk with great enthusiasm,

Mr. Thomas Hyde Hills said: On behalf of the Pharmaceutical Society and myself, I beg to thank Dr. Greenhow for the kind manner in which he has proposed the toast, and the hearty way in which it has been received. Having commenced the evening by telling you that I did not intend to bore you with long speeches, I shall adhere to what I said, the more so as most of the gentlemen here are members or associates of the Society, and consequently must know the position and working of the Society as well as I do. At the same time I will remind the company that, although much has been accomplished, much remains to be done; and we must not relax our efforts to carry out the original design of the founders, of having every dispenser of medicine an examined man. I therefore call upon you to support the executive of the Society in carrying out the work so ably commenced by the founders, many of whom, I am sorry to say, have been taken from among us since our last anniversary.

Dr. Richardson, F.R.S., in proposing the last toast, said: If "to do good by stealth and blush to find it fame" were a worthy ambition, it certainly had been fulfilled by the body whose welfare he had to propose, "The British Pharmaceutical Conference." He well recollected the birth of the Conference at Newcastle, having just then been emancipated from the throes of a long research into the physiological action of a very important chemical body—nitrite of amyl. As he was leaving the lecture room, he heard for the first time that a section of the Pharmaceutical Society was about to devote itself to the study of scientific pharmacy by means of a yearly meeting. He little thought at that time, and he believed few of his own profession thought even now, of the wonderful labours which had since been performed by that Conference. But those who had watched the change in pharmaceutical matters during the last twenty or thirty years had seen something really startling. The alligator stuffed was gone, Friar Lawrence's basket was forgotten, and the old gentleman who mixed snuff with his liquorice powder was heard of no more. On entering a pharmaceutical establishment now you found everything well ordered, the chemicals well arranged, and a dispatch before unknown. On talking to the dispenser, you found him, as a rule, equal in his own way to other men of science—a man who could speak on chemistry on equal terms, and sometimes even better than the physicians themselves, who could define drugs by their chemical formulæ, who could give you information with regard to botanical history, and who might perchance touch on the physiological ground, and point out with acumen not only who were the men who were advancing medicine by a study of therapeutics, but also the experiments by which these sciences were advanced. What was the cause of this remarkable advance throughout all parts of England? It needed only a glance at the transactions of the Pharmaceutical Conference, and the whole thing was plain. After looking over the series of questions proposed for investigation, he could say that no Society, not excluding the Royal Society itself, was showing in a more simple, manly, or business-like way the progress of science than the Pharmaceutical Conference. Many men of science were not sufficiently men of business, and in their scientific pursuits failed to keep a faithful and accurate record of their work; but this business element, which pharmacists could not escape from, seemed to him to enter so forcibly into their scientific work, that it would by-and-by make their investigations of greatest importance in all matters relating to therapeutical medicine. In wishing success to the Conference, therefore, he was only wishing success to his own profession, and he must repeat Dr. Greenhow's congratulation at the election this year of two members as Fellows of the Royal Society. A former President of the Conference, Mr. Daniel Hanbury, was a distinguished Fellow of the Royal Society; and he well recollected that gentleman putting into his hands, at the meeting of the British Association at Exeter, the first specimen of chloral which reached this country. On the success of pharmacists depended largely the success of the physician. Those who were experimenting in medicine felt day by day, and hour by hour, that without the aid of the pharmacist, to produce for the world the weapons which they (the experimentalists) forged, they never could be practically successful. He was sure that if the whole profession of medicine were present, they would join with him in wishing "Success to the Pharmaceutical Conference." He begged to couple with the toast the name of the Treasurer, Mr. Schacht.

Mr. Schacht, in responding, said he much regretted the absence of the President, Mr. Groves, not only because he was one of the brightest ornaments to pharmacy, but because if he had been present it would have fallen to his lot to have responded to this toast, which had been so flatteringly proposed by Dr. Richardson. He (Mr. Schacht) did not quite understand why, as Treasurer, he should be called upon, unless it was considered that, having so little to do he must have something to say. However, he highly appreciated the honour of being allowed, even for a few minutes, to represent that which he considered to be a most important section of the pharmaceutical body; though he could not help feeling during Dr. Richardson's speech something like a twinge of conscience. He had been more than once credited with being the parent of this Conference, and with so fair an offspring it was only natural that he should cling somewhat tenaciously to every title which he might possess to such a distinction. At the same time, his original idea was not precisely that which subsequently obtained; it having been rather that the Pharmaceutical Society itself should peregrinate, and that as it visited the various great centres of pharmacy throughout the country it should put forward for discussion all subjects in the least degree interesting to pharmacists. Other men, however, took up the subject, such men as Brady, Reynolds, and Attfield, all of whom, he was sorry to say, were absent on that occasion, and they saw a possible way of escaping from the elements of difficulty, if not of danger, which appeared to attach to his original proposition, by separating the subjects which might have involved difficulties from those which were free, and they had more or less carried out their object. He, however, true to his old instinct, had been, he feared, somewhat guilty of marring their intended efforts in that direction, having been as great a sinner as any in introducing discussions on subjects which were not simply scientific; still, he hoped no great mischief had been done up to the present time, and he was anxious now to make somewhat of a recantation of his old doctrine—having come gradually to the con-

clusion that it would be very much better for the interest of pharmacy if the operations of the Conference were more limited to subjects of a purely scientific and practical value, avoiding any discussion of those allied subjects which, for distinction, might be called pharmaceutical politics or ethics. He was all the more inclined to say this after what they had just heard, which was extremely gratifying, that their labours in a pure scientific direction had been recognized outside of their own body, at the hands of the medical profession, and more eespcially by that section of it which was itself distinguished for its scientific reputation. He could not help thinking that there was a great and high future for the Pharmaceutical Conference, and that that high altitude would be obtained by their devoting all their energies to the pursuit of pure scientific pharmacy.

During the evening the band of the Royal Horse Guards, under the direction of Mr. Charles Godfrey, played a choice selection of music.

THE COMMITTEE ON THE ADULTERATION ACT.—EVIDENCE RESPECTING THB SALE OF DRUGS, ETC.

Some important evidence was given on Thursday last before the Select Committee of the House of Commons, appointed to inquire into the Adulteration Act, as to the adulteration of drugs, and as to the manner in which chemists and druggists have been, and are likely to be, affected by the operation of the Adulteration Act. Mr. CLARE READ presided.

The first witness examined was Mr. HORNER, who, in reply to the Chairman, said: I am a wholesale druggist, more especially connected with imported goods than manufactured articles. It appears that under the Act it is not necessary that a guilty knowledge should be proved to constitute the offence. Many drugs are imported into this country in an impure condition; few, indeed, as imported, would be absolutely pure. For instance, take such an article as scammony; 80 per cent. of resin in it would be considered very good. This article is used principally as a purgative in combination with other things. Considering the countries where these drugs are prepared, you can scarcely expect the natives to take such care in the collection of the article as would prevent any extraneous mixture getting in. Absolute purity is almost an impossibility. It would be incorrect to say that the bulk of the articles are intentionally adulterated, because in many cases the adulteration creeps in during collection, while many articles are adulterated in other ways. Opium is adulterated. There is a sale of opium in the City to-day, which is adulterated; if pure, the article would be worth 32*s.* per pound, but, as it is not pure, it will sell for about 7*s.* 6*d.* per pound. It will be bought by morphia makers, who will make as good a commercial article out of it as though they paid a higher price. Musk is imported much adulterated. As to resins and gums, it is also a fact that they come into this country much mixed with other ingredients—others kinds of gums. Gum arabic I may instance. I think a most important article to be taken is sulphate of quinine, because it is so largely used. It was formerly made from one description of bark—calisaya. Now a great number of other kinds of bark are brought to this market, containing a very much smaller amount of quinine, but they are sold for their value, and the quinine is extracted from them. If you were to prohibit the use of such bark, the country would go without quinine, because the bark from which it is supposed to be got does not exist in sufficient quantity. There are some drugs imported into this country which are certainly impure—some by accident, some by the process of manufacture, and some by the fraud of the original collectors. I think that the articles most adulterated are liquids—essential oils. They are more easily adulterated, and have been especially so since there have been no duties. When there were duties upon these articles, the merchant who imported them did not care to pay the duty upon a low quality of article. There is no doubt those duties were a great protection at that time. Still, we should not like to go back to them. In my opinion, the Adulteration Act presses harshly upon the vendors of goods, though, as far as the wholesale houses are concerned, the operation of the Act has not been felt by them; but we have seen cases where it has pressed hardly upon those who dispensed medicines. Some chemicals are liable to rapid decomposition. The retailer has been the person who has been injuriously affected by the Act. In regard to protecting him from selling an article which has been adulterated abroad, I think the retailer seldom gets an article in that state, as the wholesale houses take care to supply him with an article of good quality by assorting these goods for him. For instance, myrrh, brought here in its original state, will be mixed with several kinds of gums; but the retailer does not get these, as the gums are eliminated. Without the intervention of the wholesale houses, I do not suppose the retailer would ever be able to get a really good article. The wholesale dealer acts as a protection to the retailer, to a great extent, against adulteration. I think it should be necessary in these cases to prove a guilty knowledge on the part of the seller. I don't think there should be any prohibition of these adulterated drugs coming to this country. London being the great drug-market of the world, to do that would probably put difficulties in the way of business and would greatly interfere with trade. The greater portion of these drugs are re-exported, not taken for home consumption. The United States consume drugs largely, and get them from this country. I am not sufficiently cognisant of the matter to be able to suggest any alterations in the Act. I think there should be somebody or other to whom the discrepancies of analysts should be referred. The analysts are very uncertain in their operations. I think referees should be appointed, who ought to be consulted and give advice before prosecution. As to the sort of referees, if there were three or four competent persons appointed, one by Government, I think it would be a good thing, and they should all be chemists.

Examined by Mr. WELBY:—As to the methods of collecting these articles, a great many of them are brought from very out-of-the-way places, India or Arabia, and probably there are various trees producing gums in the same place, and the drugs are collected in a very careless manner. With regard to the barks from which quinine is extracted, they are not sold as quinine. The quinine is extracted from them. I do not think there is any adulteration after the goods leave the importer.

Examined by Sir H. PEEK: I am not aware that there is a laboratory at Somerset House. The oil from sweet and bitter almonds is very different. When the sweet almonds are the dearer, bitters are mixed in, and *vice versâ*, and it is perfectly impossible by the eye to distinguish the sweet from bitter almonds. There is a large consumption of opium in this country, but not in proportion to the population. The consumption of opium is nothing like so large here as it is in the United States. Of course the principle of opium is morphia. That is nearly all made in this country. I cannot say anything as to whether a person taking a dose of London-prepared opium and a dose of Scotch opium would get twice the strength in the former case.

Examined by Mr. GARNIER: Scammony is a great deal adulterated before it comes to England. I don't think it is adulterated here. There have been some prosecutions at Glasgow, and fines were, I believe, imposed. It came out there that out of seventeen samples of scammony none were pure. The commoner kinds, called skillet, contain 60 or 70 per cent. of flour.

Examined by Mr. MUNTZ: I certainly think it is desirable that a prescription made up in one part of the country should have the same effect as that made up in another part. I believe it is a common case not to find it so. There are large manufacturers of medicines from

drugs in this country. These medicines are made for London, for the provinces, and for exportation. I do not know the relations of purity in the goods made for London, the provinces, or for exportation.

Re-examined by Sir H. PEEK: The object of the manufacturers in using goods of low quality is to produce an article at a low price. The Government use, for postage-stamps, etc., the cheapest kind of gum—dextrine—but I cannot say that some of the gum is so bad that people have got disease of the mouth through wetting the stamps with their tongue.

Mr. HODGKINSON (Aldersgate Street), examined by the Chairman, gave the following evidence: I have heard the evidence of the last witness as to adulteration, though I should not call it adulteration. It is more of a mixture—mixed accidentally. There is a certain amount of mixture in scammony which is not adulteration. As far as we are concerned, the Act does not touch us at all. Generally speaking, with regard to the adulteration of drugs, it is done abroad; though, of course, there are people who are mean enough to adulterate their things here. Opium is very largely adulterated abroad. As mentioned by the last witness, there is a sale in the City to-day of opium which will not fetch more than one-fourth of the value of good opium. I would not prohibit the importation of these impure drugs, because that would drive them away from this market to some foreign market—Hamburgh, perhaps—and the drugs of this country would be in a worse position, because the very best as well as the worst sorts come here; but in that case we should have to depend upon the Continent, and we should not be able to choose the best sorts, which are now usually retained by the merchants in this country. The most impure qualities are purchased for abroad by foreign buyers. The foreign buyers are more numerous than the English buyers. I agree with Mr. Horner that the wholesale dealers are the means of procuring for the retailer better goods. The great number require assorting before they are of any use. Myrrh, for instance, consists of all sorts of gums. These are all cast out, and the retailer only gets myrrh. The same remark applies to several other things. I have no fault whatever to find with the Act, and, so far as we are concerned, its operation has not been in any way injurious.

Examined by Mr. MUNTZ: Since the duties have been taken off, London is the great drug-market for the world. I do not think it is at all desirable to have any inspection or interference with the trade at all. At the same time I agree that the prescriptions made up in one part of the country should have the same effect as in another. There is much more equality than there was formerly—say ten years ago. As a rule you will find that prescriptions are much the same in one place as another. In this respect there has been a great improvement of late years. I assume adulteration as being quite a distinct matter from accidental mixture. We get drugs from abroad in both these conditions,—drugs accidentally mixed, not pure, but still a fair standard of quality. On the other hand, we get them notoriously adulterated.

Examined by Mr. COLMAN: The Act does not touch our trade at all. It touches the retailer, not the wholesale dealer. The Act practically passes over the wholesale man, and seizes upon the retailer.

Examined by Viscount BARRINGTON: My view of adulteration is that it is a thing purposely done for the sake of increasing profits. An article may not be pure, and still not be adulterated, because the mixture may be accidental, and not to any great extent. If we received these drugs impure, we should try that they did not get to the retailer in that way. Chloroform, I should say, is not adulterated. I never heard of chloroform being sold which contained little or no chloroform, and if there had been such a thing, probably I should have heard of it.

By Dr. BRADY: There is a good deal of opium consumed in our fen counties, but not so much as formerly, the sanitary state of the country having been improved. The class of opium consumed there is fully up to the ordinary standard. The retail druggists do not adulterate their goods. I should say that druggists, as a body, are much too respectable for anything of the kind. The fact of prescriptions differing to some extent, may be accounted for by the drugs becoming stale.

By Mr. BACKHOUSE: I do not believe there is any extensive system of adulteration carried on in this country, either by the manufacturer or seller.

By Mr. GARNIER: Alluding to the case of scammony adulterated with flour, I do not think any respectable druggist has any business with it, unless he may have some nostrum of his own in which he may mix the article, and that is the way the cheaper kinds of scammony are got rid of. I am aware of one druggist having been fined at Glasgow for selling scammony adulterated with flour. I have not heard of any convictions in London.

By Sir H. PEEK: I should not call accidental mixture an adulteration. If scammony only contained 78 per cent. I should not call it an adulterated article, though I should say it was not up to the standard. But it would not necessarily be adulterated. It would be worth no one's while to reduce an article two per cent.

By Mr. HEYGATE: The relations of opium are uniform now, and have been since 1867. Calomel is the same thing all over the country.

By Mr. WELBY: The country chemist in a small town may not have such advantages as the London chemist, who conducts a larger business, and has a better selected stock, and his articles are fresher. Still, I think there is very little difference between them. A good country druggist would supply you with drugs of equally good quality as those you would get in London. He certainly might easily do so if he chose to take the trouble.

By Sir H. PEEK: Expensive drugs do not deteriorate so much. Opium would be opium years afterwards, though it might get drier. Castor oil is frequently placed by chemists so that the rays of the sun may draw the colour out, but, supposing the bottles were to stand there for a couple of months, it would not alter the medicinal properties of the article.

By Mr. MUNTZ: Ipecacuanha, properly kept, would keep a long time, though if not thoroughly dried it would become mouldy. James's powder, such as used in the navy, would not be adulterated. A country chemist, if he were a respectable man, would not sell another article for this.

Re-examined by Mr. WELBY: I do not think country druggists are considered so much inferior to those of London. The country druggist can get the best article if he is disposed to pay the price. It depends entirely upon the man himself. If he is a good druggist he will give you quite as good an article as you will get in London. In London, you are quite as liable to get the very worst article as you are in the country. Less drugs are now purchased from the grocers in the country, because the grocers have no right to sell drugs, and I think the sale of drugs has been taken out of their hands almost entirely since the Pharmaceutical Society obtained its charter. The grocers' drugs were very inferior to the druggists', as they kept them so long that they spoiled.

By Dr. BRADY: We send a great deal of drugs to Ireland. In Ireland there are the apothecaries, who are allowed to dispense prescriptions, and the chemists, who are not allowed to dispense. From the apothecaries you can get very good drugs. The chemists there buy cheaper things to sell to the poor.

Sir H. PEEK: If I understand this gentleman right, an article which the druggist may lay in perfectly pure, for want of sale, twelve months hence may render him liable to prosecution.

Witness: I do not go so far as that. That is an extreme case. He may keep an article long enough to deteriorate. He would be punished then, I suppose, not for the badness

of the article, but for his want of judgment in not throwing it away.

Mr. CARTEIGHE (Dinneford and Co., Bond Street) was next examined by the Chairman. He said: I am a pharmaceutical chemist. With regard to the deterioration of chemicals and pharmaceutical preparations, there are a certain number of very important articles which do materially deteriorate without becoming absolutely bad, from wanting in a certain strength, that strength being one of the properties for which the original substance was used or prescribed. That arises in the nature of things. A formidable article to mention is prussic acid. It is ordered that a weak solution of that article shall be sold of a certain strength—2 per cent. of hydrocyanic acid and 98 per cent. of water. Inasmuch as this acid is extremely volatile, it follows that such a preparation, unless it were kept in a sealed tube, would lose a portion of its volatile contents; and a medicinal preparation of prussic acid actually having been dispensed this morning might to-morrow morning be deficient in strength. Ultimately it may go on until there is none of the original acid in it. Chlorinated lime is also largely sold by druggists for disinfecting purposes. Its value depends upon the volatile constituent, chlorine, and this volatile substance disappears, day by day, as the jar is opened in the ordinary course of sale. Under the Act as it at present stands, it could be held that a druggist is liable for selling chlorinated lime which did not contain the standard amount of volatile chlorine. In other words, a *bonâ fide* seller might to-day sell this article which is fresh brought in from the manufactory perfectly good, and in a few days it would be a little less good, though not bad, and ultimately it would lose the whole of its volatile properties, if it had not been properly protected. There is a preparation of soda—chlorinated soda—which is used in medicine, and sold also for disinfecting purposes. It seems difficult and very hard, to insist that a druggist should be held responsible for the strength and so-called purity of an article so liable to change. Then there are a number of essential oils—essence of lemon is a case in point. It is a substance used in confectionery and in domestic cookery very largely, and it has the habit, if I may so express it, of changing into a substance closely allied to it chemically, but practically very different in itself. Under certain circumstances, it may change into or become contaminated with turpentine, and this change may take place within a comparatively short period, and may not come to the knowledge of the seller. Various essential oils used for flavouring are what we call oxidized, slowly burnt up. In short there are in the druggist's shop a certain number of articles which cannot, and, in my judgment, should not be liable to a hard and fast law. They can be only dealt with by the intelligence of the person who sells them; and there must be a certain margin of purity or impurity allowed, or a certain discretionary power invested in those who have to prosecute under these circumstances. Purity is quite a comparative term. As druggists, we have to do very rarely with purity. The Act assumes that there is such a thing as purity, but I submit that there is no such thing. Thus, as to pure water, it is very difficult to obtain it and retain it pure for any length of time. Therefore, I hold that purity is a comparative term as applied to water, and in a large measure to many of the preparations sold by druggists. In such a case as effervescent citrate of magnesia, there is a different signification attached to it by the public than in the chemical terms. Those names have got into use, and the public ask for the articles by the name which they have been accustomed to; and notably, as regards citrate of magnesia, a druggist was fined for selling an article which he presumed was the article required. In fact, druggists are, to some extent, the interpreters of the language of the public as between themselves and medical men, who use special technical names. Take the case of quinine. If a person came into the establishment with which I am connected, and asked for an ounce of quinine, he would not get quinine. He would get sulphate of quinine, that is to say, quinine plus something else. We should assume that to be the preparation required. It has certain advantages over other preparations, and it is the article mostly required, and popularly known by the public as quinine. Under the Adulteration Act I understand a case has been brought forward where a chemist has been fined or reprimanded for selling this sulphate of quinine for pure quinine. There is no fraud in selling these articles in their ordinarily accepted names, and it is in many cases a great convenience to the public. I think it is desirable that we should have a better definition of adulteration; it is a question of degree. As chemists, we cannot deal with it under any other head. It is desirable to appoint certain skilled persons, with proper chemical knowledge, as referees. I should say, if possible, a chemist with a knowledge of pharmacy, a medical man, and with him some technical man, possibly engaged in business connected with pharmacy. The Pharmaceutical Society has, since its establishment, done all it could to discourage the adulteration of drugs. Practically, the Pharmaceutical Society, since its foundation thirty-three years ago, has been the Adulteration Act for its own class, and has materially improved the condition of chemicals and pharmaceutical preparations throughout the country. The great object has been to educate the sellers, so that they might know something of the materials in which they are in the habit of dealing. With regard to the relative strength of drugs in different parts of the country, they should certainly be the same throughout the country. Before the year 1864, there used to be three distinct Pharmacopœias. The Phamacopœia is the orthodox book by which the dispenser of medicine works. By these books some of the preparations varied in strength, but in the year named, a book called the British Pharmacopœia, in contradistinction to those of London, Edinburgh, and Dublin appeared, and by an Order in Council, this was made the recognized book throughout the United Kingdom. Since then there has been a greater uniformity of preparations. There have been cases of hardship where the retailer has been prosecuted under this Act. These have been very serious for the chemists. As members of the Pharmaceutical Society, our view is that our reputation is worth more than that of an ordinary dealer. If a chemist is charged with what the Act calls adulteration, he loses the confidence of his customers, and loses his repute, even though he shows that there was no real adulteration; but it is so difficult to explain these technical matters to the magistrates, that the case may be withdrawn, or he may be convicted; as in the case of the citrate of magnesia, the seller was convicted of selling an adulterated article. If a chemist is indicted for adulteration his customers would think him incompetent, and fear that he possibly might poison them by making mistakes. In fact the question comes much further home as regards our class than as regards any other class; and, as members of a Society for the prevention of adulteration, we think it is rather hard that we should be at the mercy of a hard and fast clause of the Act, as it stands. As the Society has certain powers now, one way of meeting the difficulty would be, besides having skilled assessors, to allow the Pharmaceutical Society to proceed in the matter, and fine the delinquent in the first instance, and if he were very troublesome, strike his name off the Register. It is possible that the powers of the Society might be extended in this way with advantage. It should not be incumbent upon anybody to prosecute upon the mere certificate of an analyst. Supposing an analyst found there were 79 per cent. of resin in scammony, he would be bound to certify accordingly, and a prosecution might result, whereas there should be some person competent to say that there was in this case no adulteration. There should be either certain power in the hands of the Pharmaceutical Society itself, or some assistance got from it in these cases, or there should be a Central Committee, one member of which should be a

professional chemist, one a medical man, and the third a man knowing something of pharmacy, and with a business knowledge.

Examined by Mr. WELBY: As a matter of fact, any person coming to our establishment for quinine would get sulphate of quinine. The sulphate is a more manageable salt, generally used in chemistry. It is the quinine which is always ordered by medical men: the other is seldom used. The pure article would be a great deal dearer and more troublesome to manipulate.

By Sir H. PEEK: I am aware that there is a very good laboratory at Somerset House. I dare say that it might be made, with some necessary alterations, to answer the purpose of a central authority. I think the character of a chemist in these cases more valuable than the character of a grocer; because the grocer, if convicted, can set up again under another name, but the chemist has no such facility. There is no register of grocers. Whether a person be a grocer or a chemist, the mere indictment is the real evil.

By Mr. GARNIER: The Pharmaceutical Society has not made any suggestions as to the remedy of the Act in its corporate function. That would imply that the Society was averse to it, whereas it is most desirous to encourage the sale of pure things, and it is anxious to assist the Government in this respect.

By Mr. MUNTZ: Pharmacists are now an educated class. The assistants are much better than they used to be. There have been cases of poisoning of recent years. Accidents will occur. I think it would be a good thing for assistants of dispensers to pass an examination, as on the Continent. With regard to prescriptions dispensed in town and country, my experience has shown me, of late years, that there is no difference. There are perfectly competent men throughout the country who keep perfectly good preparations. Essence of lemon left to itself will turn into turpentine.

Mr. WILLIAMS, examined by the Chairman, said: I am pharmaceutical chemist and a manufacturer of chemicals. I agree generally with the evidence of Mr. Carteighe. I may explain that the use of technical terms must be taken in a wide sense. The use of certain terms is perfectly understood by chemists, but not understood by the public, and when they use them they generally make a mistake. I think we should have a definition of adulteration, so as to exclude those quibbling prosecutions which have taken place. Some of the prosecutions have been merely upon technical points, which have nothing to do with adulteration. I see no harm in using technical terms known to the public; in fact, they are necessary, as the public will not learn the more scientific terms.

By Mr. MUNTZ: Prescriptions should be made up exactly as medical men write, and in accordance with the Pharmacopœia. The effect of the prosecution in the citrate of magnesia case was that the man had to leave his shop, and the children cried after him, "There is the man who adulterated his drugs."

By Dr. BRADY: Since the establishment of the Society, the calling or profession of the chemist has gradually improved. The drugs which are now used are more carefully prepared than they were twenty or thirty years ago.

By Sir H. PEEK: The present system of analysing will never work satisfactorily. There are too many analysts, and they are not sufficiently remunerated for the onerous duties which they perform.

Mr. SANDFORD, examined by the Chairman, said: I am a pharmaceutical chemist. I see the necessity not so much to remedy the Act as the application of it. I think it is positively necessary that there should be a guilty knowledge on the part of the seller. Certainly I do not think it is wrong to sell preparations under their conventional terms. With regard to the citrate of magnesia case, there was no fraud at all. Wilful admixture should be punished. A better definition of adulteration should be decided upon. It would be advisable to have some referees, as has been suggested.

By Mr. MUNTZ: In scammony 80 per cent. is considered a high quality. If a druggist sold scammony containing only 40 per cent. he should be punished.

Sir H. PEEK: Can you imagine the analyst stretching a point to show himself a very clever fellow?—Yes, I can imagine such a case.

By Mr. WELBY: As we are subject to such penalties under the Pharmacy Act, it is only fair that we should not be liable under the Adulteration Act.

The Committee then adjourned.

At a previous sitting, on Monday last, the Committee took evidence respecting the adulteration of tea. Two witnesses—representatives of the tea trade—gave evidence generally to the effect that green tea must not be considered to be adulterated because it is "faced," that the analysts did not possess any very profound knowledge of the article, that they had in consequence most materially differed in their certificates of analyses, and that all tea should be examined in bond, and no spurious tea be allowed to pass into consumption. It was mentioned incidentally that the retailers do not adulterate, that the adulteration is performed in China, and chiefly is to be found in the Caper tea which comes from the Canton district. Mr. Cadbury, of Birmingham, then gave evidence with regard to the manufacture of cocoa. He is an advocate for the sale of pure cocoa, unmixed with sugar and farina, and contends that the ordinary cheap soluble cocoas should be classed under the category of "choco late," and should not be allowed to be sold as cocoa at all. In his opinion the addition of starch renders cocoa heavy and indigestible, and the cocoa would be better without it. He mentioned that in France the law enacts that the percentage of starch should be stated on a label, and he recommended that the same practice should be adopted in this country. He did not think it necessary that the proportion of sugar should be stated. With regard to the ingredients in soluble cocoas, he informed the Committee that there is about fifty per cent. of cocoa, about twenty per cent. of starch, and thirty per cent. of sugar. Pure cocoa, from which the fat had been extracted, was largely sold and consumed in this country, and he thought that the demand would increase. He did not believe that any of the leading manufacturers had been guilty of adulteration. By extracting the oil of the cocoa he gave it as his opinion that the value of the article was increased as a nitrogenous food, and that it was rendered more valuable as a flesh-former.

The committee, on the conclusion of this evidence, opened up entirely new ground, by commencing to explore the mysteries of the milk trade.

Mr. Barrow, manager of the Express Country Milk Company, said that he was in favour of prohibiting the sale of skim milk. There was a great difference in the milk of different cows—that was as to the percentage of water it contained. The addition of water was very easily detected. As to making a verbal declaration at the time of sale, he did not think that would work altogether satisfactorily, as people would object to taking water away in the jug; the milkman might have a printed label outside his cans, stating whether he sold milk and water or skimmed milk, etc. As to the analysts, he complained that they did not seem to know much about milk. The milkmen were desirous of having some certain standard of purity by which they could guide themselves, but the analysts did not seem to be able to fix upon any such standard. He thought such a standard should be arrived at, if possible. He was of opinion that it would be a more equitable thing if tradesmen could get analyses made at the same price as was paid under the Act. It would be advisable to take samples of milk for analysis at the railway stations when it reached town, and he thought an inspector should be appointed for that purpose, so that the source of supply might be kept pure. The majority of analysts gave such decisions that he had not much faith in them, but there were some very clever men amongst their ranks.

The Pharmaceutical Journal.

SATURDAY, MAY 23, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ANNUAL MEETING.

THE Annual Meeting of the Society, which has taken place this week, cannot be characterized as having been other than tame if it be compared with its immediate predecessors. Fortunately, we have no longer spirited dissensions on the subject of poison regulations, nor are we agitated by those feminine distractions which occupied so much time last year. The Council Report, it is true, dealt with two subjects of great importance to the trade at large and to the Society's future—education and the management of the Benevolent Fund—but neither of these subjects roused the meeting to anything like animated discussion. Even the altered condition of the School of Pharmacy failed to elicit any remarks.

We should be loth to attribute this reticence on the part of members of the Society to mere apathy or indifference, and are more disposed to regard it as an indication of the general acknowledgment that the present is a period of transition in which it is especially suitable to work and wait—to work individually, so far as may be in one's power towards the attainment of those objects which led to the formation of the Society, and to wait collectively until prevailing conditions shall have been so modified by individual efforts for advancement as to coincide more satisfactorily with the aspirations of the Society's founders.

But, while recognizing this feeling as one which we believe to be prevalent among even the most active-minded members of the Society, we cannot refrain from expressing some regret that the proceedings of the present annual meeting have presented a somewhat stereotyped character. Mr. ATKINS, in moving the adoption of the Report, was, of course, true to the project in regard to which, we are glad to say, he has nailed his colours to the mast—viz., the enforcement of an adequate scholastic examination as an indispensable qualification for the admission of apprentices to the business of the pharmaceutist. This is a point to which we are disposed to attach especial importance, as one lying at the very outset of the path towards an elevated condition of pharmacy. No better evidence of the fact can be needed than the record of failures in the Society's Preliminary examination, and this is more especially the case when it is considered that the candidates presenting themselves for this examination are not for the most part lads seeking to ascertain and test their fitness for entering upon that course of practical training and special study which alone can render them competent to carry on the business of pharmacy with credit or profit to themselves and with due advantage to the public. Much more frequently those who come up for this examination have already spent several years in the attempt to obtain a knowledge of the business. The fact that so large a proportion of these candidates fail to satisfy the present meagre requirements of the Preliminary, is a sufficient proof that in very many instances the pharmaceutical career is entered upon without proper preparation, and without that amount of elementary education which is, as a rule, essential for success.

While agreeing thoroughly with Mr. ATKINS in the opinion that the passing of the Preliminary examination should be invariably made a condition of admissibility as an apprentice, we are equally disposed to go with him in urging that it is desirable this examination should be discontinued by the Pharmaceutical Society, as soon as circumstances will permit; inasmuch as it is in no sense technical or professional, but purely scholastic and literary. We trust that when the time comes for making a bye-law to this effect, there may be a provision that certificates of competent legally constituted bodies shall be accepted for this examination, and that the production of such certificates may be made as compulsory in regard to apprenticeship as registration under the Pharmacy Act is in regard to commencing business as a pharmacist.

In the remarks which fell from Mr. PICKERING on the subject of provincial education, we were glad to recognize indications of a more correct view of the case than we have hitherto been able to give him credit for. The next best thing to being right is to confess one's error, and it must be admitted Mr. PICKERING very gracefully acknowleged that the shortcomings in regard to provincial education were not, as he once supposed, solely attributable to the Council of the Society.

Mr. VIZER'S remarks on the administration of the Benevolent Fund were of the same tendency as those he made last year. In most other respects he agreed with the Report, and as to education he expressed his desire to see the standard raised rather than lowered.

Among the other subjects discussed, the most important were the new Scholarships proposed by Mr. SCHACHT, and the Adulteration Act in its operation on chemists and druggists, on both of which we hope to have something to say very shortly.

The question whether there should be an increase in the number of annuitants from the Benevolent Fund was also discussed again, though in a manner somewhat vague and inconclusive. This was probably due to a feeling that the decision of this question was more a matter for the Council than for the General Meeting.

THE CONVERSAZIONE.

On Wednesday evening, after the Annual Meeting of the Pharmaceutical Society, the usual Conversazione was held in the South Kensington Museum, the use of which was again kindly granted by the Lords of the Committee of Council on Education. The reception commenced at Eight o'clock, and three thousand one hundred and fifty visitors responded to the invitation of the President and Council, being a larger number than on any previous similar occasion. During the evening the band of the Royal Horse Guards performed a choice selection of music in the large court, and some glees and madrigals were beautifully sung to successive audiences in the Lecture Theatre.

THE LIVINGSTONE MEDICAL MISSION INSTITUTION.

Evangelical enterprise among the heathen has hitherto been successful in proportion to its adoption of medicine as an auxiliary. With the view of tightening the bonds between the medical and the theological functions of the missionary, an institution was founded in Edinburgh some thirty-three years ago; for eighteen of which it numbered as one of its members the late Dr. Livingstone. Its success in training the medical missionary has been such that many applicants for admission are attracted to its halls—more in fact than it can accommodate. By the death of Livingstone, an excellent opportunity presents itself of adding to its resources while suitably commemorating that distinguished man. It has been proposed to found, on the basis of the existing institution, a new and larger one to be called the "Livingstone Medico-Missionary Institution," wherein a greater number of young men can study with increased facilities. The sum of £10,000 will be required for the building. Of this, £1,000 has been already subscribed; and we hope that the remainder will come in with an alacrity worthy of the twofold object contemplated. When we consider how much science owes to the educated, particularly the medically-educated, traveller—how our knowledge of plants, drugs, and natural history in general has been extended by the missionary explorer, from the days of the Jesuit propagandists downwards—we can scarcely be wrong in anticipating that among the subscribers to the "Livingstone Medico-Missionary Memorial," not a few will be votaries of medicine in all its departments, and include the scientific pharmacist as well as the enlightened physician.

The vacancy in the Philadelphia College of Pharmacy, occasioned by the sudden death of Professor Procter, has been filled by the appointment of Mr. Joseph P. Remington as Professor of Pharmacy. Mr. Remington, whose name will be familiar to our readers as a frequent contributor to pharmaceutical literature, has had the advantage of acting for some years as lecture assistant to the late Professor Parrish and Professor Procter.

On Thursday evening the consideration of the Juries' Bill in Committee was resumed in the House of Commons. When clause 72 was reached, the Committee decided to report progress. There still remain thirty-three clauses to be considered.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

May 12th, 1874.

Present—Messrs. Buchanan, Gilmour, Kemp, Kinninmont, Tait, and Young.

Professor Maclagan was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Nine candidates were examined. *Three* failed. The following *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

*Shum, Arthur George .....Edinburgh.
Jeanes, George .....Alverthorpe.
Munday, John .....Bridgnorth.
Equal. { Gordon, John .....Aberdeen.
Equal. { Drysdale, Joseph .....Edinburgh.
Guy, William Adolphus .....Kemberton.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Four candidates were examined. *Two* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Harding, George ....Dartford.
Parry, William .....Liverpool.

EXAMINATIONS IN LONDON.

May, 1874.

Present on the 13th — Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

14th — Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Southall, Taylor, and Umney.

15th — Messrs. Allchin, Barnes, Benger, Bottle, Carteighe, Corder, Cracknell, Davenport, Gale, Martindale, Schweitzer, Taylor, and Umney.

Dr. Greenhow was present on the 13th on behalf of the Privy Council.

MAJOR EXAMINATION.

Four candidates presented themselves. *Two* failed. The following *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Cleave, Samuel Whiteway .....Bodmin.
Hall, Edwin .....Weston-super-mare.

MINOR EXAMINATION.

Seventy-eight candidates presented themselves for examination. *Fifty-nine* failed. The following *nineteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

*Overton, John.....Bristol.
Gooding, Henry .....Woburn.
North, Josiah .....Reading.
Smith, Alfred .....Nottingham.
Starling, William Egerton .....Tunbridge Wells.
Lovegrove, George Elliott .....York.
Illsley, Thomas Brown.....Belper.
Fryer, Arthur ....Ayston.
Cassie, Ralph James Forbes Leith .....Aberdeen.
Stanley, Thomas .....Alcester.
Grove, Harry Nicholas .....Walsall.
Barton, William .....Preston.
King, George.....Surbiton.

---

* Passed with Honours.

Baldwin, Arthur Henry .....Clifton.
Elliott, William Thomas .....Stowmarket.
Equal. Gardner, Edward .....Pendleton.
Equal. Good, George Arthur .....Weston-super-mare.
Equal. Holt, William .....Blackburn.
Equal. Knight, William .....Hinckley.

The above names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's Examination:—

Certificate of the College of Preceptors.

Harrison, Frederick .....Brighton.

Certificate of the University of Cambridge.

Axford, John William.....Coventry.

MEETING OF THE COUNCIL,

May 20th, 1874.

MR. T. HYDE HILLS, PRESIDENT, IN THE CHAIR.

MR. A. BOTTLE, VICE-PRESIDENT.

Present — Messrs. Atherton, Betty, Brown, Frazer, Greenish, Hampson, Mackay, Owen, Radley, Robbins, Sandford, Savage, Schacht, Shaw, Stoddart, Sutton, Urwick, and Williams.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society :—

Cleave, Samuel Whiteway.
Hall, Edwin.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

Hall, Edwin .....Bretforton.
Hulme, Richard Gleave .....Pau.
Kirton, Christopher Henry.....Hull.

Chemists and Druggists.

Baker, Frank.....Sandwich.
Doughton, Thomas William ...Notting Hill.
Thomas, William .....Builth Wells.

ASSOCIATES.

The following, having passed their respective examinations, and being in business on their own account, were elected "Associates in Business" of the Society.

Minor.

France, Joseph .....Rotherham.
Jeans, George .....Martock.
Ness, Thomas Henry.....Torquay.

Modified.

Halley, Alexander .....Glasgow.

The following, having passed their respective examinations, were elected "Associates" of the Society :—

Minor.

Barton, William .....Preston.
Elliott, William Thomas .....Stowmarket.
Gardner, Edward .....Pendleton.
Gooding, Henry .....Woburn.
Grove, Harry Nicholas.....Walsall.
Holdgate, Arthur .....King's Lynn.
Hoyles, George.....Lincoln.
Lovegrove, George Elliott .....York.
North, Josiah .....Reading.
Starling, William Egerton .....Tunbridge Wells.
Walmsley, Robert .....Clitheroe.
Wood, Henry T. Gibbons .....Hull.

Modified.

Parry, William .....Liverpool.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary Examination, were elected "Apprentices or Students" of the Society :—

Allatt, Arthur Edward.....Bradford.
Bartlett, Hubert .....London.
Berry, Henry Burton .....Gloucester.
Biggs, Walter Lyle .....Hampstead.
Clay, William .....Cromford.
Dewhurst, Thomas .....Preston.
Ellis, George .....Banff.
Franciosi, Eugène Auguste de...London.
Gamble, Arthur Gompertz .....Grantham.
Gibson, John Hanson .....Leeds.
Hanham, John .....Irlams o' the Height.
Hirst, Francis .....Highbury.
Jones, Jabez A. .....Birmingham.
Laslett, Thomas George ..... Hull.
Page, Joseph ....Willenhall.
Parkinson, Frederic William ...Peterborough.
Phethean, James .....Bolton.
Redford, George Alfred .....Liverpool.
Roberts, Thomas ....Margate.
Silvers, William Brighton .....Camberwell.
Stuart, Frederick .....Great Yarmouth.
Walker, William .....Aberdeen.
Weedon, Joseph .....Crawley.
West, John Lever .....Ashby-de-la-Zouch.
Westerman, Arthur .....Wakefield.

Several Members and Associates who had neglected to pay their subscriptions on or before April 30th, as specified in the bye laws, were restored to their former status, subject to the payment of the subscription for the current year and a fine of half the same amount.

An Associate of the Society before July, 1842, was restored to his former status upon payment of the current year's subscription and a fine of five guineas, and was afterwards elected to membership.

The names of Henry Wakefield, of 3, Hedgerley Park Terrace, Turnham Green, and Thomas Shields, of 78, South Street, Greenwich, were restored to the Register of Chemists and Druggists.

Mr. SAVAGE said a question had been mooted, whether it would not be desirable to call a special meeting of the new Council immediately on their election, for the purpose of choosing a President and Vice-President for the ensuing year.

Mr. WILLIAMS said these elections were so important that they should not be conducted in any informal manner.

Mr. SAVAGE said he made the suggestion in order to prevent informality, because until the meeting in June there was neither President nor Vice-President, which might be inconvenient in case it were necessary to summon either the Council or the Parliamentary Committee for any special purpose.

Mr. W. SCOTT BROWN remarked that the same question had been mooted previously, when he had expressed the opinion, to which he now adhered, that it was undesirable to have any special meeting. The delay would hardly be more than eight or nine days, and the new Council required a little time for consideration before making their selection.

After some further conversation, in the course of which the President remarked that if re-elected on the Council he would endeavour, with the aid of the Vice-President and officers, to carry on the business of the Society satisfactorily until the next meeting of the Council, it was decided to adhere to the established practice.

The Council then adjourned to the Annual Meeting.

THE THIRTY-THIRD ANNUAL GENERAL MEETING OF THE PHARMACEUTICAL SOCIETY.

Wednesday, May 20th, 1874.

MR. THOMAS HYDE HILLS, PRESIDENT, IN THE CHAIR.

The Thirty-third Annual General Meeting of the Members of the Pharmaceutical Society of Great Britain was held at 17, Bloomsbury Square, on Wednesday, May 20th, at twelve o'clock.

The SECRETARY having read the notice convening the meeting,

The PRESIDENT said that, before rendering the Annual Report of the Council, he would take advantage of his position as President to say a few words, and would commence by expressing his sincere regret—a regret which he felt confident was shared by his fellow-members of the Pharmaceutical Society, and all connected with Pharmacy—at the loss of their old friends, Thomas Newborn Robert Morson and Henry Deane. Both gentlemen had associated themselves with the Society from its commencement, and remained firmly attached to its fortunes until their deaths. Much had been written respecting these two worthy men in the PHARMACEUTICAL JOURNAL and the *Chemist and Druggist*, and he would not say more than again express his deep regret at their loss. Peace to their memory!

But since coming to the meeting he had received the following letter from Mr. Thomas Morson:—

"124, Southampton Row, May 20th.

"To the Council of the Pharmaceutical Society,—

"In accordance with a wish I have cherished in my mind ever since the death of my beloved father, I have now the pleasure of presenting his portrait to the Society. That many friends who have been associated with him in the establishment of the Society, and who still survive him, may recognize in that portrait the likeness of an old friend, and recall to their minds the remembrance of many pleasing hours, is the sincere wish of

"Yours very respectfully,

"THOMAS MORSON."

Mr. Morson was a very old friend, not only of the Society, but of himself personally, and therefore he might be pardoned a little emotion on such an occasion. He would now move that the Society accept, with grateful thanks, this tribute of friendship from the late Mr. Morson's son, which he believed might be taken as a pledge that the latter gentleman would still continue to do all he could for the advancement of the Society.

The VICE-PRESIDENT said he had much pleasure in seconding this proposition, with a view to having on the walls of the Society such a pleasing reminiscence of one who had laboured so long for the Society.

Mr. SANDFORD said, as an old member, he trusted he might be allowed to add a word or two in remembrance of his two dear friends who were gone. It needed nothing to recal Mr. Morson to their minds, or the great work he had done to advance the Society; but he looked with great pleasure on the portrait now placed before the meeting, and he thought it impossible to produce a better likeness. What he rose especially to say, was this, that this beautiful portrait had been painted from a photograph taken some years ago, when all the members of the Council were photographed by Messrs. Maull and Co., and he thought it would be a very pleasant thing if the same gentleman who had been so successful in this case were asked to paint a similiar portrait from the photograph which they possessed of Mr. Deane. Mr. Deane had been a President of the Society. He had done as much as any one to perfect the examinations, and to bring the Board of Examiners into training, and if the members could, among themselves, arrange for having such a portrait painted, he thought it would be a very suitable companion to the picture now before them.*

The motion was then put, and carried unanimously.

The PRESIDENT, continuing, said he would also mention the names of two other gentlemen who had been taken from them during the year, who had once been members of the Council, and had always taken great interest in the Society, Messrs. Lea and Meggeson. He might also say a few words on a subject alluded to in the Report, namely, early closing, which, he was glad to say, was increasing among their body. His own opinion was that they had inflicted these long and tedious hours of business upon themselves, and it would be their own fault if the evil was not rectified. He would not say that patients should not be supplied with medicine or anything else they might require, after certain hours, but he would suggest that all gentlemen should follow the example of those who advocated and practised the early closing movement. In reference to this subject he might mention that he himself, in conjunction with some of his neighbours, had tried the experiment of putting up the shutters at any earlier hour, thus giving the public an unmistakable sign that they wished to curtail as much as possible the hours of ordinary business, and he had had no reason to be dissatisfied with the result. With respect to the Adulteration Act, a select Committee of the House of Commons was at present sitting to consider it. The Council of the Pharmaceutical Society were not unmindful of the interests of the trade with respect to it, and evidence would probably be given on the following day before the Committee. The Juries Bill was also at present in Committee, and if it passed, as he hoped it would, they would be able to congratulate chemists and druggists, as well as pharmaceutical chemists, on being exempted from serving on juries.

It was agreed that the Report, copies of which had been previously printed, and circulated amongst the members, should be taken as read.

REPORT OF THE COUNCIL.

THE year of office on which your Council have now to report has been marked by some important changes, concerning which it is satisfactory to have this opportunity of conferring with the general body of the Society.

Not forgetting the fact that the Pharmaceutical Society was established "*for the purpose of advancing chemistry and pharmacy, and promoting an uniform system of education of those who should practise the same,*" your Council have, after due deliberation, so altered the course and conduct of the educational establishment committed to their care as to bring it more strictly into accord with the altered circumstances of the Society.

In 1841, and for some years after, it was absolutely necessary in promoting Pharmaceutical education, that the Pharmaceutical Society should itself provide a school, there being no systematic course of instruction then in existence whereby students could acquire that amount of professional knowledge which the founders had declared to be absolutely necessary, as well for the safety of the public as for the advancement of pharmacy. But as that advancement, promoted by the efforts of the Society, became recognized by the medical profession, and by the legislature as a natural sequence, circumstances very materially changed.

*At the close of the meeting, several gentlemen expressed a desire to carry out this proposition by a subscription limited to one guinea from each subscriber, and gave their names as a commencement. Mr. Sandford took charge of the list, and will be glad to receive communications from others who may be anxious to join in this mark of respect to Mr. Deane.

The Charter of 1843 established the Society on a permanent basis, but left it a *voluntary* institution. It gave power to the Council to fix the qualification of members, and to examine all candidates for admission, but as membership of the Society secured no privileges beyond the bounds of the body corporate, it mattered little to a chemist and druggist, so far as the right to carry on his business was concerned, whether he enrolled himself as a member or not.

The Pharmacy Act of 1852 carried matters a little further, by creating and protecting the title of Pharmaceutical Chemist—a title which became so recognized and appreciated by the public as to acquire a material value.

Although the assumption of that title was voluntary, and consequently education was voluntary also, this may be said to have been the commencement of the change in the position of the Society to which allusion has been made.

In the year 1868, an immense addition was made to the powers of the Pharmaceutical Society; so great indeed that no person could, after the Pharmacy Act of that date came into full operation, "*sell, or keep open shop for retailing, dispensing, or compounding poisons, or assume or use the title 'Chemist and Druggist,'*" unless previously examined and registered according to the provisions of that Act.

This was the crowning point in the change which had been going on from the foundation of the Society. Membership of the Society was still voluntary, but examination was compulsory, and therefore education became necessary to enable a man to commence business. In the meantime other public opportunities of studying chemistry and pharmacy had arisen, and, as attendance at a special school was not enforced by law, it became a question whether the Society should continue *commercially* interested in one from which students would pass to an Examining Board appointed by its own Council.

The further question arose whether at the present time it was desirable to continue or discontinue the practice of giving instruction to students at an unremunerative charge. Such a system in the early days of the Society was wise, politic, and even necessary; but the propriety of its continuance had become problematical.

In considering these matters, the Council decided that, although it was one of the objects of the Society *to promote Pharmaceutical education*, it was not its duty *to defray the cost of educating young men coming into the trade.*

In carrying out this decision, it was however desirable to give the fullest effect to the appliances for education existing in Bloomsbury Square, and to ensure a school at which students might have the means of obtaining the necessary instruction under the Professors who had hitherto so ably conducted the classes.

The proceedings of the Council respecting the new arrangements have been fully reported. They may be summarized by the assurance that, whilst relinquishing all contingent financial advantage, and reducing the outlay of the funds of the Society to a definite annual charge, the Council still retains its controlling authority over the system of instruction pursued in the school.

The Finance Report now before you must not be taken as a guide to calculate the future cost of the School of Pharmacy; it is the statement of the receipts and expenditure of the year 1873, and consequently embraces part of a session under the old system.

It is yet too early to judge of the results likely to arise from the recent change. The number of students attending the lectures in both classes has been below the average of former years, but in the earnestness of their endeavours to profit by the instruction given, a marked improvement has been reported. In the laboratory, Professor Attfield has had the usual average number in his class.

Your Council have observed with regret, a large number of failures among the candidates presenting themselves for examination.

Month after month the examiners have been engaged for three, four, or even six days, and though many good men passed, a very large percentage of the candidates has been rejected.

Time, it is hoped, will correct this state of things, which throws so much additional and unpleasant labour on the examiners, and is so discreditable to the candidates.

The Council would once more urge upon Masters the desirability of requiring all youths, before entering upon their apprenticeship, to pass the Preliminary Examination, or an examination by one of the recognized Boards now working in all parts of the country.

Were such a custom general, a better hope would exist that the young men introduced into pharmacy would, by their proved superior school training, be capable of pursuing their pharmaceutical studies to such good purpose as to be able to pass the Minor and the Major Examinations with credit, and that thus this somewhat unfortunate condition of things would disappear.

It is of the utmost importance in the future of the Society that the Major Examination should be passed, as from pharmaceutical chemists alone can Examiners be chosen, and, after a certain time, Members of the Council elected.

An important change has been effected in conducting the Preliminary Examinations.

Nearly five years ago, in order to save candidates the trouble and expense of a journey to London or Edinburgh, it was arranged that by means of written papers sent from the Boards of Examiners, the examination might take place, so far as the candidates were concerned, in any town in which a local secretary of the Society resided. Objections arose to this system, and after very careful consideration of the subject, and a due investigation as to the requirements of each district, certain centres have been chosen at which these examinations will in future be conducted. It was deemed right that the candidates, instead of being brought to the house of a local secretary, should assemble in some room elsewhere, convenient for the purpose, thus removing the liability of the superintendent being interrupted in his supervision by the ordinary calls of business; and that the persons superintending these examinations should be in some slight way remunerated for their trouble. This will add weight and value to the examinations without causing unreasonable trouble to the candidates.

It will be remembered that some years since the library was thrown open in the evening, but as so few readers attended, the practice was discontinued.

Recently, however, the "early closing" movement has spread among chemists, and in the hope that assistants and apprentices liberated earlier from

FREDERICK ANDREWS,
FREDERICK BARRON,
WILLIAM HODGKINSON,
EDWARD HORNER,
WILLIAM SQUIRE,
Auditors.

March 27th, 1874.

business would take advantage of the time so gained for reading and study, the Council resolved to place, not only the library, but more recently the museum also, at their disposal, from 7 to 10 o'clock, p.m.

To render the library available for the use of the Society as far as possible, the librarian has been authorized to defray the cost of carriage of books borrowed by members and associates in business residing in the country, either to them or from them, as may be most convenient; the circulation of books has thereby been increased.

A new and complete catalogue of the library has been published; one of the museum, enriched by short descriptive notes, is in course of preparation.

A proposition to found Scholarships from the funds of the Society has recently engaged the attention of the Council, such scholarships to include a complete course of instruction in the Society's School and a money grant of some definite amount towards the necessary expenses of the student during the term. It has been suggested that young men throughout the country would be stimulated by the hope of gaining at once an honourable distinction and the means of prosecuting their studies in the Laboratory at Bloomsbury Square, that education would thereby be generally advanced, and therefore that the necessary outlay would be a justifiable expenditure of the means at disposal. The question is most important, and the mention of it in this report will probably elicit an expression of opinion at the Annual Meeting which will enable your future Council to judge whether or not the measure would be sufficiently appreciated to justify its adoption.

It will be seen by the financial report that the donations and subscriptions to the Benevolent Fund in 1873 did not exceed, indeed did not quite equal, those of 1872. Your Council regret that there is not a more general support in a matter so important, not only to members of the Society but to all on the Register of Chemists and Druggists. In the correspondence which has appeared in the JOURNAL respecting this Fund, some of the writers have stated their opinion that there is no necessity to subscribe to it; others attribute to the Council a parsimonious spirit in administering relief to the necessitous. Your Council may say with confidence that no deserving case has ever been denied relief.

It must have been observed by the discussions in the Council, that some members are anxious to enlarge the number of annuitants, departing from the hitherto prevailing custom of electing no more than the interest on the invested capital will provide for, making the permanence of their annuities in fact dependent on the annual subscriptions. The decision on this point will, of course, be in the hands of the incoming Council, who will be called on next month to "*determine as to the expediency (financially) of electing pensioners in the month of October.*"

A pensioner once elected should never be allowed to doubt the permanence of the grant, and to prevent that doubt arising, if the new proposition be accepted, the subscriptions must, by sustained effort, be kept up, as the funded capital must ever remain intact. This is indeed a weighty matter for consideration.

During the past year prosecutions have taken place under the Adulteration Act, and an interpretation has been put on some of its clauses, contrary in spirit to the intention of the promoters of the Bill when before Parliament. It would be in entire opposition to the principles of the Pharmaceutical Society to connive at the sophistication of drugs, or even to encourage the use of those of an inferior quality; but it must have been observed with regret that vexatious proceedings have been instituted, in which some of the magisterial decisions, although *technically* right, have been *equitably* wrong.

There is some probability that an amendment of the Act will be made in due time, as the matter has been brought forcibly before the Government; and a Select Committee of the House of Commons has been appointed to inquire into the subject. It will be the duty of your Council to submit to that Committee a representation of those points in the Act which press unfairly on Chemists and Druggists.

The "Juries' Act Amendment Bill," brought in by the Attorney-General last session, fell through, but another has been introduced to the House of Commons which contains a clause exempting Chemists and Druggists from service on juries.

Notice has been given by Sir John Lubbock of his intention to introduce a "Shop Hours Regulation Bill." That must also be watched, to prevent the passing of any such restrictions as those he would have placed on trade in his Bill of 1873.

The obituary of the Society for the past year shows but too plainly that death has been active amongst us. In addition to the loss of an unusually large number of members, we are also deprived of the good counsels of some of our earliest friends and most able and zealous supporters—of men who assisted at the foundation, and largely contributed to the successful rearing of the superstructure of this Society. No less than four, who formerly held seats at this Council, have passed away during the year. Mr. Lea, of Worcester, who for four years was an active member; Mr. Meggeson, whose services to the Society, particularly on the Finance Committee, will be remembered, was so well known that his name must be familiar to all; Mr. Morson; and Mr. Deane.

The two last named gentlemen were so actively engaged, and so long conspicuous in the interests of pharmacy, not only as members of Council, but also as Examiners, that more than a passing allusion to them is demanded. It may be said they were both men of world-wide reputation, and all must join in lamenting the loss in them of two of the brightest ornaments that ever adorned our ranks, two in whose practice the *trade* of a chemist and druggist was indeed raised to a *profession*.

When they first became connected with the drug trade, it was overcast by the dark shade of ignorance, but theirs were not minds to rest content in that gloom, and by their inherent love of science, and wisdom in applying science to the common things of life, they were mainly instrumental in dispelling it.

Men of less generous spirit would have been content with a position rendered the more distinguished by their superiority to the generality of their fellows. Not so Mr. Morson and Mr. Deane. As soon as the opportunity offered, they, with William Allen, Jacob Bell and others, some whom we have lost, some whom we yet retain among us, worked nobly through the means of this Society to elevate all chemists and druggists to the higher level which they now occupy, and, although not for the last few years Members of Council, never ceased in their interest for the well-being of the Pharmaceutical Society, in which their names must ever be held dear, and your Council can-

not close this report without thus placing on record a tribute to their memory.

The following registers were placed before the meeting:—

Register of Members, Associates and Apprentices of the Society.
Register of Pharmaceutical Chemists.
Register of Assistants.
Register of Apprentices or Students.
Under the Pharmacy Act, 1852.
Register of Chemists and Druggists.
Under the Pharmacy Act, 1868.

Mr. S. R. Atkins (Salisbury) moved the adoption of the Report in the following words :—

"That the Report of the Council now read be received and adopted, and printed in the Society's Journal and Transactions."

He said the Report, as a whole, was pre-eminently satisfactory, though he would not say that it was not open to criticism on some points, either with regard to the elegance of its diction or subjects which might afterwards have to be debated. Still, as a terse, condensed expression and *résumé* of the position, and anticipations of the future, it commended itself to his own judgment. There was one point, however, to which he wished to call special attention, and that was the present position of the Preliminary examination. He would remind the meeting that the Preliminary examination had passed through at least two, and was about to enter upon its third aspect or quarter, and his desire was that it should as soon as possible enter upon its fourth and final one. Its history was briefly this: In the earlier days they were accustomed to send their apprentices to clergymen, ministers, schoolmasters, or graduates of the universities, who had a reputation for sound scholarship, to be examined in these matters, and although he had known a great many youths go up to be examined very few were refused; from which it appeared that either the young men of that day must have been marvellously clever, or the net of to-day must be marvellously fine in its meshes, as so many were rejected, and he was afraid the truth was but too evident. The second phase of the subject was that they were about to quit, and he believed it had worked fairly well. He hoped nothing he had said would lead to the inference, and he wished most emphatically to disclaim that in the brief paper he sent to Bradford last year he wished to convey the slightest idea that the examination had not been fairly and honestly conducted by the Local Secretaries, for he believed it had worked fairly well. But it was now about to pass into the third aspect, which was an alteration in detail from No. 2. He desired to see something different altogether with regard to the Preliminary examination. It was purely a scholastic or literary, in no sense a technical or professional one. It ought to be strictly preliminary, which unfortunately very often it was not, or at least it was preliminary only to a deal of disappointment and heartrending dissatisfaction on the part of parents, guardians, and youths, since more than 50 per cent. failed. Strictly, it should be preliminary to a chemist having anything to do with the training a young man for pharmacy. He thought the corollary attached to that proposition was that it should be conducted by bodies purely scholastic and literary. He knew the objection which had been raised to this, namely, that if there were now 50 per cent. of failures what would they be if all the candidates were obliged to be examined by the universities whose examinations were much more difficult? He was quite aware of that; but he was prepared with an answer which he hoped would disarm the objection thus naturally raised. He had recently been taking into his counsel an able schoolmaster in his own town, whose school was affiliated with the College of Preceptors, and he found there were three grades of examination connected with that body. The first grade had four special subjects, but did not include Latin. In an appendix, however, to the instructions, he found that the Pharmaceutical Society accepted a certificate in either of the three grades, if only Latin were added to it. His suggestion, therefore, was that the examinations of this body should be accepted, in place of Preliminary Examination conducted by themselves; and he should be prepared at a later opportunity to move a resolution to that effect. He might, before sitting down, be allowed to pay a passing tribute to the memory of the two great men who had passed away. Of Mr. Morson, he could not speak with anything like personal acquaintance, having only met him on one occasion in the country. But from Mr. Deane he had received a great deal of encouraging assistance; and he believed one of the last acts of his life was to write him a kind letter, in which he said: "Dear Atkins—Persevere in your view of the Preliminary Examination."

Mr. Jameson (Hastings) seconded the resolution.

Mr. A. Pickering (Hull) said that, financially, the Report was again a success, which he was very glad to see, but there were one or two matters which were to his own mind subjects of regret. Before entering upon them, however, he felt that they owed a debt of gratitude to the members of the Council, especially the London members, for the very large amount of time they had devoted to the interests of the Society. The Report itself was pregnant with many subjects of importance to the rising generation; particularly the allusion in the fourth page to the large number of failures amongst the candidates, but he thought that result was partly owing to the injudicious rules and regulations in years gone by, respecting grants made for provincial pharmaceutical education. He found, however, that these injudicious rules were now at an end, and that the Council were desirous and anxious to utilize their means as far as possible for the promotion of pharmaceutical education in the country. As he had had occasion to take the Council to task previously for their niggardliness in this respect, so he must say he now felt ashamed that so small a portion of the funds had been applied for by provincial members for the purpose of advancing the education of those committed to their care. He trusted, however, that in the next Annual Report a great improvement in that respect would be noticed. Another passage in the Report referred to the importance in the future of young men passing the Major examination, but he thought there was room for more than one view on that subject. No doubt it was a source of regret that so few, comparatively, presented themselves for the Major examination; but before censuring them they must bear in mind the position which pharmacy occupied in this country, and he would ask whether there was any legitimate prospect to a young man who qualified himself by passing the Major examination, of obtaining any sort of return for his trouble and expenditure. He looked upon pharmacy in its present position as a disgrace to the intelligence of the country, and to the Government. If a young man had passed his Major examination he had not that position given to him by the Government which he ought to occupy. He did not say this without being prepared to prove it, and there could not be a stronger proof than was seen in the appointment of public analysts. Hitherto a pharmacist had stood a very poor chance indeed of being elected to that office, and where he had been elected, ten months had elapsed before the appointment had been confirmed. His own opinion, however, was that there was no man so well qualified for such an appointment as a man who had studied in that institution and had passed his Major examination. He was persuaded that the Government never intended that persons should be appointed public analysts, whatever might be the letters which they put after their names, who avowed before a magistrate that they never knew there was any other Pharmacopœia in existence in England than the British Pharmacopœia of 1867; who had never heard of the one of 1864, and had no notion of there having been such a thing as a London Pharmacopœia. He considered such a

man utterly unfit for the appointment; but such men did hold the office, and evidence had been given in courts of justice which had been the laughing-stock of every pharmacist in the country. He alluded to the cases of sweet spirits of nitre and milk of sulphur; and when it was considered that the very lives of their fellow creatures were dependent upon the reports which these public analysts put forward, he thought it was only proper that those who appointed them should take care that they were fully qualified to discharge the duties. Pharmacy in this country was in a very different position to that which it held on the Continent, where there was a broad line of demarcation drawn between the prescriber and the dispenser. Why should they not have a College of Pharmacy as well as a College of Physicians and of Surgeons. Had they a College of Pharmacy, and did the College of Physicians place pharmacy in the care of that college, they would never have seen such an abortion, for it deserved no other name, as the British Pharmacopœia of 1864. He believed pharmacy would never occupy its true and legitimate position, until a broad line was drawn between the practice of medicine and that of pharmacy; and when that was done there would be more inducement to young men to pass the Major Examination. A proposition had been made to form scholarships from the funds of the Society, and if there were means at command he did not see that there could be any objection to it. But before that object was attempted, he thought they ought to place themselves in a different position from that in which they were at present. He trusted much more would be expended throughout the country in promoting the welfare of the junior members of the trade. Another clause of the Report referred to the Benevolent Fund, as to which he had expressed his opinion on previous occasions. He had no doubt that if the investments were varied they might with advantage increase the number of annuitants 25 per cent.; he wished the Benevolent Fund every success, but at the same time it was a source of regret to see so large an amount of money invested to produce so small a return. He was one who thought that they might, even without varying the investments, increase the number of annuitants out of the donations and subscriptions, though he did not suppose it would be desirable to absorb the whole casual income in that way. He believed there was now a Parliamentary Committee sitting to consider the Adulteration Act, and he thought it was much to be regretted that the adulteration of drugs should have been included by Parliament with food and drink in that Amended Act, because a great deal of the annoyance and injustice which members of the trade had suffered from had been caused by incorporating the Pharmacy Act of 1868 with the Adulteration of Food and Drink Act. If such public analysts were to be appointed in future as had been in the past, it was quite necessary that either some Committee or Council of the Society should be appointed to supervise the prosecution of those charged with adulterating drugs; since there were many drugs imported in an impure state, and it would be impossible for retail chemists to analyse every article they received into their shops. Many men were incapable of doing it, and if they were their whole time would not be sufficient for the purpose. He hoped, therefore that the Council would endeavour to obtain such an alteration of the law that the pharmacist, whenever he might err, should be prosecuted by his own Society, and not by a man who averred that he did not know there was any difference between the sweet spirits of nitre of the London Pharmacopœia and the spirit of nitrous ether of the British Pharmacopœia of 1867.

Mr. Vizer (London) said there was nothing in the Report but what he could fully agree with, and he was happy to see so satisfactory a one published. At the same time he desired to draw attention to one paragraph regarding the examinations, in which surprise was expressed at the number of failures. That, he thought, might be very easily explained, inasmuch as they were so close upon the time when an alteration would take place in the character of the examinations; and this induced a large number to present themselves who were really not at all competent to pass. He had always been an advocate for a very fair examination being passed, and had no idea that they should lower the standard of qualification; indeed, he would rather see it increased, believing that was the best way to obtain the esteem and respect of the public, and in the end to become more fully recognized by those in higher positions. As had been said with regard to the Pharmacopœia, no doubt it was a pity that the body of practical pharmacists had not been more thoroughly taken into council as to the preparation of a work on which so much depended. Another passage in the Report expressed a desire to elicit the opinion of the meeting on the subject of establishing scholarships, and he must confess his own opinion was against them. He did not see that at the present time there was a sufficient demand on the part of the students for such a measure, especially when he recollected that only last year it was stated that the Senior Bell Scholarship had been given up in consequence of only three having been granted since the year 1861. That of itself, he thought, showed there was not that hankering desire on the part of young men for a higher-class education which they would all delight to see. It might be, perhaps, accounted for to a large extent, by the expense necessarily involved in young men giving up so much time to the extra work, without any tangible prospect of an immediate return; because it costs a young man a great deal of money to come up to London, and spend his time in the Laboratory for several months; and he somewhat agreed with Mr. Pickering on that point, that, if there were funds to spare, he would rather see them more liberally given to provincial associations. In that way young men would be able to prosecute their studies in their immediate neighbourhoods, and would be more encouraged than by being induced to come to London. With regard to the Benevolent Fund, he could not agree with Mr. Pickering, except that no doubt the money might be better invested. He had no sympathy with the idea of electing annuitants to be paid out of the subscriptions. Without reiterating what he said last year, it was palpable and self-evident to his mind that to elect annuitants on the small precarious income from subscriptions which they now received of £743, would be a most dangerous proceeding, and he should decidedly object to it. The Report mentioned that the Council, in June, would have to decide upon the expediency of electing annuitants in October. He should like to know if that meant that there was not sufficient money funded to supply the annuities.

Mr. Sandford said there was no positive law forbidding the Council to elect annuitants on what might be called the subscriptions, but it had been the custom hitherto to elect no more annuitants than the funded property would provide for. It was for the Council every June, according to the regulations, to say whether or not annuitants should be elected in the following October.

Mr. Vizer said he should reiterate his objection to annuities being paid out of subscriptions, and he only had one word more to add, viz., to express his hearty concurrence with what had been so well said by the President and other gentlemen, with regard to the loss sustained by the Society in the death of two of its most valued members. With regard to Mr. Deane, he could fully endorse what had been said of him; he had received many a mark of kindness from him, and had always looked up to him as one of the pattern men of pharmacy. He thought, therefore, the suggestion made by Mr. Sandford was a very excellent one; and it had also occurred to him whether the pages of the Journal might not be sometimes embellished by such a likeness of deceased notabilities, accompanied by a short biography; not as a commercial transaction, but simply as a mark of respect, which the members could keep by them.

Mr. Slipper (London), referring to the question of the

Adulteration Act, and a case reported in the JOURNAL a few days ago of a prosecution in Glasgow, said it appeared to him a most monstrous case. The analyst, or someone on his behalf, sent to purchase from a retail chemist an ounce of a drug, scammony, which he should think was not required in ounce packets by one person in a million. He thought it a monstrous thing to prosecute the vendors of such a drug by way of protecting the British public from being supplied with adulterated articles, and to prosecute persons for adulteration which they had not committed, having sold the drug just as they had received it from the wholesale house. It was quite a different thing in making up a prescription. If precipitated sulphur were ordered in a prescription, of course they must use it according to the British Pharmacopœia, but if a customer asked for milk of sulphur it was a different thing. The public had been used to buy this and mix it with treacle, milk, and other things; and if they purchased the precipitated sulphur they got a thing they did not like, and which they often brought back, saying it was not the right article. About two years since he had introduced the legitimate *Sulphur præcipitatum* in his business to sell retail, but repeatedly he had it brought back again; and he was therefore obliged to sell the milk of sulphur, as a commercial article which pleased his customers. Mr. Pickering regretted that more pharmacists had not been appointed public analysts. He feared that had arisen in some measure because as yet there were not a very large number of such persons who were qualified to fill that position. He believed, however, that if young men would take more advantage of the opportunities now afforded them of increasing their scientific knowledge, they would stand a very good chance of obtaining offices of that kind; but, at present, there would be great difficulty in some districts in finding a fit person for such a position, more especially on account of such gentlemen being retail shopkeepers in the locality. Some members of the Society, however, had been appointed to this office, and, from all he had heard, had filled it with great credit to themselves. He did not think there was any feeling against pharmacists, provided they were thoroughly qualified. If, however, aspirants to such positions would not take the trouble to attain that knowledge which it was in their power to obtain when they were young: if they would not go in for the Major examination and pass it, they could not expect to fill such positions as Mr. Pickering had referred to, but the blame would be to a great extent upon themselves. Many young men of the present day seemed as if they wanted a nurse to take care of them—as if that Society was to feed them all their lives; they did not seem to have the necessary energy to make their own way as such men as Mr. Morson and Mr. Deane had done; in fact. they seemed to want to be crammed with knowledge rather than to acquire it for themselves. They had more time now for study than formerly, salaries were larger, and would be larger still, but the number of open shops, he believed, would be less; in fact, he considered the whole trade was in a state of transition, and this ought to be borne in mind, and young men ought to make use of the advantages offered to them. With regard to the Benevolent Fund, he was sorry to see that it did not increase as it ought; and it had occurred to him that the annual dinner might be made subservient to that object. He believed there were many sources from which they might get some assistance if an effort were made on the occasion of this annual dinner, and that perhaps £200 or £300 a year might be obtained in that way.

Mr. MACKAY begged to draw particular attention to the paragraph in the Annual Report with reference to the proposition to found scholarships. He was not quite certain whether the members present understood the position in which the Council stood with reference to that very important subject; but it might be gathered by reading the following passage from the Report:—"The question is most important, and the mention of it in this Report will probably elicit an expression of opinion at the Annual Meeting which will enable your future Council to judge whether or not the measure would be sufficiently appreciated to justify its adoption." He might say that the question had occupied the attention of the past Council for some considerable time, and the reason for its being brought so prominently forward in the Report was simply that the Council was a good deal divided in opinion as to the propriety of founding these scholarships. He had no hesitation in saying for himself, that, whether returned to the next Council or not, he decidedly objected to the proposal; and if time allowed, he might give very good and sufficient reasons for holding this opinion. One important reason was that, as a Society, they really had not funds. Before building a house it was necessary to see that you had a good sound foundation on which to erect the walls, but glancing at the accounts he could not see that they had money enough to found these scholarships. He said so because, on going back two or three years, it appeared that their annual income during that time had been of a very exceptional character. He would not analyse the sums, because he hoped the Annual Meeting would, before separating, give a decision upon the principle; and if it was the desire of the majority that the scholarships should be instituted, it would be for the future Council to determine as to the details. The original idea of Mr. Schacht in bringing this subject forward was that there should not be fewer than ten or twelve of these scholarships; but, looking at it as an £ *s. d.* question, it appeared that this would cost, roughly, between £600 and £700 per annum. This amount looked large, and he believed the Council pretty well decided that it was too great a sum, and therefore it had been proposed that the number should be cut down; but there were others on the contrary who desired to see the number even increased. He wished to impress on the meeting the desirability of giving a clear indication to the next Council what this meeting wished them to do; and if favourable, leave it to them to work out the details. His objection to the proposed scholarships were: first, want of funds; and next, that the money, if at command, would be spent injudiciously. He could not conceive what advantage it would be to a young man to give him the sum of £60 a year with which to come, perhaps, from some district in Wales or the farthest part of Scotland to London, there to study, pay his fees at our own school, and manage to live on the balance, equal to about £30; though he feared it would be more like starving than living. He had a notion that the money could be spent in a much better way than by founding scholarships. They all knew the old story of the waggoner who invoked the assistance of the gods to get his wheel out of a rut; he was told to put his shoulder to the wheel, and having done so he was much more successful than in his invocations. Now, he thought the funds of the Society had not been spent so well as they ought to have been, in really promoting pharmaceutical education. He would not not say whether it was the fault of the Council or of the Provincial Associations, but he regretted it exceedingly; and to come back to the story of the waggoner he thought the members might help themselves very much in the way in which many members, as well as chemists and druggists, had already done. To illustrate this, supposing a lad applied to be taken as an apprentice, he would of course enter on trial; but before he passed the threshold he might be told, If you like the business after one or two months' trial, and if the intended master is pleased with you, then before you are bound you must undergo the Preliminary Examination of the Society; and when the deed of indenture was drawn up, not only should the young man be bound to pass the Preliminary, but both the young man and the master might equally bind themselves to this extent—that if there were lectures, either in the town or within an easy distance, the young man should be bound to attend, and the master in turn should be bound to give him time and opportunity to do so. No doubt it would be said that was all very well in large towns, but what

was to be done in small towns and villages? They must follow the same principle. In such cases he considered the master was honestly and fairly bound to give a young man time to read and study, so that when he came to the close of his apprenticeship he might be able, if he liked, to migrate to some large centre, and to take advantage of such courses of lectures as might be given there. This practice had been followed for many years in Edinburgh, and with the very best results. For his own part, he thought that the Council should give assistance by money grants wherever it was asked, and as liberally as possible, provided there was evidence given that such grants would be properly used. In some arguments at the Council Board, the proceedings of the Royal Commission on scientific instruction had been several times referred to, and he thought the following extract from the Report of the Commission worth reading to the meeting. It bore the names of the Duke of Devonshire, Sir John Lubbock, Sir J. K. Shuttleworth, W. Sharpey, T. H. Huxley, G. G. Stokes, H. J. S. Smith, and B. Samuelson:—"With regard to Provincial Museums it is recommended that in connexion with the Science and Art section of the Education Department, qualified naturalists be appointed to direct the collection of specimens, in order to supply whatever deficiences exist in the more important Provincial Museums; and also in order to organize Typical Museums, to be sent by the Department of Science and Art into the provinces, to such Science Schools as may be reported to be likely to make them efficient instruments of scientific instruction. That a system of inspection of Provincial Museums be organized, with a view of reporting on their condition, and on the extent to which they are usefully employed, and whether the conditions of the loan or grant from the Department of Science and Art have been fulfilled." He thought there was something there which the future Council might operate upon with good effect. He maintained that in places throughout England, Scotland, and Wales, where there was a desire to promote the education of young pharmacists, each individual case should be judged on its own respective merits, and such assistance given as would be satisfactory. The chief requirements, perhaps, being the establishment of a fair museum of drugs and chemicals, comprehending good and bad specimens, and various other preparations likely to interest young pharmacists; and, if possible, a small well-selected library, with, above all, a free room where these young men could meet and study and do good for themselves and others. This system had now been fairly tried on a large scale in Edinburgh. Since November, 1872, the result had been that they had had between 1400 and 1500 visits from young men who had highly appreciated the use of the museum, reading room, and library. During the last year they had nearly 900, and the numbers were going on increasing. Of course, this was viewing the system he advocated under the most favourable circumstances, because Edinburgh was really a large centre, and being a recognized branch of the Society, with examining powers, many young men were induced to visit the city; but he quite thought some such arrangement as he had hinted at, differing only in degree, might be adopted with very good results in many of the smaller towns, and he really thought that would be money well spent.

Mr. Humpage (London) said the remarks of Mr. Mackay so completely commended themselves to his judgment that he was quite persuaded it was the right thing to do. With regard to the scholarships, his impression was that a great deal more had been done for the young men than they had done for themselves. When it was thoroughly understood, as it has been understood now for some time, that young men had to be examined before they were entitled to a certain position, it was not right for them to be apprenticed without being properly educated in the first place, and then to demand that that Society should give them the instruction which they ought to have had before entering upon the threshold of business. And, pained as one was to look through the Journal month after month and see the numbers rejected, he could not help feeling that this was the result of ignorance. A short time ago he had been speaking to a gentleman in a respectable position in the country, about a son, 21 years of age; and asking him a few questions, he found that he knew nothing at all of science, even as it was found in the Pharmacopœia, for the father said he should send him up to London, when he could spare him, for six weeks, in which time he would be licked into a condition to pass the examination. He did not of course assent to that view, but he was immediately told that A., B., and C. had done so. He could only say that if they had done so, having gone up with such a small amount of education as this young man had of a pharmaceutical character, they had deceived the examiners. He hoped, therefore, the Council would keep the examiners up to the mark. If the gate might be called six feet high now, he should prefer, if any alteration were made, that it should be raised to seven feet, and by persevering in that course he believed the evil would be remedied. It ought to be felt by the young men throughout the trade generally that if a youth was apprenticed he would have such an examination to pass, and that he must study—that he must, from the first week he entered upon it, be learning something. The only maxim in such cases was *nulla dies sine linea*. Let him add every day a trifle to his knowledge, and at the end of his apprenticeship he need not fear the examiners. For instance, he knew a young man who came from the provinces about a year and a-half ago, having had but a very indifferent education. But, at that time the Preliminary examination being much milder, he succeeded in passing it, and during his apprenticeship he looked well into his Pharmacopœia, and not only so but he purchased a collection of specimens which he studied as he read, and so made himself acquainted with them. When he came to London and applied for a situation, he said he must have a little time for study—that he should like to go to Bloomsbury Square one morning a week, and go through the Museum and pick up what information he could. The principal, appreciating this kind of spirit, gave him the time and at the end of nine months he actually had the assurance to present himself to the examiners, and he passed in honours without having attended one lecture. He therefore maintained that it was the young men's own fault that they so frequently failed.

Mr. Wiggin (Ipswich) said he had not intended to offer any observation, but, as one of those ogres who had been so fearfully depicted by Mr. Pickering, namely, a public analyst, he felt bound to make one observation. Having been in association from the very commencement with the Society, he ought to know what its objects were in some degree, and one of them was the improvement of the retail trade and the improvement of the quality of the drugs sold to the public. The Society had up to the present done that to a great degree, as none knew better than those who were in the retail trade thirty years ago. Now some gentlemen found fault with prosecutions for selling milk of sulphur, but it was notorious that in many instances it contained 50 per cent. of sulphate of lime. So that they were poisoning the public by selling such an article as a preparation of sulphur, when it was not. The spirit of nitre was an open question, but a great deal was to be said on the other side, and he certainly thought the Society would not be doing its duty if they did not in every way assist the Government in ensuring that the drugs sold to the public were of such a kind that they might place reliance upon them. The fault had been laid on the wholesale houses, and in that room 20 years ago the same gentlemen were considerably attacked on the same score. He thought it was not entirely their fault, but that of people who wanted 1*s.* 6*d.* for 1*s.* If the wholesale firms were paid the price of a genuine article, they could sell it as well as what they did in many

cases. He must therefore take exception to the expression in the Report that vexatious proceedings had been instituted, in which some of the magisterial decisions although technically right had been equitably wrong. He confessed he did not understand what that meant. If a thing were sold to the public as a genuine article, which is proved to be adulterated, then it was equitably wrong; but as equitable meant right he did understand the exact meaning of the phrase.

Mr. WATTS (London) suggested that there should be periodical meetings of the members of the Society held, in which these subjects might be discussed, as they affected the trade very largely, and if in order he would move a resolution to the effect later on.

Mr. STACEY (London) said there were two or three matters mentioned in the Report, all touching on the education question, which was a large one, and he thought they should all be considered together. Mr. Pickering had remarked that there was no return for those who passed the Major examination, but it struck him that the return and the benefit to such was in their own breast. They must never forget that the education given in that Society could not teach a man how to make his business successful; it could not teach him habits of business, and whatever examination he passed it did not follow that therefore he would be a better tradesman or that he would obtain a larger return. He might be more successful in his business if he combined the requisite qualifications with good scientific knowledge; but the real return was the knowledge which he acquired, together with the honour and position which it gave him. With regard to the scholarships, it appeared to him that this was only part of the large question of education which he was not prepared then to enter fully into, but it had often struck him that the Society did not take it up as a whole and as the scope of the question demanded. Mr. Pickering had thrown out the idea of a College of Pharmacy, but that would be going beyond anything they had at present, and he believed the subject of education was one which the Council would have great difficulty in dealing with piecemeal. There was the matter of the Minor and Major examinations, in which there were differences of opinion; there was the important question of the Preliminary examination, and there was this question (of still greater importance in some minds) of the scholarships. His own opinion most decidedly was that the Society was not in a position at present to found these scholarships; that it was neither ready in a pecuniary nor in an educational point of view. The Report referred pretty fully to the question of the Benevolent Fund, on which a great deal had been both said and written for some time past. It appeared to him the first requisite was to understand clearly the meaning of an annuity. He took it you could not grant an annuity from any other than invested property, and he did not imagine there was a man of business connected with the Society who would think it possible to grant an annuity without the certain means of doing so. That point, therefore, seemed to settle itself. But he would be inclined to go a little further, seeing the general feeling of the Society, and, if practicable, he would throw out a hint to the Council that there should be two columns of subscriptions—one for the annuitants' fund, to be invested, and another column for annual grants. This might possibly produce a great deal more assistance, and so carry out better the objects of the fund. When there were hundreds and thousands ready to give 10*s.* or £1 for the purpose of the annual grants, it seemed a pity that it should not be obtained and appropriated under the direction of the Benevolent Fund Committee.

Mr. GUYER (Torquay) wished to put one question with regard to the scholarships. Did the Council intend, if these scholarships were founded, to have a consolidated fund for the purpose; or was it the intention to pay them out of the revenue; and if they adopted the latter mode, was it certain that they would be able to maintain them? If not, it seemed to him a great fallacy to establish scholarships for a few years and then have to abandon them. On the other hand, if they were to have a consolidated fund, how was the money to be raised, unless some generous individuals would come forward with large endowments? With regard to education generally, he thought the examinations were not at all too low at present, and that in time they might be raised to a higher level. They would never succeed as a pharmaceutical body, until they compelled young men not merely to come up and pass their examinations, but also to go through a certain career of study at recognized schools of pharmacy. His own impression was that, instead of masters having apprentices with premiums, it would be far better for all parties if the lads were to undergo twelve months' special study before entering the business, and then be apprenticed without paying any premium. It had also been said that young men were being educated too highly, and that they did not like to go into small towns afterwards. But look at the medical profession, which set a bright example in this respect. You never heard any of them complain of having to go and do the work of charity in small hamlets and villages, even after passing the highest medical degrees. If they could do so, surely the young men who came there and passed their examination might be content to do their work for a few years in small towns.

Mr. SCHACHT desired to say a word or two on the question of the scholarships, particularly as he regretted to find that, so far, every observation made had been in opposition to it. All the written criticisms, all the suggestions, all the spoken criticism, and all the mild applause which he had heard, had indicated a feeling against the proposed scholarships. Of course, if that were the general verdict of the trade, he was the last man to say a single word more upon the subject. Indeed, supposing that day that anything like an opinion was distinctly stated that the Society had better wipe its hands of the subject of education altogether, the future Council would know a little more clearly what to do; and he, in common with Mr. Mackay, hoped the meeting would be very clear indeed in their expression of opinion on this matter. But before that was done, he wished to say one word upon the scheme as conceived in his own mind, as there seemed to be a little want of accuracy about it. It had been contended that the Society should not institute these scholarships until it had done more for the abstract question of provincial education. But the notion, as conceived by himself, was, that this was only one of the processes, and one of the most commendable, for accomplishing that object. He had already introduced one scheme, which fell to the ground, tending in that direction, but the difficulty then felt was exactly the same as was felt now. They could not teach in many centres directly, but his idea was that they might promote education in various centres indirectly. That scheme was thought to be too elaborate, and he must say he felt his ardour somewhat damped by finding that not a single individual gave him any aid in that effort. Every criticism was adverse, but no one suggested a better scheme. Another effort was now made, and he found himself, unfortunately, in the same position. He did not complain, however, and if it was understood that nothing of this sort was wanted, he should be delighted to sit still, and save himself both time and thought upon it for the future. But he should wish it to be clearly understood what the question was. They felt it was impossible to teach directly, but it was thought they might promote education indirectly in some way. This proposal was simply that of offering so many prizes, and was the same as had been universally adopted for the development and promotion of education in the whole history of civilization. If it did not commend itself to the Society, let it drop; but there was nothing exceptional in it, nor was there anything problematical about it. Certain prizes were offered, and, of course, a great many would contend for them. A great many ran in a race, although one only obtained the prize. He believed it

often happened that perhaps thirty horses ran for the Derby, though only one could be the winner; but the matter did not stop there. How many were trained? He was not much of a sportsman, but he believed that sometimes as many as 150 entries were made; and the effects were not limited to even that number, because years before that trainers had been directing their energies to the obtaining of this great prize. In the same way the prize of a scholarship, or a medal, or anything of that kind, though only obtained by one, conferred a benefit on a great number, because many actually competed, and many more probably commenced training for the competition, even if they did not continue to the end. That was the result he hoped to see from the establishment of these scholarships. Then, it was said they could not afford them; but for the last three years they had funded about £1500 a year. This appeared by the figures, and he saw no reason to doubt that the income would be maintained, and that something like £700 or £800 a year might not only be depended upon, but would be largely increased. Such a scheme would appeal to the intelligence of everyone who had hitherto been deterred by want of sympathy, and very likely the subscriptions would be largely increased, because a large amount of interest would be enlisted, and it would strengthen their hands in every direction. This difficulty about means had been pretty well ventilated in the Council; and he thought it was pretty much agreed that there was no reason to dismiss the scheme on that account.

Mr. ATKINS said he should like Mr. Schacht to explain his scheme as shortly as he could, in order that they might understand what was proposed. He hoped, also, that Mr. Schacht would not think they were unmindful of his great efforts, or that he had not the sympathy of the whole body of pharmacists with him. The very criticism, in fact, which had been bestowed upon his work was the very best compliment which could be paid to it.

Mr. SCHACHT said the suggestion first occurred to him in this form, that they should grant a number of scholarships consisting of free access to the teaching in that institution, and a certain money grant to enable the students to avail themselves of that teaching. The fees for the instruction would be about £30, and if that were supplemented by a money grant of about an equal amount, it would be a handsome prize to offer. Even if it would not pay for every expense to which the student would be put, it would largely assist him, and he did not see that it was any argument against such a scheme that they did not pay every expense. He believed if a fair number of these prizes were offered, a large number would strive to obtain them, and thus a great start would be given to the educational effort throughout the country.

Mr. STODDART remarked that in his opinion the word "Scholarship" was the great stumbling-block on this question. Mr. Schacht, with himself and others in Bristol, had been striving earnestly for some time to do what they could for the education of young men, and he thought they had been as successful as any other city in the kingdom. They found, in their experience, however, that it was difficult to get young men to come to classes merely from the love of study, and that about three-fourths wanted some further inducement. If he understood rightly, Mr. Schacht's idea was to furnish them with this inducement. He might as well mention that having for two years omitted giving prizes, they found that the young men had not shown that energy which they did when prizes were offered. In the present year, prizes were again given, and they saw that the same feeling which existed in a small degree had grown to a much stronger one, and those who came to the classes took greater interest in them and had derived much more benefit. He had seen fifteen students, each of whom had a good-sized memorandum-book filled from beginning to end with notes they had taken of the instruction given them, and he believed if the examiners could look through those books they would find they had written very full notes on all the subjects which had been taught. It was evident that this was so, because it had been the custom each week to ask questions on the subject of the previous lesson, and about 60 per cent. were found to answer very fairly. The idea was to stimulate these young men, and the details formed a secondary point. It was suggested to give £30 for the fees, and £30 for lodging and expenses, and he thought there could be no doubt that this would afford a considerable stimulus to education in the provinces. Of course in the country they could not afford to pay professors, and therefore had to do the best they could. Before sitting down, he must make one remark with reference to the Adulteration Act and the milk of sulphur question. It had been said that even fleas had smaller fleas to bite them, and it appeared that this milk of sulphur was sometimes adulterated, for he had had four samples come under his notice which would not burn at all, there being no less than ninety per cent. of impurities. He had always sold precipitated sulphur and had found no complaints. With regard to wholesale houses, he thought, if they were fair and honest to themselves and gave their orders without asking the price, no wholesale house would deceive them. But if you told a man who had three prices that you must have the lowest, you could not expect to get a good article.

Mr. ROBBINS, as one who had brought forward the question of the Benevolent Fund at the Council Board, said he should wish to make a remark or two upon it, though he had not come prepared to go into it fully, as it was not going to be decided by that meeting. He had taken considerable pains to go into the matter, though he had not the data with him. Some gentlemen had been very emphatic upon the point that it was quite absurd to grant annuities unless they had funded property to the necessary amount. Having gone into the question very narrowly, and examined what was being done by other societies, he found they departed from that rule; for when they had provided a considerable amount of funded property, they judged what number of annuitants they should put on according to the annual income they received; and they were safe in so acting, because each year, after they got a certain number on their list, they could depend on a certain number dying off. His proposition at the Council had been one of a very mild character. Finding at the first meeting that only one annuitant was proposed to be elected, although there were five applicants, he certainly thought they could do more, and suggested that two might be elected, but was then told there was not sufficient funded property for the purpose. Fortunately for the applicants, one poor widow died shortly after, and gave another chance, so that two were elected; and the same thing would occur in the present year. He had shown by figures that if two annuitants were added every year, the number would scarcely ever reach to twenty; and, having taken the statistics of other societies, he found in one case where they had put on something like 208 annuitants, they derived the greater portion of their income from annual subscriptions, and that the deaths each year amounted to about fifteen per cent. Therefore, if they elected only two annually, the number would scarcely reach twenty, and they had ample funds for that purpose. It was evident that they had not sufficient annuities for the wants of the Society, but at the same time they had a larger sum than was necessary to give casual relief, and he came to the conclusion that the greatest benefit was conferred by granting annuities, and not by giving doles. If you gave a small sum, sufficient to carry a person on for twelve months, they felt uncertain what they were to do at the end of that time. But if there were a deserving case it should be taken in hand at once, and by granting an annuity the poor individual would feel he was provided for for life, and they would be doing a real benefit. As it was, they had a large surplus of funds which was doing no good, and they were restricted in its application, simply from adopting this policy of not granting annuities out of annual subscriptions. He

had shown by figures that if they put on annuitants to the number of twenty they would only add £180 a year to the present expenses; and as the subscriptions amounted to something like £800 a year, this would be less than one-fourth of their revenue. He had also shown that if they only employed the money received more liberally, almost any amount could be obtained which was wanted. The Society had now been established something like thirty-three years; but it started with the idea that before it did any good it must have £10,000 invested. The consequence was that only during the last five or six years had any annuities been granted, and before that time the subscriptions were about £70 or £80 a year. Out of that they gave away something like £50 or £60, so that there was an increase of about £20 every year. Immediately, however, the funded property was sufficient to grant annuities, the subscriptions came in much larger; showing that if they only did good with the money, pharmacists, or any one else, would come forward to assist. A great many people had spoken to him on the subject, saying they did not care to subscribe when their money was simply taken and invested. They liked to see someone enjoying it. He had also endeavoured to show that if annuitants to the number of twenty were elected, and the subscriptions ceased entirely, so that they had to pay all the annuitants out of capital already accumulated, taking the average deaths which would occur, and putting them down at a lower standard than he had done, in five or six years the number would be reduced to fourteen, as at the present, and the capital would not be diminished by more than £700. This showed that there was no real danger of the invested capital suffering. He thought, however, it would be a mistake to elect a large number at once, they should elect two every year until they had twenty annuitants. At any rate the matter might be safely left in the hands of the Council, for he had never come across a more careful body of men with regard to money. Whatever their decision might be, he had now done his duty in the matter, and he had one satisfaction at least, namely, he found that during the last year a sum had been given away more than double the amount of that of any former year.

Mr. CARTEIGHE suggested that the question of scholarships, and provincial education generally, be referred back to the Council. He had always understood that the Council of twenty-one members, elected by such a large constituency, were intended to carry out the work which was given to them, and as an individual he objected year by year—for this was the second instance of the kind—to have questions submitted for the consideration of the whole body of members. The members could not, collectively, not having all the facts before them, give to such subjects that consideration and judgment which the Council could, and he should be very sorry for the proposal of Mr. Schacht to be entirely negatived at the time when their laboratory was far from full, and when the state of general education was rather low. He hoped, therefore, the subject would not be summarily dismissed.

Mr. URWICK said he considered the whole of the arguments had been against Mr. Schacht's proposal, therefore, if the Council wished to learn the opinion of the meeting, it ought to be further argued. He, himself, after giving a great deal of consideration to the subject, sincerely sympathized with Mr. Schacht in this scheme, which was a system that had always been found to answer, wherever there was a school or a college. It was intended to lead young men to study, because it was found that lads, up to a certain age, had not in them sufficient determination to keep them to work of this kind. It was very often not until they attained the age of twenty or twenty-one that they felt an ambition to get on, when, perhaps, the opportunities were no longer available.

Mr. BURDEN (London) thought it would hardly be safe to give any annuities for which they had not funded stock to insure their payment. But there was one point in connection with the Benevolent Fund, which he thought open to improvement. One of the applicants this year had been a pharmaceutical chemist for six years, but he had been waiting until he attained a certain age before he could apply for an annuity, although his case was a very hard one, he having been deprived of his sight, and thus prevented from earning his own living. He thought that in a case like that the Council might allow the election to take place at once.

The PRESIDENT said he would make one or two observations on the discussion before putting the resolution. In the first place, he wished to know from Mr. Stoddart whether he had ever applied to the Council for aid for the Bristol Association. On receiving a reply in the negative, he said then they had no reason to complain. He never knew of any application which had not received the best attention of the Council, and in almost every case a grant was made. With respect to what Mr. Pickering said about the Major examination, he considered it very important that every one who had any brains should pass that examination. He always looked upon it that their business was one which did not require capital so much as brains; in fact, a man who had brains had capital, and could make his own position. He was happy to inform Mr. Pickering that two members of the Society had just been elected fellows of the Royal Society, and a third had been so honoured for some time. There was, therefore, every inducement for a man to come forward and do all he possibly could; and after taking such a position he could not only place himself high in the scientific world, but, generally speaking, he could so apply that science as to benefit his own pocket. He did not himself approve of the idea of connecting the annual dinner with the Benevolent Fund, but the Secretary was always ready to receive any donations from gentlemen who had money to spare, and he would remind them that there was also what was called a Casual Fund, which the Secretary had been instrumental in forming, and which would be all the better for a little assistance. With regard to the case mentioned by Mr. Burden, the Council were obliged to obey the regulations as to age, but the person referred to might have applied earlier, and he would then have received a grant although he could not have been elected as an annuitant.

The resolution was then put, and carried unanimously.

Mr. URWICK said he hoped it would be understood, with regard to the question of the scholarships, that there was no lack of funds.

Mr. PICKERING begged to say one word in explanation, namely, that he never had been in the habit himself of selling adulterated drugs, and did not keep milk of sulphur on his premises.

Mr. WATTS said he should like to move that periodical meetings of the Society be held, to take into consideration trade questions.

The PRESIDENT said he, and the members of the Council, had already quite sufficient work to do, and he hoped nothing more would be put upon them. The ordinary monthly meetings of the Society were open to discussions on all matters affecting the trade.

Mr. ATKINS then moved—

"That the Preliminary Examinations of the Pharmaceutical Society of Great Britain be discontinued after the year 1876, and that the certificates of legally constituted examining bodies be accepted in lieu thereof."

He said that, if such a resolution were passed, it would go as an instruction to the incoming Council to take the necessary steps. He must say that he most earnestly sympathized with Mr. Schacht in his noble effort to promote the spread of education, and it was only a question of detail on which he differed with him. He rather agreed with the suggestion which had been made, that the whole matter should be remitted back to the incoming Council. But, with regard to the Preliminary Examinations, having turned the matter over very carefully in his own mind, he thought it would be far better conducted by scholastic bodies outside their own Society, like the Universities and the College of Preceptors.

Mr. SLIPPER seconded the motion. He thought such a plan would be more satisfactory to all parties, and it had been already adopted by the Veterinary College.

Mr. HAMPSON thought this motion was somewhat out of order, no notice having been given of it; and it was a matter of such great importance that he thought that course should have been adopted, in order that many gentlemen not then present might have had an opportunity of discussing it.

Mr. SCHACHT also urged on Mr. Atkins the desirability of withdrawing his motion. It was, perhaps, a little uncourteous in him to do so, after the kind expressions Mr. Atkins had used towards himself; but the consideration which weighed with him was this, they were all exceedingly anxious that every youth who was taken as an apprentice should pass the Preliminary examination, and that being so, he thought they should not put the slightest impediment in the way of that being done. For that reason he had done all he could to make the number of centres appointed for conducting these examinations as large as possible; because, as they had no legal power to enforce such a regulation, the least they could do would be to put no impediment in its way. It was a matter which had been urged repeatedly. It was perfectly optional for those who preferred it, to pass the examination of any of those bodies, but in many cases it would be very difficult for youths to do so. It was to meet those cases that the Preliminary examination was continued, and he therefore urged that, at any rate at the present time, it would be inopportune to pass such a resolution.

Mr. SANDFORD said several members of the Council were very anxious to adopt a resolution of this kind when the bye-laws were altered. It had been suggested that Mr. Atkins was not in order, but he might easily become so by prefacing the resolution with the words, "That it is desirable." It was not competent to the meeting to say it should be done, because that could only be regulated by a bye-law.

Mr. ATKINS said he should be very happy to adopt the suggestion of Mr. Sandford, as he only wanted to elicit the feeling of the great body of pharmacists, in order that the incoming Council might know what their opinion was. He was very glad to say that, by means of argument and discussion, the desirability of the Preliminary being passed before apprenticeship was generally acknowledged through the trade. His one point was that, this being a strictly literary and scholastic test, it should be conducted by literary and scholastic bodies.

Mr. BROWN suggested that if the motion were carried in its present form it would appear rather dictatorial to the incoming Council, who would feel bound to immediately take the subject into consideration, and alter the regulations in accordance with it. He would suggest, therefore, a further alteration, by which the resolution, if carried, would simply request the incoming Council to take into consideration the desirability of pursuing the course recommended.

Mr. URWICK said he upheld as strongly as anyone the desirability of youths passing the Preliminary Examination before being apprenticed, but no notice had been given of this motion, which, although it would not much affect London members, might very materially affect the chemists and druggists in the country, and therefore he hoped it would not be pressed.

Mr. ATKINS said he had accomplished what he wished in bringing the subject forward, and as he had no wish to divide the meeting, he would withdraw the motion.

The Scrutineers to examine the voting papers for the election of Members of Council and local secretaries, were then appointed.

Mr. WATTS moved a vote of thanks to the President and Vice-President for their services during the past year, which was carried by acclamation.

The meeting was then adjourned until Friday at eleven, to receive the Report of the Scrutineers.

ADJOURNED MEETING.

Friday, May 22nd, 1874.

MR. THOMAS HYDE HILLS IN THE CHAIR.

The Scrutineers brought up their report as follows:—

SCRUTINEERS' REPORT.

We, the undersigned Scrutineers appointed at the Thirty-third Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following:—

Voting Papers received		1166
Disallowed from informality		15
Votes registered		1151
Received by post too late	57	
Sent under cover to the Secretary	9	77
Unsigned by Voters on envelopes	11	

Hills	1047	Owen	502
Sandford	1018		
Schacht	1010	Baildon	405
Mackay	994	Atkins	391
Bottle	976	Stacey	383

FREDERICK ANDREWS, *Chairman*
GEO. S. TAYLOR.
GEORGE MEE.
M. E. FOSTER.
T. HOWARD HALL.
ROBT. RICHMOND, JUN.
SYDNEY PLOWMAN.
ALEXANDER B. LEWINTON.
H. W. POUND.
EDWARD L. CLEAVER.
THOMAS JULL.
GILES YARDE.
WILLIAM GULLIVER.
JOSEPH KETTLE.
JOSEPH LEAY.

May 21st, 1874.

The Chairman then declared the Council for the ensuing twelve months to consist of the following members:—

COUNCIL.

ATHERTON, JOHN HENRY, Long Row, Nottingham.
BAYNES, JAMES, 24, Waterworks Street, Hull.
BETTY, SAMUEL CHAPMAN, 6, Park Street, Camden Town, N.W.
BOTTLE, ALEXANDER, 37, Townwall Street, Dover.
BROWN, WILLIAM SCOTT, 113, Market Street, Manchester.
FRAZER, DANIEL, 113, Buchanan Street, Glasgow.
GREENISH, THOMAS, 20 New Street, Dorset Square, N.W.
HAMPSON, ROBERT, 205, St. John Street Road, E.C.
HILLS, THOMAS HYDE, 338, Oxford Street, W.
MACKAY, JOHN, 119, George Street, Edinburgh.
OWEN, JOHN, 51, Holloway Road, N.
RADLEY, WILLIAM VALENTINE, 74, Market Place, Sheffield.
RIMMINGTON, FELIX MARSH, 6, Ivegate, Bradford.
ROBBINS, JOHN, 372, Oxford Street, W.
SANDFORD, GEORGE WEBB, 47, Piccadilly, W.
SAVAGE, WILLIAM DAWSON, 4, Park Road East, Brighton.
SCHACHT, GEORGE FREDERICK, 7, Regent's Place, Clifton.
SHAW, JOHN, 24, Great George Place, Liverpool.
STODDART, WILLIAM WALTER, 9, North Street, Bristol.

SUTTON, FRANCIS, Bank Plain, Norwich.
WILLIAMS, JOHN, 16, Cross Street, Hatton Garden, E.C.

There being only the requisite number of candidates (five) for the office of auditors, the Chairman declared the following duly elected for the ensuing twelve months :—

AUDITORS.

ANDREWS, FREDERICK, 23, Leinster Terrace, Hyde Park, W.
BARRON, FREDERICK, 2, Bush Lane, E.C.
HODGKINSON, WILLIAM, 127, Aldersgate Street, E.C.
HORNER, EDWARD, 20, Bucklersbury, E.C.
SQUIRE, WILLIAM, 5, Coleman Street, E.C.

The Scrutineers also handed to the President their report of the return for the election of Local Secretaries.

Mr. ANDREWS said that this year was somewhat remarkable from there having been a larger number of candidates for election on the Council than in any former year, with one exception. It appeared to him a matter of regret that many members did not take the trouble to vote, and that many who evidently had the desire had deprived themselves of their privilege, either by sending their papers later than the time legally required, by not enclosing them in their official envelopes, or by not erasing a sufficient number of names.

The Secretary remarked that there had been 3200 voting papers issued.

Mr. ANDREWS could only account for so few being returned by the fact that the business of the Society had been satisfactorily conducted by the Council; and he congratulated the meeting upon the difference there was between the present time and twenty years ago, when there had been the large number of candidates, to which he had previously referred. Then, all was disquietude and anxiety; now everything was working harmoniously and, he believed, beneficially.

Mr. RIMMINGTON proposed a vote of thanks to the Scrutineers.

Mr. GREENISH, in seconding the motion, remarked that he had formerly, for three years, acted as Chairman of Scrutineers, and one of the most important and arduous duties in connection with the Society was that of the Scrutineer. He thought some greater acknowledgment than a mere vote of thanks was due to those gentlemen for their services.

The SECRETARY observed that on the present occasion the Scrutineers were occupied continuously from ten a.m., until nearly six p.m., and that the work was really very exhausting.

A vote of thanks to the Chairman was passed by acclamation, and the meeting separated.

Parliamentary and Law Proceedings.

MISTAKE IN LABELLING A BOTTLE. — CENSURE OF A MEDICAL ASSISTANT.

On Wednesday, May 13, an inquest was held at Masborough, respecting the death of Mr. William Raybould. It appeared from the evidence that for the past seven years Mr. Raybould had suffered from heart disease, and had been attended for that complaint by Messrs. Robinson and Knight, surgeons, of Rotherham. On the previous Monday, the deceased's symptoms became worse, and his wife consulted with Mr. Knight, who prescribed for him. He ordered two kinds of medicine to be prepared, one to be taken by the deceased, and the other, containing belladonna, to be applied externally. These were made up by his assistant, Mr. William Brent. On Tuesday morning, shortly before six o'clock, the deceased had a severe attack of angina, and took some of the medicine which was labelled to be taken internally. According to the testimony of Mrs. Raybould, some of the liquid was spilled from the glass in which it was administered, and the deceased took at most only about a tea-spoonful. He gradually became worse, however, and lapsed into a state of semi-unconsciousness. Mr. Knight was sent for, and was in attendance soon afterwards. While in the room where Mr. Raybould was lying, Mr. Knight happened casually to look at the medicine bottles which were on the mantel-piece, and found that the labels had been transposed, that directing internal application having been put on that which ought to have been applied externally, and *vice versâ*. After making inquiries, which showed that the deceased had taken some inwardly, Mr. Knight, without alarming either the dying man or his wife, at once took possession of the bottles, and proceeded with haste to his surgery, where he procured a stimulating draught to be administered. He returned to Mr. Raybould—who had vomited—to whom he gave the mixture he had brought. The deceased, however, did not recover from the state of exhaustion into which he had fallen, and died about half-past eleven o'clock the same morning. Mr. Knight, after consultation with Mr. Robinson, gave the bottles as they were when he first took possession of them, to Mr. Inspector Hey, whom he informed of the facts of the case. The Coroner, Mr. Dossey Wightman, was at once communicated with, and he ordered that a *post-mortem* examination should be made.

Mr. H. J. Knight, surgeon, of Rotherham, said: I have attended the deceased about seven years for heart disease. I prescribed for him, but did not see him on Monday, when his wife consulted me. I saw him about ten o'clock on Tuesday morning, when I was called in. I found him in a state of great exhaustion. It was then my opinion that it arose from heart disease, and it is my opinion now. I prescribed for him then. I had not looked at the medicine bottles then. I gave him some brandy. I saw on looking at the bottles on the mantel-piece that the labels had been reversed, which I had not seen before. I asked Mrs. Raybould if he had been sick, and she said he had. I did not tell her then because so little had gone, and I thought it would only agitate her more. I went away and got some medicine, and returned and administered it. I stayed with the deceased until he died at half-past eleven o'clock.

The coroner: Was there anything at all in the manner of his death which suggested to you that he died from anything else than heart disease?

Witness: I should not have thought so unless I had seen the bottles; but I thought it only right and proper, as there had been a mistake, to bring the matter forward.

The Coroner: Then I may say that in your opinion all the symptoms were consistent with heart disease.

Witness: Yes.

The Coroner: Is it probable that the medicine given in mistake accelerated death?

Witness: It might.

The Coroner: If he only swallowed a tea-spoonful?

Witness: If he swallowed a tea-spoonful of the mixture it might possibly have accelerated his death.

Mr. William Bent deposed: I have been in the service of Messrs. Robinson and Knight for three months. Previously I had been in the service of Mr. Brown, near Manchester, for about four years, off and on; and also of Mr. Clarke, of Manchester, for about eighteen months. I was apprenticed to my uncle, who was a surgeon at Manchester. I prepared the medicine in these two bottles from a prescription of Mr. Knight's. I put the labels on. They are not labelled correctly. The label on the smaller one should have been on the larger one. I did it in mistake, I am sorry to say. While I was dispensing the medicine an urgent case came from the Holmes, and my having to catch a train to go thither caused me to be in a hurry, and hence the mistake. The smaller bottle was for outward application. I am not aware that I had previously made up medicine for the deceased. I never made a mistake of this kind before.

Mr. W. H. Pearce, surgeon, of Rotherham, deposed: I made a *post-mortem* examination of the body this morning

with Dr. Hardwicke. The cause of death is disease of the heart in the great vessels. I do not find anything different from ordinary cases of heart disease. His taking the medicine in the way named might possibly have hastened his death, but I found nothing to show that it had done so. His stomach was slightly turgid. That might have arisen from his taking the wrong medicine. That medicine might have been the exciting cause of death, but not the predisposing cause. There was only a small quantity of fluid in the stomach, which smelt strongly of camphor, which Mr. Knight stated had been given as an antidote. The small bottle contains belladonna, of which I found none in the stomach.

Dr. Hardwicke coincided with the statement of Mr. Pearce as to the result of the *post-mortem* examination.

The Coroner then said that after the evidence of the medical men who had made the *post-mortem* examination, the jury could come to no other conclusion than that death had resulted from natural causes. There was no doubt that Mr. Bent had done a very careless thing in labelling the bottles wrongly, and he got out of a very fearful position very easily indeed. It might have been a very serious matter for him—he might have caused the death beyond all doubt of a human being. It was often his (the Coroner's) duty to censure people very severely; but in the present case, Mr. Bent being a man of education and experience, he hoped it was not necessary to do so, for he must feel what a position he had placed himself in. He hoped it would be a caution to him as long as he lived. If the evidence had been different—if the doctors had proved and stated that in their opinion the deceased had died in consequence of taking the medicine from the bottle wrongly labelled, he (Mr. Bent) would have been placed in a very undesirable position. He (the Coroner) did not think he ought to conclude the inquiry without saying that the conduct of Mr. Knight in the matter had been very praiseworthy. It would have been a very simple and easy thing for him to have taken these bottles away and given a certificate to the effect that death had resulted from heart disease. Mr. Knight, however, acted as every honourable and upright man should do, and gave the bottles to the police and informed them of the circumstances of the affair. There was very great credit due to Mr. Knight, and he (the Coroner) was very glad that nothing more serious had arisen from the matter.

The jury then returned a verdict of "Died from natural causes."

Dr. Hardwicke, addressing the Coroner, said that no doubt the attention of Mr. Bent had been drawn away from the bottles he was labelling, and he had got confused.

The Coroner said: That might be an excuse, but it did not exonerate him from blame.—*Rotherham and Masbro' Advertiser.*

The Ash and Extract of Teas.

Sir,—In my note on the ash and extract of teas, published in your issue of last week, a few of the figures in the tables have been misplaced. Will you allow me to correct them, as follows?—

No. 29 sample,	Silica should be	1·08
,, 30	,, ,, ,, ...	·68
,, 42 Caper,	Total Ash ,, ...	12·13
,, 44	,, ,, ,, ...	7·13
,, 47 Gunpowder,	,, ,, ...	42·94
,, 48	,, ,, ,, ...	7·01

G. W. Wigner.

May 18th, 1874.

The Recent Discussion on the Additions to the Pharmacopœia.

Sir,—As a very old member of the Pharmaceutical Society, I venture to trespass on your space with a few thoughts suggested to me by the unfortunate discussion at the last of the evening meetings of the session which has just closed. It may be said that I should have taken the opportunity to express my opinion at the time of the meeting; in reply I can only excuse myself by saying that, although in the house early for the purpose of attending that meeting, I was prevented, by unavoidable circumstances, entering the theatre until after nine o'clock, when Mr. Smith's paper had been read, Mr. Carteighe's remarks were concluded, and Mr. Bland was finishing his speech. The opening of the discussion on the Additions to the Pharmacopœia, therefore, only came before me in print.

Now, Sir, I have always regarded the "evening meetings" as a very important institution, tending to mutual improvement, by affording means of an interchange of ideas, not only among members of our Society but also between pharmacists and the medical profession, many of whom have from time to time joined in our discussions, and many more of whom have doubtless perused the reports of those discussions in the pages of the Pharmaceutical Journal. I believe those evening meetings have greatly contributed to the better understanding which has grown up between prescribers and dispensers during the last thirty years, and I greatly regret that in endeavouring to shake off "*that ponderous, somnolent, dreary decorum of language the usages of our evening meetings seem to demand,*" Mr. Smith should have been betrayed by the spirit of "*banter*" far enough to write down—not to utter in haste—remarks which were fairly taken by Professor Redwood, and may also be regarded by those members of the Medical Council who have sat on the Pharmacopœia Committee, as an attempt to bring both the book of Additions and its authors into ridicule. Had Mr. Smith applied that ability he is so well known to possess fairly in criticism of the articles now introduced, as Mr. Umney did at a previous meeting, not a word could be said to deprecate such a proceeding; the fullest, freest, most open discussion of that kind is desirable, and I venture to believe would be acceptable to the Pharmacopœia Committee.

It seems, however, that the object was rather to prove that persons possessing more pharmaceutical knowledge than can be expected of physicians should be called to aid in compiling a Pharmacopœia. As an abstract proposal that may be right enough, and is already recognized by the Medical Council. I had the honour of a seat in the Pharmacopœia Committee, which was appointed by our own Society at the instigation of the College of Physicians, and afterwards placed in communication with the Medical Council; therefore I know how extensively our work was recognized and adopted in 1864. After that, what happened? Why, the Medical Council, to whom alone the law gives the authority to issue a Pharmacopœia, committed the work to only *four* of their members, and to those four were added, as assistants, Mr. Warington, of the Apothecaries' Hall, and Dr. Redwood, our own professor of pharmacy. Surely practical pharmacists were recognized and consulted there! If we take Dr. Redwood's account of the manner of proceeding lately adopted, I think it is pretty certain that the four-and-twenty copies of the *proposed* Additions were quite as extensively submitted to pharmacists as to physicians for approval.

Far be it from me, Sir, to object to a wider circulation of any future proposals; but I ask whether, if Mr. Smith's paper be taken as indicating the tone and temper of the Pharmaceutical Society, a request for such an extension of mutual goodwill and confidence between us and the Medical Council, or profession generally, is likely to be conceded?

George W. Sandford.

*** In consequence of the length of the reports of the annual meeting, etc., we are compelled to postpone the publication of several communications.

Communications, Letters, etc., have been received from Mr. Byles, Mr. J. McGill Murdoch, Mr. H. Chapman, Mr. C. Gerring, Mr. J. Whitfield, Mr. R. J. Shields, Mr. H. Barton, Mr. F. W. Fletcher, Messrs. Young and Postans, Mr. J. W. Lloyd, Mr. J. Barton, Mr. G. Welborn, Mr. H. S. Ellison, Mr. T. Hopkinson, Mr. A. Squire, "Sigma," "Pharmacist from 1842," "Spes," "A Titan," "Botanist," "Palmam qui meruit ferat," "Alpha," "Morphia," "Inquirer," C., G. T. D., T. P. B., J. B.

PILL COATING.

BY J. A. COPE.

The introduction of pills covered with a tasteless kind of enamel, which is perfectly soluble and harmless, is certainly a step towards elegant pharmacy, and has many great advantages over the old method of dusting pills, to prevent their sticking together and to mask the taste. The manufacture of pearl-coated pills has been carried on extensively by several firms during the last few years, and there appears to be a growing demand for the product. The bulk of these pills reach the public through medical men who send out their own medicine, and who, no doubt, are glad to be relieved of the troublesome business of pill-making. And if medical men educate their patients to prefer their pills made tasteless and as attractive as possible, it will not do for pharmacists to be behind the times. They must be able to compete on the small scale with those firms who make it their business.

Medical men are not to be questioned as to the remedies they prescribe, and few pharmacists would care to acknowledge "they did not make their own pills, but obtained them from a reliable source, and believed them to be of the purest ingredients." And it is desirable that even stock pills should be prepared on the premises. The secret of pill-coating does not appear to be in what the coating consists of, which, in most cases, is powdered French chalk, but in the way it is put on.

The following simple method I have found to give very satisfactory results, and produce pills having an elegant appearance which will bear comparison with those now in the market.

The ingredients used are powdered French chalk, and thin mucilage of gum arabic—one part mucilage of the Pharmacopœia and two parts distilled water, answers very well. The apparatus used may be found in any pharmacy, namely, a small evaporating basin, having a flat bottom, capacity eight or ten ounces two covered gallipots, one holding four or six ounces, the other about double that size, and a pill-tray.

The pills to be coated should be of good consistence, not too hard, and rolled perfectly round, to ensure their being a good shape when finished. It is well to use French chalk in the place of starch-powder when rolling them out.

Into the small gallipot put some of the chalk, and into the basin put as much mucilage as may be necessary to thoroughly moisten the quantity of pills to be coated (from six to six dozen pills may be done conveniently at one operation). Next put in the pills and shake them round horizontally until sufficiently moistened, then turn them into the pot containing the chalk, and shake them round so as to get well covered with powder; turn them on to the pill-tray and allow to remain a short time, and lastly place them in the empty gallipot and shake round, so as to polish them and shake off the superfluous powder.

To coat pills by this method occupies about the same time as to silver them, but for stock pills which may have to be kept some time it is better to repeat this process, taking care to have the first coating dry before a second is put on. This will be found to give them a firm pearl-like exterior, which preserves the pills of good shape and consistence, and prevents any change that would be likely to occur through lengthened exposure to the atmosphere.

A few trials will suggest the best way of manipulating, and enable anyone to produce a fair sample of coated pills.

Derby.

Since the above was put into type, we have been favoured with a note on Pill Coating by Mr. John Whitfield, F.C.S., of Scarborough. The details of the manipulation are essentially the same as those described by Mr. Cope; but as the result of experiments in this direction, Mr. Whitfield uses a varnish made as follows:—

Common Amber Resin . .	1 to 2 drachms.
Spirit of Turpentine . . .	1 drachm.
Oil of Geranium	20 minims.
Absolute alcohol	To make 1 ounce.

The oil of geranium may be omitted, or substituted by other essential oils at discretion. The pills should be made as hard as possible.

Mr. Whitfield remarks that some pills take the coating at once, others not so readily. In the latter case the powder should be sifted off, and the varnish applied again exactly as at first. A second coat seldom fails, and it increases the bulk of the pills but slightly. He is of opinion that there can be no objection to the resinous varnish on the ground of insolubility, as he finds when the coated pills are placed in water the covering cracks and exposes the pill more rapidly than sugar coating.

Pills containing much essential oil are not well adapted for coating.

ANALYSIS OF "VANDYKE RED."

BY G. WELBORN.

Vandyke red is a brilliant scarlet pigment, extensively employed both as an oil and water colour, also, in calico-printing and dyeing; and, while its cost is considerably less than vermilion, it almost equals the latter in richness of colour. The following notes give an outline of the method adopted in arriving at its constituents:—

A little of the powder was boiled in water. The liquid was then filtered from the insoluble matter and evaporated to dryness: a slight dirty-white residue was obtained, which did not effervesce on the addition of dilute hydrochloric acid. Ammonic oxalate gave no precipitate in the aqueous solution of the above residue. A concentrated hydrochloric acid solution of the residue gave a purple flame when heated on platinum wire in an air-gas flame.

The latter reaction indicated the presence of a trace of potassium.

A second portion of the powder was completely decomposed on boiling with concentrated hydrochloric acid, with separation of slender white crystals. The supernatant liquid was of a bright pale green colour: this was carefully poured off the crystals and set aside. The crystals were washed with a little cold water, and then dissolved in water: the solution was acidified with hydrochloric acid, and sulphuretted hydrogen passed through it. There was a copious black precipitate, which, separated by filtration and washed, was soluble in boiling dilute nitric acid. Separate portions of the latter solution were treated with the following reagents:—Dilute sulphuric acid and alcohol gave a heavy white precipitate. (These reagents remove every trace of lead from a solution of a lead salt, since the most delicate tests for this metal failed to give any indication of its presence in the filtrate.) Ammonic hydrate, a white precipitate, insoluble in excess. Potassic

hydrate, a white precipitate, soluble in excess. Potassic iodide, a yellow precipitate, soluble in boiling water. Potassic chromate, also a yellow precipitate. The above reactions were confirmatory of the presence of lead.

The green-coloured solution was next examined: it was first diluted with water, then treated with sulphuretted hydrogen to remove a trace of lead: the plumbic sulphide filtered out and rejected. Ammonic chloride, ammonic hydrate, and ammonic sulphide were added to the filtrate. There was a black precipitate: it was filtered out, washed, then dissolved in dilute hydrochloric acid and divided into three portions. Potassic ferrocyanide gave a slight blue colouration only. Ammonic hydrate, a bluish-green precipitate, partly soluble in excess to a pink solution. Potassic hydrate, a bluish-green precipitate, soluble in excess and reprecipitated on boiling. The two latter reactions indicated the presence of chromium.

All metals of the ammonic carbonate group were proved to be absent in the ammonic sulphide filtrate.

Dilute hydrochloric acid changed the colour of the pigment to yellow (that of normal chromate), and this being digested with a dilute solution of potassic hydrate, the original colour reappeared, thus showing that the pigment is basic lead chromate, or, diplumbic chromate.

It is obvious that the above reactions may be employed in estimating the lead and chromium quantitatively. Two grammes of diplumbic chromate were boiled with concentrated hydrochloric acid and alcohol, until complete decomposition was effected. The whole was evaporated to a stiff paste on a sand-bath, washed with alcohol, until the plumbic chloride was pefectly white. (Plumbic chloride is insoluble in alcohol, while chromic chloride is soluble.) The washings were filtered through a tared filter, and evaporated on a water-bath until the residue ceased to lose weight. It was pasty and of a deep green colour, and weighed 0·7 gramme. It was then transferred to a sand-bath and heated carefully, so as to avoid decomposition of the chloride; it was now found to weigh 0·65 gramme.

It was very doubtful if all the water was even then expelled. It is, therefore, preferable to decompose the chromic chloride by ignition in a covered porcelain crucible, and estimate the chromium as chromic sesquioxide.

The plumbic chloride was dried, and found to weigh 2·07 grammes.

The following equation shows the chemical changes involved in the decomposition of diplumbic chromate by hydrochloric acid:—

$$\underset{1061}{2\,Pb_2CrO_4} + 16\,HCl = \underset{1112}{4\,PbCl_2} + \underset{318}{Cr_2Cl_6} + 8\,H_2O + Cl_2.$$

The theoretical yield of plumbic chloride, from 2 grammes of diplumbic chromate is found as follows:—

As 1061 : 2 : 1112 : x = 2·096 grammes. The amount of chromic chloride from a like weight of chromate, is found by the following equation:—

As 1061 : 2 : 318 : x = 0·5994 gramme. It will be seen that these numbers are very nearly those obtained by analysis, and conclusively proves that the compound is "diplumbic chromate."

By the above process, chromic chloride is readily obtained from normal, or diplumbic chromate, in a state of purity.

THE COLLECTING AND MOUNTING OF SEAWEEDS.

In compliance with a request, the information contained in a recent article (p. 754), respecting the preparation of land plants for herbaria, is now supplemented by the following directions for collecting and mounting algæ:—

Collection.—The best places to search are pools among the rocks and mudbanks of estuaries, near the sea. Specimens thrown up on rough beaches are generally too much battered and discoloured. Growing specimens are always brighter in colour. On sandy shores the best specimens will be found floating. The best time to collect is when the tide has just commenced to flow, after the lowest ebb, as the seaweeds are then floated in, in good condition. They are most abundantly found after recent storms. An ordinary fish-kettle or two pickle-bottles may be used to bring the specimens home. These should contain sea-water and a piece of flat green seaweed (*Ulva latissima*), as this keeps the specimens fresher. The olive seaweeds should never be mixed with the red or green species; for some of the former, such as the *Desmarestiæ* and *Ectocarpi*, rapidly decompose the red species. On no account should bleached or battered specimens be brought home; all specimens should be either red, green, purple, black, or olive; no others are worth preservation. It will be well to collect a number of apparently different species before attempting to name any of them.

All specimens should be cleaned at the shore, as far as possible, before putting them into the bottles or fishing-kettles.

Mounting.—The delicate species should be mounted first, as they change colour more rapidly than the others. Sea-water should alone be used in laying out specimens. Two flat white dishes are required—one to turn the algæ into, and the other to lay out the specimens in. This is done by immersing a piece of paper just below the surface of the water, and supporting it by the left hand: the alga is then placed on the paper and kept in its place by the left thumb, while the right hand is employed in spreading out the branches with a bone knitting needle or a camel's hair pencil. If the branches are too numerous, which will be readily ascertained by lifting the specimen out of the water for a moment, pruning should be freely resorted to, as much of its beauty will depend upon the distinctness of the branching; and unless the ramifications be well shown, it is very difficult to name some species. Pruning is best performed by cutting off erect and alternate branches, by means of a sharp-pointed pair of scissors, close to their juncture with the main stem. The floating fragments should be removed, either at once or after laying out each specimen, by straining the water through fine muslin or calico. When the specimen is laid out, the paper should be raised gradually in a slightly sloping direction, care being taken to prevent the branches from running together. The delicate species are much improved in appearance by re-immersing their extremities before entirely withdrawing them from the water. The minute branches are thus floated out naturally, and show the character of the plant. The papers should then be laid *flat* upon coarse bibulous paper, only long enough to absorb superfluous moisture. If placed in an oblique direction the branches are liable to run together.

They should then be removed and placed upon a sheet of thick white blotting paper, and a piece of

washed and pressed calico placed over each specimen, and then another layer of blotting paper above the calico. Several of these layers are then pressed in the ordinary way, light pressure only being used at first. The papers, but *not* the calico, may be removed in six hours, and afterwards changed every twenty-four hours until dry. If the calico be not washed it frequently adheres to the algæ, and if the calico be wrinkled it produces corresponding marks on the paper.

Dudresnaia coccinea should not be pressed, but allowed to dry on the paper. This species will be readily recognized when found, by feeling like jelly, and being so slippery as to be with difficulty picked up.

Wrangelia multifida should be pressed as soon as possible, without draining, or it will change colour.

The *Griffithsiæ* are best laid out by putting the left thumb on a tuft, and flattening it out with a camel's hair pencil.

Coarse black algæ should be soaked in fresh water to remove some mucilage, etc., and then be pressed between two pieces of calico, and afterwards mounted on paper by means of a solution of isinglass or gelatine in proof spirit. Such of the red algæ as do not adhere well may be made to do so by brushing them over with skimmed milk. It must be entirely free from grease, however, or the paper will be marked.

The most convenient sizes of paper to use are those made by cutting a sheet of paper, of demy size, into 16, 12, or 4 equal pieces. Ordinary drawing paper answers the purpose very well. For the herbarium, each species should be mounted on a separate sheet of demy or cartridge size. Toned paper shows off the specimens well, a neutral tint answering best for the olive, pink for the red, and green for the green series. In this way room will be allowed for varieties and abnormal specimens. To render the herbarium complete, specimens with both tetrasporic and capsular fruit should be sought for.

NOTE ON GUTTA-PERCHA.

BY E. COTTERELL.

Gutta-percha has now become official. It is "the concrete juice of *Isonandra gutta*," a tall tree of the sapotaceous order. A tree, which probably numbers 50 summers, is cut down, stripped of its bark, and the juice collected in a cocoa-nut shell or plantain leaf; or else, rings are cut in the bark, about a foot apart, and the sap collected. This is afterwards inspissated by heating it to its boiling point.

Gutta-percha, as imported from Malacca, its native country, contains, as Mr. Umney * very properly observes, several impurities ; which consist of soluble salts, together with some organic matter, such as fragments of the bark, etc. It is purified by rasping with cold, and washing with warm water. Afterwards it is heated to 230°F. to expel the water, which would interfere with its cohesive power ; by being heated it is also reduced to a single mass.

Purified gutta-percha has a density of 0 979, and is a very bad conductor of electricity, for which cause it is so much used for insulating supports in electrical machines and coating the wire of electric cables.

Gutta-percha is not acted upon either by water, hydrochloric or acetic acids, alkaline solutions, or alcohol. Chloroform and benzol are its best solvents: the former is the one selected by the compilers of the "Additions ;" but had benzol been official it would doubtless have replaced it, being cheaper : with chloroform it yields "a more or less turbid solution."

There are three qualities of Gutta-percha imported:—

The best "native," which occurs "in tough flexible pieces, of a light brown or chocolate colour," in pieces of all sizes and shapes.

Inferior "native," which is lighter in colour, and more easily torn in pieces than the above.

The boiled sort, which comes to Europe in oblong pieces ; it probably consists of the two native sorts, boiled together to give it a fine appearance.

Gutta-percha enters into the composition of two official preparations :—

Liquor Gutta-percha, purified mechanically by Carbonate of Lead ; and *Charta Sinapis*, which is an imitation of the justly celebrated Rigollot's mustard leaves.

In 1848, Mr. Acton * after making various experiments with solutions of gun cotton, caoutchouc, and gutta-percha, arrived at the conclusion that a compound solution of caoutchouc with gutta possesses the requisite qualities for preserving the skin against the action of contagious poisons ; and also as a covering for the hands during *post-mortem* examinations.

The various other uses of gutta-percha, as applied to fine arts, etc., do not come within the scope of the pharmacist, and would therefore be out of place in this note.

HOW I PASSED MY MAJOR.

BY OTTO VON ROSE.

There is a wide-spread idea that it is almost impossible to pass the Major examination without going through a course of practical study at some school. Now, as I have succeeded in passing without attending any school whatever, I write these few lines with a view of removing this idea, and in the hope that they may induce a few more candidates to come forward.

I was apprenticed in a thriving suburb of London for a term of four and a half years, in October, 1867. After I had served two years of my time I became anxious about my Minor examination, and on applying to my master for time to study, I was allowed one hour and a half per day, if business permitted. Availing myself of this kindness, I set to work, and in November, 1871, succeeded in passing.

Six months later, on the expiration of my apprenticeship, I determined to become a candidate for the Junior Bell Scholarship ; but in this I was unsuccessful.

Soon after this I applied for and obtained a situation in a first-class pharmacy at the West End, where, through the kindness of the principal, I was allowed to attend the course of botanical lectures at Bloomsbury Square. From this time until after I passed I carefully avoided all newspapers and novels, as liable to distract my attention from study. I studied at least an hour and a half each day, during the whole of last year ; but it was not until after last Christmas that I really set myself to close study. About that time I fitted up for my own use a box containing all the principal re-agents, and with the help of these and a few test-tubes I managed to do some practical

* *Vide* PHARM. JOURN. Vol. viii. p. 297.

work—usually asking a friend for two salts at night, and getting up and finding out what they were before breakfast next morning.

My mornings I divided between practical chemistry and botany. For the study of the latter I bought faded flowers from a neighbouring florist; these answering my purpose as well as fresh ones, and being cheaper.

My evenings I divided between chemistry, materia medica, and pharmacy, always taking a particular subject on a particular night, so as to keep up a systematic course, without which it is impossible to do any real study.

The books I used were 'Attfield's Chemistry,' 'Pereira's Materia Medica' (last edition), 'Fownes's Chemistry,' 'Bentley's Botany,' and the 'British Pharmacopœia.' These books, though few in number, are ample for any student, as it is much better to read one book well than to half read two.

I feel sure that if any one will only adopt a regular system, and stick to it, three months will see him prepared to face the examiners and pass his examination very creditably.

Although I passed my examination without studying at Bloomsbury Square, I would strongly recommend any one who has the time and means at his disposal to do so; but it is especially to those who, like myself, are not able to obtain those advantages, that I have written these few lines of encouragement.

NOTE ON ERGOT AND ITS PREPARATIONS.*

BY EDWARD R. SQUIBB, M.D.

(*Concluded from page* 914.)

Fluid extract of ergot has also been used as a topical application to the os uteri upon cotton-wool, but is inappropriate to such uses on account of the irritant action of the alcohol. Physicians who observe closely, and who by looking for effects get rid of the trammel of arbitrary doses, appear to be most successful in the uses of ergot, and such physicians often, if not generally, use this preparation in much larger quantity than the doses given in the older books. It is most frequently used in females, and for affections of the uterus, and here an excellent indication of its maximum useful effects is easily reached in most cases by the production of uterine colic. In the treatment of fibroids, polypi, etc., it is perhaps the best practice to begin with the standard dose, and increase this until uterine colic occurs, and then diminish the dose so as to come just short of this in the succeeding continuous administration. The dangers of ergotism or ergot poisoning seem to have been overrated, since the writer has diligently inquired for such results from those who use it most largely, but has heard of no instance of hurtful effect. Dr. A. Jacobi, of New York, who has probably used it as frequently and in as large quantities or doses as any one in America, with both adults and children, and who is competent authority, and a close observer, recently replied that he had never seen an instance of ergot poisoning, nor heard of one in the practice of his associates. Notwithstanding this, he and all careful practitioners are always most careful and most watchful in this respect, and probably their exemption from bad effects depends upon their seeing indications of danger before they reach the point of danger. Besides, it is probable that the ergot poisoning described as the result of eating ergotized food, etc., could only occur among an underfed, semi-scorbutic people; or under other conditions not present in cases ordinarily requiring medication by ergot.

* Paper read before the American Pharmaceutical Association at Richmond, Va., September, 1873.

Dr. W. C. Wey, of Elmira, who has also used ergot freely, had at least one case in which it had been used in the treatment of a fibroid tumour of the uterus, with occasional interruptions, by the stomach, hypodermically and topically, during a period of more than two years, not only without poisoning, but with great advantage.

In January of 1869, Professor Langenbeck, of Berlin, first used what is loosely described as an "aqueous solution of secale" by hypodermic injection, in the treatment of aneurisms, with marked advantage. This practice is described in the Berlin 'Klinik Wochenschrift,' and an epitome of the paper is published in 'Ranking's Abstract for July, 1870,' p. 223. In the same Berlin Journal for 1872, Dr. Hildebrandt published the results of hypodermic injections of ergotin in the treatment of uterine fibroid tumours. This paper is epitomized in 'Ranking's Abstract for January, 1873,' p. 248. This treatment when tried in this country seemed to be difficult and uncertain, for want of a trustworthy and uniform preparation which should fairly represent ergot, and be adapted to hypodermic use, and at the request of Drs. J. Marion Sims, of New York, and W. C. Wey, of Elmira, the writer undertook what seemed to be a hopeless task, of making a preparation well adapted to hypodermic use.

Disbelieving in the existence of any separable active principle in ergot at all analogous to the morphia of opium, no preparation seemed available except an extract which should be soluble in an aqueous menstruum. Then knowing the difficulty with which non-diffusible extractive matters are absorbed when deposited in the subcutaneous cellular tissue, and the liability of such matters, however bland, to cause troublesome abscesses, the problem seemed to be impracticable. After a good deal of time and trouble given to the matter, and many complicated trials, which need not be detailed, the best practical result reached was that of making a solid extract of ergot by the evaporation of the fluid extract of the U.S. Pharmacopœia of 1860, at a very low temperature, by mechanical stirring.

If this fluid extract, carefully made by repercolation from good rye ergot, without any heat, be evaporated in a shallow capsule in a bath of water of 50°C.=122°F., by active and continuous stirring, until it is reduced to one-sixth of the weight of the original fluid extract taken, the result will be a spongy extract of a light brown colour, full of air incorporated by the mechanical agitation, and looking a little like pulled molasses candy. This extract has the full odour and taste of the fluid extract, concentrated by condensation, and probably has the full therapeutic value of the ergot from which it is made; and each grain of it represents six minims of the fluid extract, or six grains of the ergot from which the fluid extract was made. It is quite insoluble in cold stronger alcohol, but entirely soluble in diluted alcohol, and also is easily soluble in water, with the exception of an insignificant residue which is easily filtered out. Its solutions are slightly acid to litmus paper, and have their ergot odour strongly increased by the addition of alkalies. The concentrated solution in water is turbid before filtration, but after filtration is of a deep rich garnet brown colour. How this extract or its solutions will keep is of course unknown, but the probabilities of keeping unchanged are quite favourable in regard to the extract, but unfavourable for the aqueous solution. A five-grain pill of this extract of course represents the mean dose of thirty minims of fluid extract, or thirty grains of ergot, and it is not only much more easily taken, but in delicate conditions of stomach is much less liable to produce nausea, loss of appetite, etc. It does not, however, always agree better with sensitive stomachs than the fluid extract, nor does the stomach always tolerate it much longer. Hence it is very desirable often to relieve the stomach altogether for a longer time than the brief intermissions that can be permitted without losing ground already gained by the treatment; and to effect this, hypodermic and topical administration may be resorted to. Hypodermic medication is merely a short cut into the circulation whereby the process of digestion and assimi-

lation and the organs by which this process is affected are avoided, the absorption taking place directly from the cellular tissue. Hence the therapeutic action is more prompt; and in the case of medicines which are liable to decomposition, in the process of digestion, or to loss by entanglement with the fecal matters, smaller quantities are required to produce a given effect. But then, as most medicines are irritant, or at best liable to act as foreign bodies when introduced under the skin, they will more or less frequently cause abscess and painful irritation, and this in proportion to quantity, irritant nature, and their being more or less loaded with matters which are not diffusible. The filtered aqueous solution of this extract of ergot, though not well adapted to hypodermic use, is better adapted to it than the fluid extract, and perhaps is as well adapted as any preparation of the drug can be under the supposed required conditions. Such a solution has been used in this way with variable success. In some hands it seems to have been moderately and usefully successful, in others less so, while in some it has produced abscess so often that it was soon abandoned. The solution may be made of almost any desired strength, but that which seems to have answered best is the same as the fluid extract, or a minim for each grain of ergot represented in the extract. To make this solution, sixty grains of the extract is weighed into a small vessel and dissolved in about four fluid drachms of water by stirring. It is then poured into a small wet filter supported over a vial marked for containing just six fluid drachms, and when the liquid has passed through, the filter is rinsed through with water until the measure of six fluid drachms is reached. This solution should be made every week or two, or in the summer more frequently, until its permanence be ascertained. If desired, it may easily be made of double the above strength by halving the proportion of water, but what is thus gained in the quantity of the injection is perhaps over-balanced by the disadvantages of density in retarding the absorption.

This same solution seems well adapted to use as a topical application; the desired dose being put upon a dossil of cotton-wool, and this applied to the os uteri, with another dossil behind it. It might be inferred that this would be a very imperfect method of administration, and when first proposed by Dr. Wey as an alternative method, the writer predicted its failure, not being then aware of a somewhat similar practice in Germany as long ago as 1836. Dr. Wey, however, succeeded well and produced the characteristic uterine colic within two hours or less. This topical method may also be used by means of suppositories, and the best vehicle for the extract seems to be the mixture of gelatin water and glycerin, which, when in proper proportions, make a very firm jelly, that does not become hard, and keeps indefinitely. Beside, it melts at a gentle heat, and is readily soluble in aqueous liquids. This is but a nicer and more simple form of the compound used for the inking rollers of printers. It seems not improbable that oleic acid might be used as a vehicle for this extract, thus adapting it to dermic adminstration, but as yet no trials have been made.

THE OXIDATION PRODUCTS OF CINCHONINE.*

At the sitting of the Mathematical and Natural History Section of the Royal Academy of Sciences at Vienna on the 16th of April, Professor Hlasiwetz stated the results of an investigation of cinchonine, undertaken by Dr. Hugo Weidel.

Dr. Weidel had previously found that by the oxidation of nicotine with nitric acid, nicotinic acid, a well-crystallized and characteristic acid is formed. He was therefore induced to test chinoline in this respect, and was enabled to establish that it also yielded a similar acid.

* Transactions of the kaiserliche Akademie der Wissenschaften in Wien (1874), p. 78.

After this the cinchonine from which the chinoline had been prepared was tried, in the hope of throwing some light upon the constitution of that and similar vegetable bases, the so-called alkaloids.

In the first place the oxidation of cinchonine by means of nitric acid yielded four acids, the formation of which can be represented by the following equations:—

$$\underbrace{C_{20}H_{24}N_{20}O}_{\text{Cinchonine.}} + 8O = \underbrace{C_{20}H_{14}N_2O_4}_{\text{Cinchoninic acid.}} + 5H_2O$$

$$C_{20}H_{14}N_2O_4 + NHO_2 + 5NHO_3 = \begin{cases} \underbrace{C_{11}H_8N_2O_6}_{\text{Cinchomeronic acid.*}} \\ \underbrace{C_9H_6N_2O_4}_{\text{Chinolic acid.}} \\ 3H_2O + 4NO_2 \end{cases}$$

$$\underbrace{C_{11}H_8N_2O_6}_{\text{Cinchomeronic acid.}} + 2O = \underbrace{C_{11}H_8N_2O_8}_{\text{Oxycinchomeronic acid.}}$$

All these acids are well crystallized and definite compounds, the formulæ of which have been controlled by the analysis of several of their salts. It required a series of tedious experiments to isolate the oxidation products from the crude mixture and to purify them.

The most interesting of these four acids is the cinchomeronic acid, which is distinguished by the fact that by treating it with nascent hydrogen it can be converted into a strong non-nitrogenous tribasic acid, which in its turn can be entirely decomposed by dry distillation into a crystallizable pyro-product, carbonic acid and water.

$$\underbrace{C_{11}H_8N_2O_6}_{\text{Cinchomeronic acid.}} + 3H_2O + 6H = 2NH_3 + \underbrace{C_{11}H_{14}O_9}_{\text{Cinchonic acid.}}$$

$$\underbrace{C_{11}H_{14}O_9}_{\text{Cinchonic acid.}} - CO_2 - 2H_2O = \underbrace{C_{10}H_{10}O_5}_{\text{Pyrocinchonic acid.}}$$

Chinolic acid, the decomposition product of cinchonine, second in importance, has been recognized as a derivative of chinoline. It contains an atom of nitrogen in the form of NO_2.

$$\underbrace{C_9H_7N}_{\text{Chinoline.}} \qquad \underbrace{C_9\left\{\begin{matrix} H_4 \\ OH \\ OH \\ NO_2 \end{matrix}\right\}N}_{\text{Chinolic acid.}}$$

Cinchoninic acid is formed from cinchonine by the substitution of eight atoms of hydrogen by four of oxygen; it is possibly the carboxyl derivative of chinoline if its formula may be halved:—

$$C_{10}H_7NO_2 = C_9H_6N \,.\, COOH.$$

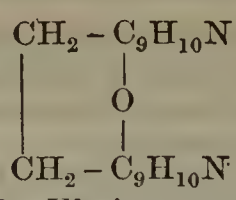
If at present it be not possible from this fact to settle the constitutional formula of cinchonine, it is manifest therefrom that neither is the constitution of chinoline, the chief product of the splitting up of cinchonine, nearer clearing up; and that the non-nitrogenous acid obtained, is not identical with any of the vegetable acids which it may resemble, nor with their derivatives. Its decomposition into pyrocinchonic acid, is analogous with that of citric acid into itaconic acid.

$$\underbrace{C_6H_8O_7}_{\text{Citric acid.}} - CO_2 - H_2O = \underbrace{C_5H_6O_4}_{\text{Itaconic acid.}}$$

$$\underbrace{C_{11}H_{14}O_9}_{\text{Cinchonic acid.}} - CO_2 - 2H_2O = \underbrace{C_{10}H_{10}O_5}_{\text{Pyrocinchonic acid.}}$$

Provisionally, therefore, we must be contented with a hypothetical formula for cinchonine, and as such, and one, moreover, that will serve to suggest further experiments, Dr. Weidel suggests—

* From "cinchonine," and μερος, a part.



By this formula Dr. Hlasiwetz considers that not only the experiments of Dr. Weidel, but also the facts ascertained in former investigations are best explained.

THE MEDICINAL AGENTS OF THE AMERICAN INDIANS.*

BY B. F. STACEY, CHARLESTOWN, MASS.

The query, "What medicinal articles are in popular use among the Indian tribes, and what properties are ascribed to such as are unknown to commentaries?" was proposed at the annual meeting of the American Pharmaceutical Association in 1870 for general acceptance; not having been replied to, it was taken up by the writer this year with the expectation of having a rich field of research. In this he was disappointed; the natural slyness and cunning of the Indian doctors render it very difficult to discover many of their medicines, and from a thorough investigation I am convinced that the list is not lengthy, and that there is but little to be learned from their school of practice or repertoire of medicinal agents. In many tribes more reliance is placed in charms and spells for curing diseases; and even when brought within the influences of civilization, the Indian when sick has refused all medicines, and looked only to incantations and the jingling of bells as a panacea to his ills. They are very prone to hang their faith on all the old traditional remedies of the past, and in many cases it is difficult to induce them to try anything else. It is related in King's American Dispensatory, that J. J. Caldas, pupil of the celebrated botanist Mutis, "who travelled from 1802 for many years in the mountains of Peru, in order to examine the natural history and geographical distribution of the cinchonas," states that the Indians who inhabit those regions, and among whom fever makes sad inroads, will not use it, believing that it heats the blood and the humours; and that the heaviest penalties are often inflicted to compel them to employ it as a remedy; and he remarks "that this prejudice is much against the fact of their ever having been acquainted with its use, as they cling with the greatest obstinacy to their inherited customs, vices, and prejudices." "Ulloa and Humboldt also express the opinion that the Indians were unacquainted with the use of cinchona."

As there is a wider difference in the histological elements, the higher in the scale is animal life, so is there a wider field for disease, and consequently for the action of remedies; we might, therefore, reasonably expect to find from these sources valuable hints, as well as useful adjuvants from aboriginal pharmacopœia, instead of which we have to confess embarrassment and meagre unreliable intelligence. The substance of my investigation only proves how little is known, and ever can be known now, to answer the above question.

Should one desire information concerning legends, religious customs, missions, dress, antiquities, moral or social condition, traditions or official relations with the North or South American Indians, curiosity could more readily be gratified. Observations concerning disease and more especially medicinal remedies, are not so generously recorded, if indeed they were ever at any time made. For one, I was never at any time able to see in the Indian character and life noble traits out-weighing repulsive barbarity. The miserable hordes of degenerate beings, enfeebled but not benefited by society, are quite likely the too common association with our opinion of the Indians; undoubtedly we do not realize the *pride, energy, self-reliance, independence of thought and action* which must have characterized their primitive simplicity. They have been compared in this condition to the cedar trees, withstanding the storms of ages; the dying of the top branches alone showing signs of decay. In one volume I saw at the Boston Public Library, published in the latter part of the last century, it was proved, at least to the writer's belief, that the Indians of the West are descendants of Jacob, and are in fact the long-lost tribes of Israel.

Before the landing of Europeans, the diseases common among the Indians were few in comparison with those which now debilitate their constitutions and thin their numbers. Tribes are mentioned in which never were known to exist any deaf, dumb, idiotic, or cases of insanity; others where only one or two instances of a deaf and dumb child or lunatic. Scrofulous and pulmonary diseases have always existed among them; probably, too, common continued, intermittent, and bilious fevers, dysentery, and rheumatism. Small-pox, however, ophthalmia, and venereal complaints in their most severe and loathsome forms, are the result of their acquaintance with civilized nations. We can imagine these maladies, their nature unknown, attacking a people exposed to storms and winds, liable to colds, with insufficient and unwholesome diet, subjected, too, to extremes of heat and fatigue, carrying heavy burdens—a deer, for example, weighing two hundred pounds—for miles, victims of intoxication and of wounds and internal injuries from fighting, furnishing material for a heightened and fatal virulence. When, too, we learn that one-half their children die before youth, we can realize why Indian tribes are now becoming among the extinct nations of the earth.

It has seemed strange to me, that, in the amalgam of races which serves to constitute the present American character, the Indian has formed so inconsiderable a constituent. Their characteristics would prove quite as desirable as the African, which some philosophers would make us believe is the only remaining element necessary to its perfection.

Where Indian tribes have received treatment from physicians at military and naval posts, the result of their experience with them is, that grave operations in surgery are not well borne, and that doses in minimum rather than maximum quantity produce better results.

The management of disease, when left to native skill exclusively, consists in the use of charms, rude forms of baths, and simple herbs. Their incantations might be compared to homœopathy, often a harmless interference, while nature effects the curative process.

One form of their baths is constructed of a wigwam, covered with hides, some three or four feet in height, in which is a large vessel of water. Into this water are plunged heated stones, and the vapour gives to the patient, seated in the inclosure a most effectual steam bath. Each tribe has its medicine men and women. Powwow, which signifies with us a noise, confusion, is in fact an Indian medical phrase, from their conjurations, attended with great noise and confusion, for the cure of diseases. Powwow is their term for a medical man, who is supposed to exercise domination over nature and the unseen world, uniting the character of priest and prophet, and often that of juggler.

Beth root (*Trillium pendulum*) is much used by the Indian women to promote parturition, uterine hemorrhage, etc.: it is also used in connection with unicorn root (*Aletris farinosa*) as a poultice for scrofula, glandular swelling, etc.

Mulberry leaves (*Morus rubra*), steeped in human urine, for fomentations in orchitis.

Wild cherry bark (*Prunus virginiana*) has always been used by them for its tonic effects, and also in dyspepsia, intermittents, and consumption.

Black cohosh (*Cimicifuga racemosa*) was given in rheumatism and for coughs. For rheumatism they used it in combination with poke-root (*Phytolacca decandra*).

* Read before the American Pharmaceutical Association at Richmond, Va., September, 1873.

Blue cohosh (*Caulophyllum thalictroides*), used by the squaws to ease parturition.

The water avens (*Geum rivale*), prominently mentioned by Dr. Wood, is valued for debility; it would appear the Chippewa Indians employ for the same purpose ragged cup (*Silphium perfoliatum*). The same tribe use yellow lily (*Nuphar advena*) in dropsy.

The well-known golden rod (*Solidago odora*) they use as a beverage in sickness, probably like our tea, for which it has been claimed it is really a pleasant substitute.

Masterwort (*Angelica atropurpurea*) aromatic is used in flatulence and colic. The *Senecio aureus*, a species of groundsel, from its saline taste, was employed externally and internally as an antidote to poisoned weapons.

Sweet clover (*Trifolium pratense*), used by the Penobscot Indians for sore eyes; also made into a salve for burns.

Night-blooming cereus (*Cactus grandiflora*), used by the Mexican Indians in irritation of the bladder, intermittent fever, difficulty in breathing, cough, etc.

The root of the *Actæa nigra*, a variety not noticed in the Dispensatory, a species of baneberry, thus classified because the berries are deemed deleterious, was much esteemed as expectorant and cathartic.

In venereal diseases, for chancre, they employ the actual cautery and a herb called Rosia, resembling, it is said, sarsaparilla.

For gonorrhœa, pills of wild pigeon manure, the therapeuties of which is not stated; also a herb named Chancelayna, which grows plentifully in California, and is a bitter astringent.

Dr. Herbert Miles, Surgeon British Army, relates his experience of the employment of the pitcher plant (*Sarracenia purpurea*) among the Nova Scotia Indians. "It is given in infusion; a large wineglass is taken; the effect of this is to bring out the eruption. After a second or third dose, given at intervals of from four to six hours, the pustules subside, apparently losing their vitality. The patient feels better at the end of each dose, and in the graphic expression of the 'Miemac,' knows there is a great change in him at once." Its action assimilates vaccination, modifies completely the disease, prevents pitting, and renders certain a favourable prognosis for the genuine variola.

Says the Scientific American, "Youpon, or Ilex cassine, a plant indigenous to the Southern States, but found only along the coast, is also used by them as an ingredient of the celebrated 'Black Drink,' which was used by the red men as a medicine, and as a state drink at some of their religious festivals. Youpon is used in some portions of the South as a substitute for tea and coffee and other stimulants; and it is reported to be very beneficial to inebriates who wish to cure themselves of their love for liquor."

Deer's tongue (*Erithroncum*), used by the Missouri tribes for breast complaints.

This brings me to the end of my list as far as I have had opportunity to catalogue.

At the present day, amongst the masses of the people and the uninformed, there is supposed to be a wealth of knowledge among the Indians concerning the treatment of disease, and "Indian Vegetable Pills," "Indian Restorative Bitters," and the host of patent medicines with the Indian prefix, are among the most saleable preparations in the market; and in our large cities there are swarms of advertising quacks, self styled Indian physicians, not one-tenth part of whom have a drop of Indian blood, and some I very much doubt ever saw a genuine "son of the forest." But the name takes; there is much in it, and always will be. Many regard the meadows, hills, and forests as laboratories, from which a medicinal agent for every known disease can be obtained, and suppose that many of these panaceas are known only to our dusky brethren.

ANALYSES OF EWE AND GOAT MILK.

BY DR. STEVENSON MACADAM, F.R.S.E.,
Lecturer on Chemistry, etc.

At the annual general meeting of the Gala Water Farmers' Club, held in the Town Hall, Stow, on Friday, May 1st, Dr. Stevenson Macadam gave an address on "Chemistry in connection with Agriculture," in the course of which he made the following remarks on the composition of ewe and goat milk:—

The nourishing properties of the various natural and artificial feeding stuffs must not only have an important bearing upon the sustenance, growth, and fattening of stock, but also on the quality of the milk yielded by cattle and sheep grazing on different pastures, and feeding on various artificial materials. Every agriculturist knows that there are certain fields where the sheep and lambs thrive better than on other fields; and such difference in the respective sustaining powers of the fields must be ascribed, in great part at least, to the respective qualities of the pastures in these fields—directly available in the grass, and indirectly available in the milk. Through the kind co-operation of my friend Mr. Lyall, of Caddonlee, I have been able to obtain five samples of ewe milk taken direct from the udders of five ewes placed under somewhat different circumstances; and having analysed these samples, I have now the opportunity of giving you the detailed results. I may mention that No. 1 ewe was newly lambed, and had been fed on turnips and second year's grass; No. 2 ewe was fed on second year's grass; No. 3 ewe was on first year's grass; No. 4 ewe was also on first year's grass, but in a different field; and No. 5 ewe was feeding on old pasture, probably 100 years old. Nos. 2, 3, 4, and 5 had been lambed for two to three weeks. The following table gives the principal results of the analyses of these samples of milk:—

ANALYSES OF EWES' MILK.

No. of Ewe.	Specific Gravity of Milk.	Cream per cent., by volume.	Total Solids per cent. by weight.	Solids not fat per cent. by weight.	Fat in Solids per cent. by weight.	Ash in Solids per cent. by weight.
1. Time of lambing...	1032·0	30	25·14	13·52	11·62	0·96
2. Two to three weeks lambed	1043·9	11	16·83	13·29	3·54	0·92
3. do. do.....	1036·2	20	19·83	12·41	7·42	0·98
4. do. do.....	1038·5	12	15·91	12·04	3·87	0·91
5. do. do.....	1027·9	22	18·55	10·48	8·07	0·94
Mean of all trials	1035·7	19	19·25	12·35	6·90	0·94
Mean of milk from Nos. 2, 3, 4, and 5 Ewes, and excluding No. 1 Ewe, being newly lambed	1036·6	16	17·78	12·06	5·72	0·94

It will thus be observed that the ewe milk taken at the time of lambing was extremely rich in solids and fat, and the milk taken from two to three weeks old varied much in quality. Indeed, excluding No. 1 ewe milk, which, being at the time of lambing, must be regarded as exceptionally high, the other samples of ewe milk ranged in specific gravity from 1027·9 to 1043·9; cream, from 11 to 22 per cent.; total solids, from 15·91 to 19·83 per cent.; solids not fat, from 10·48 to 13·29 per cent.; fat in solids, from 3·54 to 8·07 per cent.; and ash in solids, from 0·91 to 0·98 per cent.; whilst the average of the milks from Nos. 2, 3, 4, and 5 ewes, gave specific gravity, 1036·6; cream, 16 per cent.; total solids, 17·78; solids not fat, 12·06; fat, 5·72; and ash, 0·94. I am quite aware that the milk of a single ewe taken from each field must not be held as representing exactly the relative average composition of the milk from the whole or even from a score of the sheep in the respective fields; but taking the results of the analyses of the milks yielded by the ewes at Caddonlee, there can be no doubt that the milk of one ewe differs in quality, and probably also in

quantity, from the milk of other ewes grazing on the same farm and even in the same field. [Immediately after the address, Mr. Lyall, of Caddonlee, stated that probably part of the difference between the quality of the milks yielded by Nos. 3 and 4 ewes, which were both fed on first year's grass, might be due to the fact that No. 3 ewe grazed in a field which had the advantage of facing the south, and where the grass was more succulent and luxuriant, whilst No. 4 ewe grazed in a field lying to the north, and where the grass was not so succulent.]

The variation in the quality of ewe's milk is quite in keeping with the variations observed in the quality of cow's milk, as may be noticed from the following table, which gives the results of a large number of analyses of cow's milk taken from four dairies which supply milk to Edinburgh :—

Average.	Specific Gravity of Milk.	Cream per cent. by volume.	Total Solids per cent. by weight.	Solids not fat per cent. by weight.	Fat in Solids per cent. by weight.	Ash in Solids per cent. by weight.
Dairy						
A. Morning Milk	1031·46	7½	11·827	9·395	2·432	0·70
B. ,, ,, ...	1032·14	8	11·95	9·50	2·453	0·69
C. ,, ,, ...	10 3·0	8	12·36	9·91	2·45	0·69
C. Forenoon Milk.. ...	1032·3	10	13·54	10·41	3·13	0·73
D. Morning Milk	033·5	6¼	11·23	9·36	1·87	0·71
D. Forenoon Milk.....	1031·4	8½	12·58	9·74	2·84	0·71
D. Afternoon Milk ...	1030·8	9	12·43	9·52	2·91	0·72
Average of four dairies, representing forty-six cows and 66 samples of milk	1032·1	8¼	12 27	9·69	2·58	0·71
Differences in quality of milk, including all trials, but excluding partial runnings—						
Lowest	1028·3	5	10·57	8·62	1·56	0·62
Highest	1035·7	11	14·54	11·23	3·47	0 76
Difference	7·4	6	3·97	2·61	1·91	0·14

I have likewise examined, during the last month, five samples of goat milk—No. 1 sample was that taken from a goat—half-bred Egyptian—which had newly kidded ; No. 2 sample was from the same goat on the day after kidding ; No. 3 sample from the same goat during four days thereafter ; No. 4 sample from the same goat on the seventh day ; and No. 5 sample was taken from another goat where the milk was three weeks old. The results of the analyses of these milks were as follows :—

No. of Sample.	Total Solids per cent. by weight.	Solids not fat per cent. by weight.	Fat in Solids per cent. by weight.	Ash in Solids per cent. by weight.
No. 1 Goat Milk.....	29·28	21·52	7·76	1·18
No. 2 ,, ,, ...	19·42	13·58	5·84	0·97
No. 3 ,, ,, ...	18·26	12·51	5·75	0·96
No. 4 ,, ,, ...	16·18	11·52	4·66	0·92
No. 5 ,, ,, ...	13·43	9·12	4·31	0·73
Mean of all trials	19·31	13·65	5·66	0·95
Mean of Nos. 2, 3, 4, and 5, samples, excluding No. 1, being from goat newly kidded	16·82	11·68	5·14	0·89

The specific gravity and cream could only be conveniently taken in the case of No. 4 sample, where the specific gravity was found to be 1033·9, and the cream 13 per cent. by volume. The analyses demonstrate that when the goat drops the kid, the milk is extremely rich, and that the quality comes down day by day, till in three weeks it resembles, in composition, very rich cow's milk. It may be instructive to contrast side by side the quality of average cow's milk, average three weeks old ewe milk, and three weeks old goat milk, and the following table will enable us to do so :—

	Average Cow's Milk.	Average 3 Weeks old Ewe Milk.	3 Weeks old Goat Milk.
Total Solids per cent. by weight	12 27	17·78	13·43
Solids not fat	9·69	12·06	9·12
Fat in Solids	2·58	5·72	4·31
Ash in Solids	0·71	0·94	0·73

It will thus be observed that goat milk is richer than cow-milk, especially in fat, and that ewe milk is decidedly richer than either goat or cow milk on all points. It is probable that a knowledge of this fact may lead to the use of ewe milk by invalids and others desirous of having very rich milk as an article of diet.

INDIGENOUS BOTANY.*

BY G. E. DRUCE.

The advantages of the study of botanical science now scarcely require explanation, nor does its place in our pharmaceutical curriculum need apology ; the advantages are neither few nor small, and the position it occupies is not unimportant. Plant study is the true "open sesame" to the knowledge of botany, which is too often looked upon as a mere jumble of barbaric names strung most uninterestingly together, or as a necessary evil ; a subject to be crammed rapidly, as if it were some disgusting bolus to be got out of sight as soon as possible. Fortunately these opinions are gradually giving way to others more enlightened and true. The scientific names are hard only because they are strange : we do not call the terms capsule or bacca difficult, because we daily apply the first to poppy, and generally misapply the second to juniper ; we do not call the names geranium, camellia, or mignonette difficult, because they are household words ; familiarity with hard names is what collecting plants will bring to the student, till the *Hypericum*, the *Epipactis*, the *Chrysosplenium*, become equally as easy as the foreign ones already mentioned—polysyllables which only a short time before would have so upset mental digestion, that no remembrance of them would be retained save of their length and nastiness. It must not be considered that these long classical names are but a medley of haphazard letters, arranged in a haphazard manner ; on the contrary, they generally express some truth, some peculiarity, some property, hidden in the uncouth word. For instance, what can better explain the habit of the creeping St. John's wort than its specific name, *humifusum*—trailing along ; or is there not something appropriate hidden in the generic name *Erodium*, applied to the hemlock leaves ? Stork's bill—crane's bill—is an English name given to many of the geraniums, from their long fruit like a bird's neck and head—*Erodium* means heron. The *Helminthia* is so called from its *worm*-like fruit, the name recalling the word anthelmintic Names such as *vulgaris*, *arvensis*, *saxatile*, and *uliginosa*, denote frequency of occurrence and place of growth. Thus you would look in fields for *Knautia arvensis* or *Ranunculus arvensis*, on heaths for *Galium saxatile*, or among bogs for *Stellaria uliginosa* : those who have seen the great sheltering leaves of the butter bur can better appreciate the strange name, *Petasites*, derived from a Greek word meaning umbrella, and will not think the name *Lithospermum*—stony nutlets—misapplied to the hard-fruited gromwells.

It will be seen that something more is required of a botanical student than the mere gathering of plants, for that is no higher intellectual effort than collecting postage stamps ; while it requires patient perseverence to name plants with only book aid, yet the progress made, though perhaps slow, must teach one something of the science—must make one wish to know more. Every plant you may gather has something worthy of notice ; the meanest

* Read before the Northampton Pharmaceutical Association, April 27, 1874.

weed or gayest flower presents some peculiarity of structure, some strange habit, use, or property, and it is the discovering these habits, uses, and properties that gives much of the charm to our collections, and greater additions to our knowledge.

Let us take as the type of an order, the daisy—whose generic name, *Bellis*, is derived from a word meaning pretty, and its specific name, *perennis*, on account of its duration of growth—and see if any information is suggested by the "wee pinky tipped" favourite of Burns. Looking at the flower we see an outer ring or whorl of green organs, which looks like a calyx; next comes the pretty white part that forms an apparent corolla, and inside these is a collection of yellow organs which look uncommonly like stamens and pistil. This is a casual but most incorrect description, yet an explanation that doubtless has been given when an imperfect book student has been shown a flower and tried to examine it for, perhaps, the first time. But look at the daisy under a 2 or 3-inch binocular, or with a triplet, and you will say "Why, it looks like a lot of flowers;" and is it not so? Be a vivisector for once, cut out a piece of the yellow centre—disc it is called—and you will see that each yellow piece is really a complete flower, having, it is true, no calyx, but an elegant little funnel-shaped lobed corolla, not divided into petals, *i.e.*, monopetalous. Split open this little yellow corolla and you see some thread-like things called filaments, expanding at the top into what are called anthers. These anthers you see grow together round a central body, which is called a style, and has at the top a viscid space called a stigma; it is here bifid and has plano-convex lobes. This mode of anther growth is called syngenesious. The white ring or ray, apparently consisting of petals, consists really of flowers having no stamens, and the corolla is monopetalous, one side being elongated into a strap-shaped process, which forms the pretty white ray. The green outer organs of apparent sepals are really bracts, arranged in two rows, forming an involucre. The leaves are of a somewhat unusual shape—spathulate. This strange compound growth of flowers upon a common receptacle is called composite, and gives the name to one of the largest and most important natural orders, *Compositæ*, and the still stranger manner in which the anthers grow together round the style, their filaments remaining free, gives the name to one of Linnæus's artificial orders, *Syngenesiæ*. This syngenesious growth of anthers is very characteristic of the *Compositæ*. In other plants of this order, as the dandelion, the calyx is present as well as the corolla, and is that little plume which remains behind upon the receptacle after the corolla has withered and gone, and which the country youngsters blow to see "what's the clock." These plumes form pretty micro-polariscope objects when mounted in balsam; sometines, as in the plume thistles, this pappus calyx is beautifully branched. The fruit is fastened to these little parachutes, which are wafted about hither and thither by every passing breeze, till the rough appendages at the bottom of the fruit fasten it to some convenient anchorage, or drops down some crevice in the parched ground, and at some future period, under auspicious circumstances the seed germinates, grows, and produces a plant. It is not a little remarkable that when ground is turned over, as on railway banks, the most numerous of all the plants which appear are these pappus-bearing *Compositæ*.

But turning from the daisy to the buttercups, a great difference in appearance at once strikes our notice. Let us look at the little celandine, *Ranunculus ficaria*, Wordsworth's "star-like celandine." We see the calyx is formed of separate, distinct sepals, and the corolla with its golden burnished petals also distinct; coming next, situated on the thalamus—marriage bed—are the stamens which scatter the golden dust—pollen—with which the botaniser gets "foot gilt" on passing through the meadows; then next to the stamens in the centre is the compound pistil, consisting of several parts called carpels, and as these are distinct, the pistil is apocarpous; these form when ripe, achenia. The leaves are generally cordate in shape and glossy; the root is tubercular, and, from these tubers being formerly used in hæmorrhoids, the old English name for the plant—pilewort—was given. Another of the *Ranunculaceæ*, the marsh marigold, *Calsha palustris*, the "marish flower" that adorns boggy meadows and brook sides, is also worth notice on account of its green calyx which on expanding changes to burnished gold, making up by its showiness of sepals for the absent corolla. Next, another meadow plant but not resembling the preceding, is the cuckoo flower, *Cardamine pratensis*, In this plant the calyx is divided into four sepals and the corolla into four petals, which are arranged in the form of a Maltese cross. Plants with this cross arrangement frequently belong, and in fact give the name, to the order *Cruciferæ*—cross-bearing. The stamens are six, two being much shorter than the other four, an arrangement called tetradynamous; the two shorter stamens shed their pollen *towards* the stigma, the four longer *from* it. The tetradynamous stamens are very characteristic of the *Cruciferæ*, which is a truly natural order; all the plants in it are wholesome, and many of them possess antiscorbutic properties. The fruit, very rarely produced in this plant, is a siliqua or bean pod, being a long compressed pod with two valves joined to a centre partition by their faces; in the shepherd's purse, *Capsella Bursa-pastoris*, another cruciferous plant, the fruit is a silicula, the term given to a short and broad siliqua; whereas in the swine's cress, *Senebiera Coronopus*, the fruit is indehiscent.

A question often asked by beginners is, Where shall we gather plants? You cannot go anywhere without making some addition to your collection.

> "Everywhere about us are they glowing,
> Some like stars to tell us spring is born,
> Others, their blue eyes with tears o'erflowing,
> Stand like Ruth among the golden corn."

If you choose the meadows, now golden with buttercups, you may find the beautiful meadow saxifrage, *Saxifraga granulata*, with its peculiar root appendages; the early purple orchis, *Orchis mascula*, which will show you the gynandrous growth peculiar to orchids; or the tuberous earth nut, *Bunium flexuosum*, type of the *Umbelliferæ*, and the clovers, grasses, and sedges in abundance. Or if you prefer the highways, you may find Jack by the hedge, *Alliaria officinalis*, smelling strong of some allyl derivative; the herb Robert, *Geranium Robertianum*; while in places the sunny hedgebanks are blue with ground ivy, ale-hoof, *Nepeta Glechoma*, or the still prettier germander speedwell, with its two stamens; or trailing by the side of the dusty road, the silver weed (goose grass), *Potentilla anserina*, or its relation the cinquefoil, *P. reptans*; while masses of the avens, *Geum urbanum*, which has been recently pointed out as an adulterant of arnica, and whose root you should make acquaintance with; then the great favourite of the "Yarl" women, yarrow, *Achillea millefolium*, and agrimony, *Agrimonia Eupatoria*, the odorous violet, the red and white campions; or on the hedges, the dog rose and the *Lonicera Periclymenum*, the woodbine "which loves to crawl up the low crag or ruined wall;" while straggling over the hedges "white with May," the black bryony is showing its glossy heart-shaped acuminate leaves. Should you choose the cultivated fields, you see the *Veronica arvensis*, *hederifolia*, etc., the dead nettles, the "rank fumiter," *Fumaria officinalis*, the lovely scarlet pimpernel, *Anagallis arvensis*, the "burning spurge," *Euphorbia helioscopia*, oozing milky juice at every wound; or where the glaring red of the poppies, *Papaver Rhœas* and *dubium*, please, with their picturesque contrast, all but a farmer's eye. Should you take a forest walk, you need not be idle, nor your vasculum remain unfilled; for, if not too late in the season, you will see "thickly strewn in woodland bowers anemones their stars unfold;" the lovely crab blossom, blushing like the sky at morn, or in some dark nook, the delicately streaked corolla of the wood sorrel, *Oxalis acetosella*, with its trifoliate leaves, emblem of the blessed Trinity, or "the primrose stars in

the shadowy grass," the bugle, *Ajuga reptans*, with its creeping scion, and the barren strawberry ; while in some shady place great patches of the herb mercury cover the delicate little moschatel, or the blackthorn borders are brightened and whitened by the brittle *Stellaria Holostea*. Then sitting down near some lime tree, with its sweets attracting the bees and bright hairstreaks and fritillaries which sport about in the bright sunlight, you count your treasures while you not altogether neglect the inner man, and rise up with renewed vigour to look after the vulnerary's wood sanicle, and find not only that but the graceful ladies' mantle, *Alchemilla vulgaris*, with its crenated leaves (and the white bryony, growing its little cucumbers, type of the purgative elaterium and colocynth) ; or, again, the pink ragged robin and yellow archangel vie with the blue bells and dog violets, in beauty as in number ; or, taking to the ridings, you may find the eye-bright, *Euphrasia officinalis*—"the little euphrasy that gives dull eyes to wander leagues around," " the eye-purging euphrasy ;" or should you go for a canoe voyage down the river, you will see quite a different flora, "the blue forget-me-nots that grow for happy lovers," the chaste water lilies, with their peculiar structure, their large cells and spicular raphides, and their flowers so often showing a general transformation ; the arrow-head, *Sagittaria sagittifolia*, with its delicate flowers and sagittate leaves ; the tall *Butomus* ; the bur reed, *Sparganium ramosum*, with its stramonium-like fruit. Now sweeping by patches of creeping jenny or money wort, *Lysimachia nummularia* ; or tufts of the hairy willow herb, *Epilobium hirsutum*, with its peculiar pollen and apple-like smell. Now the banks are reddened by tufts of loosestrife, till in shallow water it takes extra pulls to get through the long waving masses of the water crowfoot. Then on again, crushing through thickets of the reed mace, *Typha*, or snatching at the yellow iris ; now quietly floating by some dark corner you find the horseradish, now again nearly hidden by the rushes and great water dock, *Rumex hydrolapathum*, which looks almost tropical from its profusion of growth. Or if, in your holidays, you should want to get "far removed from smoke of town," you go among the mountains, you will find occupation even there.

Never shall I forget the pleasures of an ascent of Cairngorme some time since, when in the Scotch Highlands. Our way first led through a part of the pine forest of Rothiemurchus, where the *Coniferæ* grow in almost Canadian profusion. Coming here and there on some little clearing where the " hewers of wood " had built their shanties in almost Canadian simplicity ; then keeping by the banks of the Spey, down which were floating rafts of timber. But as we continued our journey the river narrowed, and its appearance began to raise our piscatorial ardour, till, passing through acres of sweet gale, *Myrica Gale*, and *Vaccinium*, botanical love regained supremacy, and was rewarded by finding the *Trientalis europæa* ; then came a novel sight to us of black burnt ground and charred tree trunk—only about a yard remaining—not a bit of living green around, some forest fire having cleared a way across the forest. But soon getting to green vegetation again, passing by Lake Mydoch—where the golden eagle once had a nest—after a stiff walk we commenced ascending the mountain quickly, finding the *Saxifraga aizoides* and *hypnoides ;* now passing over a steep slope, heather-covered, soon we added the alpine ladies' mantle and *Sibbaldia* to our store ; then going over squashy bog we found the cranberry and the lovely cotton grass, *Eriophorum*, and, in ground where to stay was to sink, grew the *Lycopodium inundatum* and *Pinguicula*, butterwort. As we gained higher elevations, we found the creeping azalea, or near some little stream that looked like a silver thread falling from the snow fields above, the rare little *Arabis petræa*, or higher still some *Cetraria* or *Lycopodium* was growing, more typical of Lapland than Great Britain. And when at length we reached the summit, were we not repaid for the exertion by the grand expanse of country laying around ? Looking on one side over Loch A'An towards Ben McDhu, with the snow laying in the dark fissures of the mountain, or on the other side down into the forests of Glen More, with the deer jumping and bounding over some fern-covered knoll ; or in another direction, what a prospect of sterile beauty and magnificent wildness could be obtained. Such an array of mountain tops growing indistinct in the distance, till mountain or blue mist could scarcely be distinguished from each other !

Or should you prefer the lovely lake district, what numbers of plants you may gather in walking by the placid lakes, through the rugged passes, or in ascending the wild fells and mountains.

Walk for instance by Lake Ennerdale, through the valley of the Liza, and before you have long passed the "Angler's Lake," in some of the narrow lanes you will find the fugacious yellow poppy, *Mecanopsis cambrica :* and as you reach the boggy ground at the end of the lake, in some pool you may find the pale water lobelia, *L. Dortmanna*, and the bitter, tonic, bog bean, *Menyanthes trifoliata* ; while, growing on the rocks, the sea plantain shows its insignificant-looking spikes ; or where some little rill comes brawling down the fell side, the *Chrysosplenium* and the *Drosera*, with its glandular leaf-appendages. But the lovely views of the rocky precipices of the Pillow Mountain, with the ugly-looking rock that gives it the name, of Ennerdale Lake lessening in the distance, and the river Liza winding through the valley, compel us to leave botany for a time and we commence climbing up the stiff side that begins the Scarf Gap Pass, the rocks being covered here and there with the sweet scented mountain fern. On reaching the top we find, growing out of the rock, the bright green parsley fern ; passing on we soon lose the valley of the Liza behind Buttermere Lake, and Crummock Water comes in sight ; near the former, bordered by the bird cherry, green meadows lay with bells and flowerets of a thousand hues. Passing these and ascending gradually again till opposite the steep sides of Homster Crag, we must botanize, and, climbing recklessly up the steep sides, find *Thalictrum alpinum*, and by the side of a waterfall, *Oxyria reniformis*, the mountain sorrel with its kidney-shaped leaves, or by the side of the road in moist ground the pretty Lancashire asphodel with its spikes of bright yellow flowers, or the acrid *Ranunculus Flammula*. Then gradually descending into Borrodale, where we found the pale blue flower of the giant campanula beside the purple foxglove, and, climbing among the grass, the sweet little *Anagallis tenella*, bog pimpernel, with its tiny streaked corolla, truly a crown of glory, the large blue "pansy freaked with jet" ; and growing on old walls, on rustic bridges, out of jutting rocks, the ferns seemed everywhere, the wall rue, the spleenworts, polypody, oak and beech ferns, as beautiful as abundant.

We cannot help noticing how, on clayey ground, one series of plants grow ; on chalk, or limestone, these give place to new ; while on sandy soil, still fresh ones are found. So we find that geology has not a little to do with plant life, but that their growth has geological as well as geographical limits.

How peculiarly suited this science is to us needs scarcely an argument, for it adds still greater pleasure to the short respite from long and close confinement, not to say imprisonment, which we endure. How in the short hours devoted to this study we get knowledge, refining, enlightening, improving, teaching us

> "To look on Nature with a humble heart,
> Self-questioned where it does not understand,
> And with a superstitious eye of love ;"

leading us to art and science for help—since Botany requires a microscope to demonstrate and an artist to portray—explaining and making easy to us organic Materia Medica in the best manner, sending us to poetry for pet names for the pretty ones, opening glimpses into the distant past by the quaint, curious, suggestive, country names. These are only a few among the many advantages to be derived from a knowledge of botany.

The Pharmaceutical Journal.

SATURDAY, MAY 30, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SELECT COMMITTEE ON THE ADULTERATION ACT.

THERE are many points in the evidence of which we published a report last week, which are eminently satisfactory to those engaged in the practice of pharmacy, so far, at least, as the general repute of their calling is concerned. In the first place, there seems to have been an unanimous denial of the existence of adulteration as regards drugs to anything like the extent that is commonly—we had almost said vulgarly—assumed to obtain. No doubt many of the drugs imported into this country are impure, either by accident in collection, or by reason of intentional admixture, but in many cases this circumstance operates only as a reduction in their value, and does not make them, otherwise than relatively, less valuable for many of the purposes to which drugs are applied in the present day. Opium and cinchona bark are striking instances of this, for though much of the opium imported is below the standard quality, it is quite as well available for the manufacture of morphia. Cinchona bark of that kind which contains the largest amount of quinine is now so scarce that a serious injury would be done if any restriction were imposed upon the importation of various kinds of this bark that are inferior only in containing smaller amounts of quinine.

Some of the questions put to the witnesses by members of the Committee indicated very forcibly an exaggerated estimate of the extent to which adulteration affects the quality of drugs used for the preparation of medicine, or supplied by druggists throughout the country. Whether these questions represented the belief of the inquirers, or were merely put in order to test the soundness of popular impressions, we cannot say; but it is satisfactory to observe that they were in every way received with unqualified contradiction. As an illustration of what is now referred to, we may instance the question whether it was not notorious that chloroform is sold containing little or no chloroform at all. Again the question concerning James' Powder betrayed a total want of acquaintance with all the facts of the case; so, likewise the question whether a prescription ordering opium would not have a very different strength when prepared in Edinburgh from that it would have when prepared in London. Then, to judge from the questions asked, it seemed to be thought almost impossible to get a prescription properly dispensed in a provincial town, even such a one as York, which was by accident mentioned. On this point, obviously one of great importance, not only for the public, but equally for the general interests of pharmacy, the answers left no kind of doubt that a country druggist could supply drugs of quality quite equal to those sold in London, and that prescriptions were dispensed in the country as well as in London.

It would indeed be in itself a monstrous anomaly if this were not the case, and the mere suspicion shows that there is much room for making more widely known what is the nature of the work the Pharmaceutical Society of Great Britain has been engaged in for the last thirty-three years.

Another point referred to in the examination was the injury suffered by a druggist in consequence of a prosecution of an unfounded or frivolous nature. It was very properly contended that a pharmacist's reputation is worth more than that of an ordinary dealer, from the nature of his business. If then it be desirable to protect retail traders in general from the inconvenience and damage likely to arise from improper prosecution, this is especially the case as regards druggists. From this point of view a very strong case was, we consider, made out in favour of the appointment of some Central Board competent to consider proposed cases of prosecution, judge of the facts on their merits, and decide impartially whether sufficient ground existed for carrying out the provisions of the Act.

Our readers will be sufficiently familiar with the miscarriages that have taken place in adulteration cases to appreciate the value of some such organization for protecting the honest tradesman from becoming the victim of misguided zeal on the part of local officials who possess no special knowledge to qualify them for deciding, in many instances, whether a prosecution should be instituted or not.

In reference to this point, however, we cannot at all agree with the suggestion that the chemical department of the Inland Revenue Board should be, or could be made, the authority for reference in questions affecting pharmacy or drugs. Not that we at all disparage or undervalue the work that department has long been doing, both in its own proper sphere of action and on many occasions outside it. Our reason for this objection is the opinion that no good is done by concentrating in one department the conduct of various kinds of work. Moreover, we believe that the growing demand for the aid of chemical skill in many matters relating to the public health and local government calls for the establishment of a department of public chemistry, with officers specially capable of dealing with questions of that kind.

The tendency of much of the evidence given last week before the Committee on the Adulteration Act does not furnish any great support to that claim for exemption of chemists and druggists from liability under the Act for selling adulterated drugs, which has been urged on the ground that such drugs were

sold as obtained, and without sophistication on the part of the seller. Both Mr. Horner and Mr. Hodgkinson, while admitting that the Act presses harshly on the vendors of drugs, decidedly represented the influence of the wholesale houses as being exercised in protection of the retail dealers. They put forward, and we believe they did so justly, the view that druggists can easily obtain, even in the country, drugs of the best quality if they are disposed to pay the price. Speaking as representing the wholesale drug trade, they, in fact, disclaimed any responsibility for sales of adulterated or spurious drugs; and by implication, they threw upon the retailers the whole onus accruing in such cases as, for instance, that at Glasgow, reported in this Journal at page 824.

There is also some good reason for the fact that the Adulteration Act does not, any more than the Pharmacy Act, touch the wholesale trader. He may fairly take the position that, as a purveyor of goods to customers belonging to a specially educated class of semi-professional men, his business is to supply what is required of him, without inquiring what use is to be made of it. On the other hand, since the qualifications of the retailer to carry on the business of a pharmacist may reasonably be expected to comprize the ability to judge as to the quality of the drugs thus supplied to him, there seems to be but slender room for any repudiation of responsibility on his part if the drugs he sells or uses in dispensing are not what they should be. The grocer who pleads that the adulterated tea he has sold was supplied to him exactly in that state by the merchant, at the best cuts only a sorry figure, for who should be so well able to judge whether tea is good or bad as himself? In a business, however, where the materials dealt in are often the agents of life or death, the application of this principle is imperative.

RHEUM OFFICINALE.

Those of our readers who may wish to become acquainted with the appearance of the species of *Rheum* which Professor Baillon lately named *Rheum officinale*, upon the presumption that it is the true source of the officinal rhubarb, will find an excellent engraving of it in *The Garden* for May 23rd. The plant has a noble appearance, and it is said that although, perhaps, it may not be sufficiently hardy to withstand severe spring frosts, it will doubtless form an attractive decorative plant, either on lawns singly, or in other prominent positions, during the hottest months of the year.

THE JACOB BELL MEMORIAL SCHOLARSHIPS.

It may be useful to gentlemen intending to compete for the Jacob Bell Memorial Scholarships, to remind them that, under the new regulations, the last day on which applications can be received by the Secretary is Monday next, June 1st.

Mr. William Morgan, Ph.D., F.C.S., has been appointed Public Analyst for Swansea, at a salary of £100 per annum.

Provincial Transactions.

BRIGHTON ASSOCIATION OF PHARMACY.

A meeting of the above Society was held at 150, North Street, Brighton, on Friday, May 22nd., Mr. W. D. Savage, President, in the Chair, for the purpose of exhibiting microscopic objects.

A number of interesting preparations having been shown, the President brought the evening to a close by presenting Mr. Mathews, one of the honorary Secretaries, who is about to leave Brighton, with a handsome gold pencil-case, accompanied by a testimonial signed by all who had contributed to its purchase, expressive of their high appreciation of the services he had rendered to the Society during the time he had been Secretary, and their regret at losing him from their midst. He then made a short speech, in which he expressed the most kindly feelings towards Mr. Mathews and best wishes for his future success.

This having been followed by similar remarks from Mr. Cornish, and Mr. W. H. Smith, Mr. Mathews briefly responded, and the meeting terminated by passing the usual votes of thanks to the exhibitors and the Chairman.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, May 21st, 1874.—Dr. Odling, F.R.S., president, in the Chair. After the ordinary business of the meeting, the President called on Dr. W. H. Corfield to deliver his lecture "On the Sewage Question from a Chemical Point of View." The lecturer, after remarking that he was about to consider the value of chemical evidence on the sanitary view of the subject, compared the various systems for treating sewage, all of which might be reduced to two classes: the first, that of conservancy, where more or less of the solid matter was retained in the neighbourhood of habitations; and the other, where the whole of the excretal matter was removed along with the foul water by means of sewers. He emphatically condemned the former as poisoning the wells in the neighbourhood, and tending to produce disease; the death rate being in an inverse proportion to the efficiency of the means employed for the removal of the sewage. He subsequently discussed the methods of rendering sewage innocuous, showing that the only one of any value for this purpose was that of intermittent surface irrigation. An interesting discussion ensued, and the meeting finally adjourned until Thursday, June 4th, when the following papers will be read: 1. "On Dendritic Spots," by H. Adrien; 2. "On the Acidity of Normal Urine," by J. Reoch; 3. "Note on Kauri Gum," by M. M. P. Muir; 4. "On Certain Compounds of Albumen with Acids," by G. S. Johnson; 5. "On a Simple Form of Apparatus for Estimating Urea in Urine," by Dr. W. J. Russell and Mr. S. H. West; 6. "On Ipomæic Acid," by E. Neison and J. Bayne; 7. "On the Action of Chlorine and Bromine on Isodinaphthyl," by W. Smith; 8 and 9. "On Acetyl Sulphite" and "On a New Formation of Toluol," by Dr. D. Tommasi.

MEDICAL SOCIETY OF LONDON.

At the meeting of the Medical Society of London on the 27th of April, under the presidency of Mr. Victor De Meric, two papers were read bearing upon the administration of phosphorus. The first was by Dr. Routh, and was entitled,—

Some New Preparations of Phosphorus, with General Remarks as to their Therapeutical Value.

He stated that the paper was a corollary to his former communication on "Overwork and Premature Mental Decay." He then had mainly spoken of two preparations of phosphorus—viz., the solutio phosphori medicati, a solution of phosphorus in almond oil, with a little mucilage

and essential oil of the strength of 1-6th of a grain of phosphorus to the drachm; and the phosphide of zinc, both used by Mr. Hammond, of New York. In speaking of the effects of phosphorus as a drug, it was best to take this solution as a standard, and this pointed out the differences in the action of the other preparations. Dr. Routh then spoke of the effects of phosphorus, which were those of a stimulant in small doses, sedative, and producing a pleasant sensation of warmth, relieving neuralgia, and effective against certain obstinate skin diseases, such as eczema and acne, and he thought it retarded the progress of cancer. It was also an aphrodisiac, and appeared to improve the mental qualities if deteriorating. In larger doses it acted as an acrid poison, the peculiar feature being a burning sensation in the mucous tract, and whenever this symptom appeared it was a proof that the medicine had been carried far enough. With some persons it acted suddenly, producing, even after the first dose, sickness, faintness, and great stomach pain. Idiosyncrasy alone could account for this, and possibly decomposition. For these reasons Dr. Routh recommends the use of sperm oil, or purified neat's foot, in lieu of sweet almond oil; five drops of this solution added to a tea-spoonful of cod-liver oil improves the action of the latter in proper cases. The phosphide of zinc has been said to be inert, because insoluble, but it is easily assimilated. Rubbed up in a mortar it emits the characteristic garlic odour, and burns spontaneously when thrown over a flame. It is a weak preparation, and has been safely given in doses of one grain three times a day. Like other preparations of phosphorus, it is apt to clog up the liver, and must then be suspended for a few days. Chloro-phosphide of arsenic is prepared by bringing pure hydrochloric acid into contact with phosphorus and arsenic in a fine state of division. While the phosphide is insoluble, the chloro-phosphide is very soluble. The solution is of a clear yellow green, and pleasant taste. It is decidedly antiperiodic and effective in cases of neuralgia. This solution contains ten grains of arsenic, and 16½ of phosphorus to the ounce; the dose is, therefore, 3 to 5 minims, *ter die*. It can be largely diluted, and the author prefers one that is regulated at 15 drops. The syrup of phosphorus contains gr. 1-10th in the ℥i. The phosphorus should be added in a pure state, and finely divided with caution. It is very nice to the taste; dose 20 to 30 min. In cases of poisoning by phosphorus, Dr. Routh recommends emetics and an antidote in the form of turpentine; and in conclusion remarked that the exhilarating effects of the drug gained upon patients, and care must be taken lest in this way we introduce a new form of dram-drinking.

Mr. Ashburton Thompson then read a paper entitled

Suggestions for the safer Administration of Free Phosphorus.

He began by remarking that the internal use of phosphorus was almost as old as the discovery of the element itself, and that the medical literature of the century, dating from 1720, offered more essays on this than on any other single subject. Yet the employment of this element as a remedy was never firmly established, its history presenting fluctuations in popular favour that are unknown in the history of any other remedy. These fluctuations suggest that an element of danger attended the very great remedial properties it was found to possess. That this was the case was evidenced by the records of its use, where more than one case of fatal poisoning can be found. The author then alluded to the recorded experience of Drs. Hughes, Bennett, Eames, Cotton, and Broadbent, who gave phosphorized oil in doses equivalent to from 1-40th to 1-8th of a grain of free phosphorus in an aggregate number of fifty-two cases, with the frequent occurrence of abdominal derangement; then to his own experience of nine cases, in every one of which symptoms of poisoning had been observed—slight in all but one, in which death was hourly expected for three days. He then recited two cases of great interest, one already reported in the *Lancet* by Mr. Reedale. A child ten years old took for twenty-three days 3-5ths to 9-10ths of a grain of solid phosphorus, and the etherial solution daily, without evincing any serious symptoms, but did so after the fifth dose of 5-6ths of a grain dissolved in oil. The other case was reported by Solin. A male adult took half a grain of phosphorus in ether every twenty-four hours for nine days, and yet died of less than one grain dissolved in oil, and taken during thirty-five hours. He stated that others beside himself had found that a dose of phosphorus, poisonous when dissolved in oil, might be far exceeded if dissolved in ether and alcohol; while the excellent results obtained with the latter preparations testified to their activity. No case with the last-named solutions had been recorded. Mr. Thompson then considered what chemical change might account for the exhibition of unexpected toxic power on the part of phosphorized oil, and he asserted that phosphorized cod-liver oil might be given with the same safety as phosphorized ether or alcohol, and in the same doses. The main difference between this fish-oil and the vegetable (almond or olive) oils generally employed was, that the latter absorb very large proportions of air. As phosphorus oxidized very easily, this absorption exposed the element to change. Freely exposed to air, phosphorus passes rapidly into phosphoric acid—a harmless medicine; but it seemed plausible to the author to imagine that the density of vegetable acids, together with the peculiar manner in which they present oxygen to phosphorus, might serve to delay the element in its lowest and first stage of oxidation—viz., as hypophosphorous acid. The author then reviewed the important characteristics of this body—viz., causticity, its extreme avidity for oxygen, the ease with which it is absorbed; and alluded to a remark of Devergies, which showed that he had regarded their transformation as the cause of poisoning in Solin's case; also to Personne's recent experiments, which show that phosphorus, dissolved in hypophosphorous acid, is most readily absorbed, and becomes imbued with toxic powers quite out of proportion to the actual quantity of free phosphorus present. The author alluded to the possible influence of idiosyncrasy, and stated that, having watched more than 400 cases treated with this drug, and having carefully considered most of the hitherto recorded observations, he did not feel satisfied that any peculiar idiosyncrasy with regard to it existed, but he awaited the result of further experience. The solutions of phosphorus in vegetable oils do not, for the reasons stated, afford a safe means of exhibiting free phosphorus. The manner of preparing the oil in France consisted in heating it to about 560° F., and in England to 300°, which certainly drove off the air and water suspended in the oil, but did not avoid the dangers which must arise in the manner described from absorption of fresh portions of air and aqueous vapour, and therefore the author declined to use phosphorized vegetable oil any longer. He referred to the absorption of solid phosphorus by the stomach, and deduced the rule that it should be taken with food. Of zinc phosphide, he said that since it acted only after decomposition by the acids of the stomach it followed that many doses might accumulate and remain unchanged if the secretions of that organ were alkaline. If the accumulations were then suddenly brought in contact with acid, symptoms of poisoning would occur. This had happened in a case noted by Professor Gubler. The obvious and very necessary precaution consisted in the use of an acidulated tonic with each dose of the drug, or the dietetic employment of lemonade during the medication. Mr. Thompson concluded by stating that these rules, though simple, had never been formulated before, and he believes that ignorance of the facts on which they are founded had conferred on free phosphorus a reputation for treacherously poisonous qualities, even in remedial doses, in reality, appertaining (in the case of phosphorized vegetable oil at least) to an unsuspected admixture of combined (oxidized) phosphorus.

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of this Society was held on Wednesday, May 6th, under the presidency of M. Planchon. A paper of which the following is an abstract, was read by M. Guichard, on—

The Action of Carbon Bisulphide upon Benzoin, Tolu, the Resins, and the Gum Resins.

In a former note, the author described some large crystals which had formed in a flask where benzoin had been allowed to macerate for a considerable time in carbon bisulphide. From their origin, and a single examination made upon a small quantity of the crystals, he had been led to suppose that they consisted of benzoic acid. Further investigation, however, has shown that they contain a considerable quantity of cinnamic acid. Benzoic acid melts at 120°C., and cinnamic acid at 134°C. These crystals melted at from 130° to 131° C. Further, when treated with chromic acid they yielded hydride of benzoyl, a reaction which is characteristic of cinnamic acid. That acid, therefore, exists free in considerable quantities in amygdaloid benzoin, and its existence in Sumatra benzoin has been previously noticed by H. Kolbe, and Lautemann.

From the balsams of tolu and peru carbon bisulphide separates a resinous substance, and crystallizable acids. In order to obtain them in large crystals, the author extracted the acids from tolu with boiling water. These treated with carbon bisulphide, formed around the flask a hollow cylinder, in the interior of which were deposited large crystals that presented exactly the same form as those from benzoin. They melted at 134°C., and, treated with chromic acid, yielded hydride of benzoyl freely. They therefore consisted of cinnamic acid, which confirms previous observations.*

The ordinary resins are nearly entirely soluble in carbon bisulphide. The residue is formed of foreign organic matters, and other impurities ; and it is sufficient to filter and distil with a water-bath to obtain the resins pure. Balsam of copaiba dissolves completely, and elemi resin, mastic, turpentine resin, burgundy pitch, and colophony may be purified in the same manner. From 300 to 400 c.c. of carbon bisulphide are required for 500 grams of elimi resin.

Gum resins are not entirely dissolved by carbon bisulphide. If the liquid be evaporated a not very abundant residue is obtained, which has the appearance of a transparent yellow-brown resinous matter.

The insoluble residue presents points of much interest. That from gum ammoniacum is quite white, and if the gum was whole retains the form of the tears. If these be agitated with water, they are broken up and reduced to a milky emulsion with the greatest facility. The emulsion passes through a filter and deposits slowly a white matter, which is dried with difficulty into a grey soft mass. It is soluble in solution of potash, from which it is not precipitated by hydrochloric acid. At the same time, it gives off a sulphurous vapour that blackens nitrate of lead paper, and doubtless arises from some carbon bisulphide which is obstinately retained by the white powder, and requires the heat of a water-bath to drive off completely. It does not reduce Fehling's solution, even after boiling with dilute sulphuric acid. Ether does not dissolve the white matter, but renders it transparent and thick, like collodion, the ether floating above. It is attacked by nitric acid, which gives a yellow derivative, soluble in solution of potash. This potassic combination dissolves in strong alcohol and in water ; it is precipitated by hydrochloric acid in yellow flocks. The water from which the white matter is deposited retains, in solution, a substance that energetically reduces Fehling's liquor after the carbon bisulphide has been driven off by prolonged boiling. This liquor, evaporated in a water-bath, deposits a slightly sweet, very hygrometric, non-crystalline matter. The liquor is acid, and when left exposed to the air becomes covered with green mould. The sweet substance itself, evaporated to dryness, is also slightly acid, at any rate after some time.

Galbanum and sagapenum behave in a manner similar to ammoniacum. The carbon bisulphide dissolves a resin, and leaves a yellowish-white insoluble matter ; but this matter emulsifies more difficultly than that from ammoniacum, and it is necessary to employ boiling water. Assafœtida resembles ammoniacum in its behaviour.

The author suggests a process for purifying gum resins, based upon these properties, with the object of obtaining pure products for the preparation of plasters. The resins and gum resins are mixed in a flask with a sufficient quantity of carbon bisulphide, allowed to macerate for an hour, decanted, then macerated with a fresh quantity, and the whole filtered through lint. This product is distilled in a water-bath, and yields the resins. The insoluble residue is agitated in boiling water, when it disengages much carbon bisulphide, which may be collected by distillation. The whitish milk thus obtained is thrown upon a hair sieve, and the residue washed with a fresh quantity of water. It is then evaporated to dryness, and the product added to the resins previously obtained. For 1 kilogram of elemi and the quantities of gum resins corresponding to the formula of diachylon plaster of the Codex, in all, 1750 grams, the author employed two litres of carbon bisulphide and two litres of water. He obtained about 1205 grams of resins, 500 grams of gummy matters, whilst there were 200 grams of stones, vegetable debris, etc.

* Sce before, p. 927.

After the reading of this paper, M. Lebaigue said he thought it would be interesting to determine clearly whether the acid which exists in balsam of tolu be benzoic acid, or, as has been asserted, cinnamic acid. The size and purity of the crystals obtained by M. Guichard's method would allow of the elucidation of this controverted point.

M. Lefort described the results of the investigation by a commission upon the toxicology of phosphorus, and pointed out the insufficiency of the evidence presented by phosphoric acid or the ammonio-magnesian phosphate found in analysis. An abstract of this paper will be given in a future number.

SOCIETY OF ARTS.

The following lecture was delivered before the Chemical Section of the Society of Arts on Friday, April 24th :—

Pyrites as a Source of Sulphur, Iron, and Copper.

BY DR. C. R. A. WRIGHT, F.C.S.

In introducing the subject of the present paper, I fear that many of the remarks I have to make may be somewhat wanting in novelty, especially to those more peculiarly interested in the practical applications of the material in question. I have, indeed, no new discovery of scientific or commercial interest to bring forward but only a brief description of some of the more important industrial processes in which the mineral plays part, and of some of the more recent improvements made in these processes.

In the first place, what is meant by pyrites? This question can only be answered by a reference to some points more closely allied to pure science than to technical industry, although not absolutely without bearing on the latter. The term "pyrites" is applied by mineralogists to various substances more or less closely allied together in their chemical constitutions and properties generally, all of them agreeing in this point, that sulphur and iron are two principal constituents. To a particular variety, also containing copper, the term "copper pyrites" is applied, of which more anon ; of those varieties of which this metal is not an essential constituent, several distinct species may be enumerated, of which the more important are :—

1. Pyrites, *par excellence*, or yellow iron pyrites, the chief member of the group, consisting of iron and sulphur united in the proportions indicated by the following percentages :—

Iron	46·67
Sulphur	53·33
	100 00

Or more briefly by the chemical symbols FeS_2, whence the chemical name "Iron disulphide."

2. Marcasite, or white iron pyrites, a substance possessing the same chemical composition as yellow pyrites, but differing therefrom in various particulars, *e. g.*, its colour, its crystalline form (yellow pyrites crystallising in forms belonging to the monometric system, marcasite in shapes pertaining to the trimetric system), its specific gravity (yellow pyrites having the density 5·0 to 5·2, marcasite being somewhat lighter, having the density 4·85 to 4·9—Rammelsburg). Marcasite also oxidizes by exposure to air more rapidly than its isomeride, although yellow pyrites when in a finely divided state takes up oxygen with avidity, evolving a large amount of heat, so as occasionally to bring about spontaneous inflammation of mixtures of which this substance is a constituent.

3. Magnetic iron pyrites, or pyrrhotin, distinguished from the two preceding iron sulphides by containing less sulphur in relation to the iron, the composition approximating to the following percentages:—

Iron	60·49
Sulphur	39·57
	100·00

indicated by the formula Fe_7S_8, or as it may be written, FeS_2, 6 FeS, or Fe_2S_3, 5 FeS.

In addition to these sulphides of iron two others are known analogous in many respects to yellow pyrites, and capable of being used for the same industrial purposes as that substance; these are iron sesquisulphide, containing—

Iron	53·85
Sulphur	46·15
	100·00

indicated by the formula Fe_2S_3; and ferrous sulphide, or iron monosulphide, containing—

Iron	63·63
Sulphur	36·37
	100·00

and indicated by the formula FeS. These two bodies are rarely found in the free state as minerals, but when associated with the sulphides of various other metals, they form a numerous class of minerals known as double (or more complex) sulphides. Of these, the body designated as

4. Copper pyrites (towanite, chalcopyrite, kupferkies, &c.), is an example, it being a mineral possessing the percentage composition—

Iron	30·6
Sulphur	34·9
Copper	34·5
	100·0

indicated by the formula $FeCuS_2$, or otherwise Cu_2S, Fe_2S_3, or possibly CuS,FeS.

Closely allied to these different kinds of pyrites are several other minerals consisting essentially of sulphur united to other metals, exhibiting more or less similarity to iron; of these bodies, the sulphides of copper, lead, and zinc are the most important. Thus we have cuprous sulphide, Cu_2S, existing in copper pyrites associated with iron sesquisulphide, and also known separately as redruthite, (copper glance, vitreous copper, etc.); cupric sulphide, CuS, known as breithauptite, (covelline, indigo copper, blue copper, etc.); lead sulphide or galena, PbS; zinc sulphide or zinc blende, ZnS, etc.

(*To be continued.*)

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Alkali Act (1863) Amendment Bill.

The following is the text of a Bill to Amend the Alkali Act, 1863, introduced into the House of Commons by Mr. Sclater-Booth on the 11th May, and ordered to be printed:—

"Whereas it is expedient to amend the Alkali Act, 1863, in this Act referred to as 'the principal Act,' as made permanent by the Act of the session of the thirty-first and thirty-second years of the reign of her present Majesty, chapter thirty-six, and amended by the Public Health Act, 1872.

"Be it therefore enacted by the Queen's most excellent Majesty, by and with the advice and consent of the lords spiritual and temporal, and commons, in this present Parliament assembled, and by the authority of the same, as follows:—

"1. This Act, so far as is consistent with the tenor thereof, shall be construed as one with the principal Act, and this Act and the principal Act may be cited together as 'The Alkali Acts, 1863, 1874,' and this Act may be cited separately as The Alkali Act, 1874.

"2. This Act shall not come into operation until the *first day of March, one thousand eight hundred and seventy-five.*

"3. Whereas by section three of the principal Act, the term 'alkali work' is defined to mean 'every work for the manufacture of alkali, sulphate of soda, or sulphate of potash in which muriatic acid gas is evolved,' and doubts have arisen whether the formation of sulphate of soda in the treatment of copper ores by common salt or other chlorides is or is not a manufacture of sulphate of soda within the meaning of the said section; and it is expedient to remove such doubts: Be it therefore enacted that, The formation of sulphate of soda in the treatment of copper ores by common salt or other chlorides shall be deemed to be a manufacture of sulphate of soda within the meaning of the said section.

"4. Whereas it is provided by section four of the principal Act, that every alkali work shall be carried on in such manner as to secure the condensation of such percentage of muriatic acid gas as therein mentioned, and it is expedient to make further provision in relation thereto: Be it therefore enacted that,

"In addition to the condensation of such per-centage of muriatic acid gas as aforesaid, every alkali work shall be carried on in such manner as to secure the condensation to the satisfaction of the inspector, derived from his own examination or from that of a sub-inspector, of the muriatic acid gas evolved in such work to such an extent that in each cubic foot of air escaping into the atmosphere there is not contained more than one-fifth part of a grain of muriatic acid.

"If any alkali work is carried on in contravention of this section, the owner of that work shall be deemed to be guilty of an offence against the principal Act, and be subject to the penalties in that Act mentioned; and the provisions of the principal Act shall apply to the carrying on of an alkali work in contravention of this section in the same manner as if, wherever reference is made in the said Act to the condensation of muriatic acid gas to the extent in that Act mentioned, there were added a reference, with the necessary alterations, to the provisions of this Act relating to the condensation of muriatic acid gas.

"5. In addition to the condensation of muriatic acid

gas as aforesaid, the owner of every alkali work shall use the best practicable means, within a reasonable cost, of preventing the discharge into the atmosphere of all other noxious gases arising from such work, or of rendering such gases harmless when discharged. If he fail to use such means, in the opinion of the court having jurisdiction in respect of the penalties imposed by this section, he shall be liable to a penalty not exceeding in the case of the first offence *twenty pounds*, and in the case of a second offence *fifty pounds*, with a further sum of *two pounds* for every day during which such offence has continued, and in the case of a third or any subsequent offence *twenty pounds* for every day during which such offence has continued.

"Penalties under this section shall be recovered at the suit of the inspector, by action in the county court, in manner in which penalties for offences other than offences against a special rule are recoverable in pursuance of the principal Act.

"6. Every inspector and sub inspector of alkali works shall have the same power of inspection, examination, or testing, for the purpose of ascertaining whether the provisions of this Act with respect to noxious gases other than muriatic acid are complied with; as he has for the purpose of ascertaining whether the provisions of the principal Act, as amended by this Act, in relation to the condensation of muriatic acid are complied with, and all the provisions of the principal Act relating to the inspection, examination, and testing, and to penalties for obstructing any inspector or sub-inspector in the execution of the principal Act, or neglecting to afford to the inspector or sub-inspector the necessary facilities in relation to inspection, examination, or testing, under the principal Act, shall apply accordingly.

"7. Special rules made by the owner for the guidance of his workmen in pursuance of the principal Act may extend to any matter or thing required to be observed by them in relation to the prevention of the discharge of the noxious gases mentioned in this Act.

"8. 'Noxious gas' shall, for the purposes of this Act, mean any of the gases following, that is to say:—Sulphuric acid; sulphurous acid, except that arising from the combustion of coals; nitric acid, or other offensive oxides of nitrogen; sulphuretted hydrogen; and chlorine.

"9. Nothing herein contained shall legalize any act or default that would, but for this Act, be deemed to be a nuisance, or otherwise be contrary to law, or deprive any person of any remedy by action, suit, indictment, or otherwise to which he would have been entitled if this Act had not passed."

Notice of Motion respecting the Pharmacy Act.

The following notice of motion for Monday, June 1st., has been given by Mr. Errington:—

"Apothecaries and Pharmaceutical Chemists.—Address for Returns stating the nature aud duration of the course of study, and other qualifications, if any, required by the Society of Apothecaries in Ireland from applicants for a license to sell drugs and compound prescriptions in Ireland:

"The number of licenses so granted since the present scheme of study and examination was adopted, stating in what year it was adopted:

"The number of prosecutions for selling drugs and compounding prescriptions without license during the five years previous to the adoption of the present scheme of study and examination, and from the date of the adoption of the present scheme to the present time respectively:

"The nature and duration of course of study, and other qualification, if any, required by the Pharmaceutical Society of Great Britain, from applicants for certificate to exercise the business of Pharmaceutical Chemist:

"The number of certificates so granted from the 1st day of January, 1864, to the first day of January, 1869; and from the 1st day of January, 1869, to the 1st day of January, 1874, respectively;

"And the number of prosecutions instituted by the Pharmaceutical Society for exercising the business of Pharmaceutical Chemist in Great Britain without a certificate, during the above periods."

Prosecution under the Adulteration Act.
Alleged Adulteration of a Pharmacopœia Preparation.

At the Council-house on Friday, May 22nd, 1874, Mr. H. Fardon, druggist, of Castle Street, was summoned before two of the sitting justices, Messrs. Herbert Thomas and W. Pethick, for having citrate of iron and quinine adulterated with cinchonine and quinidine. Mr. Inskip appeared for defendant.

Mr. Yeates, the inspector appointed under the Adulteration of Food and Drugs Act, stated that he went to the shop of defendant on the 5th instant and purchased two drachms of citrate of iron and quinine. Witness paid 1*s.* for it, and then told Mr. Fardon that he was going to take it to the analyst to have it analysed, and that he (defendant) might go with him if he liked. Mr. Fardon requested him to let him have the bottle again, and he wrote upon the label the word "Howard's" above the line "From Webb, Fardon, and Co." He took that bottle, which he numbered 34, to Mr. Stoddart, who had since given him a certificate of its contents. Mr. Stoddart did not know at whose shop it had been bought. The certificate of Mr. Stoddart was read, and it was to the effect that the citrate of iron and quinine contained in the bottle was adulterated with cinchonine and quinidine.

Mr. Stoddart, the city analyst, was examined, and deposed to the results of his analysis. These showed that the salt was not wholly soluble in water, nor was all the precipitated alkaloid soluble in ether. These, with other reactions, were the reasons upon which Mr. Stoddart arrived at the conclusion that the sample of citrate of iron and quinine was not what it ought to be. In reply to Mr. Inskip, he said that the Messrs. Howard were well known as manufacturers, and that he sold no other quinine than that manufactured by Messrs. Howard. The adulteration was about half per cent. of cinchonine, but he did not think that even so small a quantity as that could be produced from quinine itself in the manufacture of Messrs. Howard, as he knew them to bve ery particular. There was nothing injurious in cinchonine, and he could not suggest any motive for the admixture. He did not attribute any motive, but thought that it must have been an accident.

Mr. Inskip said he submitted to the bench with considerable confidence that, taking the case upon the evidence of Mr. Stoddart himself, the charge must fail. Adulteration had been defined as the addition of some foreign body, and, assuming that there had been adulteration at all, the article introduced bore so infinitesimal a proportion to the bulk that it was difficult to make an estimate of that proportion. He reminded the magistrates, too, that the article introduced would not produce any injurious effect, nor would it result in any pecuniary gain, or other advantage to the vendor. Mr. Fardon purchased all his citrate of iron and quinine from Messrs. Howard, to whose reputation Mr. Stoddart had borne testimony, and he sold it in full confidence that it was pure and good, and Mr. Howard was there that day to deny the introduction of any foreign substance, and Dr. Tilden, of Clifton College, was also prepared to give evidence negativing the existence of any foreign matter, if their worships should deem it necessary that witnesses should be called. Mr. Howard, however, was prepared to admit that, owing to the absence of one of his foremen, the quinine might have been a little overheated, and that would account for the presence of the very small quantity of cinchonine.

The magistrates having consulted, Mr. Thomas said they found that the two articles alleged to have been introduced into the citrate of iron and quinine purchased by Mr. Yeates might both be derived or produced from the substance from which quinine was produced; and seeing that

they were present in such infinitesimal proportions—something less than half per cent.—they did not find it an adulteration, and dismissed the case.

Mr. Howard said, with permission of the magistrates, he desired to state that his firm were aware last summer that a large quantity of quinine had been overheated, owing to the illness of one of their foremen, and in order that it might not go out to their customers they destroyed over 2000 ounces. It appeared that Mr. Fardon was supplied with his quinine about that time, and some few ounces must have got out before they detected it.

*** The foregoing report, taken from a local paper, is not very clear throughout, and there appears to be some grave error in the account given of the way in which the presence of cinchonine was accounted for.—Ed. Pharm. Journ.

Adulterated Burnt Almonds.

On Friday, May 15th, Mr. Richard Parkin, confectioner, of No. 5, Charlotte Place, Goodge Street, Tottenham-court Road, was summoned before Mr. Knox, at the Marlborough Street Police-court, London, by John Hartley, Inspector of Nuisances for St. Pancras, for selling burnt almonds adulterated with bitter almonds, a poisonous fruit.

Mr. Hartley proved purchasing some burnt almonds at the defendant's shop, and dividing them into three parcels, and handing one of the parcels over to Dr. Stevenson, the analyst for the parish. The following certificate was handed in by Mr. Hartley, signed by Dr. Stevenson, who was in attendance to confirm the truth of it: "I am of opinion that the said article of food, namely, burnt almonds, is adulterated, the said article being made, not from the sweet almond, but almost exclusively from the bitter almond, a poisonous fruit, and I am further of opinion that the said article is injurious to the health of persons eating the same. I find that thirty per cent. of the sweetmeats consists of almonds of the bitter kind, and that each five or six ounces of the sweetmeats yields by maceration in water one grain of anhydrous prussic acid, a quantity which might prove fatal to one adult person."

Dr. Stevenson gave evidence in corroboration of his certificate.

Mr. Beard said he considered the whole matter an absurdity, and there could be no adulteration, as the articles were sold as they were got from the tree, and it was impossible for him to tell whether the almonds were bitter or sweet, there being no means of detecting the difference. Further, the defendant had no object in selling bitter almonds instead of sweet ones, there being little difference in the price, and, if anything, bitter almonds were dearer than sweet ones.

Dr. Stevenson produced specimens of sweet and bitter almonds which had been macerated.

Mr. Lumley, an almond dealer of about twenty years' standing, said he could never get Barbary almonds without a portion of bitter ones being amongst them. He could not by the appearance detect bitter from sweet almonds. He considered there was 10 per cent. of bitter almonds amongst sweet ones, and bitter almonds were dearer than sweet ones.

Mr. Samuel Cole, wholesale confectioner for forty years, stated that during his experience he had never bought almonds without there being a small portion of bitter ones amongst them, and he had never heard that they were deleterious to health. He had brought with him some fine samples of almonds, and there were bitter almonds in all of them. Bitter almonds were generally used by the higher classes for flavouring purposes.

Dr. Stevenson said that out of the sample given to him 30 per cent. only were sweet almonds.

Mr. Cooper said the object of the prosecution was to show that bitter almonds, which were injurious to health, must not be sold as sweet ones.

Dr. Whitmore, while not objecting to Dr. Stevenson's evidence, said, as the analyst for St. Marylebone, he had several samples of sweetmeats before him at the present time, and he found in them very few bitter almonds, and nothing warranting him in bringing the sellers before a magistrate.

Dr. Stevenson said it was the only case where he had found on analysis such an amount of prussic acid.

Mr. Knox, after stating that he could not see what object the defendant could have in selling bitter almonds in lieu of sweet ones, the evidence showing that no advantage was to be gained by him in doing so, said that he thought the object of the prosecution would be served by the defendant paying the costs, and promising to take every care for the future, the matter being thus made public as a warning to the trade to be careful.

The defendant was ordered to pay the costs.—*Daily Telegraph.*

Review.

A Manual of the Chemistry of the Carbon Compounds, or Organic Chemistry. By C. Schorlemmer, F.R.S., Lecturer on Organic Chemistry in the Owens College, Manchester. London: Macmillan.

A really good book on organic chemistry, sufficiently popular to meet the wants of the student and yet at the same time sufficiently complete to enable the professional man, without working his way through a mountain of periodic literature, to fill up the gaps in his knowledge,—such a book has for a long time been felt to be a great desideratum; and it is now, in this work, supplied to us by a man who is known, not only as an efficient teacher but also as one of the highest authorities on the subject. That a book written by Schorlemmer, on his own branch of Organic Chemistry, is simply excellent, is a matter of course. There is no room here for critical remarks; all we have to do is to confine ourselves to reviewing, pure and simple.

The title chosen by the author at once shows that what he means to give us is not a book on that which sometimes, in a very special sense, is called "organic chemistry," namely, the chemical history of the proximate constituents of organized matter, but nothing more nor less than an exposition of the science of the chemistry of carbon. Strictly speaking, it is true, carbon chemistry includes organic chemistry proper, but practically and conventionally, as we all know, it does not.

The barrier between mineral and organic chemistry, which half a century ago seemed impassable, was first broken through by Wöhler's discovery of the synthesis of urea; but it was not thereby by any means demolished. For a long time after this great scientific event, it was thought that, although such penultimate products of the breaking down of organic compounds as urea might be producible, synthetically, from their elements, organic substances proper—alcohol, sugars, real organic acids, and the like—could originate only through the agency of that mysterious thing called vital force. The great discoveries of Liebig, Wöhler, Dumas, Laurent even, wonderful as was the light they threw on the realm of organic chemistry, did not *directly* serve to bridge over the gulf that still separated it from the inorganic kingdom. Wöhler's brilliant discovery was, and remained, an isolated fact, the very significance of which, as the first step in synthetic organic chemistry, was only half comprehended until Kolbe taught us to prepare acetic acid from bisulphide of carbon, *i.e.*, a truly organic substance by what virtually amounted to a synthesis from the elements. Since that time the most brilliant discoveries in organic synthesis rapidly followed after one another; and now-a-days, since by the labours of Kolbe, Würtz, Berthelot, Piria, Mendius, and others, we have come into possession of systematic methods for producing any fatty alcohol, acid, amine, etc., that could be

named—including even those fatty ethers which were formerly known only as organic fats—nobody doubts that the discovery of the synthetic formation of *any* organic body is merely a question of time, and that nature, in building up even the most complex substances, employs no other forces than those, which, in the laboratory, we have at our free disposal.

But how is it, then, that up to the present day, carbon-chemistry is set apart from the rest, and looked upon as almost an independent science? Liebig, many years ago, defined organic (*i.e.*, carbon) chemistry as being the chemistry of *compound*, in opposition to inorganic chemistry as that of *elementary*, radicles. But this definition, satisfactory as it was at the time, can no longer be accepted. We now know fully well that radicles, as such, are mere fictions, the conception of which is as unavoidable in the theory of inorganic as in that of organic compounds. And yet, at the present day as much as ever, we find it quite natural that the chemistry of such a *peculiar* element as carbon should be considered for itself, independently of the rest. But what is it that gives to carbon its *peculiar* character? Here Schorlemmer has made a very happy hit; carbon *is sui generis*; but *not* on account of its high atomicity, or of its power of combining with itself—other elements show the same peculiarity, and in some cases the complexes formed possess a high degree of stability. What does constitute the specific nature of carbon is this, that, *given a complex of carbon atoms, and every disposable affinity in it can be saturated by means of hydrogen with formation of stable compounds.* We all know that; but—

"Selbst da wo's am Begriff nicht fehlt,
Stellt oft das rechte Wort nicht leicht sich ein;"

and Schorlemmer has found it. It almost amounts to a new idea.

After developing this definition out of a consideration of quantivalent elements in general and carbon in particular, the author, in the succeeding chapters, gives a general view of the constitution of carbon compounds, on the basis of Kekulé's theory of the concatenation of atoms; which he tacitly adopts as the best mode of summing up what is known of the facts, while Crum Brown's graphical notation serves him as an instrument for expressing its ideas. The author naturally starts with the simplest carbon compounds—viz., the paraffins (marsh gas and its homologues), and very lucidly shows how, by the substitution for 1 H in a given paraffin of a Cl, OH, NH_2, COH, COOH, we produce the chloride, alcohol, monamine, aldehyde, acid; and how the same replacements, when effected twice, lead to the formation of the corresponding diatomic compounds. He next considers the case of one or more couples of hydrogen atoms being simply eliminated *without* subsequent replacement, which leads him on to the allyl and other dehydrogenated "*wasserstoff-ärmere*" compounds, and, in the case of the C_6 series, to that important class of bodies called "*aromatic compounds.*"

After this theoretical introduction follows a short and concise, but perfectly sufficient, description of the methods of elementary analysis and of vapour-density determination; to which is appended a very clear exposition of the rules for deducing, from the data obtained in the elementary analysis (when given conjointly with the vapour-density, or, in the case of an acid, with the basicity and the percentage of metal in a well defined salt) the *true* empirical formula of a carbon compound.

But such a formula, although it not merely gives us the correct percentages of the several elements but represents the true *atomic composition* of the molecule, and consequently sums up in itself *all* the ways in which the molecule can possibly split up in its reactions—just for this reason, does a little too much of a good thing. What, if the study of organic chemistry is to be at all possible, we absolutely want, are formulæ which, of the vast number of potential transformations, single out those which under known circumstances can actually be realized, and give the greater prominence to those which are the more probable.

The extent to which this important problem has been solved, in an elementary book, can only be shown by examples; and this, consequently, is the course which our author adopts. He first shows, by the examples of ordinary alcohol and of acetic acid, how, in bodies like these, all *reversible* reactions, without exception, can be summed up in *one* typical formula, *e.g.*, in the formula $\left.\begin{matrix}C_2H_3O\\H\end{matrix}\right\}O$ for acetic acid. He then (with this same example) illustrates the fact that such a formula will never disagree with those transformations in which the molecule splits up into two carbon-groups. In the case chosen, for instance, these deeper-going changes (formation of carbonate and marsh gas, or acetone, etc.) can be at once depicted, in the original formula, by splitting up the "acetyl" into CO and CH_3. And if, in more complex compounds, the secondary radicles, even, will not account for all known metamorphoses, we always find that the consistent successive application to these radicles and their constituents, of the same principle which leads to the setting apart of the C_2H_3O in the $C_2H_4O_2$, will suffice to complete the image *without* disturbing the structure of the formula as it was at the previous stage. So, at least, it has been found to be the case with all well-studied compounds; and with regard to these, at any rate, we can assume that what ultimately results from the successive splitting-up of radicles, viz., those formulæ in which the atoms themselves figure as radicles of definite atomicities, to some extent represents, not, of course, the arrangement of the atoms in space but at least something like "the manner in which the attractive forces of the atoms forming the molecule are distributed."

After having thus given, so to say, an apology for the previous introduction, as an indisputable dogma, of the concatenation theory, the author now applies it to the explanation of some representative examples of isomerism proper, *i e.*, that kind of isomerism which prevails, for instance, between the two propyl alcohols. The cases of metamerism and polymerism which are taken up next, after all that preceded, are easily disposed of, and thus the purely chemical part of the general division is brought to a close.

The next chapter is devoted to the consideration of the dependence, in carbon compounds, of physical properties on chemical constitution. Here, on the small space of nine pages, we have before us a more complete *résumé* of all that can be clearly formulated of the results of the well-known researches of Kopp, Landoldt, and others, than we have ever met with in any other chemical text-book.

The author now—after the interpolation of a short chapter on fractional distillation, explains to us his way of classifying carbon compounds, and then in the rest (which, of course, is the body) of the book, gives a systematic exposition of the chemical history of the most important of known carbon compounds. The matter is arranged as follows:—First come the *cyanogen* and the *carbonyl* compounds, *i.e.*, those compounds in which these radicles form the central nucleus of the whole, and are not merely tacked on to something more complex, as, for instance, in cyano-substitution products. After the chapter on the carbonyl family, the author first gives a general view of fatty compounds, hydrocarbons, alcohols, acids, etc., and then proceeds to a detailed description of the individual substances, which are grouped according to the quantivalence (atomicity) of their characteristic radicles, and within each group, arranged according to the number of carbon atoms contained in these radicles. The non-saturated compounds are appended to those saturated ones to which they are most nearly related, genetically or otherwise. Thus, for instance, the allyl compounds are appended to the glycerine family; pyromucic acid, furfurol, pyrrol, to mucic acid, etc. That the aromatic compounds are *not* disposed of in this way, but treated for

themselves, needs scarcely be said. In fact, very nearly one half of the descriptive part of the book is entirely devoted to them. They are divided into two classes—1st. Those containing one; and 2nd. Those containing two or more benzol-nuclei. In this division Kekulé's hexagon theory everywhere serves as a basis for the explanation of genetic relations and isomerisms.

Of this part of the book more especially we should very much like to give a few extracts, as examples of the admirable treatment of the subject, but we have already more than filled up the space which this journal can allow for the review of even such an important book as this, and so we will confine ourselves to saying—with regard to this part no more than the rest of the descriptive division—that the amount of information it contains in its pages is simply miraculous, and that yet it never degenerates into a mere register. In a short compendium like this the author, of course, cannot afford to lecture to the reader; in many places the *facts* are simply put down as isolated molecules, but these are so clearly and transparently shaped, that, with the true student, the intermolecular medium of interpretation comes quite by itself. In short, a *better* book than this on organic chemistry has never been written—in any language.

BOOKS RECEIVED.

THE STUDENT'S GUIDE TO MATERIA MEDICA; in accordance with the latest Issue of the British Pharmacopœia. By JOHN C. THOROWGOOD, M.D. LOND. London: J. and A. Churchill. 1874. From the Publishers.

A SIMPLE AND EXPEDITIOUS WAY OF ESTIMATING THE VALUE OF MILK AS AN ARTICLE OF FOOD. By JOHN HORSLEY, F.C.S., etc. Cheltenham: S. H. Brookes. 1874. From the Author.

Obituary.

Notice has been received of the death of the following;—

On the 12th May, 1874, Mr. James Jones, Pharmaceutical Chemist, of Newcastle-on-Tyne. Mr. Jones had been a Member of the Pharmaceutical Society since 1847.

On the 11th April, 1874, Mr. William Anderson, Chemist and Druggist, of Edinburgh.

On the 14th April, 1874, Mr. George Stannard Tooke, Chemist and Druggist, of Lakenham.

Notes and Queries.

[395]. SHEEP DIPPING COMPOSITION.—A good formula for a Sheep Dipping Composition to cure the scab in sheep, is asked for by C.

[396]. PLATE POWDER.—Can any correspondent supply a good formula for plate powder, white or red?—BETA.

[397]. TOOTH PASTE.—"*Alpha*" asks for a recipe for tooth paste, which will not effervesce or ferment out of the pots.

[398]. PREPARED SILICA.—Can any reader inform me who is the maker of the "Prepared Silica" recommended for plate powder?—ARTHUR DECK.

[399]. CORTEX RHAMNI FRANGULÆ.—Mr. E. A. Turner wishes to be informed where the Cortex Rhamni Frangulæ is to be obtained, also the dose, and the best means of preparing it (PHARM. JOURN., May 9th, 1874, p. 889).

POISON REGULATIONS.

Sir,—Allow me to call the attention of those interested in the trade to the suggestion made by Mr. Carter, Coroner for East Surrey, in your impression of May 9th.

"That in future enactments it should be ordered that *all* poisonous substances, of whatsoever nature, have a label with the word 'Poison' affixed to them whenever sold to the public."

This suggestion appears very reasonable. If it be for the good of the public that certain poisons be required by law to be labelled, why not all? It is to be hoped those in authority will not allow this suggestion to pass by unheeded. Where is the consistency in the Act that requires tr. camph. co. to be labelled "Poison," while such articles as carbolic acid, chloral hydras, plumb. acet., and a host of proprietary medicines containing strong poisonous matter, are exempt. Should it occur that additions be made to Parts 1 and 2 of the regulations for selling poisons, it appears that the sale of such should be confined strictly to qualified persons. At present the regulations are so loosely observed that it is almost useless to the public or the trade. Many instances can be produced by almost every country chemist of daily infringements by grocers and general shopkeepers, and those who style themselves herbalists.

I trust Mr. Carter's suggestion will not be lost sight of.

P. R. B.

THE RECENT DISCUSSION ON THE ADDITIONS TO THE PHARMACOPŒIA.

Sir,—Any remarks by Mr. Sandford, on questions relating to what may be considered the political and ethical sides of pharmacy, are always well worthy of serious consideration. In this view his letter in the last JOURNAL cannot be allowed to pass quite unnoticed by me. There are, however, but one or two points on which I wish to say a word. With the particular opinions and feelings of regret expressed, I have nothing to do; men will differ in these matters as long as men exist, and Mr. Sandford has as much right to his views as I conceive I have to mine; but Mr. Sandford, like Dr. Redwood, endeavours to attach to my remarks a personal signification they certainly do not possess, for he says that I have been betrayed to write down remarks which were fairly taken by Dr. Redwood as an attempt to bring both the Addendum "and its authors" into ridicule; and that they may be so regarded by the Medical Council. Now, I at once dispute this. I see nothing whatever in the paper which can be fairly considered as ridiculing "the authors;" and I think it would sorely puzzle Mr. Sandford to point out any remarks bearing in that direction, or sustaining such an assumption. I certainly should be very much astonished to find the Medical Council entertaining such a notion.

Dr. Redwood, in his speech, alluded to some imaginary animus, to which I gave a most emphatic denial in the succeeding JOURNAL; Mr. Sandford cannot fail to have seen this. I am, therefore, the more surprised that this fancied charge of personal feeling or animus should have been reiterated. For the second time I distinctly deny having been influenced by any personal feeling whatever; I should have made precisely the same remarks if the book had arisen by spontaneous evolution, without any paternity at all. Shall I be required thrice to speak plainly on this point?

As to bringing the book itself into ridicule, that is a very different matter. If such be possible it is the fault of the book alone, and should not be set down to the critic.

Mr. Sandford seems to think the criticism was in some way an unfair one; but he fails to intimate in what the unfairness consists. In point of fact, it is as clear as noonday that the sting of my remarks lay, not in the diction or language, but in the *truth* these served to clothe. To this moment, although a cloud of indignation has been raised at the phraseology, no answer has been vouchsafed to my query why certain well-known and constantly employed preparations were not introduced. This may be the fault of those occult four-and-twenty pharmacists who were consulted by

the Medical Council. Whether these gentlemen were really representative men or not, we have no certain knowledge; so far as pharmacists generally are concerned, they are about as mythical as the "four-and-twenty blackbirds" of nursery fame; but, unlike these, now the Addendum "pie" is opened, they "don't begin to sing." Dr. Redwood incidentally mentioned Mr. Squire, but am I to understand this as explaining why Parrish's Syrup, for instance, is not found in the Addendum? There's a strange coincidence here. Either the compilers knew, or they did not know, of the popularity of this syrup. If they did not know, then clearly they were incompetent for the duty they had undertaken, that is, if the preface to the Addendum rightly sets forth their business. If they did know, as no doubt they did, then for what reasons have they not "thought it desirable to supply the requisite information" concerning that preparation?

Just one word more. Mr. Sandford in his last sentence inquires "whether, if Mr. Smith's paper be taken as indicating the tone and temper of the Pharmaceutical Society," etc., etc. IF! Well, *if* your uncle were your aunt, matters would be serious, no doubt; but as my paper does not indicate the tone and temper of anything or anybody besides myself, the Society need not fear, but may go on its way rejoicing in the sunbeams of medical "good will and confidence."

EDWARD SMITH.

May 26, 1874.

THE SALE OF BENZINE.

Sir,—Allow me, through the medium of your Journal, to inform "Chemicus" and others who may be interested in the sale of benzine, that a policy of fire insurance extends only to the shop and dwelling house connected therewith, and that benzine, etc., may be kept in an outhouse or cupboard safe in the yard at rear of premises without infringement of fire policy.

ROBERT OWEN FITCH.

ANALYSIS OF TEA.

Sir,—The paper by Mr. Wigner, published in your last issue, affords valuable confirmatory evidence of the remarkable constancy which genuine teas exhibit in their percentages of soluble ash. In nearly a hundred samples which I have examined during the last few months, I have not met with a genuine black tea yielding less than 2·8 per cent. of ash soluble in water. It is rather remarkable that Assam teas furnish less than the average; green teas, on the other hand, a higher amount. In one of the latter I recently found 3·8 per cent. Mr. Wigner determines the soluble salts by difference; I prefer to make a direct estimation by evaporating the aqueous solution, as, if the result is normal, further treatment with hydrochloric acid is unnecessary. In estimating the silica, the hydrochloric solution should always be taken to dryness, and the residue treated with a little more acid, or soluble silica will be lost. I do not attach much importance to the estimation of alkali, as it could afford no criterion as to the presence of adulteration, except, perhaps, in the case of exhausted leaves which had been re-dried with potassium or sodium carbonates. The flame test, however, detects the latter, and in either case the soluble ash would be suspiciously high.

I think Mr. Wigner goes to unnecessary trouble in determining the aqueous extract, and its ash. The proportion of insoluble matter gives precisely the same information, whilst the tediousness of two exhaustions is obviated. I never employ less than two grammes of tea, which I boil with successive portions of water (about 70 c.c. at a time) till the liquid comes off colourless. In this decoction, I estimate astringent matter by acetate of lead*; and the insoluble residue, dried at 110° C., at once indicates the amount of extractive matter by difference.

Tatton, Southampton, May 19th.

* *Chemical News*, vol. xxix., p. 189.

"*Erin.*"—(1) We do not know of any fixed time for the meeting, but information could be obtained at the office, 32, Soho Square. (2) Messrs. Trübner and Co., Ludgate Hill, Messrs. Williams and Norgate, Henrietta Street, Covent Garden, or any respectable foreign bookseller.

"*Spes.*"—(1) The regulation as to age does not come into force until after the 31st of December next. (2) The candidates are expected to know the proportions of the active ingredients of Pharmacopœia preparations.

J. Barton.—Southall's "Organic Materia Medica of the British Pharmacopœia" is published by J. and A. Churchill, price 2*s.* 6*d.*

W. H. C.—We have handed your specimens to the Curator, Mr. Holmes, who will communicate with you respecting them.

W. Y. O.—(1) Lichens grow on rocks and trees, seaweeds in salt water. There are also differences in their reproductive organs, for an account of which you are referred to 'Bentley's Manual of Botany.' (2) A thick mixture of hydrate of lime and water.

"*Remus.*"—Commercial Leptandrin is prepared by precipitating with water a tincture of the root of *Leptandra virginica*, a plant indigenous in the United States. See *Amer. Journ. Pharm.*, vol. xxviii., p. 510.

C. Gerring.—(1) *Lamium Galeobdolon*, Crantz. (2) Guarana is prepared from the seeds of *Paullinia sorbilis*, a Brazilian Sapindaceous plant. See vol. iii. of the present series, p. 773.

T. P. B.—It is impossible to determine plants with certainty without the flowers. No. 2 is probably *Calamintha acinos.*

"*Botanist.*"—We are not acquainted with any such work.

"*An Apprentice*" is referred to the rule respecting anonymous contributions.

H. Chapman.—Care should be taken that the acetate of potash be not alkaline. If it is, it should be made neutral by the addition of a little acetic acid. The mixture would then probably keep fairly, although it would not be a stable mixture under any circumstances.

"*Inquirer*" (Taunton).—Melt about ʒss of white wax and pour into a warm mortar; add the carbolic acid and the extract of opium, the latter being first made softer, if necessary, by two or three drops of water. Mix all together, and when sufficiently cooled the mass may be rolled out.

"*Theta.*"—(1) This question should have been addressed to the Registrar. (2) In July next. (3) Yes; and all candidates for the Minor examination "must have passed the first or Preliminary examination."

Messrs. Young and Postans.—We have no knowledge of the preparation mentioned, and have not been able to learn anything of it.

"*A Dispenser.*"—We have asked a friend to examine the nature of the change, and will acquaint you with the result.

"*Inquirer*" (Exeter).—See Dr. Squibb's paper in the present number of the Journal, p. 956.

J. B.—(1) We are unable to decipher the prescription sent. (2) Probably the pills referred to are prepared from a private formula. (3) It would depend upon the manner of selling and labelling, and the purpose for which it was sold.

"*A Pharmacist from* 1842."—The answer given to "*Fair Play*" on p. 868, will convey to you our opinion on the subject of your letter. We believe that the course you hope for would only tend to promote the evil you complain of. If there really be any general desire on the part of registered Chemists and Druggists to incur the trouble and expense involved in the course you suggest, the proper plan would be to communicate officially to the Council of the Society to that effect, in the shape of a memorial.

M. P. S.—See the paper on Croton Chloral, by Dr. Liebreich, before, p. 510.

"*A Yorkshire Tyke.*"—Although we do not attach much value to the use of pharmaceutical titles on labels, etc., your communication is too uncomplimentary to those entitled to use the letters A.P.S. to admit of its publication.

G. T. D., *A Titan*, and *Palmam qui meruit ferat.*—We are obliged for your communications, but we think that enough has been written upon the subject of "legs" as a pharmaceutical qualification.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. R. H. Parker, Mr. B. Condy, Mr. Brevitt.

THE DECOMPOSITION OF MILK BY KEEPING.

BY EDWARD LAWRENCE CLEAVER,

Assistant-Demonstrator in the Laboratories of the Pharmaceutical Society.

At a recent prosecution under the Adulteration of Food Act, it was stated in the evidence for the defence that unless milk be analysed before it is six hours old the results are not reliable, implying that decomposition proceeds at a rate sufficiently rapid to destroy a large portion of the solid matter after that period of time. This is really a most important point, because it is rarely possible to analyse samples within the time above stated; with the object therefore of gaining some definite information on this subject, I made a series of experiments, the results of which are stated below.

There are several points which exercise some influence on the decomposition of milk, namely:—

1st. *Temperature.*

2nd. *Exposure to the atmosphere.*

3rd. *The relative poverty or richness of the milk.*

The present note only gives the results of experiments on an average sample of milk at the ordinary temperature; but I hope at some future time to publish a series showing the behaviour of different samples under varying conditions. A quantity of milk, purchased early in the morning, was divided into several small portions and placed in bottles, which were tightly corked. One portion was analysed immediately after purchase, and the rest from time to time. The results, taken at a temperature of 70° F., were as under:—

No.	Date of Analysis.	Total Solids.	Fat.	Ash.
1	April 30th, 1874	12·48	3·6	·7
2	May 1st, „	12·37	3·6	·7
3	„ 2nd, „	12·18	3·6	·7
4	„ 4th, „	12·12	3·6	·7
5	„ 6th, „	12·09	3·6	·7
6	„ 8th, „	12·07	3·6	·7
7	„ 12th, „	11·97	3·52	·7
8	„ 18th, „	11·97	3·4	·7

It will be seen from these experiments, extending over a period of three weeks, that decomposition does not, in an average sample, proceed at a very rapid rate; and that in an analysis made even after two or three days the error would be inappreciable.

It was suggested to me that if milk which had become sour were neutralized with soda, the volatile acids formed would be retained instead of being volatilized by the heat, and that the solid residue would therefore not suffer loss. On trying this plan, however, no difference was obtained from previous results.

But there is one source of loss to be guarded against when milk has become very old, and that is the deposition of mineral matter of some kind on the sides of the containing vessel, to which it adheres very firmly; under the microscope it has a distinct crystalline structure, but at present I have not been able to determine the exact nature of the compound.

THE ADDITIONS TO THE PHARMACOPŒIA.

BY H. BARTON.

Practically interested in the Pharmacopœia Addenda as we all are, it is evident that we have not all come to the same conclusion about its contents: some looking upon it as an uncalled-for and very defective compilation, others, with myself, seeing in it the stamp of careful consideration throughout; and as, so far, the discussion appears to have run pretty much *contra*, perhaps indications from the personal experience of one of the *pros* may not be altogether out of place.

First, I am very glad to see an old friend, *Tinctura Quinæ Ammoniata*, brought to honour and authority, prepared according to the formula published by Mr. Ince some years since with *simple* spirit of ammonia and proof-spirit. It is a very favourite preparation with several physicians and surgeons here, and much liked and repeated by patients who say they could never take the usual preparations of quinine. At the same time, we have often heard disappointment expressed when the preparation has been procured in establishments where stronger solutions of ammonia or *aromatic* spirits have been used, the observation usually being, "It did not suit me; I could not go on with it." So frequently have I heard such a remark, that I do not hesitate to say that the now authorized formula, with its dilute ammonia and absence of aromatic, will be preferred by the majority of patients, and its introduction will conduce to a pleasant uniformity so far as this article is concerned.

Liquor Magnesiæ Citratis I look upon as a valuable and agreeable addition to the Pharmacopœia. The "Limonade purgative" of the French Codex is immensely popular in France. During the siege of Paris we were called upon almost daily to supply it to one or more of our expatriated visitors, they paying 1*s.* 6*d.* per dose in preference to taking Seidlitz powders or magnesian citrates, etc., and that, be it remembered, at a time when economy was at least a temporary necessity with them.

Extractum Glycyrrhizæ Liquidum.—The compilers of the Addenda may be congratulated upon the introduction of another uniform preparation. For many years we have made a fluid extract from the Solazzi liquorice cut up and suspended (on a perforated rest) in distilled water, and then evaporated at about 120° to produce fl℥xvi. from each avoirdupois pound; once, at the request of a physician, we prepared about a gallon of "succus" from recent root, and a most agreeable preparation it turned out to be, thus much indicating a demand for some liquid preparation.

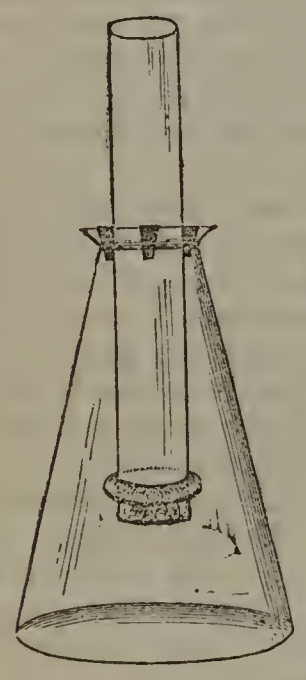
Amyl Nitris.—We have met with a colourless variety, of abominable odour, and intensely disagreeable to the patients; it is therefore satisfactory to note, in the "characters and tests" indicated, "an ethereal liquid of a yellowish colour, and peculiar, not disagreeable odour."

Chloroform Water is not the useless thing some would lead us to suppose. How often is the dispenser annoyed at the separation of chloroform upon the addition of chloric ether to mixtures containing bromide of potassium or nitro-hydrochloric acid, both of which may be added to chloroform water without such separation; so take the good, and despise not little bounties.

Syrupus Chloral differs from the syrup hitherto usually sent out under that name; nevertheless, when full doses have been given, the amount of sugar

has been found an objection, and consequently chloral in substance is generally ordered in prescriptions. I must confess to a prejudice against crystals, from once receiving a bottle of them bearing Dr. O. Liebreich's label, which, when made into syrup and solution, after a short time developed an odour of benzine. Since that time we have used dry cake, and, to ensure uniformity, made each bottle into a 50 per cent. solution as soon as opened, before dilution could take place from the absorption of moisture, which would be the case if a bottle of the chloral in substance remained for some time in current use.

Injectio Morphiæ Hypodermica.—Again, the profession will surely approve a uniform preparation. I apprehend the most likely source of variation might be through waste in washing the precipitated morphia, and suggest the following modification of a filter which may be used with advantage for that purpose.



Take a piece of large glass tube, or one of the smallest glass lamp chimneys, cut a disc of filtering-paper large enough to tie over the bottom, and secure it with a piece of muslin over it; also tie on to the glass three or four cork wedges, so as to enable the operator to suspend the cylinder in a precipitating jar or wide-mouthed bottle. Wash the precipitated morphia, and after it has been sufficiently drained, carefully remove the muslin and paper together, blow the moist mass from the tube into a capsule, and with a few drops of water remove any morphia adhering to the glass; then re-secure the muslin and paper, reversed (paper outside), and pass through it some of the prescribed water, which will carry every particle of morphia into the receiving capsule, and obviate the one chance of loss.

Some of our members seem afraid that soap for suppositories will be too irritating; that is a question for the medical profession. I can only say an old prescription for piles used to go the round here—half Castile soap, the remaining half extract of hemlock, to be made into suppositories, and I never heard any charge brought against them on that score.

Phosphorated Oil, after Mr. Méhu's formula, I find at the end of eighteen months perfectly limpid, so scarcely anticipate much likelihood of change in the more dilute preparation.

Pepsina.—If the authorized formula furnishes an article similar to "Pepsina Porci, Dr. Beale," as prepared by Messrs. Bullock and Reynolds, we may fairly anticipate that it will have a medicinal value far above that of the average commercial specimens hitherto supplied.

Brighton.

SYRUPUS FERRI PHOSPHATIS.

BY A. WILLSON,

Dispenser to the West London Hospital.

The difficulty of preparing a syrup of phosphate of iron which could be preserved from alteration for a reasonable period, led me, some time ago, to make some experiments upon the subject, which have resulted in my adopting the following formula, which I have found eminently successful.

Prepare the ferrous phosphate in the usual manner, being very careful to wash it perfectly free from the acetic acid formed during the process. Dissolve the moist phosphate in 7 drachms of syrupy phosphoric acid (sp. gr. 1.500), instead of the 5½ ounces of diluted phosphoric acid, as directed in the Pharmacopœia; when dissolved, add sufficient distilled water to make the solution measure 1½ ounce, and keep in a well-stoppered bottle. One drachm of this solution added to 7 drachms of simple syrup, forms a syrup in every respect identical with that of the B.P.

The use of syrupy phosphoric acid will be found far more convenient than the old mode (Groves' process) of evaporating the diluted acid.

Glycerine has been strongly recommended as a substitute for sugar in this syrup, but, so made, it is frequently objected to by the patient, as not being so thick as usual; and as a Liq. Ferri Phosph., prepared as above keeps well, its use is rendered quite unnecessary.

Hammersmith, May, 1874.

SUGGESTIONS TO BEGINNERS IN PHARMACY.*

BY THE LATE PROFESSOR WILLIAM PROCTER, JUN.

The following paper, written for the benefit of young pharmacists in the United States, is almost equally valuable to those in this country:—

When a boy enters an apothecary's shop with the view to becoming a pharmaceutist, he is at first employed in a great variety of services: as in opening and closing the shop, sweeping and dusting, cleansing mortars and other utensils, washing bottles, grinding, bruising, and garbling drugs, cutting herbs, stirring evaporating liquids, cutting, pasting, and attaching labels, bottling liquids, etc.—engagements requiring but moderate skill; after a time, however, the boy becomes aware that he is only on the surface of the knowledge he came to acquire, and that it is necessary for him to read and study. If he is thoughtful and earnest, and is fortunate in finding himself associated with a kindly disposed clerk, who will give a proper direction to his inquiries, and encourage his desire for knowledge, he soon gets sufficiently within the subject to find the great extent of its range and the variety of its detail.

The first effects of this impression are sometimes strongly discouraging and depressing, but if he perseveres, and has mastered the idea that all knowledge is of gradual growth, that like the stalactite it grows by accretion from without, as well as, plant-like, by development from within by thought-action, he will soon become reconciled to the process, and employ his spare time in its pursuit. But what shall the boys do who have no guide in a well-disposed associate, or who may be so unfortunate as to be the victim of a churlish or tyrannical clerk, or of an oppressive illiberal employer, or what is nearly as bad, to be placed at service with an ignorant, ill-qualified preceptor?

In considering the query, it has appeared feasible to undertake a short suggestive essay, which, without entering deeply or systematically into the subject of pharmaceutical tuition, may succeed in aiding this extensive class of learners, and at the same time afford a help to well-disposed apothecaries, who really desire to aid their boys, but who are at a loss how to advise them.

The *special* knowledge requisite to the apothecary is of four kinds, viz.:

* Read before the American Pharmaceutical Association, at Richmond, September, 1873.

1st. A practical acquaintance with the implements and apparatus of pharmacy, and with the methods of using them in all kinds of manipulation.

2nd. The intelligent use of this apparatus in making preparations of the Pharmacopœia, so as to adapt it to the nature of the material treated, which involves not only some acquaintance with the physical laws but also with the nature and composition of drugs.

3rd. The study of the scientific relations of pharmacy as explained in works on Chemistry, Materia Medica, Botany, and Physics, and a thorough acquaintance with the physical appearance and properties of drugs.

4th. That important part of the business involved in getting medicines ready for the sick, as well on the prescription of physicians as on ordinary demand by consumers, where a maturity of judgment has to be exercised in regard to the correctness of substances required. The construction of the Latin language, and some knowledge of its vocabulary, is absolutely necessary in this department in many countries, though less indispensable in the United States.

In view of all this knowledge to be gained, it must be apparent that the native ability, and the preliminary education of the boy, have much to do with his success in mastering its details. So important is it that the beginner in pharmacy should be well grounded in the ordinary branches of school education, that in several countries abroad, none but such are admitted to apprenticeship, with some knowledge of the classics superadded. When, therefore, he brings with him some rudimentary knowledge of the sciences as taught in the best common schools, our novice is well equipped to make progress in the avocation he has chosen, and needs only perseverance to succeed.

The text-books upon which the beginner has mainly to depend are, the United States Pharmacopœia, the United States Dispensatory, and some one or more works on chemistry and pharmacy, with a Latin dictionary and, when possible, Webster's dictionary. One of the first lessons is to get a practical acquaintance with the labels in the store, in connection with the substances labelled; this is the groundwork of his study of the business, and is essential to progress in other directions. The habit of abbreviating labels on shop furniture and in prescriptions adds much to the trouble of the novice in learning them, and it has sometimes happened that he has never thoroughly acquired the terminations of the words so as to use them with facility. A good plan is to commence with a shelf of bottles or a row of drawers at a time, and, by the aid of the officinal list of the Pharmacopœia and the Index of the Dispensatory, to copy the names in full into a rough note-book in *columns*, placing the English name in line. He should be assured that the labels are correct for the substances contained, and then by close observation get as clear an impression of the appearance, taste, and odour of each substance as possible. Another shelf or row should then be taken and proceeded with, observing from time to time to exercise the memory and the senses on each preceding lesson till it becomes familiar. This brings us to consider for a moment the manner of consulting the Pharmacopœia and Dispensatory for this purpose. The Pharmacopœia officinal list is arranged alphabetically, and the same arrangement applies to the groups or kinds of preparations, as well as to the individuals of each group. The *officinal names* (or authorized names) in full, with the regular English name, and a brief definition of the nature and natural source of the substance is given. Most Materia Medica names will be found in this list, whilst preparations will be found in the second part of the book, and most easily by consulting the index. Special attention should be given to the spelling of the Latin names and their terminations. For example, suppose our young friend in his first lesson has a drawer labelled "Colocyn.;" referring to the list he finds "*Colocynthis*," translated "Colocynth," and described as the fruit of Citrullus colocynthis "deprived of its rind." He naturally desires to know what sort of fruit, what are its qualities, what sort of a plant yields it, where it grows, what it is used for, etc. To get these answers he must go to the Dispensatory, article "Colocynthis," where he will find all he desires to know about it; but *this* inquiry may well be left until he has considerably extended his superficial knowledge of drugs and their correct names.

The immense size of the United States Dispensatory, and its comprehensiveness of detail, render it a formidable object as a text-book for the beginner, until he gets the key to its construction, and finds it almost as easily consulted as a dictionary, having an alphabetical arrangement. The greatest difficulty it presents is its fulness, and the longer time necessary to consult it. But it is by no means necessary for the beginner to read each entire article: for instance, in the example above stated, he can easily find that colocynth is a fruit like the mock-orange, growing on a vine with leaves like those of the watermelon; that its pulp is exceedingly bitter and purgative, that it comes from Northern Africa, and enters into several valuable medicines.

In an establishment where the preparations of the Pharmacopœia are made for its own dispensary, the beginner has a great advantage, as from the first he can witness processes more or less interesting, and which arrest his attention. Though at first only as an aid, or perhaps coming in at the close to cleanse the apparatus, he soon learns enough to be useful, and then if he is willing and obliging, he has the *open sesame* of rapid advancement. In this way a three months' apprentice has taken charge of the weekly supply of citrate of magnesia in a careful and reliable manner, and has felt encouraged and sustained by his conciousness of being useful, and of advancing in knowledge. When he becomes conscious of a desire to enter the field of book knowledge, and make it assist his observing faculties, and explain his difficulties, a great point has been gained in his onward progress. Let us suppose his first trouble in washing mortars to arise from Prussian blue, which resisting his best efforts, he applies for help, and is told to use solution of potassa, the magical effect of which makes a deep impression on his mind. When evening comes he sets to work with the Dispensatory, at the article Prussian blue, and soon gets at sea in chemistry which he cannot understand; but he succeeds in learning that potash forms a soluble salt with Prussian blue, and thus detaches it from the porcelain surface, setting oxide of iron free. At the same time he glances at "*Potash*," learns its origin from wood-ashes lye, that it is a *base*, neutralizes *acids*, forms *salts*, dissolves *fats* and forms *soap*, and many other facts.

Now it is not to be expected that our young friend has gotten a very clear insight into the chemistry of these subjects; but if intelligent he has seized the leading points, and will not rest until all is understood by subsequent study. The habit of close observation of colour, taste, odour, shape of outline, and configuration of parts, should be cultivated as one of the most valuable aids in gaining knowledge, as he progresses from day to day; and by cultivating a habit of using the pencil to imitate the form and construction of objects, whether drugs or apparatus, it will be found to aid the memory decidedly.

We will suppose our lad is set at grinding senna in a Swift's mill, for fluid extract. It is light work but tedious, and in the frequent resting-spells his curiosity is attracted to the drug. He finds several distinctly shaped leaves, notices that at the base they are mostly *uneven*, but some are not, that when chewed the drug colours the saliva quickly, and that it has a peculiar odour. If he is critical he may find leaf-stalks, seed-vessels, etc., and by the time he has ground ten pounds he is pretty well acquainted with the sensible characteristics of senna. When evening arrives he resorts to his Dispensatory and finds that there are several kinds of senna, and it takes him some time to decide that the mixed character of what he had been grinding fixed it as the Alexandrian, or

Upper Nile senna. He notes the kind of plant, gets a hint of its commercial history, what it contains, what liquids are best to extract its virtues, what medical properties it has, and what preparations are made from it. He then re-examines the leaves in view of his reading, looks at his school atlas for Nubia and Abyssinia as the country of its growth, and the next time he is sent to a large drug store asks to see a *bale* of senna, and he is pretty well booked up on senna, and will not forget it. All this will take several evenings. Senna is but one of a long list of vegetable drugs that in his first year's experience will practically come to his acquaintance, and, by following the same course, an outline of whose history will be grasped, and gathered into his storehouse of memory for future use.

At the very beginning of the Pharmacopœia is a notice of the weights and measures used in pharmacy, and at the end of the Dispensatory a much longer notice describing the French and other weights and measures. Now as pharmacy is a business constantly requiring exact quantities by weight and measure, the beginner should from the first familiarize his mind with the officinal weights and measures, and the manner of using the scales or balance, and the measures of capacity, as well as the relations of troy weight to avoirdupois or English weight, and metrical or French weight. He should also try his hand at dividing a given quantity, say a drachm, into ten parts with a spatula, by the eye, and then weigh each one, and see how it varies from six grains, the proper weight of a tenth. For the same reason that he exercises his memory to grasp knowledge, he should exercise his senses and muscles to acquire skill, constantly keeping in mind the old adage "that whatever is worth doing should be done well." In the simple matter of wrapping packages in paper there is a wide field for skill. Some never learn how to do it neatly, especially doses of powders. Others give so neat and regular a finish to their work as to make it attract attention. The wrapping of bottles and boxes in paper, and especially the tying of bundles, all are worthy of close attention until habitual skill is attained.

In the matter of cutting, and attaching labels to bottles and boxes, the same range of skill exists, and to be always neat requires care in gaining the habit at first.

In the manner of handling the pestle in trituration, in contusion, pill-making, or in emulsionizing, or of managing the spatula in mixing ointments or powders, there is a wide margin for grades of skill and neatness.

Cleanliness in pharmacy is a virtue that ranks with *order*, and without these the shop practice becomes more or less demoralized. Clean glassware, bottles, graduated measures, white mortars, bright spatulas, and a clean, orderly counter, add wonderfully to the pleasure of dispensing, as they do to favourably impress the patrons of a store. The habit of restoring bottles to their proper places after using them, that of keeping all receptacles suitably filled ready for use, and that of labelling every vessel or package that is set aside, are among the most useful that contribute to shop order and comfort. The amount of trouble and annoyance saved by habitual attention to these shop morals, by *all* the employés, can only be appreciated by those who have seen the working of both plans, and drawn their conclusions.

It is to ingraft and fix these and other important habits, that our colleges require four years' apprenticeship or training at the dispensing counter and in the laboratory, before granting their diploma; a requirement which should be most strictly carried out.

But a new experience awaits our novice; he is to take part in a chemical operation attended with some care and labour,—the making of Vallet's pill-mass of carbonate of iron. After weighing certain quantities of sulphate of iron and carbonate of soda, he separately dissolves them in boiling water containing a portion of syrup, strains the solutions to remove undissolved particles, and mixes them, when cold, in a vessel just capable of holding them, when, to his surprise, a thick, pulpy, bluish-white mixture results, which separates into a solid precipitate and a clear liquid above. The liquid is drawn off, and its place filled with pure boiled water containing syrup, and the whole intimately mixed, allowed to settle, and the process repeated, and the sediment finally drained on a cloth filter, tied, expressed, mixed with sugar and honey, and on a water-bath evaporated with constant stirring, until when cool it has a solid pillular consistence. The points in this process to attract his attention are: the reason that mixing the clear solutions produces a sediment, why boiled water is used, why the washing water is sweetened, why honey is used, and, finally, why a water-bath is employed. After the tedious process of stirring is concluded, and the pill-mass stowed away yet warm in jars, the Dispensatory will answer all these queries clearly and satisfactorily, if appealed to, and he will have added a chemical chapter to his experience, involving the law of double decomposition, and the power of sugar to prevent or retard atmospheric oxidation, and the process of decantation and filtration.

This is only one of many chemical processes that he will be called on to take part in, long before he will be able to attend lectures at college; or, if this is beyond his reach, before he can make progress in the study of chemistry sufficiently to understand chemical reactions. It is this excited curiosity, this desire to understand phenomena daily occurring, that is to stimulate his efforts at self-improvement in knowledge, and finally give him the victory over adverse circumstances. Some of the greatest minds devoted to chemistry in the past have thus begun their career. Scheele, the discoverer of so many important organic bodies; Davy and Liebig, so justly celebrated as chemists and investigators, were all at one time apothecary boys, groping in the dark bravely until they found light for themselves and all others. But our beginner is getting sufficiently advanced to be called a student, he is in his second year, and looking forward to attending lectures next winter, when he will enter systematically on the study of the science of his business, and clear up hundreds of little theoretical difficulties that have bothered him in his progress. He begins to see that botany is necessary to understand materia medica, and that the laws of physics or natural philosophy have much to do with explaining the phenomena of steam apparatus, of solutions, of crystallizations, and of taking specific gravities; and he rightly desires the aid of handbooks. For the former, Dr. Gray's little work, 'How Plants Grow,' will serve his purpose; or 'Lindley's Outlines of Structural Botany;' and for physics some work like 'Ganot's Popular Physics,' will do for awhile; but Mueller's will be more satisfactory for advanced students. Special works on manipulation, chemical and pharmaceutical, are of great value. The great book of Faraday on Chemical Manipulation, so simple in its language, but so full in its meaning, has long been out of print; but 'Campbell-Morfit's Chemical and Pharmaceutical Manipulations,' is a good substitute, and well illustrated. Bowman's Chemistry for the beginner in analysis, is good; but for the more advanced student, Dr. Attfield's Chemistry, written with a view to the needs of the student of pharmacy, is excellent. In fact, the literary aids to the student are so numerous that he is often confused in choosing a guide, and it is of the utmost importance that he should keep his mind clear to his main object, the building up layer on layer, regularly and solidly, the superstructure of his own professional knowledge, on the solid foundations he has laid by his first and second year's devotion to the rudimentary services in the laboratory and at the counter. If successful, his reasoning powers will have been exercised freely, his judgment matured, his memory well stored with facts derived from study or from observation and experience, and he will be well fitted to receive the honours of graduation, and to go out into the world as a disciple of Æsculapius in the service of his fellow-men.

THE REACTIONS OF ACIDS WITH OIL OF PEPPERMINT, AND THEIR BEARING ON THE FORMATION OF CHLOROPHYLL.*

BY M. A. FREBAULT.

With the object of combining the hydrocarbon of oil of peppermint with picric acid, the author heated gently together an alcoholic solution of that acid with some of the essential oil; water was added to dissolve the excess of acid, and the mixture left to stand. Twenty-four hours afterwards the oil, which had collected at the surface of the liquid, presented a magnificent green colour. This formed the starting point for the author's investigation.

Action of Picric Acid upon Oil of Peppermint.—If oil of peppermint be agitated with picric acid, nothing is observed at first further than that the picric acid partially dissolves, and communicates its yellow colour to the oil; but in half an hour the mixture is coloured manifestly green, and in twenty-four hours this colouration acquires a great intensity. If a slight heat be applied to the mixture the green colour appears more rapidly.

This green product, exposed to the air upon water during four or five days, acquires the reddish-yellow colour of dead leaves. Introduced floating on water into a test-tube containing nitrogen, the colour is retained for some time; but in oxygen it disappears more quickly. Treated several times with cold water, the washings remove each time some of the picric acid together with a red colouring matter, and finally the essential oil remains of a reddish-yellow colour.

The green product has a strong red fluorescence, and in an alcoholic or ethereal solution, this phenomenon is still more marked. Treated with solution of caustic potash or ammonia, a picrate of the base employed is formed, and the essential oil remains of a reddish-yellow colour. When the green product is distilled from caustic potash, a colourless liquid passes over into the receiver, and there remains in the retort a black mass analogous to that obtained by treating oil of peppermint with chromate of potash. The distillate no longer yields the green reaction with picric acid. Nascent hydrogen reduces the green product, and transforms it into a brown substance. If, instead of operating in the cold or with a gentle heat, the solution of picric acid in oil of peppermint is boiled for a few moments, it passes from the green state to yellow-brown, and then reddish-brown. Upon the addition of ammonia it quickly forms red crystals, which are probably picramate of ammonia, and some crystals of picrate, whilst in the midst of them is disseminated an amorphous powder of a beautiful red colour. This red powder is soluble in water, insoluble in benzine and oil of turpentine, and very slightly soluble in ether and alcohol.

That oil of peppermint is a reducing agent is shown by its producing the characteristic colour of Prussian blue in paper saturated with a solution of ferric sulphate and ferricyanide of potassium. At the boiling temperature it partially transforms the perchloride of iron to the state of protochloride, and the perchloride of mercury is also partially reduced to calomel. Submitted to dialysis in alcoholic solution, the picric acid diffuses through from the green product, together, no doubt, with a little menthene, the solid and crystallizable portion of the essential oil. This solution has a bitter, sweetish, and slightly cool taste. Distilled in a water-bath it leaves a yellow residue, which, treated with sulphuretted hydrogen and ammonia, gives the intensely red colouration of picramate of ammonia. The alcoholic distillate has the cool taste of oil of peppermint due to the menthene.

It was thought interesting to investigate whether the reaction took place between the crystallizable portion or the hydrocarbide of the essential oil and the picric acid; whether the green reaction was also produced with oil of pennyroyal, which contains no stearoptene. The phenomenon of colouration was found to be limited to the oil of peppermint, except that it occurred also with oil of chamomile; but in that case there is no combination, the green being produced by the mixture of blue and yellow, and there is no red fluorescence.

The reaction between oil of peppermint and picric acid is so clear, that the author thought picric acid might be used in testing for the presence of that essence in a mixture of essential oils, and, *vice versâ*, that oil of peppermint would be a suitable test for the presence of picric acid. For this purpose he made a mixture of several essences, about two grams, to which he added two drops of oil of peppermint. This was shaken with a solution of ten centigrams of picric acid in about fifty grams of water. At the end of twenty-four hours the essential oils collected on the surface, and presented a very perceptible green tint. In a second experiment, a decoction of barley and hops was made, to which an extremely small quantity of picric acid was added. The liquor was filtered, and a portion of it agitated with fifty centigrams of oil of peppermint in a test-tube. The green colour was very evident after twenty-four hours.

The author has made no experiments with beer, but he suggests that it might be tested by evaporating the suspected beer to the consistence of honey, treating the extract with alcohol to which a few drops of nitric acid have been added, filtering the liquid, concentrating and agitating with a little oil of peppermint. Nitric acid is used for the purpose of oxidizing any acid that may have been reduced to picramic acid by the action of sugar in the beer, and to saturate the lime salts present.

Action of other Acids on Oil of Peppermint.—The question as to what this colouration is due may receive some elucidation from observation of the action of other acids upon oil of peppermint, which has not yet been carefully studied. The following are the principle effects noted by the author:—

Sulphuric Acid produced at first a rose colour, then reddish-yellow, passing rapidly to reddish-brown. When ether was added it acquired a beautiful yellow colour, whilst the lower portion of the mixture was coloured red. When water was added and the mixture shaken the liquid separated into two layers, of which the lower acid aqueous layer was rose-coloured, and the uppermost ethereal layer took a greenish blue tint and had a strong red fluorescence.

Hydrochloric acid induced a rose colour rather slowly. Upon the addition of ether this became faintly green. When water was added the underneath layer was rose-coloured, but the ether retained its green colour. In some experiments a blue colour was produced.

Nitric acid caused first a rose colouration, then red, soon becoming greenish. Upon adding ether and water and shaking, the underneath layer was rose, and the ether rising to the top took a violet-blue grey colour.

The blue and green tints were rapidly altered by the action of air and light.

These observations were made upon pure and quite colourless oil of peppermint. When the yellow or greenish-yellow tinted oils frequently met with in commerce were employed, the phenomena of colouration were much more intense with sulphuric and hydrochloric acids; whilst with nitric acid the ethereal layer acquired a magnificent green colour and a strong red fluorescence. The rose colouration first produced by the acids had a violet reflection. Moreover, when chloroform was employed in the place of ether, sometimes a violet or a grey colour was obtained, the latter being the result of a mixture of yellow and violet, or perhaps red and green, or even blue and orange.

From the foregoing, the author concludes that the colouration produced by picric acid when reacting upon the oil of peppermint is not a property peculiar to itself, but common to the strong acids; that the picrate of the hydrocarbide which he sought was not produced; that it

* Abstract of a paper in the *Répertoire de Pharmacie*, vol. ii. p. 199.

was not a case of oxidation *pur et simple* as might have been supposed with picric acid. He looks upon the colouration as a phenomenon dependent upon the separation and combination of the colouring matters contained in the oil of peppermint. He thinks that the acids split up the oil into five colouring principles, red, blue, green, yellow, and violet; and that, according to the quantity and nature of the acid employed, one or other of these principles is obtained, or perhaps a grey resulting from a mixture of two complimentary colours.

Relation of the Green Colouring Matter to Chlorophyll.—The author remarks upon the striking analogy which appears to exist between the green substance obtained by the action of acids upon oil of peppermint and chlorophyll, which is set forth in the following table :—

Chlorophyll.	Green Matter obtained by the Action of Acids on Oil of Peppermint.
Strong red fluorescence.	Strong red fluorescence.
Becomes reddish-yellow in the air (dead leaves).	Exposed to air, it is changed into a reddish-yellow substance.
Treated with alkalies it becomes yellow.	Treated by alkalies, it becomes yellow.
Reduced and decolorized by nascent hydrogen.	Reduced and transformed into a brown matter by nascent hydrogen.
Yellow leaves become green by the action of acids.	After being made yellow by alkalies, again becomes green when treated with acids.
The green and blue colours obtained by the action of acids on chlorophyll are decomposed by light.	The green and blue colours obtained by the action of acids upon oil of peppermint are decomposed by light.

This comparative table presents points of great resemblance, of which the most important doubtless is the fluorescence, the red fluorescence being characteristic and confined to these two substances. Supposing it probable that in both cases the appearance is due to chlorophyll, the author endeavours to explain its formation in the oil of peppermint. He considers that as his experiments were made with colourless oil of peppermint it is necessary to assume that the constituent elements of chlorophyll exist in that essence; but that probably they exist there in a state of reduction, and that it is only under the influence of acids that a kind of synthesis of the chromule takes place. The blue principle (Frémy's phyllocyanine) and the yellow principle (phylloxanthine) are, so to speak, in a latent and colourless state, either in consequence of reduction or their combination with the other colouring principles present in the oil. Under the influence of acids the phyllocyanine is regenerated, and at the same time the phylloxanthine, separated from the red and violet principles, unites with the blue especially to form the green colour. With picric acid and nitric acid the green colouration is more intense than with the other acids, because an oxidizing action is combined with a separative action.

According to this hypothesis, which the author proposes to test by further experiment, chlorophyll, or at least its constituents, are volatilizable in the state in which it actually exists in oil of peppermint. The greenish colour which is seen in the oil when imperfectly rectified would then be due probably to chlorophyll, of which the elements have not been completely altered in a first distillation.

Action of Chloral upon Oil of Peppermint.—The rose colouration which takes place when hydrate of chloral is shaken with oil of peppermint, which was pointed out by M. Carl Jehn,* has also been the subject of experiment by the author. He has come to the conclusion that the colour is produced in the oil of peppermint and not in the chloral hydrate, and that it only occurs when the chloral hydrate used is acid, it being more intense in proportion as the chloral hydrate is more acid. But he has not yet been able to experiment with perfectly neutral specimens. In this case the reaction would be due to the formic acid contained in the chloral hydrate, or possibly to hydrochloric acid resulting from partial decomposition.

* See Pharmaceutical Journal, before, p. 556.

THE CONSTITUTION OF BLEACHING POWDER.*

BY C. SCHORLEMMER.

The author was much surprised by reading lately a paper by Goepner, "On the Nature of Chloride of Lime," in which he revives Berthollet's view, that the bleaching compound contained in it is simply a combination of lime and chlorine, and decomposed by acids into its constituents. He says that, although we find in all handbooks the statement that a solution of hypochlorous acid is obtained when a solution of bleaching powder is distilled with a dilute acid, as if the experiment had been made hundreds of times, this is a mistake; and the reason why the error has maintained itself so long is, that hitherto no reaction was known by which free chlorine and hypochlorous acid could be readily distinguished. Such a reaction has, however, now been discovered by Wolters, who has found that when chlorine-water is shaken with mercury, only mercurous chloride is formed; while with aqueous hypochlorous acid it yields a brown, crystalline oxychloride, which is readily soluble in hydrochloric acid. In employing this method for detecting hypochlorous acid in the liquid obtained by distilling bleaching powder with a small quantity of hydrochloric or sulphuric acid, Goepner could not find a trace of hypochlorous acid.

To this the author remarks that Gay-Lussac, in his classical research "On the Compounds of Chlorine with Bases," recommends, as a ready means for preparing a dilute solution of hypochlorous acid, to distil a solution of bleaching powder with dilute nitric acid. This experiment has since been repeated hundreds of times. Roscoe shows it every year in his lectures, and the laboratory students perform it in the course of their practical work. A perfectly colourless distillate is thus obtained, which is a much more powerful bleaching agent than freshly prepared chlorine-water. This is quite sufficient to show that the distillate contains hypochlorous acid. But why did Goepner fail in detecting it? Is it the fault of the analytical method? To decide this, hypochlorous acid was prepared by distilling a solution of bleaching powder with dilute nitric acid or sulphuric acid. On shaking the distillate with mercury, the brown oxychloride was formed in each case. Another argument against the existence of a hypochlorite in bleaching powder Goepner finds in the fact that the chlorine used in the manufacture always contains hydrochloric acid, and thus more calcium chloride is formed than would correspond with the formula $CaO\,Cl_2$. When bleaching powder is exhausted successively with small quantities of water, this excess of calcium chloride is found in the first solutions, while the following contain calcium and chlorine in the proportion corresponding with the above formula. This, however, only proves that bleaching powder is not a mixture of calcium chloride and hypochlorite, but that it contains the compound $Ca\begin{cases}Cl\\OCl\end{cases}$, or has the constitution which Odling has assigned to it. Williamson has shown that a solution of hypochlorous acid is also readily obtained by passing chlorine into a mixture of water and finely divided calcium carbonate, and distilling as soon as the carbonate is dissolved. In this reaction the above compound is probably also first formed and then decomposed in the following way :—

$$CaCl(OCl) + Cl_2 = CaCl_2 + Cl_2O.$$

The Pharmaceutical Journal.

SATURDAY, JUNE 6, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE NEW COUNCIL AND THE NEXT ELECTION OF ANNUITANTS.

AT the meeting of the Council on Wednesday last, the general satisfaction of the Members of the Pharmaceutical Society with the conduct of its business, shown by the recent re-election of all the available members of the previous Council, was endorsed by that body in the re-election of its former officers, Mr. THOMAS HYDE HILLS as President, Mr. ALEXANDER BOTTLE as Vice-President, and Mr. JOHN WILLIAMS as Treasurer. But these offices, though honourable, are far from being honorary in respect to service; and no one was astonished to hear the report that Mr. HILLS had come to the determination to decline to resume the office of President if it were offered to him. The news, therefore, that the unanimity of his colleagues has overcome his reluctance and secured to the Society his services during another year will, we believe, be cordially welcomed by the members.

Besides the natural curiosity as to the choice of leaders, a considerable amount of interest has been excited in the question which the Council had to decide at its first meeting, respecting the election of annuitants on the Benevolent Fund in October next. A few words will suffice to make plain what they have done. The principle hitherto adopted in deciding the number of annuitants to be elected, has been not to exceed the income derived from the interest on the invested money. This now amounts to £14,000, the interest on which is just sufficient for fourteen annuities of £30 each. At the present time thirteen persons are in receipt of such annuities, so that, had the ordinary course been adopted, only one annuitant could have been elected next October. The Council, however, have resolved that four shall be elected, or three more than are provided for by interest of invested capital; and thus they have initiated the experiment of entering into permanent engagements based upon faith in the continued and extended generosity of the subscribers.

The course has been taken by the Council, doubtless, in deference to the opinion repeatedly expressed in the correspondence columns of this Journal and advocated by Mr. ROBBINS, that a more free distribution of the funds would induce a greater influx of subscriptions. That it is an experiment must not be forgotten, and one that did not awaken any great enthusiasm at the annual meeting. As Mr. BETTY aptly remarked on Wednesday last, the past prosperity of the Fund is proof that the principles upon which it has been administered have been sound; and he vouches that for two years no deserving applicant has been sent away unrelieved. It is urged, however, by some, professing to be representative of many more, that these casual grants lack the element of certainty which makes an annuity so grateful to those already weary of life's anxieties. Challenged again and again to test and prove the generosity of their brother pharmacists, the Council have, after mature consideration, picked up the glove. It is now for the challengers to show that they are not of those who turn their backs in the day of battle.

AN EVENING WITH DR. DOBELL.

A PLEASANT *réunion* took place at 84, Harley street, on Thursday evening last, at which were assembled a number of the disciples of Æsculapius and Galen. A variety of novelties were exhibited, chiefly medical appliances and preparations of new remedies, amongst which was shown in action a process of poulticing by steam. A mode of applying steam for this purpose has been practically worked out by Dr. DOBELL, in which a current of steam is made to pass through waterproof bags, and is passed off as condensed water, by means of an india-rubber tube, below the patient's bed. The bags, of different sizes and shapes to suit the parts to which they are to be applied, have an exterior coating of flannel or other non-conducting material, and can be kept *in situ* with an absorbent layer, if necessary, either wet, dry, or medicated, as the case may require, placed between them and the body. Messrs. MAW, SON and THOMPSON supply the apparatus, and bags of all sizes. Messrs. MAW, likewise, sent several other medical appliances. Messrs. MAYER and MELTZER exhibited a very compact portable electric battery; Mr. T. HAWKSLEY a Hunter's portable apparatus for producing vapour and hot air baths; Messrs. KROHNE and SESEMAN, Dr. Siegle's steam spray inhaler. Sphygmographs and aspirators of various kinds were also shown. Dr. SPENCER THOMPSON's ice preserver and butter cooler were unfortunately empty, or their utility might have been tested on that evening particularly. Of articles possessing more pharmaceutical interest, Messrs. HEARON, SQUIRE, and FRANCIS exhibited a large specimen of guaranine; Messrs. P. and P. W. SQUIRE exhibited Lin. Potassii Iodidi cum Sapone, made with hard soap and also with curd soap, Coca leaves and tincture, Liq. Fuci Vesiculosi, Liq. Vincæ Majoris, Liq. Ferri Chloroxidi, Tinct. Gummi Rubri, a bundle of Cannabis Indica and its extract, and Pulv. Glycyrrhiza Comp., B.P. and P. Boruss.; Messrs. SAVORY and MOORE exhibited Coca and its tincture, Guarana and its tincture, Cort. Eucalypti Globuli and tincture, Pancreatine and Pepsine, and coated pills of these; Messrs. CORBYN and Co., an improved double valve Inhaler, Perles of Sulphide of Calcium and of Sulphide of Sodium;

Mr. HAMPSON, specimens of his Sugar-coated Pills; Mr. MARTINDALE, a collection of preparations contained in the new "Additions to the Pharmacopœia" and some Fumigating Pastilles of Nitre, a substitute for nitre paper. Mr. J. B. BARNES represented elegant pharmacy with medicated effervescing draughts; Mr. COOPER, with his effervescing lozenges. Messrs. REW and Co. also exhibited Carbolized Ether, Hydrate of Chloral combined with Camphor, and other preparations.

"SCIENTIFIC EVIDENCE" AND THE ADULTERATION ACT.

SPEAKING of the uneasiness and dissatisfaction caused by the conflicting nature of the evidence which has been given by public analysts and others in several prosecutions under the Adulteration Act, the *Times*, in a recent leading article, says:—

"The present complaint arises really from the way in which the professional witnesses are ticketed off beforehand as the property of the one side or the other, and are expected to give evidence accordingly. There ought to be no such ticketing off. Questions which arise on which skilled evidence is requisite—and there will of course be many of them—should be referred to a qualified and impartial tribunal, and the answer obtained should be final for the matter under dispute. In this way only can those scandalous scenes be avoided which now perpetually recur in our Courts of Law, and make our administration of justice too frequently a by-word for its manifest absurdities. Something of this kind ought, no doubt, to have been done long ago. Foreign jurists are simply amazed at our present system, and regard it only as one among many instances of our strange and incomprehensible customs. Nor is it only that a change is requisite. Practically, too, there could be no great difficulty in making it. The manner of the appointment of the proposed tribunal in each case; who, if any, should form permanently a part of it, and in what way they should be required to examine and report—all these would be matters of detail, which could be arranged easily as soon as the attempt was *bonâ fide* made to settle them. Any system would be better than one which not only offers a direct premium on false evidence, but seems contrived for the express purpose of obscuring the very points which most need to be brought into the clear light of day. If our correspondent's suggestions are followed in reference to evidence under the Adulteration Acts, it will be, at all events, a step in the right direction. It will need, however, if the whole evil is to be met, to be supplemented by a much larger measure, dealing generally with the manner in which the evidence of all Experts is to be taken in our Courts of Law; and such a measure cannot, without grave mischief, be delayed much longer. The present system by which scientific witnesses are selected by the parties to a suit, poisons evidence at its very source."

MILK DRINKING IN NEW YORK CITY.

MILK, which through the operation of the Adulteration Act has lately received a certain rehabilitation of character in this country, is reported to be furnishing the latest sensation in "drinks" in New York city. According to the *Scientific American*, milk drinking has received an unusual impetus through the establishment of restaurants where the diet is confined to a few simple articles of farinaceous food and to bowls of milk and cream supplied at moderate prices. The idea appears to have originated some five years since with the proprietor of a small baker's shop in a back street, who had a monopoly of the business for some time, making large returns. Others, attracted by the gains, embarked in the business, and by a natural process of selection, from the little baker's shop have evolved the more pretentious restaurants. The most popular of these are said to be thronged by all classes, from bankers and merchants, clergymen and lawyers, to errand boys; showing that if this sudden increase in milk drinking be a popular mania, it is one that is widely diffused. As much as twelve hundred quarts on a cool day, and half as much more on a hot day, is the quantity of milk said to be consumed in a single establishment, by an average of twenty-five hundred persons.

PORTRAIT OF THE LATE HENRY DEANE.

THE following gentlemen have already sent in their names as subscribers to the fund which was proposed at the Annual Meeting for placing a memorial portrait of Mr. DEANE in the Council Room of the Pharmaceutical Society, and Mr. SANDFORD, of 47, Piccadilly, will be glad to receive early intimation from others who may wish to join in this tribute of respect to so worthy a member of the Society, and so eminent a pharmacist. It was understood that the subscriptions should not exceed one guinea.

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

IT is announced that the meeting of the Association Française pour l'Avancement des Sciences for this year will be held at Lille, August 20 to 27, under the presidency of M. WURTZ.

APPOINTMENT OF ANALYSTS.

DR. ALBERT JAMES BERNAYS, of St. Thomas's Hospital, has been appointed Public Analyst for the district of St. Saviour's, Southwark, *vice* Dr. BIANCHI, resigned. According to the *Standard* the terms of the appointment are that the salary shall be £105 per annum, and that during the year the analyses *shall not greatly exceed one hundred!* If this be correct, the local authorities may be congratulated upon even so limited an amount of zeal for the public morality as a step in advance, and preferable to accepting gratuitous services.

Mr. ALFRED WILLIAM SMITH, chemist and druggist, has been appointed Public Analyst for Rye; the remuneration to be 5s. to 10s. per analysis.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

Wednesday, June 3rd, 1874.

Present—Messrs. Atherton, Baynes, Betty, Bottle, Brown, Frazer, Greenish, Hampson, Hills, Mackay, Owen, Radley, Rimmington, Robbins, Sandford, Savage, Schacht, Stoddart, and Williams.

Mr. Hills was called to the Chair until a President should be chosen.

The minutes of the previous meeting having been read and confirmed, the first business was the election of officers and committees for the ensuing year.

Election of President.

On a ballot being taken, Mr. Thomas Hyde Hills was unanimously re-elected President. He thereupon thanked his fellow members for the honour they had again conferred upon him.

Election of Vice-President.

Mr. Alexander Bottle was also re-elected Vice-President, and acknowledged the compliment.

Election of Treasurer.

Mr. Williams was again elected to discharge the duties of Treasurer during the coming year, and also returned his acknowledgments.

Election of Secretary and Assistant Secretary.

Mr. Elias Bremridge was re-appointed Secretary and Registrar, and Mr. Richard Bremridge Assistant Secretary and Deputy Registrar.

The Conversazione.

Votes of thanks were unanimously passed to the Lords of the Committee of Council on Education for their kindness in allowing the use of the South Kensington Museum for the annual Conversazione; also to the official staff of the Museum for their services on the same occasion.

Appointment of Committees.

General Purposes:—the whole of the Council; to meet as occasion may require.

Finance:—Messrs. Greenish, Hampson, Owen, and Robbins. The Committee to meet at three o'clock on the day preceding the meeting of the Council.

Library, Museum, and Laboratory:—Messrs. Betty, Greenish, Hampson, Robbins, Sandford, and Williams.

Mr. Schacht suggested that this Committee should meet on the Tuesday prior to the Council meetings, in order to enable country members to attend it.

Mr. Sandford said it had been found necessary that one of the Committees should meet in the middle of the month, as various matters occurred which it was very desirable to have the advice of a Committee upon.

Mr. Hampson thought it very undesirable that the most important work of the Society should be all done by the London members. He should be very glad, therefore, if this Committee could hold its sittings on the day previous to the Council meeting.

Mr. Robbins said the General Purposes Committee was not utilized as it might be.

Mr. Atherton suggested that the House Committee should meet in the middle of the month, and the Library Committee meet on the Tuesday preceding the Council meeting.

Mr. Betty said that the House Committee did not require to meet every month.

The above mentioned gentlemen were then elected, with power to add to their number, and thus enable any country members to attend when business was to be transacted in which they took a special interest.

House:—Messrs. Betty, Greenish, Hampson, Robbins, Sandford, and Williams.

Benevolent Fund:—Messrs. Atherton, Brown, Frazer, Greenish, Hampson, Mackay, Owen, Rimmington, Robbins, and Sandford.

Law and Parliamentary:—It was proposed that this Committee should consist of the whole of the members of the Council; but, after some conversation, it was considered undesirable to have so large a number, and the following names were selected:—Messrs. Atherton, Baynes, Betty, Brown, Greenish, Mackay, Owen, Rimmington, Sandford, Savage, Schacht, and Williams.

Pharmaceutical Education:—Messrs. Atherton, Baynes, Betty, Brown, Frazer, Greenish, Mackay, Radley, Rimmington, Schacht, Shaw, Stoddart, and Sutton, were appointed a Committee on this subject, to take the place of the former *Provincial Education Committee*.

Evening Meetings:—The President, Vice-President, the Professors, and the Editor, were appointed a Committee to superintend the arrangements for the Evening Meetings.

The President and Vice-President are *ex officio* members of all Committees.

Appointment of Editor and Sub-Editor.

Dr. Paul was re-appointed Editor, and Mr. F. Passmore Sub-Editor, of the Journal for the ensuing year.

Local Secretaries.

The appointment of Local Secretaries was deferred until next month, the returns not yet being complete.

The British Pharmaceutical Conference.

The President read a letter he had received from Mr. Michael Carteighe, Local Secretary to the Conference, stating that the meetings were arranged to take place on the 6th and 7th of August next. Also stating that the Local Committee were anxious to make the necessary arrangements for holding a Conversazione on the evening of the 6th, and desiring to know the views of the Council with regard to holding the same in the premises of the Society. The President suggested that it would be very desirable for the Society to invite the Conference to a Soirée in the Society's House.

After some conversation, it was unanimously resolved, on the motion of Mr. Sandford, seconded by Mr. Atherton—

> "That the Society, through its Council, do invite the members of the British Pharmaceutical Conference to a Conversazione to be held in this House, on one evening of the first week of August.

The President read a letter he had received from Dr. Williams, President of the Medical and Chirurgical Society, stating that that Society would hold a Soirée on June 9th, and asking if the Pharmaceutical Society would send any specimens of drugs or chemicals for exhibition. It was decided that the Library, Museum, and Laboratory Committee take the matter into their consideration.

Library, Museum, and Laboratory.

The report of this Committee was read. It recommended the purchase for the Library of 'Pavy on Dietetics,' and Thorpe and Muir's 'Qualitative Analysis.' The Librarian reported that the average attendance had been, in the day, 19·36; in the evening, 6·36; being an increase of two on the previous number. The average daily attendance in the Museum had been nine. Books had been sent out under the new regulations to thirteen persons in the country. The average attendance at Professors Redwood's and Bentley's lectures had been from 28 to 30. Professor Attfield had reported that there had been 80 entries in the Laboratory since the commencement of the session; and that there were about 38 students now at work there.

The report and recommendations were received and adopted.

Parliamentary Committee.

This Committee met on the 21st May, when, having considered the evidence which it would be advisable to tender before the Select Committee of the House of Commons, they adjourned to the Committee-room. An abstract of the proceedings before the Committee on that day has been published in the Journal.

Mr. Sandford said the Committee would meet again on the morrow, and he could not help thinking, that the Act would be considerably amended. He then proceeded to give further details of the proceedings before the Committee, and read a clause which the solicitor had drawn, and which he had handed in to the Chairman of the Committee in response to a question whether he had any addition to suggest to the Act. The purport of the clause was to take away from any ordinary informer the power of proceeding against a chemist, and to leave all such proceedings in the hands of the Society. He had since received a letter from the solicitor, suggesting that he should be authorized to send another copy of this proposed clause to the Chairman of the Committee, with notes and explanations; but he (Mr. Sandford) had thought it better to take no further step in the matter until after the meeting of the Council. He was not himself quite convinced that it would be wise on the part of the Society to undertake the duty of prosecuting members of the trade for adulterations, but he would, *pro formâ*, move that the clause be taken into consideration.

Mr. Betty said he had read the report of the evidence given before the Committee with great interest, and, as far as he could understand, the Committee purposed recommending to the House of Commons the utilization of the public laboratory at Somerset House. The question therefore was, whether they should adopt, and endeavour to obtain the insertion of a clause such as had been referred to, which would, in effect, impose on that Society the duty of public prosecutor in cases of adulteration of drugs; or, whether they had not better leave it, as at present, in the hands of the Government. He thought it would be a most undesirable position for the Society to take, believing that when they went beyond their original scope as an examining and registering body they would be lowering themselves, and taking up a position which they ought not to fill.

Mr. Schacht asked if the responsibility of prosecuting persons for selling adulterated drugs did not already lie upon the Society, under the Pharmacy Act.

Mr. Betty said no doubt it did, according to the terms of the Act; but virtually under the Adulteration Act the power rested with other people, and had not hitherto been exercised by the Society. He thought it would be better to leave it in the hands of an independent body.

Mr. Rimmington thought it would not be desirable to insert any clause in the Act removing entirely the responsibility from the seller of drugs; or else it would be found that no seller would ever have a guilty knowledge, and all sorts of things would be sold with impunity.

Mr. Savage thought they ought to pause before they decided on doing what they could to hand over to any other body the powers they possessed, and which if once parted with would never be recovered. It appeared that as yet they had not thoroughly understood what their duties were; but if the Act were amended and were carried out in a different manner, he did not think the Council would shrink from performing their duty.

Mr. Schacht said the Society had obtained certain statutory privileges, and in return certain duties were imposed upon them. He was rather inclined to think that it would be better to get the present difficulties removed than to give up their authority altogether.

Mr. Radley also thought it would be more satisfactory to the trade at large if prosecutions for adulteration in the case of drugs were left in the hands of the Society, because there were many peculiar questions arising which only some one practically acquainted with the trade could fairly decide upon.

Mr. Williams said the principal point urged by the witnesses before the Committee, as he understood, was that the Society had no wish in any way to do away with the Adulteration Act, but only that it should not be oppressively exercised. A suggestion had been thrown out that all questions concerning drugs should be considered in the first place by certain experts, namely, a member of the College of Physicians, a pharmaceutical chemist, and an analytical chemist, who should act as a kind of grand jury before any prosecution could be instituted. One member of the Committee of the House of Commons also appeared strongly in favour of making use of the laboratory at Somerset House as a kind of Court of Appeal in case of varying analyses; and he was so far in favour of that view, that he thought if ten or twelve centres were established in England, with thoroughly well qualified and well paid analysts, it would be much better than having local analysts in every district.

The report and recommendations of the Committee were then unanimously received and adopted.

Infringement of the Pharmacy Act.

The Secretary drew attention to the case of poisoning at Colchester, reported in the Journal for 20th April (p. 865). Some aconite had been sold by a Mr. Webster, of East Hill, Colchester, medical herbalist, and the purchaser died; attention had been called to the case, and the solicitor had been instructed to communicate with Mr. Webster upon the subject. The solicitor now stated that, having written the usual letter preliminary to taking proceedings for illegally carrying on the business of chemist and druggist, Mr. Webster had called upon him and paid the amount of penalty and costs.

Finance.

Various accounts which had been examined by four members of the Council, acting as a Finance Committee, were ordered to be paid, and £100 was granted to the North British Branch to meet current expenses.

Congress at St. Petersburg.

Mr. Hampson moved:—

> "That two members of this Council be deputed to represent the Pharmaceutical Society of Great Britain at the fourth meeting of the International Pharmaceutical Congress to be held at St. Petersburg in August next, and that a sum not exceeding £80 be set apart to defray the expenses incident to their journey."

He hoped the Council would be unanimous in supporting this resolution, because he thought they ought to keep up their dignity amongst European pharmacists, and send a deputation to the approaching Congress.

Mr. Schacht had great pleasure in seconding the motion, more especially because when the subject was mooted before he might have appeared to have opposed the idea. That, however, was not his intention, his only desire being to postpone consideration of the question until they were better prepared to dispose of it.

Mr. Betty said he was rather surprised at this motion being brought forward, no notice of it having being put upon the Agenda paper.

The Vice-President said it was ordered to stand over for discussion at the present meeting; therefore all members of the Council had had notice of it, although by accident it was omitted from the Agenda. He thought the amount proposed to be expended was very moderate, and it was not really a question whether they would get an immediate return for it.

Mr. Baynes said he should support the proposition.

Mr. Williams said he had taken the opportunity of speaking to many leading members at the recent Conversazione, and they all expressed the opinion that it would be a disgrace to the Society if they were not represented at this Congress.

Mr. SANDFORD thought it would be better to delay passing this resolution till the next meeting, as an answer need not be sent until the 15th of July; they might in the meantime see what the questions for discussion at the Congress were, and be in a better position to say whether or not there was any necessity for the Society to be represented; for his own part he saw no necessity for it.

Mr. BROWN said the matter had already been postponed once and ought now to be decided.

After a few words from Mr. Hampson in reply, the motion was put and carried by a large majority.

It was then resolved unanimously that Messrs. Greenish and Sutton be appointed a deputation to go to St. Petersburg, and the President, Vice-President, Messrs. Betty, Schacht, and Hampson were appointed a Committee to confer with them as to the views on the various points of discussion which they should advocate at the Congress.

BENEVOLENT FUND.

Messrs. Bottle, Greenish, Hampson, and Owen had sat as a Committee to consider applications for assistance, and upon their recommendation the following grants were made :—

To the widow of a chemist and druggist at Gosport, £20.

To the widow of a recently deceased annuitant, £10.

To the widow of a chemist and druggist at Batley Carr, £10.

The name of Sophia Wick, of 44, Cambridge Street, Pimlico, and that of Dorothy Phillipps, of Batley Carr, were ordered to be placed on the list of "approved candidates for annuities."

A letter was read from Mr. Large, of New North Road, suggesting that, as in some other societies, there should be two classes of annuitants—one class consisting of those who had been members and subscribers to the fund, who should receive annuities of £30 per annum; and a second class, including those who had not been members or subscribers, and who should receive annuities of a less amount. The letter was referred to the next meeting of the Council for consideration. A letter was also read from Mr. Reynolds, of Leeds, reporting the manner in which he had disposed of the £20 recently granted to a widow in his neighbourhood.

The VICE-PRESIDENT said, according to the regulations, it was now the duty of the Council to determine as to the expediency of electing annuitants in October next. The question had been a good deal discussed as to whether they should go beyond the principle they had hitherto followed of only granting annuities to the extent of the interest upon their invested capital, without expending one farthing of the annual contributions in this manner. He was quite convinced that the time was now come when they might safely depart from that conservative idea, and might trench to some extent on the annual income of the Society. Since the last election, one annuitant had died; and he would propose now that four annuitants be elected in October next. This had been fully gone into by the gentlemen who acted with him as the Benevolent Fund Committee, on the previous day, and they had arrived at the conclusion that they might safely go to this extent, treating it as an experiment and leaving it to another year to determine whether the principle should be further extended. He begged to move therefore—

> "That it is expedient (financially) to elect pensioners on the Benevolent Fund in October next, and that four pensioners be elected accordingly."

Mr. BROWN had much pleasure in seconding the resolution. For a long time he had been a strenuous upholder of the old policy of only granting annuities out of the invested capital, but a Committee having been appointed to take into consideration the means of increasing the fund and inducing the members at large to take a more active interest in it, they were led in the course of their investigations, principally through the exertions of Mr. Robbins, to believe that they might safely depart from that policy. The broad fact was, that for many years past they had not expended one-fourth of their annual income in casual grants, and they thought therefore the time was now arrived, when, having a large invested capital, they might safely expend a part of the current subscriptions, still leaving a large surplus to be invested. It was not necessary to go on investing money as they had done, and he believed the proposed arrangement would tend to increase the popularity, as it certainly would the usefulness, of the fund. He thought they might safely go to the extent of electing four annuitants in October next, and probably on some future occasion they might go further.

Mr. OWEN supported the resolution.

Mr. BETTY moved as an amendment:—

> "That annuities on the Benevolent Fund be granted solely from the proceeds of invested capital."

If he had had any doubt that that was the right principle it would have been removed by the remarks of the two gentlemen who proposed and seconded the resolution, for it seemed to him they were diametrically opposed to each other in the reasons they gave: the proposer saying it was a matter of experiment, whereas the seconder put it on the broad principle that they should grant annuities out of annual subscriptions to the Society. He was content to take it on the main ground of the proved wisdom of the course they had already adopted as laid down by the founders of the fund. They had at present a very prosperous fund, which was certainly the best evidence of the wisdom of their principles, and they ought to be very cautious before departing from them. It would be impossible to lay down the principle that they ought to provide annuities for as many persons as applied for them; but, having sat on the Benevolent Fund Committee for two years, he was in a position to say that no deserving case had been sent away unrelieved. The question at present was, what form that relief should take, whether it should be in the form of annuities or of casual grants. He had a strong conviction that, in all matters of finance, safety was the main element for consideration, and though certain societies to which Mr. Robbins had referred on previous occasions had been able to grant annuities out of annual subscriptions, he considered that they were in very exceptional circumstances, and that their experience was no guide for the Pharmaceutical Society. He contended that the financial position of certain great London hospitals was a monitor to show the wisdom and necessity of having a large invested capital, for how frequently were those dependent on annual subscriptions obliged to make piteous appeals to the public in order to defray their current expenses.

Mr. BROWN said he had not the slightest idea that any amendment would have been proposed, or he should have made a different kind of speech in seconding the resolution.

Mr. SANDFORD, in seconding the amendment, said he believed the correct principle was that on which they had hitherto acted. If they looked to the recent annual meeting for support, there could be no doubt that the expression of opinion there was decidedly in favour of adhering to the old plan, and paying annuities out of invested capital only.

Mr. BROWN said he did not think it was a fair assumption to make.

Mr. SANDFORD said that opinion was repeatedly expressed, and he thought it was the general feeling of the meeting. He believed if a vote had been taken upon it, it would have been almost unanimous. It would be a great misfortune if annuitants ever had the slightest doubt about the permanence of their annuities.

Mr. SAVAGE said he had at one time been of the same opinion as that expressed by Mr. Betty, but better information had led him to a different conclusion; and he believed if the annual meeting had clearly understood the whole circumstances of the case, their decision or expres-

sion of opinion would have been of a very different kind. He hoped the resolution, which he considered a very moderate one, would be passed, seeing that it would absorb but a very small amount of the annual subscriptions.

Mr. FRAZER said he was quite satisfied that what was given out with one hand would be more than recovered with the other, and it would be very easy at any time to retrench if they went beyond their means.

Mr. ROBBINS said he would not detain the meeting by going into the several reasons which he had laid before the meeting, or otherwise he might easily have replied to the observations which had been made.

Mr. RIMMINGTON said he was in the same position as Mr. Robbins. He could mention several societies which gave very large amounts in annuities, though entirely supported by voluntary contributions.

A division then took place on the amendment, with the following result:—

For.—Messrs. Betty, Hills, Radley, Sandford, and Williams.

Against.—Messrs. Baynes, Bottle, Brown, Frazer, Greenish, Hampson, Owen, Rimmington, Robbins, Savage, and Schacht.

The amendment was therefore lost.

Mr. BAYNES said it might, perhaps, dispose of the objection of some gentlemen if the annuities were divided into two classes, one paid from the interest, and the other from the subscriptions.

Mr. BROWN said that could be discussed in Committee.

Mr. BAYNES said he would not move the resolution if it tended to stop the decision of the question.

Mr. WILLIAMS then moved as an amendment to the original motion, and Mr. Sandford seconded:

"That two annuitants on the Benevolent Fund be elected in October next."

Mr. BETTY asked if the invested capital would provide for two.

Mr. WILLIAMS said not quite. It was certainly leaving the principle to a certain extent.

The VICE-PRESIDENT drew attention to the regulation which called upon them to decide at that meeting the question how many annuitants should be elected.

The amendment was then put, and lost by a large majority.

Mr. BAYNES said if the proposition were voted upon without further discussion, he would move

"That annuities be of two classes, one granted from interest on invested capital, and another from annual subscriptions."

Mr. BETTY seconded the proposition.

Mr. SAVAGE said he could see no possible good in dividing them.

The VICE-PRESIDENT said this was not really an amendment to the motion.

The amendment was therefore withdrawn, and the original resolution was then put and carried.

Mr. ROBBINS said if an annuitant were elected he was elected for life, but the annuity was not granted to him and his successors for ever. Therefore, from year to year they could very easily determine how many annuitants should be elected, according as their subscriptions came in.

Mr. SANDFORD said he did not quite understand the suggestion of Mr. Baynes. How were the voting papers to be filled up?

Mr. BAYNES said he did not wish to press it in any way. He had only proposed it out of consideration for the feeling of gentlemen present who objected to the new principle.

Mr. BETTY then, according to notice given, drew attention to an advertisement which had appeared in the PHARMACEUTICAL JOURNAL of May 9th, in which, as he said, an unjustifiable use had been made of the name of the Society in connection with a trade article. After giving a brief history of the transaction, he moved:

"That Messrs. Churchill be instructed that the advertisement referred to was incorrect in certain particulars; and that, therefore, the Society, exercising their rights as proprietors, could not sanction the insertion of any statement, which, on the face of it, contained a misrepresentation of facts."

Mr. SCHACHT suggested that it would be better if instructions were given to the publisher not to insert any advertisement containing the name of the Society, without previously submitting it to the Secretary.

Mr. HAMPSON thought such a resolution would be very difficult to carry out in practice.

The VICE-PRESIDENT said that advertisements for assistants often contained the name of the Society, and under such a resolution the publisher would not be able to insert them without reference to the Secretary, which would be very inconvenient.

After some further discussion, it was decided to refer the whole matter to the Parliamentary Committee.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemist.

Cleave, Samuel Whiteway .....Shanghai.

Chemist and Druggist.

Lewis, Nathaniel James .....Neston.

ASSOCIATES.

The following, having passed their respective examinations, and being in business on their own account, were elected "Associates in Business" of the Society.

Minor.

Connor, Thomas Haigh .....Alresford.

Modified.

Thomas, William .....Southampton.

The following, having passed the Minor Examination, were elected "Associates" of the Society:—

Baldwin, Arthur Henry .. ..Clifton.
Guy, William Adolphus .....Kimberton.
Harrison, James .....Sunderland.
Munday, John .....Bridgnorth.
Overton, John .....Bristol.
Shum, Arthur George .....Edinburgh.
Knight, William .....Hinckley.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary Examination, were elected "Apprentices or Students" of the Society:—

Creer, George .....Castletown.
Madeley, Edward Stanbury.....Barnes.

Several members who had neglected to pay their subscriptions in proper time, were ordered to be restored to their former status on payment of the subscription for the current year, and a fine equal to half the amount.

THE LATE HENRY DEANE.

A letter was read from Mrs. Deane, acknowledging the letter of condolence from the Society respecting the death of her late husband.

Mr. SANDFORD announced that he had already received the names of thirty-four subscribers to the fund for painting the portrait of the late Mr. Deane, and as the subscription was limited to £1 1*s.* each, he should be glad to receive sufficient names in order to make up the amount required—£100.

Provincial Transactions.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The annual meeting of members of the above Association was held on Friday, May 29th, at the Great Western Hotel; Mr. Wm. Southall occupying the chair, in the room of Mr. Grieves (President), who was unavoidably absent.

The Secretary read the annual report, in which it was stated that the Council had decided to give up the rooms in the Quadrant, one reason being that the books and specimens could be more useful if allowed to be taken to the homes of the students, instead of the latter being compelled to go to the rooms for the purpose of study. The other reason was that the change would effect such a saving in funds as would allow the Council to reduce the annual subscriptions of members and associates to 2*s.* 6*d.* and 1*s.* 6*d.* respectively. By this reduction it was hoped that the number of members would be considerably increased. Two important pieces of legislation were going on at the present time which affected the interests of chemists and druggists, and concerning which the Council would invite an expression of opinion. The first of these measures was the Adulteration Act. Though it was desirable that adulteration should be detected, yet the Act was working very unfairly in some instances, and should, therefore, be carefully watched. The other measure was the Juries Bill, which was in committee, and should it pass, chemists and druggists, as well as pharmaceutical chemists, would be exempt from serving on juries. It had been thought that, as chemists were closely confined in shops, an effort should be made to take advantage of one of the bank holidays for an annual excursion. Such an excursion would offer a good opportunity to the botanical students to examine fresh specimens, and so render interesting what was now a very dry study. The report concluded by an expression of regret at the death of Mr. George Dymond.

The statement of accounts showed receipts for the year amounting to £65 2*s.* 5½*d.*, which the expenditure exceeded by £4 9*s.* 10*d.*

Mr. Barclay was elected president of the Association, and Mr. W. Jones, hon. sec. Other officers were appointed.

The usual votes of thanks having been passed, Mr. Barclay opened a discussion on the Adulteration Act. While showing the advantages of the working of the Act, and complimenting Professor Postgate, the author of it, who had honoured the Association by his presence that night, he complained of the unjust nature of some prosecutions which had taken place under it, and instanced the citrate of magnesia case, popularly, though wrongly so-called; spirit of nitre, which is liable to decomposition, and at the best is very uncertain in its composition, and if tested when freshly prepared, three months afterwards would show very different results; quinine, in which the sulphate was the article invariably wanted by the public; and milk of sulphur, for although he would always recommend pure precipitated sulphur to be sold, yet when it was contended by some who were constituted authorities under the Act that milk of sulphur was lime and sulphur, and not pure sulphur, it showed the unfair working of the Act. In the scammony prosecution, had the resin of scammony been supplied, which cost less than half the price of the other, the prosecution would have fallen to the ground; in the arrowroot case there was no adulteration; the conviction was on technical grounds; in a more recent arrowroot prosecution the chemists had a complete answer to the charge, and were prepared to prove the absence of either adulteration or injury through over-drying; but when the case came on for hearing the analyst sent a medical certificate to say he was unwell, and asked for a remand for five or six weeks; the charge in the meantime, which has publicly made, hangs over the parties, and they have no redress. Chemists were subject to penalties for selling drugs which do not answer the B.P. test, but it is impossible to get such in some cases, excepting as rare specimens, which would be fit for a museum. He instanced gum benzoin, which is extensively sold in Birmingham for French polishing: the test is that it must be *soluble* in alcohol and solution of potash; thus no chemist would be safe if this is acted upon. Essence of lemon decomposes and renders the seller liable, although he may be ever so careful in buying and storing. The remedy for these cases would be in having referees, one of whom should be

a pharmaceutical chemist, for magistrates and medical and ordinary analytical chemists do not understand these technical questions. He moved that the chairman should be requested to sign the following memorial, on the part of the meeting, to the Chairman of the Committee on the Adulteration Act; and that Mr. P. H. Muntz, M.P., should be requested to present it:—

"Inasmuch as the Adulteration Act has been found to be in some cases oppressive in its operation, your memorialists, the members of the Midland Counties Chemists' Association, beg to lay the following suggestions before the Committee now inquiring into the Adulteration Act:—(1) That in all cases the person buying goods for analysis should divide the article into two portions, and hand over one portion under seal to the vendor for independent analysis. (2) That referees should be appointed by the Government, and that one of them should be a pharmaceutical chemist. (3) That in case of an analyst reporting that an article is adulterated which shall be proved to be genuine, the prosecutors shall be compelled to advertise the verdict in the newspapers of the district, so that the reputation of honest dealers may be protected. (4) That guilty knowledge should be necessary to constitute an offence under the Act. (5) As it appears from the report of the examiners in committee that the members have an erroneous idea of the capability and respectability of the chemists in the country as compared with those in London, your memorialists suggest that one or more country druggists should be examined before the Committee of the House of Commons."

He showed the necessity of by quoting the last clause from the evident misconception the members of the Committee of the House of Commons have of country druggists. Mr. Hodgkinson is reported in the PHARMACEUTICAL JOURNAL to have replied to a question put by Mr. Muntz, "a country chemist, if he were a respectable man, would not sell another article for James's Powder." The same witness said, in reply to Mr. Welby, "I do not think country druggists are considered so much inferior to those of London." He did not impute anything to Mr. Hodgkinson, but this showed, by the questions put, what was in the mind of the members.

On the resolution being put, it was amended on the motion of Mr. Arblaster, "That three sealed samples be made at the time; one for the chemist, one for the analyst, and the other for an independent analysis;" and by Mr. Southall, "That particulars of the charge should be given when the summons was issued."

The resolution having been seconded, Mr. Postgate explained in detail the various clauses of the Adulteration Act, supporting the resolution, and stating that he had already made some of the suggestions contained in the memorial.

The resolution was passed, and the proceedings terminated.

SOCIETY OF CHEMISTS AND DRUGGISTS OF IRELAND.

The monthly meeting of the above Society was held in the Society's rooms, Molesworth Street, on Monday evening, June 1st, Mr. E. M. Hodgson, President, in the chair.

There was a large attendance of members and associates. After the usual routine business, a long conversation took place in reference to the proposed alteration in the Pharmacy Laws in Ireland. A letter from the Apothecaries' Company was read, inviting a deputation from the Society to wait on the Hall to discuss several amendments to their Bill, suggested by the Society. A deputation was then formed, to consist of the president, secretary, treasurer, and committee of the Society, and the following gentlemen: Messrs. W. Allen, J. T. Holmes, J. O'Brien, and Stanley Oldham.

The deputation was authorized to take whatever action they thought desirable in the interests of the Society.

Parliamentary and Law Proceedings.

THE SALE OF VERMIN KILLERS.

On Tuesday, May 26, Mr. F. W. Johnson, Coroner, held an inquest, at Staleybridge, on the body of Job Lee, aged 44, a machinist. After a heavy drinking bout of ten weeks, deceased worked a day or two and then had another relapse. On Saturday night he purchased two threepenny packets of "Gibson's Manchester Vermin Killer" at the shop of Mr. J. Rigby, botanist and herbalist, representing that he wished to destroy some "black-jacks" and mice. Mr. Rigby sold him the powders, and warned him of their poisonous quality. On Sunday morning, he began to vomit very severely, but that his wife attributed to his debauch. In the forenoon he paid another visit to Mr. Rigby's shop, and bought some more "Vermin Killer," Mrs. Rigby serving him. He told her he had killed some mice with the powders he purchased on the Saturday, and that he intended to kill more. He went to bed in the afternoon, and his wife went out to tea at a neighbour's. On returning home at eight o'clock in the evening she found him lying dead in his shirt on the bed-room floor. She had never heard him threaten his life, but he appeared to have been in a low-spirited way for some time. Not the least trace could be found in the house of the powders or papers in which they were wrapped, and, according to the evidence of his wife, the mice, etc., of which the deceased had spoken, existed purely in his own imagination. The Coroner said the case was a very suspicious one, but as there was no actual proof that the deceased had taken the poison, or had it administered to him, the only verdict the jury could return was that of "Found dead." Verdict accordingly.—*Stockport Advertiser.*

PROSECUTIONS UNDER THE ADULTERATION ACT.

THE SALE OF COLOURED TEAS.—IMPORTANT DECISION BY THE COURT OF QUEEN'S BENCH.

In the Court of Queen's Bench on Saturday, May 30, the case of a Birkenhead grocer, named Roberts, was heard on appeal which raised an important question on the Adulteration Act—whether the sale of any article, as tea, which is adulterated can be excused on the ground that it is known to be so in "the trade." The Act says "that every person who shall sell any article of food or drink with which to his knowledge any ingredient injurious to health has been mixed, and every person who shall sell as unadulterated any article of food or drink which is adulterated shall for such offence be convicted." The appellant keeps a shop at Birkenhead for the sale of tea, coffee, etc., and a person went to his shop and asked for "some green tea," which was served to him by a shopman, and he bought two ounces of it for which he was charged 5½d. The purchaser then informed him that he bought it for the purpose of analysis, and the shopman told him that he was authorized by his employers to guarantee all their green tea of the value of of 3s. per lb. and upwards as genuine green tea. The tea was afterwards analysed by a public analyst, who stated that it was adulterated by a thick facing of mineral matter and Prussian blue—that is, it was painted or "faced" with gypsum and Prussian blue for the purpose of colouring it, and this was the adulteration charged. The tea was sold in the same state in which it came from abroad, and the seller did not in any way cause the tea to be "painted" or "faced" in this country. A sample of tea was produced by the public analyst before the magistrates, which resembled in colour and appearance what is popularly known as green tea, and it was proved to be neither "painted" nor "faced." He also proved that he had analysed other samples of teas resembling in colour and appearance green tea, and that they contained no colouring matter. It was also proved that tea which is imported from China as green tea and

generally known as such in the tea trade is painted and faced in the manner and for the purposes stated, and that the sample proved not to be painted or faced was imported from Japan, and not known generally in the trade as green tea. It was contended on the part of the tradesman that the merchantable article imported into this country, known by the name of green tea in the tea trade, is a painted or faced tea, and that it is not a natural simple production of nature, and that therefore a vendor of green tea cannot be taken to represent that he sells only the leaves of the tea plant unaffected by any process; that green tea was sold in the state in which it was imported from China, and that the painting or facing was done there, and not in this country; and that painting or facing tea for the purpose of colouring it is not an adulteration within the meaning af the Act. But the magistrates were of opinion that as the practice of painting and facing tea sold as green tea (though known to those engaged in the tea trade) is not known to the public. The sale of this tea to a purchaser who asked for green tea was a sale of an adulterated article as unadulterated, and they accordingly committed the tradesman, following the decision of this Court in a case of sale of bad butter. The question was whether the tradesman was properly convicted.

Mr. C. Russell, Q. C., and Mr. Segar were for the tradesman who appealed; and Mr. Poland appeared in support of the conviction.

On the case being opened,

The Lord Chief Justice observed that the question seemed to be, whether an article could be adulterated with impunity if the adulteration was notorious in the trade.

Mr. Justice Blackburn observed that it appeared the adulteration of tea was not so known to the public. It was not suggested that everyone knows the tea they buy is adulterated.

Mr. Russell said he denied that this tea was "adulterated," because it was not found to be injurious to health, and the article was merely altered in appearance.

Mr. Justice Quain asked: Is tea "food" or "drink," or a "drug?"

Mr. Justice Blackburn: It is all these—it is "food," "drink," and "drug," at all events, it is clearly one or the other, and so within the Act.

The Lord Chief Justice: The question seems to be whether it is adulterated if mixed with gypsum and Prussian blue.

Mr Justice Blackburn: It being clear that it is sold as genuine, and that the public have no general knowledge that it is not so.

The Lord Chief Justice: It was sold as genuine, was it not? Does not genuine green tea mean tea as grown and dried in the ordinary course of things?

Mr. Russell: This was sold "in the ordinary course of things;" it was not adulterated by the tradesman; it was the article usually known and sold in the trade as green tea.

Mr. Justice Quain: You say it is the article known and sold in the trade as "green tea?"

Mr. Russell: Just as sherry is sold, though few of us probably ever drank a glass of genuine sherry.

Mr. Justice Quain: I believe it is usually dressed with gypsum.

Mr. Justice Blackburn: However, let us take one thing at a time. This is tea. Is not gypsum or Prussian blue an adulteration of it? Alum is an adulteration of bread. If a wine merchant sold me sherry mixed with gypsum I would not, if I knew it, employ him again.

Mr. Justice Quain referred to the case of butter.

Mr. Justice Blackburn observed that the public at large do not know the green tea is thus adulterated, although it is known in the trade.

Mr. Russell cited Johnson's definition of "adulteration" —"an admixture of some foreign matter which corrupts."

Mr. Justice Blackburn: Well, are not gypsum and Prussian blue "foreign matters," and do they not corrupt the tea?

The Lord Chief Justice: I should not like to drink tea so corrupted. Is it excused because it is a practice in the trade?

Mr. Justice Archibald: The public don't suppose they are buying tea mixed with gypsum and Prussian blue.

Mr. Justice Blackburn: The public think they are buying green tea. The learned in the trade know better. But it is not known to the customer. Tell a man you are selling him tea mixed with gypsum and Prussian blue, and then he can buy it if he likes; but you don't tell it to him and you sell it to him as green tea. How is that excused because it is "commercial" green tea? Why might there not be a "commercial" butter if there may be a "commercial" tea? When a man buys claret, does he suppose he is buying sloe-juice? I should be sorry to hold that was not an adulteration.

Mr. Russell urged the mixture of wine with alcohol was.

The Lord Chief Justice pointed out that wine could not be kept without alcohol, and that alcohol was very different from gypsum.

Mr. Russell still urged that there was no adulteration, and that it was the commercial article known in the trade as "green tea." It was thus coloured when first known and dealt with and imported as green tea.

Mr. Poland, in support of the conviction, argued that it appeared genuine green tea was known in the trade, and that this tea was sold as genuine, but was not so, as it was mixed with noxious mineral substances. That being so, it ought to be declared to be so to the customer.

Mr. Justice Blackburn: The effect of that would be that it would check the importation of Chinese tea unless they ceased to colour their teas. But I don't know if that would be a result to be regretted.

Mr. Poland urged that it was the very result aimed at by the Act—the suppression of the traffic in adulterated articles. The public bought tea, not tea and paint. It was distinctly stated that the public did not know it.

The Lord Chief Justice observed that it must be taken that the tradesman knew of the adulteration, for it appeared that it was known in the trade.

Mr. Justice Blackburn: In this instance, as the purchase was for analysis probably the purchaser did not expect it to be genuine.

Mr. Poland urged that it was stated that the public did not know of the adulteration, whereas the trade knew of it.

The Lord Chief Justice pointed out that knowledge of the adulteration was not essential to the offence if the article was sold as genuine when it was, in fact, adulterated. It is the duty of those who sell articles as adulterated to find out whether they are so or not.

Mr. Poland urged that the tradesman was bound to give notice to his customers of the existence of adulteration.

Mr. Russell, in reply, urged that there was no adulteration of green tea, but that the green tea sold was, in fact, thus adulterated when imported; the adulteration assumed the pre-existence of a genuine article, but here no such article existed in the trade.

Mr. Justice Blackburn.—It is common, no doubt; though I incline to think that it is not so common as is stated, but it is not a necessary characteristic of green tea.

Mr. Justice Quain.—It is expressly stated that it is done for the purpose of colouring the tea.

Mr. Justice Archibald.—It is stated that the tradesman represented the tea as genuine green tea.

Mr. Justice Blackburn: Does that mean tea which is genuine, or tea which is sold and imported as such?

The Lord Chief Justice: Does not that depend upon the impression conveyed to the mind of the customer?

At the close of the argument, the learned Judges consulted together, and then,

Mr. Justice Quain asked: Is it to be taken that the tradesman knew of the adulteration?

Mr. Russell thought not.

The Lord Chief Justice said it was stated that it was known "in the trade," and the tradesman was in the trade.

Mr. Justice Blackburn: Surely he must be taken to have known it, though, in the view I take of the Act, that is wholly immaterial as regards this part of it.

The Judges consulted again, and then

The Lord Chief Justice proceeded to give his judgment that the conviction was right. I cannot help thinking, he said, though my Brother Quain doubts, that this is a case of the sale of an article as unadulterated, which is, in fact, adulterated. Is it adulterated? I think it is, for this process of painting is surely an adulteration. It is known in the trade that it is so, but it is not known to the customer. Further, it is sold to him as "genuine," for the tradesman here expressly warrants it as genuine green tea. It is not material upon this section of the statute whether the tradesman knew of the adulteration; but if it were material, I think it appears that the tradesman must have known of it, for it is known in the trade. It is stated that the tea which comes from China is very generally thus dealt with, but that will not excuse the seller under this enactment if he sells as genuine that which is, in fact, adulterated. This is an adulterated article; it is not the article the public think they are buying; on the contrary, if they knew what it was they would not buy it. Therefore, it is selling the adulterated article as genuine, and that is an offence within the statute.

Mr. Justice Blackburn concurred. The first part of the enactment, he said, was directed against the selling mixtures containing deleterious ingredients, the second was directed against the selling any adulterated article as genuine. This did not require knowledge of the adulteration if there was adulteration in fact and the article was sold as genuine. And here it was so; for "green tea" meant the natural leaf of the plant simply dried, and certainly mixture with gypsum and Prussian blue did not properly nor necessarily form any part of the process of making it. It was, indeed, stated that it was known by "all" the trade that green tea was thus adulterated; but he suspected that this was not so generally the case as was supposed, and at all events, it was not necessarily or properly so. Where the article was a compound and not a natural article, and required in the process of making it some foreign ingredient—as alcohol in the making of sherry or *liqueur*—it might not be an adulteration; but gypsum was not such an ingredient, nor was it necessarily used in the drying of green tea, and, therefore, the use of it was an adulteration. Then, it appeared, the article so adulterated was sold as genuine, and the offence was complete.

Mr. Justice Quain said he was sorry to differ from his brethren, but he could not think this an offence within the Act. Here was a small shopkeeper at Birkenhead convicted for selling tea just as it was imported by great merchants from China. He could not think that this was intended to be an offence under the Act. Practically, the shopkeeper sold the only article known as green tea, and he did not alter it at all, but sold it as he bought it—as the "green tea" of commerce.

Mr. Justice Archibald, however, agreed with the Lord Chief Justice and Mr. Justice Blackburn in thinking this a case within the Act. Knowledge, he said, under this section, was immaterial; but if it was, the shopkeeper was in the "trade," and the adulteration was known in the trade. On the other hand, it was not known to the customer who bought this as "genuine green tea," whereas, in point of fact, it was adulterated.

Conviction affirmed.—*Times.*

Declaration of Admixture at Time of Sale.

In the Court of Common Pleas, on Thursday, May 28, an appeal (Pope *v.* Tearle) was heard by Lord Chief Justice Coleridge, and Justices Brett and Grove sitting *in banco*, against a magisterial decision under the Adulteration Act. The information was for selling Colman's mustard as unadulterated, against the provisions of the recent Act. The magistrates had dismissed the summons, stating a case for the Court.

The appellant was an inspector of weights and measures; the defendant was a grocer. The defendant on selling the mustard had stated that it was not sold as pure mustard, and a label upon the box bore the inscription "Warranted free from injurious admixture, but not sold as pure mustard." The analyst stated that it was mixed with a quantity of wheaten flour and turmeric, not injurious to health.

Mr. Merewether appeared for the appellant; Mr. Wills, Q.C., and F. M. White for the respondent.

The question of law was whether it was necessary for the respondent to do more than declare that the mustard was not pure, and whether he ought also to have declared the quantity and nature of the admixture.

The Court held that the respondent had complied with the provisions of the Act, and was entitled to judgment. —*Times.*

The Adulteration of Butter.

At the Bow Street Police-court on Saturday, a shopkeeper, of New Street, Covent Garden, was summoned for selling adulterated butter, and the case presented features of great interest. Mr. Douglas Straight was retained for the defence, and, in the first place, objected to the summons on the ground that it did not disclose any offence within the meaning of the statute. It was necessary under the Act that it should appear on the summons that an adulterated article was sold as unadulterated, whereas this summons did not state anything of the kind. He contended that it was bad on the face of it.—Mr. Dangerfield, for the prosecution, said that it was not likely that any shopkeeper would say he sold adulterated goods, nor that people would buy such goods if the statement were made. He said this was merely a technical objection, and the case must be heard on its merits.—The magistrate ultimately overruled the objection, and the case was proceeded with.—The local inspector proved the purchase of the butter, which he had sealed up in two different packets in the shop, and one of these packets he left at the laboratory of St. Martin's Vestry for analysis. The other packet he retained in his own possession, and now produced it.—The official analyst, Mr. G. A. Anderson, next gave evidence. He said he recollected finding this sample of butter on the table of the laboratory. It was sealed up with the Vestry seal, and marked No. 1. He analysed the butter and found it contained water, 1·07 per cent.; and an admixture of butcher's fat, the precise quantity of which he was not able to determine, but the presence of which he detected by qualitative analysis. This adulterated butter, when melted, had a congealing point of about 67° F., while pure butter was about ten degrees less, congealing at about 57° or 59° F. Again, he had what he termed a saponification test, which, when applied to pure butter, produced certain appearances which were not developed in the case of this adulterated article. The saponification test was this:—When he saponified pure butter he uniformly found that it darkened in colour, that it saponified easily, and the olein, which was subsequently separated, was dark in colour, and on cooling formed a sort of jelly. In manipulating fatty matter, not butter, the reverse was the case, the fatty matter not being improved in colour, as they got what he described as a light sherry-colour fluid ley. He might also mention that the smell of pure butter in melting, and exposed to a temperature of 212° was sweet and characteristic. When adulterated butter was thus dealt with, however, the odour was entirely different from that which he had described.—Cross-examined by Mr. Straight, the witness said he was aware of the fact that in the celebrated butter case of Liverpool—Fitzpatrick *v.* Kelly—

the results obtained by the first analyst were shown to be not correct by the results obtained by subsequent analysis. In this butter which he had analysed there was more than eight degrees of adulteration. He could not precisely estimate the quantity of butcher's fat. He had taken great care that the butter should not be depreciated before he analysed it.—This being the case for the prosecution, Mr. Straight contended that the certificate of the analyst did not comply with the terms of the Act, especially as to the tenth section. This section directed that the sample taken by the inspector should be sealed in the presence of the analyst, by the inspector, and could thus be produced if required; whereas in this case, as was shown by the evidence, this had not been done, in fact, quite the contrary course of proceeding had been adopted.—Mr. Flowers considered the point raised by Mr. Straight to be fatal to the case, and he should accordingly dismiss the summons.—Mr. Straight further mentioned that the certificate was defective, inasmuch as it did not say whether the adulteration was injurious to health.—Another summons of a similar character was withdrawn.

American Diplomas.

At the Wolverhampton Police Court, on Wednesday, May 27, before the Stipendiary, Mr. Wm. Follows appeared, upon remand, charged with improperly using the title of "Dr." Mr. Stratton supported the complaint, which was lodged by Dr. Freeman, of St James's Square; and Dr. S. Evans (instructed by Mr. Dallow defended. The defendant is in business as a chemist and druggist in North Street, Wolverhampton; and the evidence of Dr. Freeman was that upon his shop-door there was a brass plate, with the words "Dr. W. Follows, member of the medical College of Philadelphia," and that in his shop there were labels announcing the hours of attendance of "Dr. Follows." The offence charged was the use of the word "Dr.," for the defendant's name was not upon the British Medical Register.

For the defence, it was urged that Mr. Follows was exempt from penalty because he had set forth the source of his diploma. He had never claimed to possess an English degree; but he was now preparing to take one, and with that view he had entered himself as a student at the Queen's Hospital Birmingham. In October, he gave notice to the Clinical Board of that Hospital that he had ceased to practise as a physician; and during the interval he had not practised.

Dr. Freeman: He has; he has attended on two of my patients! Of this the explanation offered was that the defendant had been called in, but had received no remuneration for his services.

Dr. Freeman: Why, he came to my surgery and said he could not get the man to pay him. This the defendant himself denied. The American diploma was produced, in compliance with the request of the Stipendiary.

His Worship, in deciding the case, said he thought the defendant had really "falsely and wilfully" attempted to obtain credit from the public by the diploma. It was, he thought, the grossest fraud that could be made upon the public. He saw, however, no reason why, if the defendant undertook not to practise as a physician, and paid the full costs, the case should not be dismissed. To enable the defendant to carry out this decision, the case would be adjourned for a month.

The defendant: That being the case, I shall apply for a summons against Dr. Freeman for using the title of "Dr." on his brass-plate; which he, no more than I, has a right to do.

The Stipendiary: You must apply for that in the right place; but let me tell you that you will not have the slightest chance, for his name is on the Medical Register. —*Birmingham Daily Press.*

Review.

The Naturalist in Nicaragua: a Narrative of a residence at the Gold Mines of Chontales; journeys in the Savannahs and Forests; with observations on Animals and Plants in reference to the theory of evolution of living forms. By T. Belt, F.G.S. London: Murray.

Since Bates's "Naturalist on the River Amazons," few books of travel have been published containing so much of interest and novelty to the naturalist as the one before us. The author is a mining engineer who combines with his professional work the habits and the keen powers of observation of the naturalist. Few countries are so rich in objects of interest of every kind as the Central American republic with a considerable portion of which the author had the opportunity of becoming acquainted. Landing at Greytown, the capital, he first proceeded up the river San Juan to the lake of Nicaragua. The country through which this river runs is one of the centres of the India-rubber trade; the export of this article from Greytown having increased from 401,475 lbs., valued at 112,413 dols., in 1867, to 754,886 lbs., valued at 226,465 dols., in 1871. Parties of men are fitted out with canoes and provisions, and proceed up the rivers far into the uninhabitable forests of the Atlantic slope, where they remain for several months. The tree from which the rubber is obtained is quite different from that which produces it in the Amazon country, the latter being *Siphonia elastica* belonging to the order Euphorbiaceæ, the former a species of wild fig *Castilloa elastica*, easily known by its large leaves. The milk is run out in a liquid state into large tin bottles, and is coagulated by adding to it a decoction made from a liana, *Calonyction speciosum*, in the proportion of a pint to a gallon of the rubber, which is then made into flat round cakes. In the warmer plains of Nicaragua the wine-palm, *Cocos butyracea*, is grown, and the process of manufacture of the fermented liquid is very simple. The tree is felled, and an oblong hole cut in it just below the crown of leaves, eight inches deep, and passing nearly through the trunk. The juice of the tree immediately begins to collect in this hollow, scarcely any running out at the butt where it has been cut off. In three days the hollow will be filled by a clear yellowish wine, and this will continue to secrete daily for twenty days, during which the tree will have yielded some gallons of wine.

The great interest of the volume is in its stories of the wonderful forms of animal and vegetable life of the western tropics; and we have seldom met with anything more interesting than some of the author's narratives of the habits of humming-birds, monkeys, and other tropical animals, and his descriptions of some of the extraordinary mimetic animals; of the *Marcgravia nepenthoides*, with the pitchers attached to the flowers from which the humming-birds sip the nectar, and in so doing act as carriers of pollen; and of the *Melastomas* with leaves which furnish a direct provision of houses for the ants. His account of the habits of some of these ants deserves more space than we can afford. With regard to the instinct, or, as he prefers to call it, the intelligence of these creatures, he narrates how one of their number which he had purposely imprisoned by placing a stone upon it, and another which he buried in clay all except its antennæ, were rescued by their comrades, which were fetched for the purpose by the individuals who first discovered the misfortune of their companions. On another occasion he watched a wide column of ants crossing a water-course along a small branch not thicker than a goose-quill. They widened this natural bridge to three times its width by a number of ants clinging to it and to each other on each side, over which the column passed three or four deep; when, but for this expedient, they would have had to pass over in single file and treble the time would have been consumed.

Mr. Belt is an ardent disciple of Darwin, Wallace, and Bates in their doctrines of evolution and natural selection; but his enthusiasm is always tempered with the sound judgment of a careful and experienced observer.

Notes and Queries.

[399]. CORTEX RHAMNI FRANGULÆ.—Please inform Mr. E. Turner, and any other parties anxious to know, that I have lately imported a bale of true Cortex Rhamni Frangulæ, and that I can supply him with any quantity. The formula for the decoction is given in the PHARMACEUTICAL JOURNAL, 3rd series, vol. ii., page 152. I am daily receiving letters with a request to supply this bark, and most gratifying and favourable accounts of its action.—H. C. BAILDON, 73, *Princes Street, Edinburgh.*

[400]. LIQUID ANNATTO.—Can any readers favour me with a good formula for the preparation of liquid annatto, for cheese colouring, etc.?—ENQUIRER.

[401]. AERATED LEMONADE.—W. J. N. will feel obliged to any reader who can give a formula to make Aerated Lemonade (from the lemon juice) clear and bright.

[402]. COCKROACH DESTROYER.—Could you inform me, through the medium of the PHARM. JOURNAL, the best destroyer for cockroaches and beetles, one not injurious to domestic animals?—A.X.H.

Correspondence.

THE ADDITIONS TO THE PHARMACOPŒIA.

Sir,—I don't know whether Mr. Smith includes me among the blackbirds he wishes to hear sing, or whether he thinks I have already sung enough; but, as he seems anxious to elicit information on points with reference to which I may be supposed to have some knowledge, it will perhaps be expected that I should answer his questions, and add a few remarks to those I was enabled to make on the Additions to the Pharmacopœia in the short time allowed me for the purpose at the conclusion of our last evening meeting.

Mr. Smith appears to consider the subject one in the discussion of which a "bantering," facetious style is most appropriate, and strict observance of the principles of logic unnecessary. I do not propose to attempt to follow him in the spirit of the communications with which he has favoured the readers of our JOURNAL, and which, although evidently congenial to his taste, is not so to mine.

The addition to our national Pharmacopœia of thirty-four medicines which had no previous official recognition could not fail to attract the attention, and call forth an expression of the opinions, of those whose duty it is to dispense, as well as of those who prescribe, these and other medicines. The subject is necessarily an interesting and very important one to the pharmacist as well as the physician, and it might be expected to be, as it usually has been, discussed in a spirit of seriousness and just appreciation of the responsibilities of those who are called upon to use, as well as of those who have produced, the work.

The preparation of the British Pharmacopœia has been entrusted by the Legislature to the Medical Council, who are solely and entirely responsible for its production and maintenance as a fair and sufficient exponent of the medicines recognized and used by prescribers, and sanctioned by the highest medical authorities. The work being intended as a medium of communication between prescribers and dispensers of medicine, conveying to the latter an authorized description not only of crude drugs but of processes involving pharmaceutical skill and experience, by which these are prepared for use, a practical acquaintance with the details of such processes is an essential qualification in those who undertake its production. But as all the medicines are designed for the use of physicians, it is right that, while they are enabled to avail themselves of the assistance of practical pharmacists in devising and describing processes and products, they should retain a controlling power over the whole of the matter. The extent to which members of the pharmaceutical body may expect to be consulted and allowed to take part in the construction, improvement, or alteration of this important work, will depend not only upon the character they have acquired as educated, skilled, and experienced pharmacists, possessing a practical knowledge of the art of preparing and compounding medicines, but also upon the judgment of which they have given evidence in the use of their knowledge, and the disposition they manifest to render such assistance as they are capable of giving in their special department, without pretending to or assuming a position and influence to which they are not entitled. Practical pharmacy is not the only knowledge required in the construction of a Pharmacopœia, and although many members of the pharmaceutical body are distinguished proficients in this and other knowledge which the authors of such a work should possess, they do not monopolize the whole of such knowledge, and are not the only persons who may desire to be consulted in this application of it.

As intimated by Mr. Sandford, the Medical Council have fully recognized the importance of associating pharmaceutical with medical knowledge in the compilation of a pharmacopœia, and ample opportunities have been afforded to the Pharmaceutical Society collectively, and its members individually, for exercising the "privilege" of contributing by their advice and assistance to the introduction of improvements in the British Pharmacopœia. The first edition of this work, in 1864, bore unmistakable evidence of the use then made of matter which had been prepared by a Committee of the Pharmaceutical Society, and the Society itself might be said to have been represented among those engaged in the compilation of the work by a former active member of that Committee. From that time to the present the Society has not only been represented, as stated by Mr. Sandford, but repeated messages have been conveyed through me from the Pharmacopœia Committee of the Medical Council to the Pharmaceutical Society and its members, to the effect that any information or suggestions the latter might be enabled to offer, with the view of assisting in the preparation of a future edition of the Pharmacopœia, would be thankfully accepted and duly considered. There appear to be those, however, who think, and Mr. Smith and Mr. Carteighe are among the number, that practical pharmacy ought to be more largely and directly represented than it is in the Pharmacopœia Committee. It has been stated by Mr. Carteighe that the editor employed by the Medical Council to act in conjunction with the Pharmacopœia Committee and assist in the preparation of new editions of, and additions to, the British Pharmacopœia, was overweighted by members of the Committee, and probably had "to deal with elements very difficult to manage." With reference to this statement, I must be allowed to say that there is not the slightest foundation for it. Since I have been associated with the Committee I have always found the greatest unanimity to prevail, and a tendency to place, I fear, too much reliance on my judgment where questions of a purely pharmaceutical character have arisen. When it became a question whether in reprinting the Pharmacopœia any new matter should be added, it was seen and at once admitted by the Committee that there were some important medicines, not included in the work, that ought to be officially recognized and described; and some new forms of medicine for which authorized formulæ were required, and I was requested to prepare, in the form of an appendix, a description of such articles as appeared to be most suitable for introduction into the Pharmacopœia. This was laid before the Committee as the basis of the proposed Additions, and one of the earliest uses I was allowed to make of it was to submit it to a meeting of the Pharmaceutical Society on the 5th of February, 1873, when, after explaining its general purport, I stated that "the Pharmacopœia Committee were anxious to obtain as extensively as possible the opinions of pharmacists with reference to these and other additions which it might be thought desirable to make to the Pharmacopœia." I also stated that the subject would probably be under consideration during the remainder of that year (1873), as the reprint of the Pharmacopœia was not expected to be required before the commencement of the next year. The subject was again discussed at subsequent meetings in March and April, when several suggestions were made, some of which have been adopted.

But, besides this direct appeal to the Pharmaceutical

Society, the Committee were brought into communication with several practical pharmacists, including members of some of the leading retail, wholesale, and manufacturing houses, who might be fairly described as "*representative*" men. If it is any satisfaction to Mr. Smith to know, I may state that among the articles suggested to be included in the Addendum, was Parrish's Chemical Food; but, although the Committee were cognizant of the fact that this is a largely advertised and much used proprietary medicine, they did not consider it desirable to introduce any suggested formula for it into the Pharmacopœia, but thought it might be left with chlorodyne, nepenthe, and other secret remedies to enjoy the kind of reputation these nostrums have acquired, until some more definite, reliable, and satisfactory information has been obtained with reference to them. It will not, I presume, be contended that even extensive use among medical men is always a sufficient justification for giving to a medicine the highest sanction it can receive by introducing it into the Pharmacopœia. Extensive use is sometimes due to other causes than intrinsic merit.

I may remark here that after direct appeal to the Pharmaceutical Society, repeated discussion of the subject at public meetings, and communication during several months with practical pharmacists in various parts of town and country, no material alteration was made or even suggested in the list of articles originally proposed; and, excepting that two new preparations of ipecacuanha, which it had been intended to include, having failed to realize all that was expected of them, were struck out at my instigation, and two other preparations added, the proposed Additions remained very much as they were originally, and copies, corrected up to the end of 1873, were sent to all the members of the Medical Council for their revision and remarks. That these copies passed into the hands of many practical pharmacists in England, Scotland, and Ireland was proved by the numerous communications returned with them to the Committee. It is unnecessary for me to enumerate the individuals from whom these communications emanated, but I may confidently state that they were all carefully considered by the Committee, with my assistance, and although many differences of opinion were expressed in them, these were generally found to balance each other. The result was that all the articles inserted in the proof-sheet remained, and that five additional medicines were introduced, namely, areca nut, larch bark and its tincture, compound powder of liquorice, and ammoniated tincture of quinine. I cannot say that I think the list has been proportionally increased in value by the additions resulting from the more extended appeal to practical pharmacists which was finally made, but this no doubt arose from the fact that the most important medicines had already been introduced into the list. Under the circumstances of their recommendation, however, I fully and cordially concurred with the Committee in approving of all the additions and alterations made, from first to last.

And now I would ask any dispassionate man, acquainted with the medical and pharmaceutical practice of this country, to set the medicines included in the Addendum against an equal number taken from any part of the Pharmacopœia, and say whether the former suffer in importance by the comparison. Can it be said of nitrate of ammonia, nitrite of amyl, hydrate of chloral, hypodermic injection of morphia, the preserved juices of belladonna and hyoscyamus, compound scammony pill, compound elaterium powder, pepsin, the hypophosphites of lime and soda, phosphorated oil, and phosphorus pill, that these are out of place, or that their omission would not have been justly and generally condemned? Are not acetic ether (recommended years ago by the Pharmacopœia Committee of the Pharmaceutical Society), chloroform water, mustard paper, liquid extract of liquorice, solution of citrate of magnesia, and tincture of fresh orange peel, typical medicines required by the tendency to pharmaceutical refinement? Has there not been a desire expressed by many members of the medical profession for the introduction into the Pharmacopœia of a form for suppositories not of a greasy character; and should this be disregarded? Are oxide of bismuth, which, like acetic ether, was suggested by the Pharmaceutical Committee, precipitated oxide of mercury, required for recently introduced medicines, areca-nut and larch-bark, which are recommended on high medical authority—are these medicines worthy of a place beside many others of no greater pretensions which already occupy a place in the Pharmacopœia? Surely those who object to their introduction might have expressed their opinions and supported them with reasons, at a time—for ample opportunity has been afforded—when the doing so could have influenced the result.

Exception has been taken to the form for phosphorus pill on the ground of its not being readily disintegrated when introduced into the stomach; but this merely involves a question of prescribing, for if it be mixed with a little soap, one grain of soap to three of the pill-mass, it forms a pill that breaks up readily in water, and is in every way unobjectionable. Of course the soap can only be properly added in dispensing, and should therefore be ordered in the prescription, for after the addition the mass cannot be kept under water.

It might be said of phosphorated oil, even more justly than of phosphorus pill, that it cannot be administered without further preparation, and this also involves a question for the prescriber, who will find the following a suitable prescription for an emulsion:—

℞.

Olei Phosphorati	fl. ℥j.
Vitelli Ovi	fl. ℥ij.
Liquoris Potassæ	fl. ℥j.
Syrupi Tolutani	fl. ℥vj.
Aquæ Chloroformi, ad	fl. ℥vj.

Misce secundum artem.

Here again, judgment, that now of the dispenser, must be exercised; and it will be found that if the ingredients be put together and mixed in the order in which they are written a less satisfactory result will be obtained than by mixing the first two ingredients and adding the syrup and water before the addition of the alkali.

Differences of opinion have been expressed with reference to some of the other preparations, but although there has been no evidence of a reluctance to raise objections, sometimes on the slightest possible grounds, I am not aware of any case in which a general disapproval has been manifested; and as opinions thus expressed appear to be pretty nearly balanced, it is obvious that the result must have been the same whether the articles or processes referred to had been retained, altered, or rejected.

The contents of a Pharmacopœia may be divided into two classes. There are some articles which, in everybody's estimation, are there by right and of necessity, but there are also many with reference to which there will always be differences of opinion; and two Committees would never be likely to agree upon such a question as which articles shall be turned out of the Pharmacopœia, and which admitted into it?

T. Redwood.

June 2nd, 1874.

Carbolic Acid Suppositories, B.P. Addendum.

Sir,—Mr. T. H. Williams cannot, I think, have followed the simple directions of the B.P. Addendum for the preparation of these.

I expected, from the remarks he made, to have had great trouble in their manufacture.

The form given was carefully followed, and the suppositories made in a short time, with no trouble.

Edward Pratt, M.P.S.

P.S.—The morphia and tannic acid suppositories were just as easily prepared.

High Cross, Barnstaple,
June 2nd, 1874.

Higher Remuneration for Chemists.

Sir,—It cannot be denied that in these days of high rents, high wages, and of high prices of materials, and when a higher scale of payment is demanded in all mechanical trades, that a higher remuneration for chemists and druggists' work is very desirable; and it strikes me that, were the chemists *in a body* to demand at the present time higher prices, the public would believe that they were only following the example of other trades.

Need I give examples of the small remuneration of chemists? Take the common Seidlitz powder. In the large town in which I live, the general price is one shilling for the box of twelve powders. The price of this old household medicine has remained the same, perhaps, for forty years,—ever since they were put into the box form. Consider the

low remuneration for this. A nice box, twelve powders in blue paper, and twelve in white, carefully prepared, all for one shilling! Think of the time required to put up one box only, at the same time the neatness and accuracy in so common a matter, plus the learning which the chemist is supposed to have acquired, all required and displayed for one shilling!

Could we not have two or even three shillings for this work? And, if we had, it would not be a high price compared to the rate of remuneration given to others in other trades or professions.

A short time since I had a tooth extracted under the influence of nitrous oxide gas. The charge was 3*s.* 6*d.* A high price, compared to the prices we get for equally responsible work.

It is questionable whether the drawing of a tooth involves more responsibility, manipulation, learning, or capital invested in education, than is involved in putting up a box of Seidlitz powders, "cleanly, neatly, etc.," and why should we not receive as high a price?

But, sir, I have failed to raise the prices in my own pharmacy. I tried to get 1*s.* 3*d.* per box of Seidlitz powders. My fraternity around did not follow me, and my customers patronizing them, told me of my high charge, and I was compelled to keep to the old price.

Having a sore throat the last time I went to town, I called at a London chemist's for a few sal prunella balls. Three were given me, and I was charged 3*d.* The same quantity is sold in our town for ½*d.* I made no remark, considering he was *welcome* to six times the price for his goods if *he could get it.*

There are means within our own hands of obtaining a higher scale of payment. It is said that the country chemist is looked upon as a "Cheap Jack," and, if it be true, it is really what he deserves. Thieves have a union as well as chimney sweeps. We know this to our cost, and are we to stand still, and not advance too? One determined and unanimous move throughout our body regarding a higher rate of remuneration would be very acceptable to us, and would not be received by the public, now, with surprise, since similar demands in other trades have been granted.

A Country Major Associate.

Poison Regulations.

Sir,—Having read the letter on "Poison Regulations" signed by "P. R. B.," I consider that it opens a question worthy of consideration—"If it be for the good of the public that certain poisons be required by law to be labelled, why not all?" It also refers to the selling of poisons by unqualified persons. I would ask—are there no means of preventing oilmen from selling poisons? I have now before me a price list of an oil and Italian warehouseman, and amongst the "sundries" I see the public can obtain "spirits of salts, oil of vitriol, beetle poison, and poisoned wheat." Ought these poisons to be sold by such men? And I have no doubt that in nine cases out of ten they are sold to young children. Are they allowed to sell the above preparations because they do not come under the "Sale of Poisons Act?" If such be the case I think the sooner *all* poisons are brought within the meaning of that Act the better it will be for the profession (or trade) and the public.

H. Bartlett.

June 1st, 1874.

Sir,—Your correspondent, "P.R.B." is quite correct respecting country chemists being able to produce instances where the Sale of Poisons' Act is daily infringed by grocers and general shopkeepers and those who style themselves herbalists. I would simply refer your readers to a case of "suspected death from poison at Stalybridge," which will probably be reported in the Journal this week. How comes it that Mr. J. Rigby, Botanist and Herbalist, is allowed to *sell* two threepenny packets of Gibson's Manchester vermin killer? These vermin killers (if the poison regulations were not so loosely observed as they are) ought to have been registered and witnessed as in Part 1. schedule A, because it is known that they contain strychnine. Where is the evidence produced on this point at the inquest? Mr. Rigby certainly warned the man, but has Mr. Rigby any right to sell at all, or, are botanists and herbalists included in the Pharmacy Amendment Act as persons duly qualified to dispense and sell poisons under the Act? Not long ago a person called upon me, wishing to appoint me agent for his vermin killers. I refused, and he thereupon appointed a greengrocer, who only ceased to sell it upon my showing him a letter from the Registrar, Mr. Bremridge. After this came another person, who transferred the agency to a plumber and painter. Now, should not such persons as these be held amenable to punishment?

I could give other instances.

A Country Chemist and M.P.S.

[*** It should not be forgotten by our correspondents that they or any other persons sufficiently interested can institute a prosecution for a breach of the section of the Pharmacy Act which relates to the sale of poisons. Or if they were to send adequate evidence of such a breach of the law to the Registrar, it would at once receive attention.—Ed. Ph. J.]

Sir,—Some time since you kindly permitted me to appeal to your readers on behalf of the aged widow of the late Mr. J. T. Newby, a chemist who died last October, in Brunswick Street, Hackney Road. That appeal was anonymous, and this may perhaps be the reason why, so far as I can learn, less than ten shillings has been received for Mrs. Newby. Her husband had served his apprenticeship to the trade; he had also attended lectures on various subjects, and had been in business, chiefly in London, for nearly forty years. As, however, he was neither a member of the Pharmaceutical Society, nor registered, his widow is not eligible for a pension or grant from your Benevolent Fund. She has no means of support, and her daughters are quite unable to render her aid, being barely able to maintain themselves. Surely some of your readers will give something to cheer her declining years—she is nearly 70—and prevent her from either starving or entering a workhouse. The Rev. Mr. Kelly, of 19, Hoxton Square, N., has kindly consented to receive subscriptions for Mrs. Newby.

W. Bathurst Woodman, M.D., etc.

6, *Christopher Street, Finsbury Square, E.C.*
June 2nd, 1874.

"*Army.*"—See the regulations printed at p. 79 of the present volume of this Journal.

"*Enitar.*"—If the gum was received in powder, possibly it contained an admixture of tragacanth. If not, please to send a specimen for examination.

J. M. J. (Conway).—Persons who are on the Register by virtue of having been in business before August 1st, 1868, are eligible for election as Chemist and Druggist Members of the Society, but not as Pharmaceutical Chemists.

J. W. Yeats.—Bentley and Redwood's Abridgment of Pereira's Materia Medica; Royle's Materia Medica, Oliver's Lessons in Elementary Botany.

G. H. G.—See two papers in the current volume of this Journal, pp. 754 and 954.

T. P. B.—The plant sent is *Potentilla argentea.*

"*Chymist.*"—It has been stated by an American pharmacist that Unguentum Hydrargyri Oxidi Rubri may be preserved for an indefinite length of time by keeping it beneath a layer of glycerine half an inch thick. See before, vol. iii., p. 878.

W. R. F.—Wanklyn's Water Analysis, published by Trübner, Ludgate Hill.

H. M. Leigh.—First weigh the proper quantity of extract, then dry it and use it in powder.

W. Ballard.—Apply to the Secretary for particulars.

S. P. L.—See the Pharmaceutical Journal for last week, p. 953.

"*A Dispenser*" (*Leamington*).—The precipitate turns out to be a mixture of basic tartrate of iron with cream of tartar. Other salts, *e.g.*, iodide of potassium, act in a similar way. Solution of potash does not *prevent* the decomposition, as you seem to imagine; it only retards it.

Communications, Letters, etc., have been received from Mr. Cotterrell, Mr. Biddiscombe, Mr. Leigh, Mr. Finch, Mr. Ballard, Mr. Neale, Mr. Jackson, Mr. Pratt, E. S. M., A. X. H., Inquirer, and Devonshire.

TINCTURA QUINIÆ AMMONIATA.

BY JOSEPH INCE.

Some time back there was a preparation bearing this name, made by dissolving one grain of quinine disulphate in one drachm of spiritus ammoniæ aromaticus. The idea was ingenious, but as a medical formula it was bad. It laboured under the disadvantage of being prepared with the Pharmacopœial sal volatile of that date, which was unfortunate in its composition. A compound is not necessarily aromatic because strongly flavoured with essential oils, and smelling violently of cloves. The tincture I had to manufacture was free from this element of failure, for I had to work with an aromatic spirit of ammonia of unexceptionable quality. Yet this quinine solution met with little acceptance, and was finally regarded more as a chemical illustration than as a pharmaceutical remedy. It was essentially too strong, and caused unpleasant symptoms in many cases where it was prescribed.

In 1853 an amended form was published, under the name of Ammoniated Solution of Quinine, by Mr. Bastick; and to that gentlemen is its introduction due. This was quoted in the PHARMACEUTICAL JOURNAL, vol. xiii., p. 344, old series; and by myself in the same, vol. xv., p. 509. The subject should teach us humility, for neither Mr. Bastick, nor Professor Redwood, nor I, were able to spell correctly the Latin for proof spirit. The original formula was this:—

"℞

Quinæ Disulphatis	. . .	gr. xxxij
Spiritus Tenuioris	. . .	℥iiiss
Liquoris Ammoniæ	. . .	℥ss.

Mix the quinine with the spirit, and add the ammonia, which will at first precipitate the quinine, but afterwards re-dissolve it. Each drachm of this solution contains one grain of quinine. It will mix readily with water, and moreover it is necessary that it should be taken in some such fluid, as the ammonia is too pungent in the solution to be administered undiluted."

Three thoughts were then suggested:—

First, the ammonia was the one thing needful, and not any flavouring ingredients.

Second, the quinine disulphate was more soluble in spirit than in an aqueous menstruum.

Third, it seemed an unscientific thing to add water to a spirituous compound unless necessity required, and an obvious advantage was obtained.

I therefore ventured to propose another improvement, which will be found in a paper called "Trade Pharmacy."

℞

Quinæ Disulphatis	. .	gr. xxxij
Spirit Tenuioris	. . .	℥iiiss
Spirit Ammoniæ	. . .	℥ss.

M.

Not even a gentle heat is required to effect solution, nor, so far as I have any evidence, does it undergo the slightest change on keeping.

This is the preparation mentioned by Mr. Barton, but not adopted in the Addendum. I was not aware until I read the contribution of Mr. Edward Smith, that any pharmacists continued to use the old rudely constructed formula made with sal volatile, which, twenty-one years ago, was rejected by the public and discountenanced by the profession. No sooner did I prepare the tincture according to the last receipt, than I had to manufacture it by the gallon instead of four ounces at a time. The sale was considerable, and it was patronized extensively by West-end medical men, in spite of Mr. Umney's observation, "*Tinct. Quiniæ Ammoniata* has been seldom heard of previously." That is a question of locality.

I cannot altogether leave the discussion on the Addendum without a few remarks. A Pharmacopœia, British or otherwise, has for its first main intention to meet the requirements of the prescriber, who treats the matter from a therapeutical and not from a trade point of view.

It is not for us pharmacists to dictate terms for the formulæ the physician may think proper to employ.

Yet, seeing that men versed in laboratory processes and in manipulation may afford sound sensible advice, their aid is willingly accepted. Happy is it when both work together on terms of mutual respect, a result not likely to be promoted by a recent communication from Torquay. The compilers of the Addendum, keeping in sight the medical bearing of their investigations, have presented us with simple standard recipes, capable of universal adoption, and also of universal adaptation and alteration.

Had they given a concentrated saccharine solution of chloral hydrate, or a concentrated ammoniacal solution of quinine; we should have had forced upon us two preparations, useful in certain cases, but inadmissible in many others. Not the slightest veto is placed on individual pharmacists manufacturing whatever their ingenuity or their cultivated experience may suggest.

But the word *nostrum* means "ours," and is not to be translated by the sign B.P.; and, therefore, without let or hindrance, for business purposes, the house of Godfrey may still make its sal volatile; Mr. Davenport his chlorodyne; and Parrish his compound syrup of the phosphates; with equal profit to themselves, and satisfaction to their customers.

June 8th, 1874.

VEGETABLE POISONS AND THEIR ANTIDOTES.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

(*Continued from page 770.*)

Absorption of Poisons.—Poisons are generally introduced into the system by coming in contact with the lining membrane of the stomach, or more rarely by application to a wound. In either case the effects are not manifested until the poison is absorbed into the blood, and circulated in the capillary vessels. The rapidity with which absorption takes place depends upon the nature of the surface to which the poison is applied. It takes place slowly through unbroken skin, but with greater rapidity when introduced into the cellular tissue beneath the surface. When taken into the stomach it is absorbed more readily if that organ be in an empty state. The mucous surface of the small intestines absorbs poison with greater rapidity and uniformity than the stomach; this is especially the case with the rectum, so much so, indeed, that a quantity which will not be sufficient to cause death when swallowed will destroy life when administered in the form of an enema. The result of experiments shows that a

poison may be absorbed into the blood in a space of time varying from nine seconds to two minutes. In some cases, of course, it takes a much longer time. The mucous membrane of the lungs also affords to volatile poisons like prussic acid an easy entrance into the circulation. It is, however, when introduced directly into the blood that the effects of poisons are most rapidly produced. The rate of absorption will also depend in some measure upon the solubility of the poison and the rapidity of the circulation.

Absorption into the blood is in every case indispensable to the action of poisons, and until the poison has reached the arterial capillary vessels no symptom of poisoning is produced. It also appears that *only the small portion which is absorbed into the circulation produces poisonous effects*, the portion which remains unabsorbed in the stomach, having no share in causing death. The quantity required to destroy life is in some cases exceedingly small.

Action of poisons when absorbed.—The action of poisons when circulated in the system seems to be to set up a state of disease, so closely resembling those diseases which result from natural causes that it is not always an easy matter to distinguish between them. Thus, the symptoms produced by the neurotic poisons are those of apoplexy, epilepsy, tetanus, disease of the heart, and of perforation of the stomach; and the symptoms produced by the irritant poisons may be mistaken for cholera, gastritis, peritonitis, etc. The sudden and violent accession of the symptoms in spite of treatment is therefore the only reliable guide in distinguishing them. In most instances of poisoning the symptoms are manifested within an hour after the substance has been taken, the only exceptions being when the person is in a state of intoxication or when sleep follows soon after its administration. Most poisons, in whatever way they may be introduced into the system, affect one particular part of the frame. Thus, morphia, whether applied to a wound or taken internally, affects the brain; digitalis, the heart; strychnia, the upper part of the spinal marrow; aconite, the nerves of sensation; and conia the nerves of motion. It is probable, however, that these local or specific actions are caused by an influence proceeding from, or transmitted by, the brain and spinal marrow. Why they act in this way is not easily accounted for.

Cause of death.—On whatever organ poisons may act, the *immediate cause of death is, in all cases, a stoppage of the action of either the lungs or the heart.* The former may be produced by paralysis of the muscles of respiration, as by opium, or by spasm of the glottis, as by strychnia; the latter by paralysis of the muscular tissue of the heart, as by digitalis.

It seems probable, however, that poisons ultimately cause death by exhausting the nervous power of the system. It is certain that they cause a change in the physical and chemical properties of the blood, which is sometimes manifested by an alteration in its consistency or colour, the poisonous substance in some cases simultaneously undergoing a change; thus, essential oil of almonds is deoxidized into hippuric acid in passing through the system. Some poisons, however, as strychnia, nicotine, morphia, and prussic acid, undergo no change in the body. The alteration caused in the blood by poisons may be produced by their retarding the circulation, or otherwise preventing its proper oxidation, and thus destroying the power of the blood to give energy to the brain and stimulus to the heart; for it is a well-known fact that the heart's action is no more stimulated by dark unoxidized blood than it would be by hot water, and that coma and convulsions are produced as well by loss of blood as by the cerebral poisons. It is not unlikely that the chemical changes produced in the blood may be accompanied by electrical disturbance, and thus cut off the supply of nervous force. This would perhaps account for many facts that would otherwise appear inexplicable. Recent researches show that in poisoning by digitalis the muscular juice becomes acid instead of alkaline, and that the external surface is electrically negative to the cut surface instead of (as normally) positive.

The action of poisons upon the body may be modified by various circumstances, as habit, idiosyncrasy, tolerance, or intolerance of medicine.

Habit.—It is a well-known fact that this diminishes the effect of certain poisons. Thus, habit will enable persons to take poison sufficient to destroy from two to ten of their own species. This effect is manifested in the use of opium, tobacco, and alcohol.

Idiosyncrasy is that peculiar condition of body in which small medicinal doses of poisons, as opium, strychnia, arnica, or ipecacuanha, so seriously affect a person as to endanger life. Even mutton, rice, strawberries, and other harmless substances, have been known to cause all the symptoms of irritant poisoning in those who are thus peculiarly constituted.

Intolerance.—To persons who have a tendency to apoplexy a small dose of opium may prove fatal, and whenever the body is debilitated by disease (provided the nervous system be not in an excited state) poisons acquire greater virulence of action.

Tolerance.—There are certain conditions of the body in which a large dose of poison may be taken at once by one who has not taken it previously, and yet the symptoms of poisoning will not be manifested. A case is mentioned by Dr. Christison, in which a gentleman took nearly an ounce of good laudanum without any effect. I have myself seen four grains of good opium taken without the slightest effect. In some diseases, as tetanus, hydrophobia, dysentery, mania, and delirium tremens, large doses of poison are borne without effect; thus, as much as four drachms of laudanum has been given daily in tetanus without producing symptoms of narcotism. It was at one time the universal belief that the action of poisons could be delayed, and that a poison might be made to kill after the lapse of several days, weeks, or months, as desired, and in modern times the negroes of Martinique have been said to possess similar powers, but careful research has shown the absurdity of this statement.

Elimination.—That poisons begin to be eliminated as soon as they are absorbed into the blood and that the process goes on until death, or in cases of recovery until the whole of the poison has been removed from the system, is a fact well-known to physiologists. The rate of elimination is not, however, uniform, nor is it the same with different poisons. This may depend upon the decreasing power of the system or the paralysing effect of the drug upon the organs by which it is eliminated. Thus with prussic acid the muscles of respiration are paralysed before the lungs have had time to eliminate the poison; volatile poisons, such as prussic acid and nicotine, being chiefly removed from the system through the respiratory organs.

Thus it will be seen that *the chief use of antidotes*

is to support the system until nature has eliminated that small portion of poison which is taken into the circulation. In the case of volatile poisons, which act with the greatest rapidity, the respiration should be continued artificially until the poison is eliminated; and in the case of the neurotic poisons, those substances must be used which will counteract the influences that lead to asphyxia or syncope. Thus in poisoning by strychnia, a substance should be used which will relax the muscular spasms and so prevent the glottis from being spasmodically closed.

The symptoms generally produced by the different poisons will therefore be first noticed; then instances in which recovery has followed the use of antidotes; and, lastly, drugs which by their physiological action would seem likely to prove antidotal. Several methods of classification of poisons have been adopted by different writers; but as all of the symptoms seem to be caused either by direct or reflex action of the brain and medulla oblongata, those which cause insensibility will be noticed first; secondly, those in which consciousness is wholly or partly retained; and, thirdly, those which act chiefly on the intestines without particularly affecting the brain, and which are generally called irritant poisons.

The first class will include opium, belladonna, stramonium, hyoscyamus, *Cicuta virosa*, *Œnanthe crocata*, and *Æthusa cynapium*, prussic acid, tobacco, lobelia and yew.

In the second class, digitalis, conium, Calabar bean, aconite, and strychnia will be noticed.

In the third, *Helleborus niger*, *Savin*, *Colchicum*, and *Veratrum album*.

THE APPENDICES OF THE BRITISH PHARMACOPŒIA.

BY WALTER G. SMITH, M.D., DUBLIN,

Fellow and Censor K. and Q. C. P. I.; Examiner in Materia Medica, Q. U. I.; Assistant Physician to the Adelaide Hospital.

The subjoined explanation of the uses of the officinal tests will, it is hoped, prove useful to the student by way of summary, and supplies a deficiency which exists in most of the text-books on Materia Medica with which the writer is acquainted.

The Appendices of the Pharmacopœia contain a number of articles intended for the purposes of analysis, *i.e.*, of inquiring into the nature and composition of bodies, or of ascertaining the presence of adulterating agents. Appendices I. and II. are concerned with qualitative analysis, which merely seeks to determine the presence and *nature* of certain bodies, irrespective of their actual quantity; while Appendix III. is concerned with quantitative analysis, which aims at estimating the precise *amount* of the component parts of any compound, and by which we may accurately determine the strength of many chemical compounds.

Appendix I.

Alcohol. C_2H_5, HO.—For an account of its preparation and characters, see Spiritus Rectif. Test for Oleum Ricini, and for Aconitia, Atropia, Acidum Carbolicum, Zinci Valerianas.

Benzol (or benzine). C_6H_6.—Not to be confounded with benzoyl (C_7H_5O), the radicle of essential oil of almonds, mentioned under Styrax Præparatus. Test for Gurjun balsam as an adulterant of copaiba.

Boracic Acid. H_3BO_3.—To prepare solution of boracic acid, App. II.

Chloride of Barium. $BaCl_2.2H_2O$.—To prepare solution of chloride of barium, App. II.

Copper Foil. Cu.—Test for Acidum Nitricum; and for arsenic in Acidum Hydrochloricum, and Ferri Phosphas.

Gold, Fine. Au.—To prepare solution of chloride of gold, App. II.

Hyposulphite of Soda. $Na_2S_2H_2O_4.4H_2O$.—To prepare the volumetric solution of hyposulphite of soda, App. III.

Indigo. C_8H_5NO.—The blue colouring matter (indigotin) is not soluble in water or alkaline solutions, but forms several compounds with sulphuric acid. To prepare solution of sulphate of indigo, App. II.

Isinglass.—A pure form of gelatin obtained from the inner membrane of the swimming bladder of sturgeons (*Acipenser*), and other fishes. To prepare solution of gelatin, App. II.

Litmus.—Obtained principally from *Roccella tinctoria*, N.O. Lichenes, and made up with chalk or plaster of Paris into small cakes for the market. To prepare litmus tincture, App. I.

Litmus Paper, Blue.—Test for acids.

Litmus Paper, Red.—Test for bases.

Note.—The action of acids and bases on litmus is thus explained: ordinary litmus contains a *blue* salt, viz., lithmate of calcium. But, since free lithmic acid is *red*, and possesses very feeble affinities, when any other acid, even the weakest, is added to litmus, lithmic acid is displaced, and so the red colour is produced. Again, all metallic lithmates are blue, therefore when we add any base to reddened litmus (*i.e.*, neutralize the free lithmic acid) the blue colour is restored.

Litmus Tincture.—Test for Carbo Animalis Purificatus.

Oxalic Acid of Commerce.—To prepare oxalic acid, purified, App. I.

Oxalic Acid, Purified. $H_2C_2O_4.2H_2O$.—To prepare oxalate of ammonia, App. I.; and the volumetric solution of oxalic acid, App. III.

Oxalate of Ammonia. $(NH_4)_2C_2O_4.H_2O$.—To prepare solution of oxalate of ammonia, App. II.

Plaster of Paris. $CaSO_4$—To prepare solution of sulphate of lime, App. II.

Platinum Black. Pt.—Test for Alcohol Amylicum.

Platinum Foil. Pt.—To prepare solution of perchloride of platinum, App. II. To ignite substances on.

Red Prussiate of Potash (Ferridcyanide of Potassium). $K_6Fe_2Cy_{12}$.—To prepare solution of red prussiate of potash, App. II.

Subacetate of Copper of Commerce (Verdigris). $Cu2C_2H_3O_2,CuO.6H_2O$. — To prepare solution of acetate of copper, App. II.

Sulphate of Copper, Anhydrous. $CuSO_4$.—Test for water in alcohol, App. I.

Sulphide of Iron. FeS.—To prepare sulphuretted hydrogen, App. I – $FeS+H_2SO_4=FeSO_4+H_2S$.

Sulphuretted Hydrogen. H_2S. — To prepare solution of sulphide of ammonium, App. II. Test for many metals.

Note.—Sulphuretted hydrogen is an invaluable agent in chemical analysis for the detection of metals, and for effecting their separation into distinct groups, and for these reasons: All metallic sulphides are insoluble in

water, except the sulphides of the alkalies (K, Na, NH_4, L) and alkaline earths (Ba, Ca, Mg, Sr); therefore all other metals are precipitable as sulphides (or oxides) either by sulphuretted hydrogen or sulphide of ammonium. But the conditions under which the various sulphides are thrown down differ materially, and hence, by modifying these conditions, we can divide the whole family of the precipitable metals into different sections.

I. Some sulphides are insoluble in either dilute acids or alkalies, and accordingly it is immaterial in which condition the solution be; *i.e.*, either sulphuretted hydrogen or sulphide of ammonium may be used as the precipitating agent; *e.g.*, Hg, Ag, Pb, Bi, Cu, Cd (see Cadmii Iodidum).

II. Some sulphides are soluble in alkalies, and therefore the solution must be acidified previous to precipitation, *i.e.*, sulphide of ammonium must *not* be used, as it would redissolve the metallic sulphide; *e.g.*, Sn, Sb, As. (See Liquor Arsenicalis, and the preparations of antimony *passim.*)

III. On the other hand, some sulphides are soluble in dilute mineral acids, and accordingly the solution must be rendered alkaline previous to precipitation, or, what comes to the same thing, we may use sulphide of ammonium as our precipitant. Sulphuretted hydrogen will not directly precipitate them (see Ferri Sulphas.); *e.g.*, Ni, Co, Fe, Mn, and Zn. (See the salts of zinc *passim.*) Of this group of sulphides, sulphide of zinc alone is insoluble in *acetic acid.*

As to colour, most of the sulphides are *black* (*e.g.*, Hg, Ag, Pb, Bi, Cu, Ni, Co, Fe, etc.; (*a*) one only is *white*, viz., sulphide of zinc, ZnS; (*b*) three are *yellow*, viz., the sulphides of arsenic, As_2S_3, cadmium, CdS, and tin, SnS_2; and (*c*) one is *orange*, viz., sulphide of antimony, Sb_2S_3.

Tin, Granulated. Sn.—To prepare solution of chloride of tin, App. II.

Turmeric.—Its colouring matter (curcumin) is nearly insoluble in water, but is freely taken up by alcohol and ether. Alkalies change the yellow colour of turmeric to brown, but most acids, with the exception of boracic acid, produce no change of tint. To prepare tincture of turmeric, App. I.

Turmeric Paper.—Test for alkalies.

Turmeric Tincture.—To prepare turmeric paper, App. I.

To be continued.

ARTIFICIAL FORMATION OF THE AROMATIC PRINCIPLE OF VANILLA.

BY F. TIEMANN AND W. HAARMANN.

In a lengthy and elaborate paper recently published,* an abstract of which has also been read before the French Academy,† the authors describe their researches upon coniferin, from which body they have succeeded in producing artificially a substance identical with vanillin, the aromatic principle of vanilla. The following abstract will present the chief points of interest to our readers.

Among the numerous glucosides of vegetable origin there is one, coniferin, which for a long time escaped the notice of chemists and physiologists; although it is found in considerable quantity in the members of one of the most widely distributed orders of plants. This body was first found in 1861 in the juice of the cambium of the *Larix europœa*, by Hartig,‡ who for that reason called it "laricin." Afterwards, its presence being recognized in the cambium of all the pines, the name of "abietin" was conferred upon it. Finally, as it appeared to exist in all the Coniferæ, W. Kubel,§ who was the first to study it chemically, with the consent of Hartig, again changed the name to coniferin.

Coniferin may be prepared in the following manner. At the time of the formation of the wood, in the spring or early summer, such conifers as *Abies excelsa* and *A. pectinata*, *Pinus strobus* and *P. Cembra*, *Larix europœa*, etc., are felled, and the trunks are sawn into several pieces and afterwards barked. The juice of the cambium is collected by scraping the wood with a sharp instrument such as a piece of glass. This juice is boiled and filtered to eliminate albuminous matters; then evaporated to about one-fifth its original volume. After a time it deposits brown coloured crystals, which are pressed, and purified and decolorized by repeated recrystallizations and treatment with animal charcoal. The greater part of the impurities may be removed by treating the brown solution of coniferin, whilst still warm, with small quantities of acetate of lead and ammonia; the resinous and colouring matters being precipitated, whilst the coniferin remains in solution. Excess of acetate of lead may be easily removed by means of a current of carbonic acid gas.

Coniferin is slightly soluble in cold water, more soluble in hot water and in alcohol, but is not soluble in ether. It crystallizes upon cooling in white, transparent, brilliant, sharp-pointed crystals, frequently grouped in a star or rosette. Its fusing point is 185° C. These crystals become opaque and dull in contact with air, losing part of their water of crystallization, which is driven off completely at 100° C. The aqueous solution of coniferin is bitter, lævogyrous, and does not reduce Fehling's solution even after prolonged boiling. It is not altered by dilute acid in the cold, but when heated with a few drops of hydrochloric or sulphuric acid, the solution deposits a white resinous matter, which in drying ordinarily becomes yellow or orange, whilst glucose is then found in the liquor. In contact with strong sulphuric acid, coniferin is at first coloured deep violet and afterwards dissolved, communicating to the liquid a red colour; upon the addition of water an indigo blue resinous matter is precipitated. If strong sulphuric acid be poured, a little at a time, into an aqueous solution of coniferin, as the temperature rises there is formed a deposit of the white resinous matter above mentioned; then the liquid becomes violet and turbid, and, after the addition of a considerable quantity of the acid, a clear dark red solution is obtained as in the preceding case.

Moistened with carbolic acid or concentrated hydrochloric acid, after some time coniferin acquires an intense blue colour; in the sunlight this colouration is almost instantaneous. It is upon this reaction that the use of pine wood as a test for carbolic acid is based.

Kubel ascertained that coniferin is a non-nitrogenous body, which is confirmed by the authors' researches; but not having isolated, with the exception of glucose, any of the products of decomposition he could not assign to it any definite formula, though his analyses led him to consider it as—

$$C_{24}H_{32}O_{12} + 3aq.$$

After a close investigation of the substance by Messrs. Tiemann and Haarmann they have represented the molecule of coniferin by—

$$C_{16}H_{22}O_8 + 2aq.$$

which agrees very closely with the figures required by Kubel's formula.

In order to determine the chemical constitution of coniferin, the authors sought first to determine the nature of the product or products resulting from its decomposition with elimination of glucose. As before stated, dilute hydrochloric or sulphuric acid, aided by heat, split it up into a resinous matter and glucose; but the properties of the resinons matter so obtained not appearing sufficiently definite, it was determined to effect the decomposition by fermentation by means of emulsion. For this purpose 50 grams of pure coniferin were placed in 500 grams of water, 0·2 to 0·3 grams of dry emulsion added, and the mixture

* *Berichte der deutschen chemischen Gesellschaft*, 1874, p. 608.

† *Comptes Rendus*, vol. lxxviii., p. 1365.

‡ *Jahrbuch für Forster*, 1861, vol. i., p. 263.

§ *Journal für praktische Chemie*, vol. xcvii., p. 243.

kept at a temperature between 25° and 26° C. The action commenced immediately, and in a few hours the presence of glucose in the liquor could be detected. The undissolved crystals of coniferin gradually disappeared, and in their place were deposited at the bottom of the vessel white flocks which were distinguishable from coniferin by their solubility in ether. After six or eight days the process of fermentation terminated, and by that time the bottom of the vessel was covered by a thick layer of this crystalline matter, the supernatant liquor being clear and slightly coloured. The liquor containing the precipitate was shaken with ether, which removed the flocks, and upon evaporation generally left a residue of well-formed white prismatic crystals. Sometimes, however, it left an oily residue, from which crystals were obtained upon cooling by a freezing mixture. The crystals were pressed between filtering paper, and purified by recrystallization from ether. The aqueous solution, having had any remaining emulsion removed by coagulation by heat and filtering, was found to contain in solution only glucose, and, it may be, slight traces of undecomposed coniferin.

The product of decomposition, chemically pure, melts at 73°—74° C. It is soluble in ether, less soluble in alcohol, difficultly soluble in hot water, and nearly insoluble in cold. It is represented by the formula, $C_{10}H_{12}O_3$, and is derived from coniferin according to the following equation :—

$$C_{16}H_{22}O_8 + H_2O = C_6H_{12}O_6 + C_{10}H_{12}O_3.$$

If this body be dissolved in dilute alcohol, and a few drops of sulphuric or hydrochloric acid added, a white flocculent amorphous precipitate is produced, which is ess soluble in ether and alcohol, but has the same composition, and is considered by the authors to be a polymer of the original decomposition product.

The crystalline product is soluble in caustic soda, from which it is precipitated by acids in the amorphous form, and this is again re-dissolved by the alkaline solution. Like coniferin it is coloured red by sulphuric acid, and, in dissolving, colours the liquid red; but it does not give the violet reaction characteristic of the glucoside.

The pure crystalline product, when recently prepared, is quite inodorous, but after a time acquires a feeble, though well-characterized, odour of vanilla. The same odour is produced when either of the decomposition products or coniferin is heated with dilute sulphuric acid, and still more clearly when an oxidizing mixture of sulphuric acid and solution of bichromate of potash is used. The crystalline decomposition product, reduced to fine powder, was therefore triturated with water, sulphuric acid and bichromate of potash in solution added, and the mixture distilled. At first a liquid, smelling strongly of ethylic aldehyde, was obtained, in which the presence of that aldehyde could be detected. The next portions did not present this character, but were strongly acid, and diffused a well-characterized odour of vanilla. From these portions of the distillate, ether removed a body which crystallized in stellate groups of crystals, possessing in a high degree the odour and taste of vanilla.

Operating in this way the yield was very small, in consequence of the rapid resinification of the decomposition product under the influence of the sulphuric acid, and in this state it was only slowly and partially attacked by the oxidizing mixture. It was found more easy and advantageous to operate directly upon coniferin. This was done by pouring an aqueous solution of coniferin into a hot mixture of bichromate and sulphuric acid; and heating the whole together for several hours in a flask furnished with a returning condenser. After cooling, the liquid was filtered to eliminate a little resinous matter which was deposited, and then agitated directly with ether. Upon distilling or evaporating this solvent a yellowish oil was obtained, which, after some days, formed a crystalline mass. By recrystallizing this from water and decolorizing with a little animal black, fine crystals were obtained having the odour and taste of vanilla. They melted at 80° to 81° C., were readily soluble in ether and in alcohol, difficultly soluble in cold water, and more soluble in hot water. Their composition was represented by the formula $C_8H_8O_3$. In fact, this body presented the same properties and was identical in composition with vanillin, or vanillic acid, the substance to which vanilla owes its aroma. Vanillic acid was a short time since studied by M. Carles,* who prepared from it a series of salts having the general formula $MC_8H_7O_3$, in which M represents one equivalent of a metal; he also prepared iodine and bromine substitution products. The facts observed by him are stated by the authors to accord exactly with those observed by them in operating upon vanillin prepared from coniferin. The transformation of the product of decomposition is represented by the following equation :—

$$C_{10}H_{12}O_3 + O = C_2H_4O + C_8H_8O_3.$$

In order to elucidate the nature of vanillin it was fused with caustic soda. The product of this reaction was protocatechic acid, $C_7H_6O_4$. This was further identified by its transformation into pyrocatechic acid, $C_6H_6O_2$, by the separation of a molecule of carbonic acid :—

$$C_7H_6O_4 = C_6H_6O_2 + CO_2.$$

The conversion into protocatechic acid fixes the constitution of vanillin; this compound is the methylic aldehyde of protocatechic acid, the molecule of which is expressed by the formula :—

$$C_6H_3\begin{cases}\diagup OCH_3\\ -OH\\ \diagdown COH.\end{cases}$$

In fact, submitted to the action of hydrochloric acid under pressure vanillin splits up into methylic chloride and protocatechic aldehyde :—

$$C_6H_3\begin{cases}\diagup OCH_3\\ -OH\\ \diagdown COH\end{cases} + HCl = CH_3Cl + C_6H_3\begin{cases}\diagup OH\\ -OH\\ \diagdown COH.\end{cases}$$

An analogous reaction takes place with hydriodic acid; but in that case the aldehyde undergoes a more profound alteration.

Another proof of the correctness of this theory was obtained in treating vanillin with acetic anhydride and chloride of benzoyl. The prolonged action of these agents only produced the bodies

$$C_6H_3\begin{cases}\diagup OCH_3\\ -OC_2H_3O\\ \diagdown COH\end{cases} \qquad C_6H_3\begin{cases}\diagup OCH_3\\ -OC_7H_5O\\ \diagdown COH\end{cases}$$

This the authors consider a clear demonstration that the molecule of vanillin contains only a single hydroxylic group.

The constitution of vanillin being cleared up, the structure of the fermentation product, the oxidation of which engendered vanillin, became evident. This product is the ethylic ether of vanillin :—

$$C_6H_3\begin{cases}\diagup OCH_3\\ -OC_2H_5\\ \diagdown OOH\end{cases}$$

This formula explains the disengagement of ethylic aldehyde during formation of the vanillin. Moreover, in operating upon the fermentation product under pressure with hydriodic acid, alcoholic iodides were obtained in considerable quantities, which could be separated by suitable means into methylic and ethylic iodides :—

$$C_6H_3\begin{cases}\diagup OCH_3\\ -OC_2H_5\\ \diagdown COH\end{cases} + 2HI = CH_3I + C_2H_5I + C_6H_3\begin{cases}\diagup OH\\ -OH\\ \diagdown COH.\end{cases}$$

Messrs. Tiemann and Haarmann carried on this investigation in the Laboratory of Dr. A. W. Hofmann at Berlin.

LATENT PEPSIN.*

BY GEO. W. C. PHILLIPS.

It is the generally received opinion among pharmacists and scientific men that the principle, pepsin, cannot exist where there is any alcohol. This theory has been most strongly advanced by Prof. Scheffer of Louisville, whose experiments seem to point out the fact that all wines and elixirs of pepsin, necessarily composed of alcohol, contain no pepsin at all. He bases this idea on the fact that certain wines of pepsin, when digested with coagulated albumen, at a temperature approximating that of the human stomach, have no solvent effect upon it. This view being urged upon medical men, has caused all these otherwise elegant mediums for administering pepsin to be received with distrust or given up entirely. The results of experiments which I have recently made have caused me to believe that pepsin does exist, in a marked degree, in all well-prepared wines and elixirs, and only needs proper treatment to bring out its full chemical and medicinal effects. My belief is that it exists in these wines and elixirs, and that by sufficient dilution and warmth, such as they would receive in the human stomach from its juices and heat, it regains its activity. I base this opinion upon the following experiments: One ounce of Boudault's wine of pepsin was digested with one hundred and twenty grains of coagulated albumen at a temperature of 98° F. for three hours. At the end of that time the albumen was examined and weighed. The only apparent effect this treatment had upon it was to slightly colour it brown, and harden it; a slight decrease in weight was probably owing to loss of water.

This experiment was repeated, without alteration in the quantities; the only difference being in the addition of an equal volume of water to the wine of pepsin. At the expiration of three hours, the albumen was again examined. It had decreased in weight thirty grains, and presented the characteristic appearance of albumen which has been acted upon by pepsin; the sharp angles were gone, and in their place a granular surface was presented.

Another experiment with the same quantities, the water being increased to three ounces, showed a decrease in the albumen of fifty grains. A sample of the wine of pepsin used in these experiments was then examined, to determine the amount of alcohol it contained. Horsley's process, given in the *Chemical News* of October 19, 1861, was employed, and it was found to contain eight per cent. of free alcohol.

The conclusion that I draw from these and other experiments is this: That while a carefully made wine of pepsin, not containing over ten per cent. of alcohol, may, and does contain pepsin, that it exists in a latent state, and that when diluted with the juices of the stomach, at the normal temperature of that organ, it regains its activity, and will perform its digestive functions.

NOTES ON GELSEMIUM SEMPERVIRENS.†

BY JAMES SAWYER, M.D., LOND., ETC.,

Physician to the Queen's Hospital, and to the Children's Hospital, Birmingham.

Since reading Dr. Wickham Legg's interesting paper, published in the *Lancet* in May last, advocating the employment of *Gelsemium sempervirens* in the treatment of odontalgia, I have frequently used the drug among my out-patients at the Queen's Hospital, for the relief of toothache and some allied affections. As the remedy has proved a reliable one in my hands, I have thought it worth while to bring it before my professional brethren.

Gelsemium sempervirens, commonly called the yellow jasmin, or woodbine, belonging to the natural family Apocynaceæ, grows plentifully in the southern states of North America. The plant has a shrubby, twining stem; the leaves are ovate lanceolate, opposite, entire, smooth, and of a dark-green colour; the flowers are large and yellow; the corolla is gamopetalous and infundibuliform; it has five stamens, inserted on the corolla and alternate with its lobes; the pistil is composed of two distinct carpels. The flowers are so strongly scented that they perfume the neighbourhood in which the plant grows. The root, the part employed medicinally, comes to England cut up into small pieces, the larger pieces being from half an inch to two inches in length, and about a quarter of an inch in thickness. Wood zones and medullary rays are visible to the naked eye. The root is brown externally, and of a greyish colour internally. The active properties of the plant are said to depend upon the gelseminate of gelsemia.

Gelsemium is not generally known to English practitioners, although it has been largely used in medicine for some years in America. In England it has been principally employed by homœopathists and disciples of "botanic medicine." From various sources I have been enabled to gather the following account of its properties. The drug acts mainly upon the nervous system, impairing the sensibility of the sensory nerves. It has no direct action upon the heart. In large doses it gives rise to a general feeling of oppression and numbness, objects are seen double, and, if the dose be large enough, there may be complete paralysis of the voluntary muscles, and insensibility. The plant, like many of the natural family to which it belongs, is very poisonous, and should be used with caution. Several deaths from poisoning by gelsemium have been recorded. Death seems to arise from asphyxia, the result of paralysis of the muscles of respiration. The drug has been said to be a specific in the headache and sleeplessness of the drunkard; in sick-headache it seems to have proved useful; it has been recommended in some forms of dyspepsia, attended by considerable flatulence; it has been thought to aid the obstetrician in cases of rigidity of the os uteri; it has been praised as a remedy for dysmenorrhœa; and there appears to be good reason for believing that it is capable of decidedly relieving toothache and some neuralgic affections. Its virtues, like those of very many other drugs, have probably been grossly exaggerated; but I have seen enough of the employment of gelsemium to feel sure that more extended experience and careful investigation will establish it as a valuable addition to our materia medica.

American pharmacists prepare a liquid extract. The dose of the powdered root is from one to two grains. Mr. Dewson, of the Queen's Hospital, to whom I am indebted for much valuable information concerning the drug, has prepared a tincture for me. I give the formula in his own words:—"Take of gelsemium root, in coarse powder, two ounces; of rectified spirit, twenty fluid ounces. Moisten the powdered root with ten ounces of the spirit, and allow the mixture to stand for twenty-four hours. At the end of that time pack in a percolator and add the remaining ten ounces of spirit. When the fluid has ceased to flow, remove the contents of the percolator and press them. Add the pressed liquid to that obtained by percolation, filter, and make up with rectified spirit to a pint." Eleven minims are about equal to one grain of the root. The liquid extract would be best prepared from the fresh root. The tincture is only slightly darkened by perchloride of iron, and but a very small precipitate is produced; it contains, therefore, only a minute quantity of tannin, and may be prescribed with salts of iron.

Following the example of Dr. Wickham Legg, I have only given gelsemium in cases of odontalgia. In hospital out-patient practice we meet with a large number of cases of neuralgic pains in the face and jaws, associated with carious teeth. The patients are frequently ill-fed and badly-nourished women. I selected examples of the malady in which there were no very evident local inflammatory complications. In these I gave the tincture of

† Communicated to the Pathological and Clinical Section of the Birmingham and Midland Counties Branch of the British Medical Association.

gelsemium in doses of fifteen minims every six hours, in an ounce of dill-water. I very rarely gave anything else or made any local application. Out of about twenty cases I do not think the use of the remedy failed to be followed by decided and lasting relief in more than three or four instances. The relief was not usually experienced till after the third or fourth dose.

THE USE OF PETROLEUM BENZIN FOR EXHAUSTING OLEORESINOUS DRUGS.*

BY JOSEPH P. REMINGTON.

Many uses have been discovered for petroleum benzin since it became an article of commerce, and though but recently brought to notice, its applications, from thinning white lead to purifying rare alkaloids, from dissolving india-rubber to removing grease from a silk dress, have secured for this product of mother earth a name and a place not to be despised.

The immense and overgrown development of the petroleum interest has tended to reduce the price of benzin to a very low figure; the common unpurified article is a drug in the market; and although efforts are constantly made to fit it for illuminating purposes, a means of rendering it free from liability to explode, and cause fearful accidents, is yet to be discovered.

The purified benzin commands a much better price, is put to finer uses, and should alone be used for solvent purposes in pharmacy; the common article is unfit for any purpose in a preparation, for it will be sure, from its offensive odour, to leave its tracks in it.

The first requirement in answering the query, What merit has petroleum benzin as a solvent for the extraction of oleoresinous drugs, like buchu, chenopodium, etc.? was believed to be, to secure a good benzin. This was readily done, and an article having the specific gravity of 0·642 was obtained, which on being tested proved to be free from objectionable impurities, and no odour was left on a clean sheet of paper when a small portion was poured on it, and suffered to evaporate.

Eight ounces of finely powdered buchu leaves were taken, and firmly packed in a Squibb's glass percolator, with the siphon arrangement. It was found to be best, however, to substitute the rubber lid for one made of wood, the wooden lid having a groove cut in the under surface to fit the rim of the percolator, and at the bottom of the groove a rubber-band made the joint air-tight.

After allowing the powder to macerate for four days, the siphon was started, and the percolate, very dense and highly charged with extractive matter, came over, at first slowly, and afterwards rapidly; after two pints had passed, the buchu seemed to be exhausted, and so great had been the solvent power of the menstruum, as far as the chlorophyll and other colouring matter was concerned, that the residue looked as if it had been bleached.

The percolate was allowed to evaporate spontaneously, and the amount of oleoresinous extract obtained weighed 305 grains. This, at first sight, was supposed to contain all of the active properties of the drug, and in order to test it, five grains were swallowed in a little water by the writer, producing, however, but little diuresis; the dose was increased to ten grains, which had but moderate effect.

Taking the dose of fluid extract of buchu at a fluid drachm, and granting that one fluid ounce of the extract represents one troy ounce of the drug, it can readily be seen by a simple calculation, that if the benzin had fully extracted the virtues of the buchu, five grains of the oleoresinous extract obtained would produce the same effect as a fluid drachm of the fluid extract, whilst ten grains would be a large dose.

This fact suggested, that although the buchu had every appearance of being thoroughly exhausted, it might yield some activity to alcohol, and it was then percolated with stronger alcohol, and a dense dark-coloured liquid obtained, possessing a bitter taste and considerable odour.

Ten grains of this liquid produced active diuresis, and the writer has no hesitation in asserting that he believes alcohol to be much the better solvent for buchu.

Various other experiments with other drugs are now progressing, but sufficient progress has been made to justify the assertion that the uses of benzin in this direction are circumscribed; the principal objections to its use being inflammability, great volatility, requiring the use of apparatus not always at the command of all pharmacists; the odour is objectionable generally, and in many cases could not be tolerated by a weak stomach. A continuance of this subject was requested, in order to obtain further information with other plants.

* Read before the American Pharmaceutical Association, September, 1873, and reprinted from the 'Transactions.'

INSECT-DEVOURING PLANTS.*

However opposite the parts which animals and vegetables play in the economy of the world, as the two opposed kingdoms of organic nature, it is becoming more and more obvious that they are not only two contiguous kingdoms, but are parts of one whole—antithetical and complementary to each other, indeed, but such "thin partitions do the bonds divide" that no definitions yet framed hold good without exception. This is a world of transition in more senses than is commonly thought; and one of the lessons which the philosophical naturalist learns, or has to learn, is, that differences, the most wide and real in the main, and the most essential, may nevertheless be here and there connected or bridged over by gradations. There is a limbo filled with organisms which never rise high enough in the scale to be manifestly either animal or plant, unless it may be said of some of them that they are each in turn and neither long. There are undoubted animals which produce the essential material of vegetable fabric, or build up a part of their structure of it, or elaborate the characteristic leaf-green which, under solar light, assimilates inorganic into organic matter, the most distinguishing function of vegetation. On the other hand there are plants—microscopic, indeed, but unquestionable—which move spontaneously and freely around and among animals that are fixed and rooted. And, to come without further parley to the matter in hand, while the majority of animals feed directly upon plants, "for 'tis their nature to," there are plants which turn the tables and feed upon them. Some, being parasitic upon living animals, feed insidiously and furtively; these, although really cases in point, are not so extraordinary, and, as they belong to the lower orders, they are not much regarded, except for the harm they do. There are others, and those of the highest orders, which lure or entrap animals in ways which may well excite our special wonder—all the more so since we are now led to conclude that they not only capture but consume their prey. As respects the two or three most notable instances, the conclusions which have been reached are among the very recent acquisitions of physiological science. Curiously enough, however, now that they are made out, it appears that they were in good part long ago attained, recorded, and mainly forgotten. The earlier observations and surmises shared the common fate of discoveries made before the time, or by those who were not sagacious enough to bring out their full meaning or importance. Vegetable morphology, dimly apprehended by Linnæus, initiated by Caspar Frederic Wolff, and, again, independently in successive generations by Goethe and by De Candolle, offers a parallel instance. The botanist of Goethe's day could not see any sense or practical application to be made of the proposition that the parts of a blossom answer to leaves; and so the study of homologics had long to wait.

Fly-catchers.—Until very lately it appeared to be of no consequence whatever (expect, perhaps, to the insects) whether *Drosera* and *Sarracenia* caught flies or not; and

* From the *Garden*, May 23, 1874.

even *Dionœa* excited only unreflecting wonder as a vegetable anomaly. As if there were real anomalies in Nature, and some one plant possessed extraordinary powers denied to all others and (as was supposed) of no importance to itself. That most expert of fly-catchers, *Dionœa*, of which so much has been written and so little known until lately, came very nearly revealing its secret to Solander and Ellis a hundred years ago, and, doubtless, to John Bartram, its probable discoverer, who sent it to Europe. Ellis, in his published letter to Linnæus, with which the history begins, described the structure and action of the living trap correctly; noticed that the irritability which called forth the quick movement closing the trap entirely resided in the few small bristles of its upper face; that this whole surface was studded with glands, which probably secreted a liquid; and that the trap did not open again when an insect was captured, even upon the death of the captive, although it opened very soon when nothing was caught, or when the irritation was caused by a bit of straw or any such substance. It was Linnæus who originated the contrary and erroneous statement, which has long prevailed in the books, that the trap reopened when the fatigued captive became quiet, and let it go; as if the plant caught flies in mere play and pastime! Linnæus also omitted all allusion to secreted liquid—which was justifiable, as Ellis does not state that he had actually seen any, and if he did see it, quite mistook its use, supposing it to be, like the nectar of flowers, a lure for insects, a bait for the trap. Whereas, in fact, the lure, if there be any, must be an odour (although nothing is perceptible to the human olfactories); for the liquid secreted by the glands never appears until the trap has closed upon some insect and held it at least for some hours a prisoner. Within twenty-four or forty-eight hours this glairy liquid is abundant, macerating the body of the perished insect. Its analogue is not nectar but the gastric juice. The observations which compel such an inference are recent, and the substance of them may be briefly stated. The late Rev. Dr. M. A. Curtis, forty years and more ago, resided at Wilmington, North Carolina, in the midst of the only district to which the *Dionœa* is native; and he published, in 1834, in the first volume of the 'Journal of the Boston Society of Natural History,' by far the best account of this singular plant which had then appeared. He remarks, that "the little prisoner is not crushed and suddenly destroyed, as is sometimes supposed," for he had often liberated "captive flies and spiders, which sped away as fast as fear or joy could hasten them." But he neglected to state, although he must have noticed the fact, that the two sides of the trap, at first concave to the contained insect, at length flatten and close down firmly upon the prey, exerting no inconsiderable pressure, and ensuring the death of any soft-bodied insect, if it had not already succumbed to the confinement and salivation. This last Dr. Curtis noticed, and first discerned its import, although he hesitated to pronounce upon its universality. That the captured insects were in some way "made subservient to the nourishment of the plant," had been conjectured from the first. Dr. Curtis "at times found them enveloped in a fluid of mucilaginous consistence, which seems to act as a solvent, the insects being more or less consumed in it." This was verified, and the digestive character of the liquid well-nigh demonstrated, six or seven years ago, by Mr. Canby of Wilmington, Delaware, who, upon a visit to the sister-town of North Carolina, and afterwards at his home, followed up Dr. Curtis's suggestions with some capital observations and experiments. These were published at Philadelphia, in the tenth volume of Mehan's *Gardeners' Monthly*, August, 1868, but they do not appear to have attracted the attention which they merited. The points which Mr. Canby made out are, that this fluid is always poured out around the captured insect in due time, "if the leaf is in good condition and the prey suitable;" that it comes from the leaf itself, and not from the decomposing insect (for when the trap caught a plum-curculio, the fluid was poured out while he was still alive, though very weak, and endeavouring, ineffectually, to eat his way out); that bits of raw beef, although sometimes rejected after awhile, were generally acted upon in the same manner—*i.e.*, closed down upon tightly, slavered with the liquid, dissolved mainly, and absorbed; so that, in fine, the fluid may well be said to be analogous to the gastric juice of animals, dissolving the prey and rendering it fit for absorption by the leaf. Many leaves remain inactive or slowly die away after one meal; others reopen for a second and perhaps even a third capture, and are at least capable of digesting a second meal. Before Mr. Canby's experiments had been made, a similar series had been made in England by Mr. Darwin, with the same results, and with a small but highly curious additional one—namely, that the fluid secreted in the trap of *Dionœa*, like the gastric juice, has an acid reaction. Having begun to mention unpublished results (too long allowed to remain so), it may be well, under the circumstances, to refer to a still more remarkable experiment by the same most sagacious investigator. By a prick with a sharp lancet at a certain point, he has been able to paralyse one-half of the leaf-trap, so that it remained motionless under the stimulus to which the other half responded. Such high and sensitive organization entails corresponding ailments. Mr. Canby tells us that he gave to one of his *Dionœa*-subjects a fatal dyspepsia by feeding it with cheese; and under Mr. Darwin's hands another suffers from paraplegia. Finally, Dr. Burton-Saunderson's experiments, detailed at the last meeting of the British Association for the advancement of Science, show that the same electrical currents are devolved upon the closing of the *Dionœa* trap, as in the contraction of a muscle. If the Venus's fly-trap stood alone it would be doubly marvellous—first, on account of its carnivorous propensities, and then as constituting a real anomaly in organic nature, to which nothing leads up. Before acquiescing in such a conclusion, the modern naturalist would scrutinize its relatives. Now the nearest relatives of our vegetable wonder are the

Sundews.—While *Dionœa* is local, the *Droseras*, or Sundews, are widely diffused. The two whose captivating habits have attracted attention, abound in bogs all round the northern hemisphere. That flies are caught by them is a matter of common observation; but this was thought to be purely accidental. They spread out from the root a circle of small leaves, the upper face of which especially is beset, and the margin fringed, with stout bristles (or what seem to be such, although the structure is more complex), tipped by a secreting gland, which produces, while in a vigorous state, a globule of clear liquid like a drop of dew—whence the name, both Greek and English. One expects these seeming dewdrops to be dissipated by the morning sun; but they remain unaffected. A touch shows that the glistening drops are glutinous and extremely tenacious, as flies learn to their cost on alighting, perhaps to sip the tempting liquid, which acts first as a decoy and then like bird-lime. A small fly is held so fast, and in its struggles comes into contact with so many of these glutinous globules, that it seldom escapes. The result is much the same to the insect, whether captured in the trap of *Dionœa* or stuck fast to the limed bristles of *Drosera*, As there are various plants upon whose glandular hairs or glutinous surfaces small insects are habitually caught and perish, it might be pure coincidence that the most effectual arrangement of the kind happens to occur in the nearest relatives of *Dionœa*. Roth, a keen German botanist of the eighteenth century, was first to detect, or at least to record, some evidence of intention in *Drosera*, and to compare its action with that of *Dionœa*, which, through Ellis's account, had shortly before been made known in Europe. He noticed the telling fact that not only the bristles which the unfortunate insect had come in contact with, but also the surrounding rows, before widely spreading, curved inwards one by one, although they had not been touched, so as within a few hours to press their glutinous tips likewise against the body of the captive insect—thus doubling or quadrupling the bonds of

the victim, and (as we may now suspect) the surfaces through which some part of the animal substance may be imbibed. For Roth surmised that both these plants were, in their way, predaceous. He even observed that the disk of the *Drosera* leaf itself often became concave and enveloped the prey. These facts, although mentioned now and then in some succeeding works, were generally forgotten, except that of the adhesion of small insects to the leaves of Sundews, which must have been observed in every generation. Up to and even within a few years past, if any reference was made to these asserted movements (as by such eminent physiologists as Meyen and Treviranus) it was to discredit them. Not because they are difficult to verify, but because, being naturally thought improbable, it was easier to deny or ignore them. So completely had the knowledge of almost a century ago died out in later years that, when the subject was taken up anew, in our days, by Mr. Darwin, he had, as we remember, to advertise for it, by sending a "note and query" to the magazines, asking where any account of the fly-catching of the leaves of Sundew was recorded. When Mr. Darwin takes a matter of this sort in hand, he is not likely to leave it where he found it. He not only confirmed all Roth's observations as to the incurving of the bristles towards and upon an insect entangled on any part of the disk of the leaf, but also found that they responded similarly to a bit of muscle or other animal substance, while to any particles of inorganic matter they were nearly indifferent. To minute fragments of carbonate of ammonia, however, they were more responsive. As these remarkable results, attained half a dozen years ago, remained unpublished (being portions of an investigation not yet completed), it would have been hardly proper to mention them, were it not that independent observers were beginning to bring out the same, or similar facts. Mrs. Treat, of New Jersey, noticed the habitual enfolding of the leaf in the longer-leaved species of Sundew (*American Journal of Science* for November, 1871), as was then thought for the first time—Roth's and Withering's observations not having been looked up. In recording this, the next year, in a very little book, entitled "How Plants Behave," the opportunity was taken to mention, in the briefest way, the capital discovery of Mr. Darwin, that the leaves of *Drosera* act differently when different objects are placed upon them, the bristles closing upon a particle of raw meat as upon a living insect, while to a particle of chalk or wood they are nearly inactive.

The same facts were independently brought out by Mr. A. W. Benentt at last year's meeting of the British Association for the Advancement of Science, and have been mentioned in the journals. If to these statements, which we may certify, were added some far more extraordinary ones, communicated to the French Academy of Science, in May last, by M. Zeigler, a stranger story of discrimination on the part of Sundew-bristles would be told. But it is safer to wait for the report of the Committee to which these marvels were referred, and conclude this sufficiently "strange, eventful history" with some details of experiments made last summer by Mrs. Treat, of New Jersey, and published in the December number of the *American Naturalist*. It is well to note that Mrs. Treat selects for publication the observations of one particular day in July, when the Sundew leaves were unusually active; for their modes vary with the weather, and also in other unaccountable ways, although, in general the sultrier days are the most appetizing:

"At fifteen minutes past ten of the same day I placed bits of raw beef on some of the most vigorous leaves of *Drosera longifolia*. Ten minutes past twelve, two of the leaves had folded around the beef, hiding it from sight. Half past eleven of the same day, I placed living flies on the leaves of *D. longifolia*. At 12° 48′ one of the leaves had folded entirely around its victim, the other leaves had partially folded, and the flies had ceased to struggle. By 2° 30′ four leaves had each folded around a fly. . . . . I tried mineral substances—bits of dry chalk, magnesia, and pebbles. In twenty-four hours, neither the leaves nor their bristles had made any move like clasping these articles. I wet a piece of chalk in water, and in less than an hour the bristles were curving about it, but soon unfolded again, leaving the chalk free on the blade of the leaf. Parallel experiments made on *D. rotundifolia* with bits of beef and of chalk gave the same results as to the action of the bristles; while with a piece of raw apple, after eleven hours, "part of the bristles were clasping it, but not as closely as the beef, and in twenty-four hours nearly all the bristles were curved towards it, but not many of the glands were touching it."

To make such observations is as easy as it is interesting. Throughout the summer one has only to transfer plants of *Drosera* from the bogs into pots or pans filled with wet moss; if need be, allowing them to become established in the somewhat changed conditions, or even to put out fresh leaves, and to watch their action or expedite it by placing small flies upon the disk of the leaves. The more common round-leaved Sundew acts as well as the other by its bristles, and the leaf itself is sometimes almost equally prehensile, although in a different way, enfolding the whole border instead of the summit only. Very curious, and even somewhat painful, is the sight when a fly, alighting upon the central dew-tipped bristles, is held as fast as by a spider's web; while the efforts to escape not only entangle the insect more hopelessly as they exhaust its strength, but call into action the surrounding bristles, which, one by one, add to the number of the bonds, each by itself apparently feeble, but in their combination so effectual that the fly may be likened to the sleeping Gulliver made fast in the tiny but multitudinous toils of the Lilliputians. Anybody who can believe that such an apparatus was not intended to capture flies might say the same of a spider's web. Is the intention here to be thought any the less real because there are other species of *Drosera* which are not so perfectly adapted for fly-catching, owing to the form of their leaves and the partial or total want of co-operation of their scattered bristles? One such species, *D. filiformis*, the thread-leaved Sundew, is not uncommon in America, both north and south of the district that *Dionæa* locally inhabits. Its leaves are long and thread-shaped, beset throughout with glutinous gland-tipped bristles, but wholly destitute of a blade. Flies, even large ones, and even moths and butterflies, as Mrs. Treat and Mr. Canby affirm (in the *American Naturalist*), get stuck fast to these bristles, whence they seldom escape. Accidental as such captures are, even these thread-shaped leaves respond more or less to the contact, somewhat in the manner of their brethren. In Mr. Canby's recent and simple experiments, made at Mr. Darwin's suggestion, when a small fly alights upon a leaf a little below its slender apex or when a bit of crushed fly is there affixed, within a few hours the tip of the leaf bends at the point of contact, and curls over or around the body in question; and Mrs. Treat even found that, when living flies were pinned at half an inch in distance from the leaves, these in forty minutes had bent their tips perceptibly towards the flies, and in less than two hours reached them! If this be confirmed—and such a statement needs ample confirmation—then it may be suspected that these slender leaves not only incurve after prolonged contact, just as do the leaf-stalks of many climbers, but also make free and independent circular sweeps, in the manner of twining stems and of many tendrils. Correlated movements like these indicate purpose. When performed by climbing plants, the object and the advantage are obvious. That the apparatus and the actions of *Dionæa* and *Drosera* are purposeless and without advantage to the plants themselves, may have been believed in former days, when it was likewise conceived that abortive and functionless organs were specially created "for the sake of symmetry" and to display a plant; but this is not according to the genius of modern science.

(*To be continued.*)

SELECT COMMITTEE ON THE ADULTERATION ACT.

At the sitting of the Committee on Friday, June 5th, Mr. Allen, public analyst for Sheffield, was examined shortly upon the subject of the adulteration of drugs. He stated that with regard to the case of drugs the Adulteration Act had not been enforced to any great extent, and there had been few prosecutions. Even these few prosecutions, however, had mostly resulted unsuccessfully, and had been very ill-advised on the part of the analysts, who had condemned drugs as adulterated which were not fairly open to censure on that account, although there were undoubtedly many instances where drugs were adulterated. It was, for instance, customary in Sheffield to sell laudanum which contained scarcely any goodness in it. He should certainly consider it to be adulterated. In some cases a person bought such laudanum as a genuine sample, and took it in proportions as though it were perfectly genuine, and it did not act properly. There was a deficiency of opium in it, and it was coloured with burnt sugar. The ingredients were harmless in themselves, but ought not to be there. With respect to laudanum, there was no fixed standard of purity, and he thought it was desirable that some such standard of strength should be determined upon. Tincture of opium and laudanum, he might point out, were considered identical, and if laudanum were asked for in a respectable shop tincture of opium would be supplied, but in a lower class of establishment probably this would not be the case. It would have been better, perhaps, if he had said that tincture of opium was adulterated, and not up to the strength of the Pharmacopœia. Being questioned with regard to scammony, the witness said that if a druggist sold an article in which there was 10 per cent. of something not scammony, he should not give a certificate of adulteration in such a case. There must be some discretion exercised in such a case by the analyst. The best scammony did not contain more than 80 or 90 per cent. of resin. They might as well say tea was adulterated because it had three per cent. not tea. It was true that scammony was adulterated, but because it contained only 90 per cent. he did not think it ought to be considered adulterated, and he should not certify it to be so. If a parcel of scammony were brought to him for analysis, he should use his discretion with regard to it, and any analyst should do the same. In regard to drugs generally there was no defined standard, but he thought that there should be some such standard defined by a sufficient authority. For drugs which it was possible to treat in this way there should be such a treatment. Generally speaking, he was of opinion that pharmaceutical preparations could be purchased all over the country of equal strength, and as good in provincial towns as in London. It was merely a question of paying for them. He had been speaking recently to a druggist and grocer in South Wales—a tradesman who combined the sale of groceries with drugs—and he said that he received articles in the drug line which were much adulterated. Certain drugs deteriorated in value by keeping. The dealers would usually know when these drugs had gone bad, and could act accordingly. He should not absolutely prohibit the sale of the cheap drugs. In the case of scammony a great deal of the inferior varieties were used, and when a dose was taken and did not have its effect this might be due to the presence of adulteration. In the case of a mustard plaster, if it had not the desired effect it might be because there was a large amount of flour used in the manufacture of the mustard, and this was, of course, undesirable for plasters. In selling articles in the Pharmacopœia, the druggist should be guided by that. Being questioned as to the sale of medicines in the country, the witness stated that medicines should be sold all over the country of the same strength, and prescriptions should of course have the same effect. Any one making up inferior preparations should be liable to punishment.

On Monday last, Mr. F. Sutton, F.C.S., member of the Council of the Pharmaceutical Society, and analyst for Norfolk, gave evidence. He said he was not aware that the Pharmaceutical Society had given any definition of what constituted adulteration. Some drugs greatly deteriorated in value by keeping, but these were rather chemical preparations, such as Prussic acid, etc. He agreed generally with the evidence given upon this subject at a former sitting. Relative to articles adulterated abroad, he thought it was advisable that some measures should be adopted to stop largely adulterated substances coming to this country and entering into the consumption of the people. With regard to tea, he was of opinion that the examination of tea in bond would stop the importation of an adulterated article. It was very desirable to have some central authority organized, to whom cases might be referred, and he thought the laboratory at Somerset House was quite adequate to form such a central authority. With regard to mixed articles, the mere statement of percentages would not, in his opinion, be wholly effectual, as it would not indicate what the quality of the article was. His analyses of tea showed him that, with the exception of caper teas, the general average of teas sold in this country were of fairly good quality. As to teas being naturally adulterated in this country, he did not believe it. In his opinion mixed cocoas were in no way injurious to health, nor were they indigestible. With regard to the adulteration of butter, his experience did not confirm the statements to the effect that butter was grossly adulterated. He had not found it so. Butter was a fat, and it was not easy to distinguish between fats. With regard to vinegar, of which no evidence had been given to the Committee, he stated that vinegar should be made of malt, but a great many cheap vinegars were adulterated. They were not made of malt at all. There had been a great improvement of late years in the quality of cayenne and pepper. He did not consider that arrow-root was adulterated, but there was a great variation in quality and price. He was of opinion that mixed mustard—mustard condiment—was preferred by the public to the perfectly pure article. It was desirable, however, that the mixture should be stated on the label. Since the Adulteration Act came into operation there was no doubt that a great number of retail dealers who did not adulterate in any way had been greatly harassed. In regard to a satisfactory definition of adulteration—the crucial point in the matter—he agreed that the abstraction of a valuable constituent from an article was an adulteration as well as the addition thereto of a foreign ingredient. As an analyst he was paid by fees, which were four times as much as the price fixed for the public to pay. Thus, if the public paid 2*s.* 6*d.* he would get 10*s.* There had been no prosecutions under the Act in Norfolk; in fact, it had been quite a dead letter there. In country districts, where people knew each other better than in large towns, there was a disinclination to inform against dealers so that prosecutions might be instituted against them. Examined by Sir Henry Peek, the witness admitted that if he had analysed the green tea in the case of Roberts *v.* Egerton (reported in the Pharmaceutical Journal last week) he should not have given the certificate of adulteration upon which those proceedings were founded. In his opinion adulteration did not prevail to anything like the extent which was generally represented. In fact, he gave it as his opinion that some analysts were so exceedingly sharp as to be much too sharp for a proper protection of public interests. There was no doubt that some of the analysts were insufficiently paid. For an analysis of milk they would get 2*s.* 6*d.*, and that analysis, properly performed, would occupy the best part of a day. With regard to the qualifications of an analyst, chemical experience was the main point, though he must possess a knowledge of microscopy, and sufficient medical knowledge to know what would be injurious to health. There had undoubtedly been unfortunate appointments of analysts under this Act, the cause being that really competent men did not care to accept such appointments, as the remuneration was inadequate.

The Pharmaceutical Journal.

SATURDAY, JUNE 13, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BRITISH PHARMACEUTICAL CONFERENCE.

ONCE more the time for the meeting of the British Pharmaceutical Conference is drawing near. The meeting this year will be exceptional, perhaps, in more ways than one, and it is pleasant to be able to state that so far as it is possible to read the "signs of the times" the visit to London in 1874 promises to be one of the most memorable gatherings of this body. The London Local Committee, with a lively recollection of the many hearty receptions the Conference has received from pharmaceutical brethren in all quarters of the country, and mindful that the present will be the first and probably the only opportunity that London members of the trade will have for several years of reciprocating this kindness, have already sketched out a programme extending over four days, and calculated to satisfy the most diverse pharmaceutical fancies.

The meetings will be inaugurated on the evening of Wednesday, August 5th, by a Conversazione, to which the members of the Conference have been invited by the Pharmaceutical Society, through its Council. This will be held on the Society's premises in Bloomsbury Square. Thursday and Friday, August 6th and 7th, from 10 a.m. to 12·30 p.m., and from 2 to 4·30 p.m., are to be devoted, after the reception of the Report and the PRESIDENT'S address, to the reading and discussion of papers. On Thursday evening, August 6th, the members will hold their Annual Dinner. And on Saturday, the members of the Conference residing within the London postal district invite the country members to an excursion down the picturesque valley of the Thames, between Marlow and Maidenhead.

Those who remember the exhibitions at Nottingham, Norwich, and Liverpool, will be glad to learn that an exhibition of drugs, chemicals, apparatus, fittings, and other objects of pharmaceutical interest, will be held during Thursday, Friday, and Saturday, the 6th, 7th, and 8th; and will form a leading feature of the Conversazione held by the Pharmaceutical Society, on Wednesday evening, the 5th August. Indeed, we would suggest since the subsequent days will be so fully occupied in other ways, that, if found possible, it would be convenient that the exhibition should be open during the whole of Wednesday, thus affording to visitors an opportunity of examining the exhibits in a more leisurely manner.

Considering how favourable an opportunity this will afford wholesale houses of bringing their novelties and specialities under the notice of the members, we suspect that considerable tact and discretion will have to be exercised to confine the exhibition within available space.

It needs no great amount of sagacity to predict that, in point of numbers, the attendance will probably exceed that in any previous year; the London chemists and druggists would hardly be satisfied if it were not so, and their interest in the event will not be confined to any particular section of the trade. In former years the members of the Conference have been the guests, not only of local Conference members, but of all interested in the chemists and druggists' calling in the districts where the meetings have been held. A similarly catholic welcome we doubt not will now be given, not only by metropolitan members of the Conference but by all connected with the trade, to their country brethren.

Of course the "sinews of war" will be required for all this; but we may mention, without breach of confidence, that a considerable sum has already been voluntarily guaranteed. This seems to imply that Mr. CARTEIGHE, as Local Secretary, has only to make his wants known to have them supplied.

APPRENTICESHIP AS A MEANS OF PHARMACEUTICAL EDUCATION.

So much has been said and written as to the necessity of providing lectures and classes and other extraneous help for the pharmaceutical novice, now that examinations are compulsory upon all persons wishing to carry on the business of a chemist and druggist, that there is a danger of overlooking the fact that the Minor examination, upon which the legal status depends, is eminently of a practical character. Although he who is fortunate enough to be able to supplement the education he receives while apprenticed by studies in the lecture and class room and laboratory, may find his road considerably smoothed, and be thus enabled to win a higher place in the list of passed men, it is in the shop, in the application of the acquired information to his every day duties, that he can best gain the familiarity with his business which in the examination room will give confidence to himself and gratification to the examiner. Indeed, it is not too much to say that the apprentice who follows his daily calling in the spirit indicated in the excellent article by the late Professor PROCTER which we transferred to our columns last week, and who receives the assistance and practical tuition which he has a right to expect from his employer, not only studies for the Minor examination under most favourable conditions, but lays the surest foundation for those qualifications which will carry him successfully through the Major.

It is therefore with satisfaction that we this week publish a letter from "A PROVINCIAL," in which the writer does good service by recalling attention to the duty of employers towards their pupils, in respect to

practical training in the business, a duty which they cannot depute to any lecturer or class teacher, but which must be performed in the pharmacy. It is to be hoped that the rumour alluded to by our correspondent—though probably true—had reference to an extreme case, which possibly might find an explanation in the absence of any practical training, and is representative of the class that will be excluded by the bye-law coming into operation after the 31st December, 1876. But it must be confessed that known facts are more than sufficient to account for the lamentable deficiencies which have thrown upon the Examiners the painful duty of rejecting so many candidates. Indeed, the trenchant accusations contained in the quotation from the German Pharmacy Laws read almost like a bit of contemporary English history, and raise a fear that on both sides of the German Ocean pharmacists "sometimes study their "own advantage more than they do that of the "apprentice or the public," recalling the shrewd remark of HORACE :—

"Cœlum non animum mutant qui trans mare currunt."

We presume that the form of indenture of apprenticeship quoted by our correspondent is that which still generally obtains, and no form could better represent the primary object of the Pharmaceutical Society of Great Britain. That object has always been, not so much to promote the study, desirable as it may be, of physics, chemistry, or botany *per se*, as to produce the skilled pharmacist by enabling the apprentice to study the art more intelligently with their aid. This can only be properly done when the "master his apprentice shall teach and instruct, or cause to be taught and instructed, in the art of a chemist and druggist." On the one hand it is not done when the apprentice is confined to the rough and mechanical work that might appertain to a huckster's shop, which leaves him at the end of his time but at the beginning of his studies, or at best but a mere weighing, measuring, and pill-rolling machine. Neither, on the other hand, is it done, though his head may be crammed with GANOT, ATTFIELD, and BENTLEY, if he so lacks the practical application of the knowledge that he is unable to make a good pill-mass or dispense a sightly and uniform mixture.

PROPOSED PHARMACEUTICAL LEGISLATION IN THE UNITED STATES.

THE *Pharmacist* for May contains a synopsis of a Bill to prevent incompetent persons from engaging in the practice of pharmacy in the district of Columbia. It resembles in its main features others which have become law in the United States during the last four or five years. It provides that no unregistered person shall "keep open a pharmacy," or "take charge of one," or "dispense physicians' prescriptions, except under immediate supervision of a registered pharmacist," under a penalty of fifty dollars for each offence. "Graduates" in pharmacy, who shall have had at least four years' practical experience in the retail drug business, and, under certain conditions, persons engaged in the business in the district at the time of the passing of the Act are to be entitled to registration without examination; all other persons are to be examined by a "Commission" consisting of five competent pharmacists, and examination is to be preceded by "an apprenticeship of at least four years in a pharmacy where physicians' prescriptions are daily prepared."

A Bill to regulate the practice of pharmacy and sale of poisons, and prevent adulterations of drugs and medicinal preparations in the State of Illinois also, has been introduced into the General Assembly of that State, which proposes to make it unlawful for any person, unless a registered pharmacist, or a registered assistant in pharmacy, to retail, compound, or dispense medicines or poisons. The provisions for registration resemble those described above. There is a further provision, that in rural districts, where there is no registered pharmacist within two miles, it shall be lawful for retail dealers (in what is not mentioned) to procure licences from the Board of Pharmacy, at a fee of one dollar, to sell the usual medicines and poisons.

In an article published in the *American Journal of Pharmacy* for May the legality of these local Acts has been challenged by Mr. C. C. FREDIGKE, who is of opinion that they interfere with the civil rights of the citizen under the Constitution, and that, were an appeal carried to the Supreme Court of the United States, a judgment would be obtained that would stagger any Board of Pharmacy!

RHEUM OFFICINALE.

IN our issue of the week before last, we referred our readers to a fine cut of the medicinal rhubarb which recently appeared in the *Garden*. By those who are able to visit Kew, a splendid plant is to be seen at the present time, in flower, in the herbaceous department of the Royal Gardens. The sumbul, *Euryangium sumbul*, though not in flower, is also a fine plant, and in excellent health.

THE YORKSHIRE COLLEGE OF SCIENCE.

THE Council of the Yorkshire College of Science have announced that, in view of the opening of the College at Leeds in temporary premises on October 1st, they are prepared to appoint a Professor o Chemistry, a Professor of Geology, and a Professor of Mathematics and Physics. The stipend of the Professor of Chemistry, who is also to have charge of the Chemical Laboratory, is to be £300 per annum and two-thirds of the fees of the Lecture Students (excepting registered Students of the Leeds School of Medicine), and one-third of the fees of all students entering the Laboratory course. Applications are to be forwarded, not later than July 1st, to the Honorary Secretaries, Messrs. HENRY H. SALES and RICHARD REYNOLDS, 16, St. Andrew's Chambers, Leeds.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The last two meetings of the twenty-fifth session of this Association were held at the Royal Institution, on the 17th and 21st of May.

Dr. Charles Symes occupied the chair on both occasions. The following donations were announced :—The current numbers of the PHARMACEUTICAL JOURNAL, from the Society ; 'Proceedings of the American Pharmaceutical Association,' from John M. Maisch, Esq., Philadelphia ; a paper on Eucalyptus Globulus, from Professor Bentley, F.L.S., etc., and a book of botanical specimens of British plants, from Messrs. Butler and Co.

At the first meeting, Mr. Thomas Williams, F.C.S., read a paper on Antimonial Preparations.

At the second meeting (May 21st) the President delivered the following

VALEDICTORY ADDRESS.

Gentlemen,—Arrived at the close of another session, I have this evening to offer you a parting farewell. On such occasions it is customary to review the work of the six months, and see how far it has been satisfactory. It is well that we should to some extent recapitulate. The student in this way fixes his lesson more deeply in his mind ; the man of business is often able to correct errors in judgment, etc., by the same process. We cannot flatter ourselves on what has been accomplished ; and yet, with all its imperfections, the session will, I think, bear favourable comparison with its predecessors. I cannot say that I am perfectly satisfied with this general statement, and must confess to having entertained greater expectations than have been realized.

Technical chemistry has been represented by Dr. Cook, Mr. Armstrong, and Dr. Milne, with two papers on Animal Charcoal, and one on Superphosphate of Alumina, their merits and demerits, relative value, etc., in sugar refining, and one on a new form of gas. If any of you amongst our pharmaceutical element have entertained doubts as to the propriety of occupying four of our evenings on such subjects, I have not. When practical men come forward and give us the result of their experience we are sure to gain some valuable information. The various branches of science are so dependent on each other for aid, so interwoven into a network, that it is impossible to point to any one as standing aloof from all others, purely on its own merits ; and I am sure you will agree with me that pharmacy has learnt somewhat, and has yet much to learn, from technical chemistry. For example, Easton's syrup is a preparation which becomes discoloured by age and unfit *in appearance* for medicinal use ; agitation with a little washed animal charcoal and subsequent filtration removes the discolouration without impairing its therapeutic value. Again, the favourite process of the present day for the preparation of tinctures, and the one almost exclusively adopted in the B.P., viz., percolation, or displacement, was known and practised by the brewer many years previous to its use in pharmacy under the name of sparging.

Pharmaceutical education has received a fair amount of attention. Two evenings and several council meetings have been devoted to the subject, and you will ask with what result ? Let me illustrate my answer. You are doing some business, but you wish to do more. You get your premises painted anew ; you give more attention to the arrangements of the details of your counters, cases, etc. ; or you spend time and money in some other way, with the same object in view ; and when all is done, what is the result ? You do not find customers come rushing in more rapidly, or that the public have, through your exertions, acquired a taste for physic. No ; you do not see any immediate or marked results, and yet you do the same thing again and again during your career, and do not feel, after all, that it is time and money thrown away. The fact is, you get some general progressive effect, and this is exactly what we can hope for with regard to our educational movement. We do not find young men rushing to embrace our offers ; we do not find that they evince any stronger liking for study ; but we can still hope that the time will come when our efforts will develop in the establishment of an efficient and well-attended school of pharmacy in Liverpool. Judging from the results of recent examinations, we should conclude that the means of education which exist are not equal to the requirements of the present day, or that young men do not take sufficient pains to prepare for the ordeal. To my mind the mistake is just this. The revolutionary tendency of the age prompts to an increased amount of pleasure and diminished amount of labour. Pharmaceutical young men, in common with others, find this a very pleasant path to tread and put off preparation for examinations as long as possible ; they see it in the distance as something uncomfortable to contemplate and therefore most desirable to banish from the mind, presuming it will be got over in some way. Instead of this, from the day a youth enters on his apprenticeship he should devote himself to the acquirement of a knowledge of the business, not only with a view to passing the examinations but to becoming proficient in his calling. This is perfectly consistent with healthy recreation ; and I feel confident in repeating what I have on previous occasions asserted, that no pharmaceutical school, however well conducted, no amount of grinding at the eleventh hour, will supply the place of home study.

Practical pharmacy has not been lost sight of. Specimens of useful heating apparatus, exhibited by Mr. Davies ; bergamotte fruits, crystallized glycerine, etc., by Mr. Mason ; specimens illustrative of the additions to the B.P. as a donation to our museum, by Messrs. Evans, Sons, and Co. ; remarks on commercial and B.P. pepsine, by Mr. Abraham ; and some original researches on preparations of antimony, by Mr. Williams, have all contributed to give considerable interest to our meetings, and have been specially worthy the notice of those engaged daily in the manipulation of those substances and their products.

At the very interesting and instructive lecture on a new form of gas for illuminating purposes, we were honoured by the presence of ladies. If all our meetings could be rendered sufficiently interesting to attract the fair sex I am sure we should less frequently have to complain of a small attendance.

Ill-health deprived us of a paper by Mr. Sharp on the life of William Allen, which we should all have listened to with much pleasure. With his usual good nature, he was unwilling to disappoint us altogether, and at the cost of some physical suffering, gave a very interesting paper on "A Half Century of Patented Inventions Relating to the Preservation of Food."

A similar unfortunate circumstance deprived us of a paper from Mr. Alfred Tanner, and of his active co-operation.

Excessive zeal and misguided judgment on the part of some of those appointed to carry out the provisions of the Adulteration Act caused most persons engaged in business to feel some little anxiety for their reputation ; indeed, I fail to see on what grounds any one could guarantee to himself perfect immunity from these attacks. It is true, we as a body have no cause in this town to complain ; for, as far as I am aware, no single case of prosecution under this Act, which could in any way be considered unfair, has occurred. But if the authorities here have the good judgment to administer the spirit rather than the letter of the Act, there is no reason why we should not seek to gain for our less fortunate brethren the privileges which we ourselves enjoy ; and, indeed, an effort has been made, not to encourage adulteration, nor to provide a means for breaking the law, but rather to render the law such as to be within the power of every honest man to comply with its requirements. All of us did not think alike in this matter, and those who thought

differently had a perfect right to do so, but want of unity weakened our action and tended to nullify the benefit which would probably have accrued, nevertheless I have still faith that some good will result. Mr. Murphy gave us a paper on adulteration, criticising some of the provisions of the Act, which was preceded and followed by a somewhat animated discussion.

During the session, two works relating to pharmacy have been published, viz., 'Proctor's Practical Pharmacy' and the 'Additions to the British Pharmacopœia.' The former fills a place long vacant in our literature. First editions of most works admit of improvement, and Mr. Proctor's book is no exception to the rule, but it contains much valuable information and should be in the hands of every student.

The Additions to the British Pharmacopœia have come under our notice so recently that little requires to be said on it on the present occasion. At the Pharmaceutical Meeting in Bloomsbury Square, held for the purpose of discussing its details, a letter was read from Mr. E. Smith, which dealt with the matter so frivolously as not to merit serious consideration; but several of the speakers pointed out grave defects in the work, and reiterated views similar to those I had previously expressed at a meeting of this Association. I think there can be no doubt that the work is a *failure*. So was the Pharmacopœia of 1864, and no one denounced it more unsparingly then Dr. Redwood. Under these circumstances he certainly ought to have borne the criticisms of this (which should have been the child of the 1864 rather then the 1867 edition) a little more calmly than he appears to have done. His reply can scarcely be considered satisfactory, and if Mr. Smith's remarks were out of place, certainly some of the Professor's were equally so.

During the last two months pharmacy has suffered a great loss in the death of two worthy members of our calling—two who stood foremost in our ranks, and whom we could ill afford to lose. Taking, as they did, an active interest in all that tended to promote our welfare, they won our high esteem, and their memories will long live amongst us, whilst the fruits of their labours will remain to prompt others to follow in their footsteps and assist in the great work of progress. Think not that the field of investigation is narrowing. A perusal of the circular issued by the British Pharmaceutical Conference will alone satisfy you that much remains to be done, and that you should undertake your share. Every new fact elicited takes us a round higher in the ladder—enables us to see a little further in the vast area of inquiry—causes us to contemplate what more glorious truths still lie beyond our ken—gives us a noble ambition to rise higher and higher, and to enjoy, through His works, communion with the Great First Cause and Creator of All.

In conclusion, allow me to thank you for the consideration you have shown me, and the help you have afforded in rendering the session as successful as it has been.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, June 4th, 1874. Professor Odling, F.R.S., president, in the chair. After the transaction of the ordinary business of the Society, the following papers were read:—1. "Dendritic Spots in Paper," by H. Adrian. These he finds to consist of sulphide of copper formed from particles of gun-metal derived from the machinery employed in manufacturing the paper, and are far more usually found in common papers than in the better classes. 2. "The Acidity of Normal Urine," by J. Resch, M.A. 3. "On a Simple Method of Estimating Urea in Urine," by Dr. Russell and Mr. West. The apparatus employed for this purpose was exhibited, and a practical illustration given by Mr. West. 4. "On Ipomœic Acid," by E. Neison and J. Baynes. This acid, prepared by the action of nitric acid on jalapin, the authors find to be identical with sebacic acid. 5. "On Certain Compounds of Albumen with the Acids," by G. S. Johnson. 6. "On Sulphite of Acetyl," and 7. "On a New Method of Preparing Toluene," both by Dr. D. Tommasi. 8. "Note on New Zealand Kauri Gum," by M. M. P. Muir.

The meeting was finally adjourned, at a late hour, until Thursday, June 18th.

SOCIETY OF ARTS.

Pyrites as a Source of Sulphur, Iron, and Copper.

BY DR. C. R. A. WRIGHT, F.C.S.

(*Continued from p.* 967.)

Owing to the similar character of these minerals and the sulphides of iron, it frequently happens that the deposits of these substances found in nature are more or less intermixed together, *e.g.*, a deposit consisting principally of iron disulphide is found also to contain more or less copper pyrites, or other copper sulphide, or some lead or zinc sulphide; or a deposit may contain copper sulphide, in conjunction with some iron sulphide, or with the sulphide of some other metal. An immense variety of substances of this character are known, some of which are mineralogically ranged as different species, *e.g.*, copper pyrites, or the compound of cuprous sulphide with iron sesquisulphide. The more important substances of this kind from a commercial point of view are, however, minerals, not exhibiting any great definiteness of composition, but consisting essentially of yellow iron pyrites, intermixed with larger or smaller quantities of copper pyrites or some copper sulphide, together with more or less considerable amounts of other metallic sulphides, notably arsenic, zinc, and lead. All these bodies are commercially designated as pyrites, and it is with substances of this class that the present paper has more especially to do. Copper pyrites and minerals approximating thereto, *i.e.*, containing more than a very few per cent. of copper, are usually treated by the metallurgical processes for smelting copper ores, and the iron and sulphur therein contained are usually not utilized in this process.

Using the term "pyrites" in this wide and somewhat loose sense, the substances met with in commerce may be divided into two classes, viz., those not containing copper in quantity greater than traces only, and those containing small quanties of the metal up to a few per cent.; the latter ores are usually termed cupreous pyrites, or, preferably, cupriferous pyrites or cupriferous sulphur ores.

Usually the deposits found naturally in any quantity are more or less intermixed with earthy and siliceous matters, and when the amount of such admixture becomes large, the ores are frequently rendered of little or no value Carbonaceous substances are also present in the pyrites of the coalmeasures (coalbrasses), greatly interfering with some of its applications. In addition to these substances the pyrites of commerce ordinarily contains small quantities of arsenic, lead, and zinc, and not unfrequently other metals and metalloids, such as silver, gold, thallium, manganese, antimony, selenium, etc.

The following tables give a general idea of the composition of some of the various kinds of pyrites in practical use, derived from various localities. Of these, the first mentioned (Huelva and Tharsis ores) possess the greatest amount of practical importance, on account of the extent of the natural deposits, the scale on which they are worked, the amount of copper contained, and the large and increasing quantities of metallic copper now actually extracted from them. The comparative freedom of these ores (viewed on the large scale) from ingredients other than iron, sulphur, and copper, and more particularly from admixed earthy and siliceous matters, also gives considerable importance to them as a source of these three substances.

The limits of space necessarily imposed on the present paper forbid anything like an exhaustive and comprehensive view of all the various processes and improvements that have been from time to time proposed in reference to the extraction from pyrites and its allied minerals of the three constituents—sulphur, iron, and copper. A general view of the subject, with a brief sketch of some of the more important of these special processes, is all that can be attempted.

The use of pyrites, copper pyrites, and analogous minerals, such as zinc blende, in the manufacture of the different "vitriols" (green vitriol or ferrous sulphate, blue vitriol or cupric sulphate, and white vitriol or zinc sulphate), is of considerable antiquity, these salts having been known from an early period as being produced by the natural or artificial oxidation of these sulphur-containing minerals; and the use of copper pyrites, galena, and zinc blende, as sources respectively of metallic copper, lead, and zinc, and their alloys, also dates from a comparatively early epoch. Moreover, it has long been known that when pyrites is heated in open vessels so as to allow free access of air, sulphur dioxide is formed, whilst more recently it has been found that when the heating is effected in close vessels, sulphur is expelled as such, and may be collected by means of suitable condensing arrangements. It is, indeed, not improbable that some at least of the sulphur found in the free state in volcanic districts is actually derived from this source in this way, although a considerable portion of such natural sulphur is probably formed by the mutual reaction of gaseous sulphuretted hydrogen and sulphur dioxide, water and free sulphur being produced thus :—

$$2\,SO_2 + 4\,H_2S = 4\,H_2O + 3\,S_2.$$

As mentioned below, advantage has also been taken of this change to obtain sulphur from pyrites commercially, one portion of the mineral being heated in contact with air so as to form sulphur dioxide by the combustion of the sulphur present, another being so treated as to give rise to sulphuretted hydrogen.

As far back as the first part of the last century, processes for the extraction of free sulphur from pyrites and analogous minerals appear to have been worked in this country. Thus, in 1730, Samuel Hutchins took out a patent for "a method of extracting and preserving the sulphur contained in mundic, etc., by which this sulphur may be prepared so as to answer the end of that imported from abroad;" and in 1738, William Champion patented "a method or invention for the reducing of sulphurous British mineral and minerals into a body of metallic sulphur;" whilst in 1778, Matthew Sanderson took out a patent for "a new process for extracting a mineral sulphur from pyrites, copper, and lead ores, separating its acid, and rendering it useful for every medicinal purpose," this process being virtually a rough method of distillation of the sulphurized substances, whereby a portion of the sulphur was volatilized and again condensed separately.

The extraction of free sulphur from pyrites in this way is still practised to some extent, the apparatus employed being very simple. The ore is broken into small fragments the size of nuts, and is then piled up inside a cylindrical roasting vessel capable of holding 50 to 60 tons of material; this vessel is simply a circular wall of masonry enclosing a level floor, along which pass four flues meeting in the centre in the form of a cross. Through these the requisite supply of air enters, the floor communicating with the flues by openings here and there; the heap of ore is covered over with earth and turf, an opening being left for an exit pipe along which the vapours pass to a long condensing flue. The mass is lighted at the openings of the four flues arranged as a cross, and these openings are then partially closed; the heat generated by the combustion of a portion of the sulphur present serves to expel the rest, most of which is condensed in the main condensing flue. The operation usually lasts about six weeks, and the amount of sulphur collected is but small as compared with the quantity that is burnt and escapes as sulphur dioxide.

When heated in a closed vessel, iron disulphide parts with about $\frac{3}{7}$ of its sulphur in the free state, the main reaction being—

$$7\,FeS_2 = 3\,S_2 + FeS_2\,6\,FeS.$$

the product being a kind of "magnetic pyrites." Tubular clay retorts, arranged in rows and heated simultaneously by a furnace, are sometimes employed for this purpose: but only about a quarter of the sulphur present can be thus obtained with safety, as the residue is readily fusible, and cannot easily be removed from the retort if once fluxed.

(To be continued.)

Parliamentary and Law Proceedings.

Prosecutions under the Adulteration Act.

Adulterated Mustard.

At the Highgate Police Court, on Monday, June 8, three grocers, William Watkins, of North Road, Highgate; Edward Coldrey, of Hornsey; and Thomas Robertson, of North Road, Highgate, appeared before Messrs. Bodkin, Nicholson, and Lermitte, on summons, charged by Mr. Faulkner, food inspector, with selling adulterated mustard.

Mr. Faulkner said that he caused some sugar, coffee, and mustard to be purchased at Mr. Watkins's shop. Witness was in the shop at the time, looking after the weights and scales. No question arose about the sugar and coffee, but Professor Redwood, the county analyst,

certified that the mustard—a 2 oz. packet of Colman's—was, in his opinion, adulterated with flour and turmeric, but that the adulteration was not injurious to health.

Cross-examined, witness said that he did not hear the label—which stated that the article was an "admixture of pure mustard, with farina and choice condiments"—read. The gentleman who actually purchased the mustard by witness's direction was not now present.

By the Bench: The label was on the packet when I bought it. My attention was not called to it.

Mr. Bodkin: How can you say it was sold as unadulterated?

Mr. Faulkner: I asked for mustard, and that was given to me.

Mr. Bodkin said the whole question turned on the meaning of the word "declared," in the Act. Did that refer to words, or was the label sufficient?

Mr. White, for the defence, said the offence was to sell it "as unadulterated." This packet was sold as "mustard," and the definition was on the label, which amounted to a declaration. Everyone knew that in preparing mustard for the table it was necessary to mix it with flour.

Mr. Bodkin: The only question is whether the printed label does not meet the meaning of the word "declared." It seems to me to be clear.

Frank William Watkins, son of defendant, deposed that he supplied the packet to the purchaser. It was the article known commercially as "mustard for the table." Witness's father pointed out that it was not sold as genuine mustard, but witness could not state what was said.

The Bench held that the label was a sufficient declaration, and dismissed the summons.

In the two remaining cases the mustard was not sold in packets, but from bulk, and the purchaser had not been told that it was not genuine.

Professor Redwood certified that it was adulterated with flour and turmeric, but not injurious to health.

A fine of 5*s*. and 8*s*. costs was inflicted in each of these two cases.

Milk Adulterated with Salt.

At Greenwich Police Court, on Tuesday, June 9 Edward Pursaill, dairyman, of High Street, Deptford, appeared to an adjourned summons, at the instance of the Greenwich district Board of Works, charging him with selling milk adulterated with salt. Mr. Spencer attended to prosecute, and Mr. H. Pook for the defence. The milk in question was purchased at the defendant's premises on the 9th ult., and was at once forwarded to Mr. Wigner, the public analyst for the district, who, on the first hearing of the case, sent the following certificate, which is made evidence by the Act of Parliament :—"In my opinion the sample (named) is adulterated with about half an ounce of salt per gallon, and with a small quantity of some colouring matter, probably annatto, and that I consider such adulteration injurious to the health of children drinking such milk." Mr. Balguy explained that the case had been adjourned by him, on the application of Mr. Pook, in order that the analyst should attend personally to be cross-examined. He thought this was necessary, from the wording of the certificate then read. For instance, the certificate in reference to the amount of salt contained the word "about," and in reference to the nature of the colouring matter the word "probably" was used. These words left a doubt as to what the certificate meant. Mr. Wigner explained that in writing "about half an ounce" there were 217 grains of salt found to the gallon, and 230 grains being half an ounce, he thought his description would be more intelligible than by giving the number of grains. With regard to the world "probably," this had been used because it was utterly impossible to separate annatto from other colouring matter in the sample sent. In answer to Mr. Pook, the witness said he had not brought his books containing the entries of the analysis made, but was ready to state the steps in the process of analysing, which he did. The analysis was commenced on the 9th of May, and, from the date on the certificate, was concluded on the 23rd ult. The delay was caused in endeavouring to find other colouring matter. If cows drank from water in which rock salt was placed, the salt would not assimilate with the cow's milk. Mr. Pook complained of the delay in finishing the analysis, precluding defendant from having a counter-analysis, and asked that the summons should be dismissed against the defendant, whom he tendered as a witness to state he had neither put nor sanctioned salt to be put in the milk. Mr. Balguy ruled that defendant could not give evidence. The analyst had very satisfactorily explained the matter, and he concurred with him that the adding of salt to milk would be injurious to the health of infants. The defendant had grievously offended under the Act of Parliament, for which he would be fined £5 and costs.

Adulterated Coffee.

At Southwark, on Monday, June 8, William Stratford, grocer, White-Street, Borough, was summoned by Mr. Edwards, the sanitary officer of St. George's Vestry, for selling adulterated articles of food. Mr. Birt, the vestry clerk, attended to prosecute. Mr. Edwards said that on the 14th ult. he sent his assistant to the defendant's shop to purchase half a pound of sugar and two ounces of coffee, for which he paid 3d. Witness told the defendant he had bought them to have them analysed, and asked him to accompany him to Dr. Muter's. He declined doing so. Accordingly, witness delivered the articles to Dr. Muter, who found the coffee to be adulterated with 25 per cent. of chicory, and the sugar to contain a large quantity of acarus (sugar mite). This was very injurious, but the Act of Parliament did not meet it. The defendant said he sold the sugar as he received it, and as for the coffee, he told the man it was mixed with chicory, as pure raw coffee could not be bought at the price. The magistrate told him that he should have marked in plain figures on the wrapper containing the coffee that it was a mixture of chicory. He must pay 5s. and 7s. costs. Abraham Berry, oil and colourman, Red-Cross-street, was also charged with selling as pure mustard a mixture of turmeric, flour, and mustard. The sale having been proved the defendant said he did not sell it as pure mustard, but as "mustard condiment," which was superior to mustard. The magistrate doubted that, and ordered him to pay 10s.

Poisoning by Carbolic Acid.

A case of poisoning by carbolic acid which had a fatal termination, is reported to have occurred in Marsham-street, Westminster, on Saturday week. It seems that a Mrs. Bartrop had for some time been in ill-health, and was taking medicine. For the purposes of cleansing, her husband had purchased some carbolic acid, which was placed in the same cupboard as his wife's physic. The latter, wishing to take a dose of her medicine, went to the cupboard for the purpose, and by mistake poured out the carbolic acid and swallowed it. No sooner had she done so than she discovered her mistake, and Dr. Fenton and the house-surgeon from Westminster hospital were called in. The stomach pump was applied, but without effect, and Mrs. Bartrop was dead in less than an hour.

Imitation of Trade-Marks.

At the Mansion House, Messrs. William Prendergast and John Irish, carrying on business as the Universal Sauce and Condiment Company, appeared before Alderman Sir Robert Carden, on an adjourned summons, to answer a charge, under a provision in the Merchandize Marks Act, of exposing for sale, and for the purposes of trade, a sauce purporting to be "Yorkshire Relish," with a counterfeit trade-mark, which they knew to be forged and counterfeited.

Mr. William Powell, a partner in the firm of Goodall, Backhouse, and Co., of Leeds, wholesale druggists, deposed that they had been established eighteen or twenty years, and were the manufacturers of the sauce called "The Celebrated Yorkshire Relish." The label was their design, and as such they claimed the whole of it. They registered it at Stationers' Hall many years ago, and they had used the same label ten or twelve years exclusively.

The genuine and the alleged counterfeited labels were produced in court, and were so nearly alike in colour, lettering, and design, with certain alterations not immediately perceptible, as to be readily mistaken one for the other, at a casual glance. Evidence was given to prove the purchase at the defendants' premises of some of the counterfeited article, and that in one case the counterfeited label had been placed on a bottle of the complainants. Mr. Prendergast, one of the defendants, said there was a doubt about the matter, and when they found it out they stopped the sale.

Sir Robert Carden pointed out the general resemblance in design and colour between the labels on the genuine and imitated articles, and how easily a person buying might be deceived. He believed the defendants' label to be a false, forged, and counterfeit trade-mark, and the case, in his opinion, ought to go before a jury.

The case, however, on the first hearing, was adjourned by the mutual consent of the parties on both sides, with the view to an arrangement; and on Saturday, when they reappeared before the Court, the complainants' solicitor stated to the Bench that since the adjournment the defendants' solicitor had attended at his office, and had furnished a list of the quantities supplied to their various customers, from which it appeared that a little over 10 gross of the counterfeited sauce had been sold by them; that they had given up the remainder of the counterfeited labels, and would get back the bottles from their customers as soon as they could, for destruction. The defendants, moreover, had paid £22, part of the costs of the prosecution, and had consented to the terms of the arrangement being advertised at their expense in the *Times* and the *Grocer*, a trade newspaper.

Sir Robert Carden was not satisfied at first with that, and said the defendants ought to be punished as well. It was explained to them, however, that the case could be dealt with summarily, without going before a jury. Upon that the defendants pleaded guilty, and the Alderman fined them £10 each, which he afterwards reduced to £5 each, in consideration of their having paid upwards of £20 in costs.

The defendants paid the money.—*Daily News.*

Reviews.

PHARMACEUTICAL LEXICON: A DICTIONARY OF PHARMACEUTICAL SCIENCE; containing a Concise Explanation of the Various Subjects and Terms of Pharmacy, with Appropriate Selections from the Collateral Sciences, etc. By H. V. SWERINGEN. Philadelphia: Lindsay and Blakiston.

This is a book that is designed as a "guide for the pharmaceutist, druggist, physician, etc." It really does supply to some extent a real want. We have more than one dictionary of medical terms, but we know of no other book than that under notice which has for its special object the arrangement and definition of terms met with in pharmacy and the allied sciences. It is, therefore, worthy of a welcome in these pages, and sure of a ready recognition of such merits as it possesses.

But what would the great lexicographer, Dr. Johnson, have said of a lexicon from which etymology is shut out? According to his definition, a writer of dictionaries is "a harmless drudge, that busies himself in tracing the original, and detailing the signification of names." But Mr. Sweringen tells us in his preface that he regards the derivation of words as a matter of secondary, and comparatively little, importance, "because there is scarcely an instance in which a knowledge of the original word can give us any precise idea of the meaning of its derivative." But, of course, as he lives in a free country, he is not bound to defer to Dr. Johnson's opinion, and is at liberty to call his book by the name which pleases him best. In one "tracing of the original," however, which he does give he follows Webster and other lexicographers in saying that "Castor oil" is a corruption of "castus oil," the plant producing it having formerly been called *Agnus castus*." We should like to learn whether this is fact or fancy.

However, if Mr. Sweringen has shunned the etymology, evidently he has not feared the drudgery; for he has collected together a variety of information that is at least creditable to his industry. The book is certainly convenient for ready reference, and although the definitions are not always happy, and the arrangement is certainly not systematic, there is a clue furnished to the meaning or value of most of the terms that a pharmacist is likely to meet with in the pursuit of his calling. But that there is much need for improvement is what the author himself acknowledges. For instance, the definitions of many of the principal chemical bodies are unaccompanied by any formula representing their composition, and the verbal descriptions are in many cases exceedingly vague. To mention some of the acids. Acetic acid is said to be "an acid composed of carbon, hydrogen, and oxygen, always in the same uniform and definite proportions." Atropic acid "is an uncrystallizable salt." Benzoic acid "consists of benzyl and oxygen." If the seeker tries to run down the secret of its formula by turning to the word benzyl, he will find—

"BENZYL (*Hydruret of Benzyl*). A compound radical contained in the purified oil of bitter almond. It is composed of carbon, hydrogen, and oxygen."

Under "benzoyl" it is stated that that substance is the "radical of benzoic acid," and that it "can be isolated while treating chloride of benzoyl with sodium," but neither its formula nor that of the chloride appear to throw light upon the proportionate composition of benzoic acid. For such information it is necessary to turn to a Table of Pharmaceutical Equivalents in the Appendix, in which there is the further inconvenience that the formulæ are set forth according to the old notation only, and the name attributed to the formulæ is frequently neither that of the United States nor of the British Pharmacopœia.

To mention two other important acids, all that is said about sulphuric acid, beyond giving the synonyms, is that it is "an acid obtained by burning sulphur, mixed with one-eighth of its weight of nitre, over a stratum of water, contained in a chamber lined with sheet-lead," whilst sulphurous acid is described as "a sulphuric acid containing only two-thirds as much oxygen as the officinal sulphuric acid." Another feature, characteristic also of other parts of the book, is that some of the acids are arranged in the alphabetical order of the word "acid," and others in that of their particular names.

It must be remembered by British readers that the formulæ given of the tinctures, powders, &c., are those of the United States Pharmacopœia only. It would have been well had this been indicated by the initials, U.S.P. In many cases, such as hive syrup, a preparation which is occasionally asked for in this country, the ingredients are given, but not the quantities, thus rendering the information useless. This neglect of uniformity is apparent in many ways. Just as chemical formulæ are in some cases stated and in others are not, so the natural order of a plant is mentioned in a few cases and not in others.

The British pharmaceutist will, however, find a good deal of useful information with regard to the uses of American drugs, and to preparations of the United States Pharmacopœia.

The articles on materia medica are in some instances not up to the present date. Thus, gamboge is said to be the product of an undetermined plant; rhubarb is attributed

to *Rheum palmatum*, and other species ; and pareira brava is said to be obtained from *Cissampelos Pareira*. In some instances. too, the meaning is not very clear. Thus, an achene is defined as being a small bony fruit, consisting of a single seed, which neither adheres to the pericarp, nor opens when ripe. A strobile is stated to be "an ament, the carpels of which are scale-like and spread open and bear seeds ; sometimes the scales are thin with little cohesion, but they are often woody and cohere together into an irregular tuberculated mass." On turning over the pages to look for ament, there is no such word to be found, nor does the word cone occur, to which the above description more correctly applies ; and many botanical terms often met with, such as berry, drupe, legume, etc., are not to be found. Pepo is defined as the seed of *Cucurbita pepo*, or common pumpkin. *Adiantum capillus veneris*, is stated to be "an European species of maidenhair, or *Adiantum pedatum*." These instances show that, as a botanical dictionary, the book had better not be used, although, as a dictionary containing a large number of technical terms, and as a ready book of reference for anything relating to American pharmacy, it will doubtless be very useful. It is printed on good paper and in clear type ; and is strongly and neatly bound.

We hope to see the above defects remedied in a future edition. In a dictionary which necessarily includes so many branches of science, it is almost impossible to attain perfection in a first edition.

Besides the Lexicon proper, which extends to 427 octavo pages, there is a "Part Second," which includes a list of abbreviations used in prescriptions ; a number of "selected prescriptions ;" formulæ and doses of medicines for hypodermic medication, and also for inhalation ; a posological table ; definitions of diseases ; antidotes and tests for poisons ; table of boiling points, and several other sections that are all of more or less use to the pharmacist. We believe the London agents for the publisher are Messrs. Trübner.

QUALITATIVE CHEMICAL ANALYSIS AND LABORATORY PRACTICE. By T. E. THORPE, Ph.D., F.R.S.E., Professor of Chemistry, Andersonian Institution, Glasgow ; and M. M. PATTISON MUIR, F.R.S.E. London : Longmans, Green, and Co. 1874. Small 8vo, pp. 238.

The sixteenth volume of Messrs. Longmans' cheap series of science manuals lies before us. Having made a careful survey of its contents, we can safely recommend it to our readers as an intelligible, and, at the same time, trustworthy, guide in the department of practical chemistry to which it is devoted. But we should not be inclined to go further, and say that it presents any very obvious advantages over several other existing text-books that we could name ; and, except as a contribution to the series of science manuals to which it belongs, or because, as the production of a Glasgow professor it may possibly bear a special recommendation to students of chemistry in the north, it is difficult to see why it was written. We have every desire to give the authors of this little volume credit for their success in producing a useful book, but we cannot pretend to disguise the fact that the almost weekly appearance of new text-books, for the most part differing in no essential particulars from one another, is becoming nothing short of an intolerable nuisance. In chemistry especially is this the case, and we believe most teachers who have to deal with large classes would be glad if the array of manuals offered to the choice of the student could be reduced.

Professor Thorpe's text-book is divided into two parts. In the first is given a description of a series of preliminary experiments designed to familiarize the beginner with the properties of a few typical elements and compounds, and to afford him practice in the management of ordinary apparatus. Here he may learn how to prepare and examine the properties of oxygen, hydrogen, nitrogen, ammonia, carbon dioxide, and a dozen other equally important bodies, the manipulation of tubing and corks, the use of the pneumatic trough, and the process of filtration ; but if the student expects to find here anything that has not already been described and depicted in fifty other books since chemistry began, he will be disappointed. Perhaps, after all, such expectation would be unreasonable.

Throughout this first part sufficiently good woodcuts are supplied profusely, and the author adopts the very useful plan of summarizing at the end of each chapter the objects and results of the experiments described.

The second part of the book is devoted to qualitative analysis. Bunsen's flame tests and the use of the spectroscope are first described, and then the author proceeds to a detailed account of the wet and dry reactions by which the several groups of metallic and non-metallic radicles are characterized, and the members of each group separated and identified. In this part we do not think the book so suitable for young students as some others that have come before us ; and this partly because the explanations given of the reasons for adopting the particular methods which are recommended are very scanty, partly because the examination of the metallic groups begins at the most difficult end, with silver, lead, and mercury, and partly because we should be disposed in a few cases to doubt whether the selection of methods of separation were entirely judicious. A section further on gives an account of the detection and analytical classification of the rarer elements, and in the last two sections the student will find pretty full directions for the detection of poisons and the examination of urine and urinary calculi. Amongst the tests which are given for the identification of alkaloids, one or two reactions are mentioned which are not described in the British Pharmacopœia, nor in the ordinary text-books. Any additions to our knowledge in this direction must be welcome to students of pharmacy, we therefore quote some of these reactions, though how far they are to be depended upon as characteristic we are not prepared to say.

"Veratrine ($C_{32}H_{52}N_2O_8$).

"Strong sulphuric acid at first causes this alkaloid to form into small lumps ; these, however, speedily dissolve to a light-yellow fluid, changing to reddish-yellow, and eventually to blood-red.

"Strong hydrochloric acid forms a colourless solution, which becomes intensely red by long-continued boiling.

"This reaction is very delicate."

"Narcotine ($C_{22}H_{23}NO_7$).

"Pure strong sulphuric acid gives a bluish-violet, or in less pure specimens a yellowish colour, changing to cherry red on heating."

"Morphine.

"The formation of a violet colour upon addition of sulphuric acid, followed by a mixture of the same acid with nitric acid, is characteristic.

"If a few small pieces of manganese dioxide are added to the liquid obtained as above, it changes to mahogany colour.

"If solid morphine, or a morphine salt, is moistened with a solution of 1 part of iodic acid in 15 parts of water, and a solution of 1 part of starch in 400 of water is added, a blue colour is produced. If now a layer of very dilute ammonia is poured on this blue liquid, two coloured rings are formed at the point of contact—the upper blue, the lower brown. This reaction serves to detect $\frac{1}{200000}$th part of morphine (A. Dupré)."

In the appendix are some hints on the preparation of pure reagents which will be useful to many students. In the purification of hydrochloric acid, protochloride of tin is recommended for the purpose of removing arsenic ; and in connection with this we may remind those of our readers who may have forgotten it that protochloride of tin is a very useful and delicate reagent for the detection of arsenic, not only in hydrochloric and sulphuric acids but in salts of bismuth, antimony, and zinc, and in many other substances liable to such contamination. The test is a very simple one. A strong and acid solution of stan-

nous chloride is added to the solution of the substance, which, of course, should be free from oxidizing agents. If any appreciable quantity of arsenic is present it is deposited in the elemental form as a brown precipitate, which makes its appearance only after some time, when not more than minute traces are present.

The purification of sulphuric acid from lead, arsenic, iron, and oxides of nitrogen may be effected by heating it successively with ammonium sulphate and manganese dioxide, and subsequently distilling it, but the last part of the operation is so troublesome, and sometimes dangerous, that it is generally best to leave this to the manufacturer.

In conclusion, we may add, and this is high praise, that we have not been able to detect in the book any errors or inaccuracies worth noticing.

BOOK RECEIVED.

THE NEW CHEMISTRY. By JOSIAH P. COOKE. With Thirty-one Illustrations. Second Edition. (International Scientific Series.) London: H. S. King and Co. From the Publishers. 1874.

Obituary.

Notice has been received of the death of the following:—

On the 28th May, 1874, at Henley-on-Thames, after a lingering illness, James Henry Byles, Pharmaceutical Chemist, of Hackney Road, London. Mr. Byles was a member of the Pharmaceutical Society.

Notes and Queries.

[398.] PREPARED SILICA FOR PLATE POWDER, ETC., can be obtained of T. Crotch and Co., St. George's Terrace, Liverpool Road, Islington. I may add that it is very valuable for cleaning photographic glasses. It is also used in tooth powders, etc., etc.—W. B. FITCH.

Mr. C. Biddiscombe writes that Messrs. Read and Co., of London, are the makers of Prepared Silica.

Correspondence.

ALLEGED ADULTERATION OF A PHARMACOPŒIA PREPARATION.

Sir,—I quite agree with your foot-note to the report of the hearing of Mr. Fardon's case at Bristol, "that the report is not very clear throughout;" and, as I am made to say quite the reverse of what I did say, perhaps you will allow me to explain.

After the case was dismissed the justices gave me permission to say a few words, as our name had been mentioned; and I stated that last summer, during the illness of one of our foremen, a large quantity of citrate of iron and quinine, had been overheated in the course of manufacture; that we thought that we had stopped it all, and that none had been sent out, and regretted to find that a small quantity, of which Mr. Fardon's sample must have been part, had gone before the accident was discovered; and I also stated that the overheating had decomposed a portion of the quinine, forming the dark resinous matter of which Mr. Stoddart complained.

What Mr. Stoddart considered to be cinchonine is unquestionably a trace of cinchonidine, which, as is well known, is found in considerable quantities in most of the barks used for quinine making.

It was given in evidence that only a trace was discovered; and, though we have no doubt that our quinine would be found almost invariably free from it, where a trace does exist, such a slight defect in manufacture cannot in any sense be called an adulteration. It is annoying enough that such a mistake should have occurred and caused so much trouble, without the matter being further complicated by the misapprehension of newspaper reporters.

SAMUEL HOWARD.

Stratford, near London, E.,
June 3rd, 1874.

APPRENTICESHIP.

Sir,—It is now a good many years since I served my apprenticeship in a country town, but I well recollect that, in addition to a respectable premium being paid, a stamped document was executed, requiring on the one hand that "the said apprentice his master shall faithfully serve, his secrets keep," etc.; on the other that "the said master his apprentice shall *teach* and *instruct*, or *cause* to be *taught* and *instructed* in the art of a chemist and druggist." I have just been looking at this indenture, and wonder if similar documents, and possessing legal force, are now in fashion.

The result of the Minor examination last recorded in the Journal, when, out of 78 who presented themselves, 59 failed, is eminently unsatisfactory, and the subject is worthy of more attention than apparently it has yet received. This state of things certainly does not indicate progress, and an effort to trace the evil to its source may not be without some practical benefit.

I was scarcely prepared to hear it rumoured, on the day of the General Meeting, that a candidate for the Minor who had served his apprenticeship to a chemist and druggist, had finished that apprenticeship without being taught the composition of a Seidlitz powder. He may have been ignorant of high-class pharmacy, or a stranger to elegant pharmacy; many drugs he may never have seen, and some ugly compounds he may never have dispensed; but surely there could be no excuse for his being ignorant of the ingredients of a Seidlitz powder.

On my return home the question forced itself upon me—Is it fairly honest to take an apprentice, pocket the premium, and turn him out so lamentably deficient as must have been the larger number of those who presented themselves at this examination?

In a paper on Pharmacy in North Germany, by Mr. Greenish, the following quotations from the Prussian Pharmacy Laws occur, and they are so pertinent to the subject of this letter, that I cannot help referring to them.

"All apothecaries may take apprentices, but as they sometimes study their own advantage more than they do that of the apprentice or the public, the following has been made binding:—they must only take such apprentices as have by nature good parts, and as are sufficiently prepared by education and good moral training. In order that apprentices may not be taken from school too soon, it is enjoined they do not leave before the age of 14; and as the knowledge of the Latin language is indispensable for properly understanding prescriptions, no apprentice shall be taken until he can translate easy passages from a Latin author. *The master has further to see that the intended apprentice writes fluently and distinctly; this is particularly necessary, to prevent mistakes occurring, and the patient being mis'ed by illegible writing.*

"It is the duty of the master to provide proper books for the apprentice. It has occurred that apothecaries in many places have had other business than that of an apothecary to attend to, and that sometimes they have no *assistant*, but only three or four apprentices instead, and they prefer to take the roughest and most ignorant of boys, and also those that are too young, because they could make use of them for the rough work in their other businesses; and as the practice has led to an increase in the number of mere mechanical chemists' assistants, it is hereby ordered that an apothecary be allowed to take only as many apprentices as he has qualified assistants. If the business be so inconsiderable that one person only be employed, then no apprentice can be taken unless it be impossible to procure an assistant, or that the master be sufficiently skilful to take the place of assistant.

"To prevent the increase of badly trained assistants, it is ordered that for the future no master shall give his apprentice a certificate until the said apprentice has been examined by the Government medical officer in the presence of his master. The examination shall refer to such subjects as he has a right to expect from so young a man. He shall be particularly examined as to his practical knowledge of phar-

macy and handiness in doing ordinary work, as practical knowledge is of more importance than mere theory in an apothecary. Should it be found that he is not yet a capable assistant, it is the duty of the Government medical officer to inform him that he cannot yet leave his apprenticeship, but must remain until he has fully qualified himself. *Should it, however, appear that the master is more in fault than the apprentice and that he has neglected him or shown his own incapacity to instruct him in the business of an apothecary, that master shall be forbidden to take another apprentice.*"

I commend these pharmacy laws, which have done much to make the German pharmacist the model pharmacist of Europe, to the careful consideration of those who profess to train up apprentices; and I hope that the result of future Minor examinations may be less humiliating than the one now referred to.

A PROVINCIAL.

THE PRESIDENCY OF THE PHARMACEUTICAL SOCIETY.

Sir,—Would you kindly allow me to express an opinion, as a means of ascertaining if it be held by any number of my fellow members of the Pharmaceutical Society? I have always felt that the honourable position of President should be open to country as well as London members of the Council; and, so far as the charter is concerned, it appears to be so, but it seems to have drifted into an unwritten law, that no country member shall be elevated to the presidency. This I feel has arisen from a natural modesty of the country members, and also from a conservative tendency to observe an apparent rule. Having country members on our Council who are in every way a credit to our Society, I cannot help thinking that if the Council elected a country member to the office of President they would do honour even to themselves.

I do not for a moment find fault with the appointment of any past President, for they have all been good men, and I shall always feel proud of having been on the Council under two such men as Messrs. Haselden and Hills, as Presidents, and Messrs. Brown and Bottle, as Vice-Presidents. Knowing how well and at great inconvenience the Vice-Presidents did their duties, I do hope the time is not far distant when I shall see the higher office of President occupied by a country member.

W. W. URWICK.

60, *St. George's Road, Pimlico,*
June 9th, 1874.

"HIGHER REMUNERATION FOR CHEMISTS."

Sir,—The question of prices is one worthy at all times the serious attention of pharmacists, and especially so at this time, when rents are being doubled, and everything else in general consumption is being advanced in price. Your correspondent, "A Country Major Associate," deserves the thanks of the trade for opening up the subject once more, and I have to express the hope that something practical will result ere long: to have, first, a uniform trade-mark for pricing prescriptions; and, second, a general price-list, which will act as a guide to all the retail chemists throughout the country. This latter, however, is a thing which cannot be accomplished in a day; and it seems to me there is but one way of hastening it on, and that is, if all the large centres would adopt the plan which has been carried out with such wonderful success by the chemists of this city. I may mention that, up till two years ago Glasgow and the surrounding towns were amongst the worst remunerated places in the whole country, and now I think the price-list of the Glasgow Chemists' Association will compare favourably with that of any price-list in the country. The plan which I would advise in all large towns which have not yet united on any particular course, is to convene a meeting of employers connected with the trade (if the question of prices is mentioned in the circular, they are certain to turn out in large numbers), and appoint a committee, with power to draw up a price-list suited to the requirements of the particular locality; or, if they do not care to go to the expense of printing a list for themselves, there are, I believe, now, a goodly number of lists published throughout the country, all of different grades of charges, from which they could select the one most suited to their circumstances. There should be no puffing of the meetings in the daily prints, and no advertising publicly, but it should be done in as quiet a manner as possible. In this way the Glasgow Chemists have advanced their prices 25 per cent., and because we were united there has been few, if any, complaints on the part of the public. All the surrounding towns have followed suit by adopting the Glasgow scale. In Edinburgh, however, where a price-list has been published for a good many years, they have hitherto kept ahead of the Glasgow prices, but not a few have the idea that an amalgamation may yet take place between the Edinburgh and Glasgow committees; and then let us hope there will be a near prospect of having a committee of the Council, or a special committee sitting in London to regulate the whole scale of charges for the United Kingdom. For there can be no doubt that the fact that there is a difference in the prices in many cases between London and the country is one reason why the idea has got abroad that there is also a difference in the quality of the drugs. One thing I would urge in particular, viz., that all chemists throughout the country should use the one trade-mark in pricing prescriptions, and that every prescription should be marked distinctly. "Mel Boracis" is the mark used by Edinburgh, Glasgow, Manchester, and other places, and there is no reason why other towns should not do the same. I have often been annoyed by getting prescriptions which had been made up in English towns, without any mark at all. In conclusion, I would say that, instead of writing anonymous letters to the Journal on the question, if brethren would take action at home to unite and fraternize with their other brethren in the trade, they would do much more to advance prices, not only in their own locality, but throughout the country.

J. M. FAIRLIE.

Glasgow, June 9th, 1874.

Sir,—The letter of "A Country Major Associate" in last week's issue of the PHARMACEUTICAL JOURNAL will, doubtless, find an echo in many a domicile where pharmacy is practised; although I doubt whether the object sought by your correspondent will be attained in the present century; and I justify my opinion by the last paragraph but two in C. M. A.'s letter.

When C. M. A. and the rest of us have the courage to back our opinions, *at the risk of loss to ourselves*, then the object sought will have been attained: then, and not before.

NISI PRIUS.

J. E. G.—(1) *Glaux maritima.* (2) *Spergularia marina.* (3) *Lotus corniculatus.*

A. Young.—*Cassia lanceolata.*

C. Davies.—(1) The Preliminary examination must be passed at some time previous to going up for the Minor examination, and it is advisable that it should be passed before the apprenticeship takes place. (2) The examination is intended as a test that the candidate has received a moderately fair education in English, Latin, and Arithmetic, subjects that are well taught in too many books to allow of any being particularly specified. (3) This is a matter for arrangement between the contracting parties.

J. A. C. B.—No; since the bye-law says that "after the 31st day of December, 1874, no person shall be admitted to the Major or Minor examination who shall not have attained the full age of twenty-one years."

C. F. Passmore.—A paper on the preservation of plants for herbaria was given in the PHARMACEUTICAL JOURNAL for March 21st, p. 754.

F. W. Yeats.—After the 31st of December, 1874.

"Devonshire" Permanganate of potash is not a trustworthy test for the presence of organic impurity in water. See Wanklyn's "Water Analysis," published by Trübner.

C. Gerring.—The florets of the ray are tubular but irregular; they are also barren, but those of the disc have both pistil and stamens. The black-looking upper portion of the florets of the disc, consists of the syngenesious anthers, which form a tube through which the style protrudes. If you examine a fully expanded flower you will find all these parts.

E. S. M.—Yes; the action of the hydrochloric acid has, we think, been overlooked by the prescriber.

"Ratæ."—(1) Pages 377 and 435 of the present volume. (2) Much would depend upon what the name is.

M. Jones.—*Hypericum hircinum.* The plant is not indigenous to Britain.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Rimmington, Mr. R. H. Parker, Mr. Brown, Mr. Guyer, "Inquirer," "Crinis," "June," L. S.

VEGETABLE POISONS AND THEIR ANTIDOTES.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

(*Continued from page* 995.)

Opium.—The symptoms of poisoning by opium commence with giddiness and stupor, which rapidly increase until the person becomes motionless and insensible, the breathing becomes slow, and the pupil of the eye contracted ; as the poisoning proceeds the features become ghastly, the pulse imperceptible, and the muscles exceedingly relaxed, death generally ensuing from six to twelve hours after taking the poison.*

Cases of Recovery.—In a case of opium poisoning, recorded in this journal,† in which coma had set in and a fatal prognosis was almost certain,—the child being two years old,—fifteen minims of tincture of belladonna were given every twenty minutes. In an hour after the fourth dose, the child was to all appearance well.

In another instance, mentioned in the *Lancet*,‡ in which a quarter of a grain of atropine was injected into the arm hypodermically, consciousness was regained in eight hours, and perfect recovery took place.

In the *Medical Times and Gazette*, vol. ii., 1872, p. 268, eleven cases of recovery from opium poisoning and one failure, by the use of atropine, are recorded by Dr. Johnston. It is only right to state however, that on p. 342 of the same volume, Mr. Burness criticizes Dr. Johnston's cases of cure, and quotes Dr. Harley's opinion that the evidence of the antagonism of opium and belladonna is inconclusive. On p. 175 of vol. i., 1873, of the same journal, Dr. Johnston gives five cases of failure by the use of atropine as an antidote. In some of these cases death appears to have resulted rather from exhaustion than from the action of opium. Mr. Burness also remarks that he thinks the dose of atropine used was too large. Dr. Johnston further states that upwards of three hundred cases of opium poisoning have come under his observation, and that he knows of no other remedy which produces such marked effects as atropine used hypodermically, when the coma resulting from opium poisoning has set in ; while he has found that emetics, followed by the use of strong coffee and stimulants, are generally effectual in milder cases.

Other antidotes have also been used. A negro boy who had taken an overdose of morphia, and had fallen into the comatose state, was cured within an hour by the use of eighteen minims of Norwood's tincture of *Veratrum viride*.§

Mr. Burness‖ states that Mr. F. J. Mavor has found by repeated experiments on horses and dogs that opium is a certain antidote to strychnia, and recommends the trial of strychnine as an antidote to opium.

Antidotes.—From the evidence above given, it would appear that belladonna in the form of atropine has been successful in the greatest number of cases, and that its use as an antidote to opium deserves further experiment. In all ordinary cases, emetics, followed by the use of strong coffee and stimulants, are the best antidotes; but in dangerous cases, in which coma has set in, doses of belladonna, repeated at intervals until the pupils begin to dilate, must at present be regarded as the best and safest antidote to opium.

More deaths have been caused by opium and its preparations than by any other vegetable poison. Notwithstanding the fact that the above supposed antidotes are known, we have no record of their trial in the thirty-three cases of poisoning by this drug, which have been recorded in the pages of this Journal during the years 1870-1872.*

Belladonna.—The symptoms of poisoning by belladonna are dryness of the fauces, with a sense of constriction of the throat, flushed face, nausea, full, hard, and frequent pulse, mirthful delirium, hallucinations, dilatation of the pupils, convulsions, coma, and death in about fifteen hours.

Cases of Recovery.—A child aged six years recovered in three hours from poisoning by a drachm of *Succus Belladonnæ*, by the use of twenty drops of laudanum given every half hour until six doses had been given.†

A person, aged thirty, had been poisoned by the hypodermic injection of atropine ; in this case, laudanum, given in one drachm doses, caused complete recovery.‡ In a third case, in which six grains of extract of belladonna had been taken by mistake, two doses of thirty drops of laudanum were followed by complete reaction and convalescence.§

In a fourth case, symptoms of poisoning, induced by the hypodermic injection of nine milligrammes of atropine, were treated and cured by the injection of thirty-seven milligrammes of hydrochlorate of morphia, without any other means being resorted to.

In the *British Medical Journal* a curious instance is related by Dr. Finney, in which an hypodermic injection of atropia and morphia was used. In this case symptoms of atropine poisoning were manifested, which were removed on the administration of a further quantity of morphia, showing that when the two drugs are administered together the one which is given in the largest dose will alone produce a poisonous effect. Three cases of recovery from atropine poisoning are recorded on the same page of this journal, by three independent observers, the recovery in each case being due to the use of opium preparations.‖

Another case is on record in which 1½ oz. of liniment, containing about 25 grains of extract of belladonna, and nearly half an ounce of laudanum, did not prove fatal, and the recovery was attributed by Dr. Cotter to the mutual counteraction of the drugs.¶

Probably many other cases have never been recorded which would tend to confirm this antidotal power, or throw further light upon the action of these two drugs when used together, as is often the case in liniments.

These cases seem to indicate that opium and belladonna act reciprocally as antidotes. It has been suggested that opium should be used in all cases of poisoning in which the pupils are dilated, and belladonna in those in which the pupils are contracted,

these symptoms being thought to be characteristic of a particular state of the brain.*

Stramonium.—The symptoms of poisoning by stramonium very much resemble those produced by belladonna and hyoscyamus, but the delirium is more furious than in either, while the determination of blood to the head is less than that caused by belladonna, although more than that produced by hyoscyamus. The pulse is not much altered, or, if at all, it is full and slow, rather than frequent and hard. Owing to the incessant motion, violent perspiration and intense thirst are often present. In fatal cases death generally occurs within twenty-four hours, from paralysis of the muscles of respiration.

Cases of Recovery.—On account of the comparatively rare occurrence of stramonium in this country, there are but few cases of poisoning by it on record. One case of recovery from stramonium poisoning by the use of opium was recorded in the *Druggists' Circular* for May, 1869, but as the paper is mislaid I am not able to give the particulars.

Antidotes.—Opium is said to be used as an antidote in India, where various species of stramonium are common. From the similarity between the physiological action of belladonna and stramonium, it appears probable that opium would prove the best antidote in severe cases, and emetics in milder ones.

Henbane.—Hyoscyamus affects the brain similarly to belladonna, exciting and perverting its functions, but there is little determination of blood to the head. The pulse is small, frequent, and irregular. Occasionally the delirium takes a ludicrous form. A story is related of some monks who ate the roots of henbane by mistake for supper. Those who partook of it were seized in the night with the most extraordinary hallucinations, so that the monastery seemed turned into a lunatic asylum. One monk rang the bell for matins at midnight, and of those who attended the summons some could not read, some read what was not in the book, and others saw the letters running over the pages like so many ants.

Antidotes.—Henbane does not often prove fatal, and an emetic is generally sufficient; but from the similarity of the symptoms produced to those of belladonna, it is probable that opium would prove useful in severe cases.

(*To be continued.*)

IODIDE OF BISMUTH AND POTASSIUM AS A TEST FOR ALKALOIDS.†

BY M. YVON.

The employment of the double iodide of bismuth and potassium has been indicated for the detection of alkaloids, but the value of this new reagent has not yet been sufficiently established. The author, in a note read recently before the Sociéte d'Emulation pour les Sciences Pharmaceutiques, describes a method for its ready preparation.

The preparation of the reagent by means of iodide of bismuth, obtained according to either of the processes given in Wurtz's Dictionary, and iodide of potassium, appears to present some difficulties, the iodide of bismuth not being entirely soluble in the alkaline iodide. But it is not at all necessary to use the iodide of bismuth, and the author gives the details of several alternative processes, but for various reasons adopts the following as the most convenient :—

Take of—

Subnitrate of Bismuth . . .	1·50 grams.
Iodide of Potassium . . .	7·00 ,,
Hydrochloric Acid	20 drops.
Water	20 grams.

The subnitrate is suspended in water and boiled, and the alkaline iodide and the acid are then added. A limpid solution is thus obtained of very fine orange-yellow colour, which may be readily used as a test for alkaloids.

If one drop of this solution be poured into water, a white precipitate is produced, resulting from the decomposition of the salt by the water. This decomposition may be avoided by the addition of a few drops of an acid, the author preferring hydrochloric acid for the purpose. It is not indifferent whether the acid be added to the reagent or to the solution to be tested for an alkaloid; 4 drops of hydrochloric added to 40 or 50 c. c. of the latter being sufficient to prevent the decomposition, but a much larger quantity is required if added to the iodide reagent.

If the solution be not sufficiently acid, the decomposition takes place after some minutes, instead of occurring immediately. But the more or less deep orange-yellow precipitate resulting from the presence of an alkaloid may be confounded with the pale yellow product of the decomposition of the iodide by water.

Prepared in the above manner, this reagent deposits after some time a blackish powder which is easily recognized as iodide of bismuth, and may be removed by filtration.

The alkaloidal precipitate does not appear to present a constant composition, it seeming to vary according to the proportion of acid present in the solution. Thus, for example, in precipitating quinine from a solution of its sulphate, if only sufficient acid be added to prevent the decomposition, a beautiful orange-red precipitate is obtained; but if there be an excess of acid, the precipitate is paler and diminished in volume.

Since, therefore, the nature of the precipitate varies, and the composition of the reagent itself also changes, M. Yvon considers it would be impossible to use the double iodide of bismuth and potassium as a volumetric test; but it would be useful for the detection of alkaloids where the precautions indicated are taken.

ACTION OF CAMPHOR ON PLANT LIFE.*

In the year 1798, Benjamin Smith Barton described two experiments as to the stimulant action of camphor on plants. One was made on a tulip, which, placed in a solution of camphor, showed vigorous growth, and was longer in withering than other tulip slips of the same kind, placed in ordinary water. The other experiment was made on a withering yellow iris; through treatment with camphor it seemed, for some hours, endowed with new life. Barton came to the conclusion that camphor has a greater action on plants than any other known substance; and he compared its action to that of spirituous liquors, or of opium, on the human body, when taken in certain quantity.

These almost forgotten experiments of Barton's have been repeated, in new forms, by M. Vogel, of Munich; and they have a considerable theoretic interest. This author, who has recently communicated his results to the Munich Academy, obtained a homogeneous solution by rubbing camphor with water, and shaking camphor powder in a flask with distilled water. Two branches (alike in size and similarly conditioned) of a flowering syringa were then introduced, one into ordinary water, the other into the camphor-water. Considerable differences soon appeared: in twelve hours the branch standing in pure water drooped and was near withering; the other branch in camphor-water stood upright, and without any sign of withering—some of its buds were even developed; it was not till three days after that this branch began to wither.

* Pharmaceutical Journal, vol. iv., p. 80.

† *Répertoire de Pharmacie*, vol. ii., p. 335.

* From the *Gardeners' Chronicle*.

In another experiment, a flowering branch of syringa, which was nearly dead, was placed in the camphor-water, and a marked renewal and recovery was ere long observed, which lasted some time. Frequent repetition of the experiment with branches of syringa showed the same result in varying degree. The camphor-water seemed to have less effect on vine-shoots, and almost none on *Sambucus nigra*.

The action of camphor on cut branches of living and fully developed plants having thus been established, at least for some species, the idea naturally occurred that camphor must also have an influence on the process of germination of seeds. With this view, several seeds of *Lepidium sativum* and various other plants were taken for treatment, and they were mostly old, as the germinative force in such appears to be weaker than in fresh seeds. The seeds were spread out on some moistened blotting-paper covering a porcelain plate, and a second moist paper was put over them. In all cases the seeds thus treated with ordinary water and with camphor-water were exactly in similar conditions as regards temperature and access of air.

For the first experiments, seeds of *Lepidium sativum* of the years 1869 and 1871 were taken. The entire duration of the germinative force of *Lepidium sativum* is known to be three years. The seeds of both the years mentioned, treated which ordinary water, showed a very imperfect, retarded germination, while the seeds moistened with camphor-water germinated very soon—those of the year 1869 in twenty-four hours, those of 1871 in seven hours. A similar acceleration of the germinative process has previously been observed in treatment of seeds with chlorine.

A further experiment was made with different kinds of *Raphanus sativus major*, the seeds being of the year 1866. As the duration of germinative force of this seed is three years, or four at the most, the sowing of the specimens in a garden would, of course, have been thought useless. Treated with camphor-water, however, the seeds germinated in four days, and thus some days earlier than fresh seeds under favourable circumstances.

Seeds of *Pisum sativum* of the season 1865 showed in forty hours, under treatment with camphor-water, all the phenomena of the germinative process. Apart from the fact that *Pisum sativum*, even under the most favourable conditions, first begins to germinate after four or five days, the duration of germination of the seed is two, or at the most three, years; so that seeds of the year 1865 could no longer be sown with advantage.

With like rapidity seeds of *Cucumis sativus* germinated under action of camphor-water. In ordinary cultivation of this species of seed in garden ground, not a single grain, out of a large number sown, showed the slightest germinative movement after a long time. The example is thus a striking evidence of the peculiar action of camphor in revival of germinative force of some species of seeds.

The following flower seeds were examined in their relation to camphor-water :—*Schizanthus pinnatu*, of the year 1869, *Maurandia Barclayana, Coreopsis, Ipomopsis, Senecio elegans* of the year 1860, *Silene pendula, Silene amœna* of 1867, *Basilicum, Myosotis alpestris* of 1866, aster species of 1868, *Celosia cristata* of 1867. In all of them a remarkable influence of camphor on the germinative force was perceived. The after development of some of the seeds that were treated with camphor was observed by Dr. Raob, the seeds having been put into the ground. It is interesting to know that the traces of the camphor treatment were here also visible, the young plants showing greater vigour and freshness.

From all these facts, M. Vogel draws the inference that we have in camphor a kind of stimulant for vegetation, capable both of strengthening the force and accelerating the time of vegetation.

There are cases, however, it appears, in which the favourable action of camphor is not observed. Thus M. Vogel found that clover seeds, which in garden soil germinated in twenty-fours hours, showed no signs of germination after a longer time, when the earth had previously been mixed with camphor powder.

As oil of turpentine acts like camphor on the animal organism, M. Vogel made some experiments as to the action of water containing oil of turpentine on plants. The general result was, that this solution also accelerated the germinative process. But there was here, as evidently, an injurious action on the after development of the plants. Even in a few days the progress of the quickly developed seed ceased, and the plant deteriorated.

M. Vogel remarks in conclusion, that the process of germination, receiving of oxygen, and giving up of carbonic acid, is identical with animal respiration. From the agreement of the vegetable process in the early period of germination with the animal processes, the thought arises that precisely in reference to this, stimulants are possible whose action resembles the known stimulants of animal life.

THE SPECIAL COMMITTEE ON THE ADULTERATION ACT.

At the sitting of this Committee, on Wednesday, June 10, Dr. Cameron, the analyst for Dublin and sixteen Irish counties, gave some interesting evidence, being examined the whole day. With regard to drugs he was not examined at any length, but mentioned incidentally that they were beginning to take up that subject in Dublin. He had made several examinations of drugs, and had found a good deal of adulteration. He believed some drugs were adulterated in England and sent over to Ireland by the wholesale firms. Scammony and drugs of that kind—indeed the subject generally—had not attracted very much attention in Ireland. No doubt some drugs deteriorated by being kept—extracts, tinctures, and so on. The use of methylated spirit of wine, instead of pure spirit, was practised in Ireland to some extent. There were certain drugs imported into this country which were not absolutely pure: they were mixed with certain articles in foreign countries. Opium was constantly adulterated in the East. Absolute purity was almost impossible, many drugs being almost always impure, without any intention to defraud on the part of the buyers. In some cases he thought there was no intention to defraud on the part of the dealers abroad, the adulteration being accidental in the collection or gathering. Scammony had been adulterated to the extent of 60 or 70 per cent.—that was very extensive. It was usually adulterated with woody fibre, plaster of Paris, etc. Twenty or thirty per cent. was about usual. It was possible to get pure scammony; it was merely a question of price.

Dr. Stevenson Macadam, was questioned briefly about drugs. He had not given special attention to drugs, but he had reason to believe that the drugs in Edinburgh were as pure and strong as those sold in London. There was no danger of a physician giving an overdose to any one, from the prescriptions being made up in different parts of the country. Previous to the British Pharmacopœia there were certainly great differences, and in the case of prussic acid there were two different strengths, so that prescriptions would vary. That danger, he believed, was obviated now. Some drugs very much deteriorated by keeping; and there were some drugs which, in their manufacture and collection, would naturally contain certain impurities. He thought that the analysts were in some cases incompetent, and sometimes not adequately paid. It was very difficult to analyse drugs properly: the process was complicated, requiring some time, and the analyst he thought was not very highly paid for it. In reply to Mr. Muntz, the witness stated that possibly there were inferior druggists both in London and Edinburgh. Prescriptions might vary, more especially in medicines containing opium, which would depend upon the kind of opium which was

selected in making the laudanum and the proportions. In the average of best opium the proportion of morphia was about ten per cent. He could quite understand that serious consequences might arise from variations in prescriptions; and it was very desirable that all these medicines should be of the same strength, and that there should be a standard of purity with regard to the active principle contained in them. In reply to Dr. Brady, the witness stated that all men engaged in the dispensing of medicine should undergo some examination. That would have reference to every one making up prescriptions. Since the British Pharmacopœia had been established, the prescriptions were all dispensed in the same way all over the kingdom, so far as he was aware.

Dr. Tidy being examined, said that the adulteration of drugs was a very serious matter, especially as regarded some drugs. As an illustration, he mentioned tincture of opium. He purchased eighteen samples of tincture of opium, and found that some samples were three times the strength of others. In medical practice they knew how much depended upon tincture of opium, and there should be a uniform strength for an article of that kind. In *delirium tremens* their whole trust was upon opium. By proper opium, they could get sleep; if not, the man died. It was most important that the article should have a definite strength. He did not mean to say tincture of opium was done wilfully. In some cases opium contained more water, the weighing made a difference, and in some cases it contained more active principle: this would account for the variation. In fact, the active ingredients varied largely. It was a difficult question to decide how there could be uniformity in opium secured to the public, but he would make a suggestion upon more consideration, and give it to the Committee.

Dr. Voelcker was examined before the Committee on Monday last. He expressed his opinion that it would not be desirable to fix standards of purity for all articles of food, his idea being that each particular case should be determined upon its own merits. Prior to the passing of the Adulteration Act, milk was largely adulterated with water; but since the Act came into operation, a great deal of such adulteration was discontinued. Occasionally milk might be found coloured in the same way as butter and cheese were coloured. The analysts, he thought, had been too hard upon the vendors of milk, and, in making their analyses, had not sufficiently allowed for the variations incident to milk. He had analysed some Australian butter—that was to say, butter called Australian, but manufactured in this country. It was very bad, and largely adulterated with bone fat. "Dutch" butter was made of American lard, with a certain proportion of genuine butter, and coloured by annatto. Pure butter varied more in quality than in composition. It was certainly difficult to distinguish between butter and other fats, and it had been to him a subject of some astonishment that analytical chemists could make such positive statements with regard to the adulteration of butter with other fats. The use of alum by the bakers had greatly decreased since the passing of the Act. Relative to the question of cocoa, he said pure cocoa was rarely sold. People preferred the mixed cocoas, and also mixed mustard; and, in his opinion, mixed cocoas were not indigestible—rather the reverse. As to corn-flour, he did not agree with the statements of one witness that it was an article which contained no nutrition. He did not consider the "facing" or colouring of tea an adulteration. The practice of colouring articles of consumption was so great that the dealer had to meet the requirements of the public in this direction. The whole question of colouring was one of considerable delicacy, because if it were allowed in one article it could not very well be condemned in another. If the colouring were harmless, and did not mislead the purchaser, he should not like to condemn it. The result of his analyses of tea had been to show that tea was not adulterated. Generally speaking, with regard to the analysts, he did not think they had efficiently performed their duties. Many of them were incompetent, inexperienced in their work, and lacking in chemical training. Therefore, they sometimes made assertions which were flippant and unwarrantable; and it was not desirable that the character of the trading community should be placed in such hands. If the Act were amended the analysts should be appointed, not by the local authorities, but by a central commission; and, in order that traders might not suffer from incorrect analyses, he suggested that the analysts should be better class, and more competent men than at present; that they should be fewer in number, and that they should be better paid. He did not think there would be any difficulty in procuring such men. They should devote their services entirely to the duties arising out of the administration of the Act. He might mention that his opinions upon this subject were wholly unbiassed. He held no appointment as public analyst, and was only anxious that the Act should not become a dead letter. With regard to certificates being given by chemists eulogizing certain articles as of surpassing quality, he considered the system objectionable, and had declined to give such certificates. It was desirable that there should be some central authority appointed, to which cases of disputed analysis might be referred. A great deal of injustice had doubtless been caused by the incompetence of the analysts. He could and would define the word adulteration for all the practical purposes of the Act, but there would be some difficulty in doing this if articles of food were to be treated in the strict sense as articles of pharmacy. Speaking generally, in the samples of human food which he had examined he had not found anything injurious to health. He thought that adulterated tea would be stopped from entering into consumption if it were examined in bond. He was of opinion that, if the thing could be done, it would be better to sell all articles of food in their pure state. He did not consider condensed milk an adulterated article, although sugar was added, and usually some of the cream taken off. In such an article as this and Liebig's extract, he did not consider them adulterated, because they were special preparations, and what might be considered adulteration would be the particular excellence of the food.

Mr. J. Barringer was next examined as to "facing" tea in this country. He said he had "faced" a good deal, but since the decision in the Court of Queen's Bench in the Birkenhead case to the effect that green tea was an adulteration, he had ceased to "face" or colour tea. The quality of the tea was not in any way injured. He did not care to say what the colouring matter he used was composed of. He did not believe the facing of tea was injurious.

Mr. Horniman, the well-known tea-merchant, also gave evidence as to tea, but there was little or nothing new in what he had to say. He said his firm imported pure uncoloured tea from Java, Japan, and India, and a large proportion of the tea they sold was imported strictly pure. The uncoloured green teas were not so pleasing to the eye as the ordinary green teas of commerce.

JALAP BISCUITS.

M. Tambureau, a pharmacien residing at Guelma, Algeria, publishes the following directions for the preparation of biscuits containing the resin of jalap, which he says are of good appearance, and have an agreeable taste:—

Pure Jalap Resin	56 grams.
Powdered Sugar and Flour . . .	1000 ,,
Tincture of Vanilla	10 ,,
White of Egg	No. 20
Yolk of Egg	No. 40

Emulsify the resin with the egg yolks, add successively the sugar, tincture, and flour, and make a homogeneous paste, into which thoroughly incorporate the egg-whites previously beaten up. Divide the mass into 144 biscuits.

The Pharmaceutical Journal.

SATURDAY, JUNE 20, 1874.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACY IN IRELAND.

THE papers relating to the contemplated amendment of the law on this subject have, during the last few days, received a further addition in the shape of a circular, bearing the signature of Dr. J. MAGEE FINNY, the Registrar of the King and Queen's College of Physicians, and addressed to Dr. LEET, the Secretary to the Apothecaries' Hall of Ireland. In this letter Dr. FINNY replies, by direction of the College, to the objections* raised by the Governor and Company of the Apothecaries to the Pharmacy Bill of the College, which we placed before our readers some weeks since.†

It will be remembered, the proposition of the College of Physicians is simply to extend the English Pharmacy Act to Ireland, and that the objection urged by the Apothecaries' Hall is to the effect that this cannot be done, inasmuch as the provisions of that Act are throughout intended for Great Britain; special reference being also made to the circumstance that when the English Pharmacy Bill was before Parliament, in 1868, the Irish ATTORNEY-GENERAL successfully opposed a similar proposition to make it extend to Ireland for the same reasons.

The Registrar of the College of Physicians replies to this argument by pointing out that the proposal to introduce into Ireland, as pharmacists, duly qualified persons registered under the English Act, was nevertheless even then so favourably regarded that it was only postponed until such time as there had been opportunity to observe the working of the Act in Great Britain. In fact, when Mr. EYKYN withdrew his intended motion for an amendment of the Bill by which its operation was to be extended to Ireland, he did so only on condition of the Irish ATTORNEY-GENERAL undertaking subsequently to bring in a Bill to make the Act applicable to Ireland. The pledge given to that effect was not kept, simply because the ATTORNEY-GENERAL soon after went out of office.

Again, in the House of Lords, the desirability of extending the Pharmacy Act to Ireland was very thoroughly recognized. Lord VAUX, of Harrowden, pointed out that there were no chemists and druggists in that country in the sense understood in England, because the examinations required of dispensers of medicine in Ireland were so severe that persons would not practise as chemists; and he showed that there was, in consequence, great difficulty in getting a prescription made up in the small towns and villages. From communication with medical practitioners in Dublin, he had been satisfied by them that persons who were not apothecaries ought to be allowed to sell drugs, provided they underwent an examination suitable for ensuring competent knowledge and skill for that business. Lord GRANVILLE agreed with these views, and had no objection to the Bill being extended to Ireland. The Marquis of CLANRICARDE hoped also that the provisions of the Pharmacy Act would, in the following session, be embodied in another Bill to be made applicable to Ireland. Both the Duke of MARLBOROUGH and the LORD CHANCELLOR, at whose instance the extension of the Act to Ireland was abandoned, were unreservedly in favour of an uniformity in the laws affecting the practice of pharmacy in the two countries, and the course they actually took was instigated only by a regard to certain technical difficulties of the case which they thought would better be dealt with by a separate Bill for Ireland.

Considering these circumstances, there is good reason for the reproach conveyed by the College of Physicians to the Apothecaries' Hall for having omitted all reference to facts that were so opposed to the views they desire to support as regards the desirability of extending the Pharmacy Act of Great Britain to Ireland. We may also add that there are even more cogent arguments against the opinion that the Pharmacy Act is inapplicable to Ireland; such, for instance, as the fact that certain portions of this Act have already been extended to Ireland in the Act to regulate the sale of poisons in Ireland.

As regards the objection that the general extension of the Pharmacy Act to Ireland in the manner contemplated by the College of Physicians would deprive the Apothecaries' Company of its rightful control over pharmacy, and prove very injurious to the public, the reply of the College is a denial that the control exercised under existing laws by the Apothecaries' Hall is either "rightful" or justifiable in itself, or that it has been beneficial to the public.

In support of this denial, reference is made to the College of Physicians' Circular containing observations on the proposed Bill to amend the laws affecting the practice of pharmacy in Ireland, a *résumé* of which we gave in the PHARMACEUTICAL JOURNAL of April 18th.

Another objection urged by the Apothecaries' Company was that the proposed Bill would entitle physicians and surgeons to keep shops for compounding and dispensing medicine, without the possession of the necessary skill and knowledge. To this it is replied that the proposed Bill does not confer any such power on physicians and surgeons, as such. Section 1 of the Act 32 and 33 Vict., cap. xvii.,

* See PHARMACEUTICAL JOURNAL, *ante*, p. 847.
† *Ibid*, p. 879.

merely protects from penalties such "legally qualified practitioners" as "shall have passed an examination in pharmacy."

A third objection is that the Bill would introduce into Ireland a number of English chemists and druggists who have found a place on the Register without having undergone the course of study or the examination required under the Pharmacy Act. In answer to this it is stated that the Bill would only introduce into Ireland such chemists and druggists as are on the *Register of the Pharmaceutical Society of Great Britain*, and entitled by law to practice pharmacy in Great Britain.

The words we have put in italics clearly indicate the existence of some misapprehension, for the Register of the Pharmaceutical Society would be merely the roll of its members, and since the operation of the Pharmacy Act, 1868, is not in any way restricted to that body, the extension of that Act to Ireland would enable anyone on the Register of Chemists and Druggists to carry on business in Ireland, irrespective of their being memberss of the Society or not.

As to the supposed difficulty there might be in distinguishing English chemists and druggists from the unlicensed Irish chemist and druggist, the College of Physicians holds that since the Apothecaries' Hall and the Pharmaceutical Society would have full power to prosecute and punish anyone compounding medicine without being duly licensed by either body, their respective registers would at once afford the information necessary for the public to make this distinction.

In answering the objection that the proposed Bill makes no provision for candidates for the pharmacy license devoting time to acquiring a knowledge of practical pharmacy by a fixed term of apprenticeship or pupilage, the College of Physicians again falls into error in assuming that the Pharmaceutical Society requires, under its Acts, courses of study, and carries out a very searching examination in practical pharmacy. This is not the case, as our readers, we presume, are aware; and, however desirable such a system may be considered by some, the absence of any provision of this kind may fairly be urged to some extent as an objection to the suggested extension of the Pharmacy Acts to Ireland, where the license to practice pharmacy has so long been subject to the passing through such courses of study.

As to the supposed necessity for Irish students of pharmacy to go to England for their examination and qualification, there would not really be any compulsion of the sort, for if requisite the Pharmaceutical Society could appoint a Board of Examiners in Ireland, just as it has already appointed such a Board in Scotland, to examine candidates in that part of the United Kingdom. However, this step would not even be necessary in regard to Ireland, since the power of the Apothecaries' Hall of Ireland to examine and grant licences in pharmacy, is not interfered with in the Bill now proposed by the College of Physicians.

We have thought it desirable to place before our readers the foregoing information, since a Bill has just been brought into Parliament under the title of the Apothecaries' Licences Bill, to amend the law with reference to the licensing and practice of apothecaries, chemists and druggists, and it is to be read a second time on Tuesday next. From the general terms of the notice given it is impossible to say what may be the contemplated scope of this Bill, but we hope to be able, in our next issue, to furnish some definite information on this point.

PROPOSED COLLEGE OF SCIENCE AND LITERATURE FOR THE WEST OF ENGLAND.

On Thursday of last week the Mayor of Bristol presided over an influential meeting, held to promote the formation of a college of science and literature for the South and West of England and South Wales. The project has been the subject of discussion for some time. It may, however, be said to have first assumed a practical aspect about the beginning of last year; when the faculty of the Bristol Medical School, being about to establish themselves in new buildings, were met by the suggestion that the opportunity should be used, if possible, for the foundation of a Technical College of Science, of which the medical school might form one department. The movement met with the co-operation of Balliol and New Colleges, Oxford, in an offer of a yearly contribution of £300 from each for a period of not less than five years, upon certain conditions. The result has been the meeting last week, at which the Bishop of Exeter, the President of the British Association, Dr. Carpenter, Professor Roscoe, the Rev. Professor Jowett, and many other eminent gentlemen, were present, and at which it was resolved that the College should be established.

It is hoped that sufficient funds may be raised promptly, to allow the College to begin its operations in October, 1875; and it may be that some of our readers who look to the multiplication of such institutions throughout the country, for the future of provincial pharmaceutical education, will feel disposed to contribute towards so desirable an object. The views of the Council of the Bristol Pharmaceutical Association in respect to the proposed College are represented in the following resolution, which was read at the meeting:—"That, in the opinion of this Council, the establishment of a College of Science and Literature in Bristol is calculated to advance the objects of this Association (namely, the promotion of scientific pharmacy), by affording facilities for the study of those sciences upon which pharmacy is founded; and that the proposition to establish such a college is therefore entitled to the cordial support of the Association."

The professorships with which it is proposed to

commence are :—Mathematics ; Chemistry ; Engineering, including descriptive geometry and its applications, mechanical philosophy, and mechanism ; Mining, including geology, mineralogy, and the art of mining and surveying ; Greek and Latin, language, literature, and history ; English, language, literature, and history ; and those connected with the medical faculty.

CULTIVATION OF THE TEA PLANT IN ANJOU.

An interesting experiment in the cultivation of the Tea plant is reported to have been carried out in Anjou. The district is celebrated for the culture of the camellia, one horticulturist, M. André Leroy, having in his ground upwards of a hundred thousand of these plants. The suitability of the soil for the growth of camellias induced M. Leroy to try whether the kindred tea plant could not be raised, and he now has four or five hundred fine plants of *Thea viridis*, from eight to ten years old. They are all grafted on camellia stocks, and are planted amongst the camellias, which they greatly resemble. Each year, if the temperature has not been too cold, the extreme branches bear flowers and capsules ; the flowering takes place in April, and the seeds are ready for collection in October.

Of course it is an interesting question whether the tea produced in Anjou is as aromatic as that grown in China. Unfortunately it is not, as its infusion has not really any of the taste of tea. M. Meniere, of Angers, writing in the *Répertoire de Pharmacie*, is inclined, however, to attribute this to ignorance as to the proper mode of drying the young leaves, or, perhaps, to the absence of the more aromatic flowers of some other member of the Camellia family, which may be mixed with tea for the purpose of giving it flavour.

In an investigation for the presence of theine, and also of the quercitannic acid of Mulder, in the leaves of the Anjou plants, M. Meniere found the former of these substances in small quantity ; he has also met with tannic, gallic, and oxalic acids. But at present his experiments are not complete.

AN IMPROVED LAMP WANTED.

Aladdin's cry of "New Lamps for Old" is adopted in a slightly varied sense by the Council of the Society of Arts. The Gold Medal of the Society is offered for an improved lamp that shall produce a good, clear, steady, durable, and safe light, and be suitable for railway passenger-carriages. It must be simple in construction, and capable of being readily cleaned and repaired ; and, in judging of its merits, cost will be taken into consideration. Specimens, in a condition suitable for trial, should be sent to the Society's House, John Street, Adelphi, before the 1st of November next.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

At a meeting of the Council of this Association held on Monday evening, June 8th, Mr. W. Wilkinson, Vice-President, in the chair, the prizes awarded by Mr. Siebold in the Association's classes were presented to the successful competitors.

The following particulars of different courses were supplied by Mr. Siebold :—

Chemistry.

No. of Lectures delivered.	No. of entries.	Average attendance.	No. of Competitors for Prizes.
33	21	17	10

Materia Medica.

27	19	16	8

Botany.

20	23	19	6

Total number of entries 63
Total number of students 30

That these numbers were considerably smaller than last session was perhaps due to the fact that the fees had been nearly doubled.

The prizes, consisting of standard works on pharmaceutical subjects selected by the prize men, were then handed to them by the Chairman, who addressed a few words of congratulation and encouragement to each.

Chemistry . . . { First Prize, Mr. Naylor ; Second Prize, Mr. Unsworth.
Materia Medica { First Prize, Mr. C. W. Jones ; Second Prize, Mr. James Maxwell.
Botany . . . { First Prize, Mr. Naylor ; Second Prize, Mr. C. H. Hurst.

In reply to an enquiry as to when he found time to work up his subjects, Mr. Naylor, the first prize man in two subjects, said chiefly from 5 to 7 a.m.

The examination consisted of the following written questions, and the answers were, on the whole, very correct. In some cases, 90 per cent. of the possible marks had been obtained.

Chemistry.

1. Calculate in what proportion by volume NO and O must be mixed in order to form pure N_2O_3.
2. State how the carbonates of zinc, lead, and bismuth may be distinguished by tests.
3. Find the vapour densities of iodine, mercury, arsenious anhydride, phosphorus, alcohol, ether, and chloroform.

Atomic weights :

I=127, Hg=200, As=75, P=31, C=12.

4. State how you would convert metallic mercury into white precipitate, and explain the change by equations.
5. How is glycerine obtained?
6. Explain how pure nitrate of silver may be made from impure silver, such as coin.
7. Write down the symbols for the following compounds :

Sodium phosphate, sodium pyrophosphate, calcium hypophosphite, ferrous arseniate, potassium bichromate, borax starch, ferric phosphate, amyl alcohol, chloral hydrate, pyroxylin, platinum perchloride, gallic acid.

8. How much oxide of bismuth is obtainable from 1000 grains of the subnitrate?

Atomic weight of Bi=210.

9. What effect does chlorine produce upon acidum sulphurosum?
10. How may bromide of ammonium be prepared from bromide of potassium?

MATERIA MEDICA.

1. A mixture of 20 vegetable drugs is handed to you for examination, name the substances it contains.

2. Name the botanical sources, natural orders and habitats of the following substances: elemi, hemidesmi radix, oleum cajuputi, quassia, cusso, ergota, and maticæ folia.

3. How would you distinguish creasote from carbolic acid?

4. State the distinguishing characters of eusparia bark and the bark of *Strychnos nux vomica*.

5. How would you detect potato starch and wheat starch or other common kinds of starch in arrowroot?

6. Give short descriptions of true Vera Cruz jalap and true ipecacuanha.

7. How is elaterium tested for adulterations?

BOTANY.

1. Define the terms runner, offset, stolon, and sucker.

2. Describe the transverse section of a tree-fern.

3. Give definitions of a panicle and a cyme.

4. Explain the modes in which anthers may be attached to the filaments.

5. What is a perianth.

6. Define a capsule, a legume, and a pome.

7. Give a short description of the stem, leaves, and flowers of *Conium maculatum*.

Parliamentary and Law Proceedings.

PROSECUTION OF A CHEMIST AND DRUGGIST UNDER THE ADULTERATION ACT.

ALLEGED ADULTERATION OF SCAMMONY.

On Wednesday last, June 17, Mr. Cocks, chemist and druggist, of Chancery Lane, appeared before Mr. Vaughan, at Bow Street, in answer to a summons, charging him with selling adulterated scammony powder. Mr. Jenkins appeared on behalf of the Strand Board of Works, in support of the summons, and Mr. St. John Wontner for the defence.

Mr. Jenkins: I appear for the Strand Board of Works, in support of the summons issued against the defendant, who is a chemist, at 88, Chancery Lane, and who is summoned for having sold to the Inspector appointed by the Strand Board of Works, under the Act, a small quantity of scammony powder. It is a purgative drug, I believe, and I have the report of the analyst, who is also here himself, that it is adulterated with a small quantity of flour and chalk. I will first call the Inspector.

(*Frederick Taylor, sworn. Examined by Mr. Jenkins.*)

Are you the Inspector appointed by the Strand Board of Works, under the Adulteration Act?—Yes.

On the 28th of last month, did you visit the defendant's shop?—I did.

Where is it?—88, Chancery Lane.

You made a purchase there?—I did.

What did you buy?—Two drachms of scammony powder.

Mr. Jenkins: What did you pay for it?—1*s*.

Who served you?—An assistant of Mr. Cocks.

When you requested to be served with the scammony powder, what observation did you make to the chemist?—After I purchased it, I told him it was to be analysed; not until after I had possession of it.

Did he make any observation?—I believe he did say he was sure it was pure.

Having made the purchase, what did you do with the article you had purchased?—The following morning I took it to Mr. Piesse, the analyst, and gave him a portion of it.

The analyst appointed by the Board for the Strand District?—Yes.

And you received from him this certificate?—Yes, some days afterwards.

Mr. Vaughan: How much did you hand to the analyst About half; one drachm, or as nearly as possible.

In the same state in which you purchased it?—Yes.

[The certificate of the analyst was put in and read, stating that the scammony powder examined was adulterated to the extent of about 8 per cent. by the addition of about 5 per cent. of flour and about 3 per cent. of chalk.]

Cross-Examined by Mr. Wontner.

I may take it that personally you know nothing at all about this drug?—No, nothing whatever.

Perhaps you know what it is used for? No, I do not even know that; in fact I never heard it named before.

By whose instructions did you go to the defendant's shop?—General instructions.

In what way; do you mean that you were directed to visit every chemist's shop?—Every one in turn.

In the whole district?—Yes; every chemist in turn, the same as any other tradesman.

Were you instructed at all what representation you were to make to obtain the drug?—Simply this, that after I had purchased the article I was to say what it was for.

That is not what I asked you. I asked you if you were instructed what to say in order to get it?—I was instructed to get a certain quantity of a certain drug called scammony.

And to get it as best you could?—To get it as pure as I could.

Was the way in which you got this by representing that you wanted it for a doctor who was out of it?—No.

Be a little careful; did you not say when you went into the shop that you wanted it for a doctor who was out of it?—I did not.

That you swear positively?—I can swear it positively.

Were you told by the assistant who served you that it was not at all an article that was usually sold over the counter, and that he did not know what to charge you for it?—He must have known what to charge me for it, because he showed me a list of prices.

You know that is not what I asked you. I asked you whether he did not tell you that it was an article not sold over the counter, and that he did not know what to charge for it?—Yes.

Did he or did he not say so?—He did say so.

Did he refer to the invoice to see what he ought to charge you for it?—No, he went to the invoice to see what his employer paid for it wholesale.

So that he did not know what to charge you?—No not exactly, I believe.

He charged you 1*s*.?—Yes.

Did you tell him at the time that it was very dear, and that you had not paid more than 6*d*. anywhere else?—No, I did not.

Did you tell him it was very dear?—I told him that it was very dear, and that I had not paid more than 9*d*. anywhere else.

Did you tell him that you had paid 6*d*. at some places?—No.

Did not he tell you that they sold nothing but the very best articles, and therefore charged the best prices?—Yes, he told me that.

You were evidently surprised at the price you had to pay for it?—No, I am surprised at nothing.

Then you are a happy man. You gave it to the analyst, did you?—I did.

How many other samples have you got?—Am I bound to answer that question?

Yes?—Two.

Only two?—No, three.

That made four altogether?—Four altogether.

Did you take out the summons?—I did.

By whose instructions?—By the instructions of the Board.

Did you communicate with the analyst after you had taken it out—did you tell the analyst you had taken it out?—Yes, certainly.

When you told the analyst you had taken out the

summons, did not he tell you you had made a great mistake ?—No.

Did not he tell you that this was as pure virgin scammony as could be got in the market, and that you had made a great mistake ?—No.

You mean positively to say that ?—I do.

Did he make no remark to the effect that it was as pure as it positively could be imported ?—He did not.

If he has not said it to you, are you aware that he has said it to others ?—I cannot say that.

Mr. Vaughan : You will have an opportunity of asking the analyst.

Re-examined by Mr. Jenkins.

Is there the smallest pretence for asking you whether you obtained this drug by any subterfuge ?—No.

It is a perfectly gratuitous suggestion ?—There was nothing of the sort at all. I went in my uniform.

Mr. Wontner : It will be for the magistrate to say whether it is gratuitous, because I shall call the assistant.

Mr. Jenkins : You went as you are now, in uniform ?—Yes, as I am now.

(*Charles Henry Piesse, sworn. Examined by Mr. Jenkins.*)

Where are your chambers ?—303, Strand.

You are the analyst appointed by the Strand Board of Works for the district ?—I am.

Do you recollect, on the 29th of last month, the last witness bringing you certain samples of scammony powder ?—Yes, I do, on the 28th or 29th, I forget which day it was.

Do you recollect the one numbered 237 ?—Yes, I do.

About what quantity did he give you ?—About one-eighth of an ounce, I think.

With the request that you would analyse it ?—Yes.

In your capacity as analyst to the Strand Board of Works ?—Yes.

And you did effect that analysis ?—I did.

That is your report ?—Yes, that is the report I handed in on the 8th inst.

That correctly states the ingredients you found in the scammony ?—It does not give the result of the complete analysis, it merely points out the ingredients which ought not to be there.

But did you find 5 per cent. of flour ?—Yes, about 5 per cent. of flour, and about 3 per cent., or rather more, of chalk.

Are those substances inherent in scammony ?—Not at all.

Mr. Vaughan : What is scammony ?—Scammony is a peculiar gum resin.

A gum, is it ?—A gum resin.

Mr. Jenkins : Can you tell us what percentage of resin you would expect to find in pure scammony ?—About 80 per cent. ; sometimes more than that.

The other 20 per cent. consists of foreign substances ?—Yes, foreign substances which are natural to the gum.

Fibrous matter and that kind of thing ?—Just so, vegetable tissue and so on.

Is it a fact that flour and chalk must have been imported into the gum as an adulteration ?—Yes, they must have been added to it.

Scammony powder is an active purgative, is it not ?—Yes.

Cross-examined by Mr. Wontner.

Are you a pharmaceutical chemist, or simply a pure chemist ?—A pure chemist.

It is no part of your business to know the results of the drug, medicinally, at all ?—Not absolutely ; I merely know the effect of certain drugs.

You say that flour would not be inherent in scammony. Do you know that starch is inherent in scammony, and very largely ?—I know that all plants contain, or yield, or can be made to yield, varieties of starch, but I do know that scammony powder does not contain wheaten flour —it ought not to, at any rate.

Before we get to scammony powder, let us see if we can make the magistrate understand what scammony itself is.

Mr. Vaughan : He said it was a gum resin.

Mr. Wontner : Your worship will hear directly what it is. Is scammony a convolvolus, growing in Asia Minor ?—The plant is from which it is obtained.

Is the trade principally carried on by the natives of Asia Minor, Greeks and Turks ?—To the best of my knowledge, it is.

Mr. Jenkins : How can he know.

Mr. Wontner : I presume that, before taking out this summons, the Board of Works——

Mr. Jenkins :——Did not send to Asia.

Mr. Wontner :——Took some trouble to see what scammony is, and all about it ! I am endeavouring to get at what it is.

Mr. Jenkins : My witness has not been to Asia, and he does not know.

Mr. Wontner : I presume he has studied works, which are plentiful enough, as well as other people. Do you know that when found by the natives, first of all the leaves and branches are cut off, then the trunk is sliced off, a hole is dug round, and into the plant is fastened a shell, with the view of catching the gum as it runs out ; do you know that ?—I know it in so far as books tell me that that is roughly the process which is adopted.

Mr. Jenkins : My friend may produce any books to show that, but this gentleman cannot know.

Mr. Wontner : I will produce books enough presently.

Mr. Vaughan : I do not know at all to what point the cross-examination is directed. It may be contended, and I suppose that is the object of it, that these ingredients which are mentioned as an adulteration in some way or other get into this bowl or shell, which is put there to catch the gum.

Mr. Wontner : I shall show conclusively, presently, that the prosecution have commenced these proceedings without taking the trouble to inquire what the scammony is.

Do you know that that is a scammony root (showing a specimen to the witness) ?—I cannot say that I know that particular piece.

I do not say that particular piece. Have you any doubt that is scammony root ?—I should have very little doubt.

Do not you know that when found, the native digs a hole round this root, leaving a small space uncovered exposed to the air ; that then it is sliced off at the top, and at some prominent part of the root a mussel shell is placed for the purpose of catching the scammony juice as it exudes. Do not you know that that is the way in which it is got ?—It believe it is done so, but sometimes they do not put the shell there.

Where does the juice go then ?—It simply goes out into the hole.

On to the bark ?—Yes.

And then is scraped off with a knife ?—No ; with a shell.

I presume you would expect to find a considerable quantity of bark mixed up with the juice ?—I should, decidedly ; I should expect to find about 20 per cent.

Of bark ?—No ; but of foreign substances, not actual scammony resin.

Do not you know, as a man of science, that the ordinary way is to stick a mussel shell into the stem or root, and to catch in that shell the juice as it exudes ?—I believe that is the method usually adopted.

Do not you know that the soil in which this root grows is a light chalky soil ?—No, I do not ; I never made any examination of it.

You have not taken the trouble to inquire ?—I have not analysed it.

Do not you know that this resin or gum is extremely sticky ?—I believe it is, when it is fresh.

When it is coming out it would be then extremely likely to catch the dust from the sandy soil of Asia Minor ?—I suppose it would.

Do not you know it is the fact that a great variety of foreign matter that is found in the virgin scammony is the light dust which is caught by the gum as it is exuding and falling into these shells?—I have no doubt some portion of it is, but I know as a matter of positive fact that the whole of it is not.

Mr. Wontner: When it is caught in the shell, do you know what is then done with it?—It is then scraped out.

Do you not know that when it is scraped out, in order to manipulate and hold it, it is necessary for the natives to use flour or something so that their fingers do not stick to it?—I have heard it so stated, but not on any reliable authority.

Do not you know also that even when placed in the blocks, in which form it is imported, they are still so sticky that they are obliged to put a coating of flour, or something of that sort, over them so as to prevent one sticking to the other?—I cannot say, they may do so, I am not prepared to swear.

Mr. Vaughan: Have you any knowledge about it?—I have a knowledge that, in general terms, what this gentleman says is perfectly correct; that is, that they do use or must use some pulverulent substance to prevent the blocks of resinous sticky gum from sticking together.

Might not that be wheaten flour?—It might be wheaten flour; but I say also that there is such a thing as scammony without wheaten flour which is pure scammony.

Mr. Wontner: There is such a thing as scammony which contains 90 per cent. of the pure resin; but do not you know that that is only obtained in about the proportion of one cwt. in the year in the whole district. Do you recognise that as a sample of scammony? (Handing witness a specimen.)—That is not scammony powder.

I do not say scammony powder. This is scammony, is it not?—I am talking about scammony powder.

But if I ground this to powder, it would be scammony powder. I ask you whether this is not scammony?—It has the appearance of scammony, but I would not swear to it.

Do you mean to say that you know so little of it that you cannot tell?—That I decline to pledge my opinion to; I believe it to be scammony, but I will not swear that it is scammony.

Do you believe that the white coating you see on either side of this is wheaten flour, put over it for the purpose of preventing one block sticking to the other?—I do not believe it.

Have you any doubt of it?—I have no doubt; I do not believe it at all.

What do you think it is?—I am not prepared to say; it may be simply—it might be one of fifty things.

Now let us come to the scammony as imported into this country. Do you know as a fact that any adulteration, if adulteration there be, takes place abroad?—I believe so, I believe, almost exclusively, it is adulterated abroad.

Do you know that the finest scammony collected is collected by the Greek peasants, who are more industrious than the Turks?—I have heard it.

Do you know that the Turks, to avoid trouble, do not protect the juice as it is exuding, and therefore allow the dust to come upon it more than the Greeks?—I am not prepared to swear that I know that as matter of positive fact, I cannot say that I am acquainted with the relative working powers of Greeks and Turks.

You say you know the best produce is that collected by the Greeks?—No, I have not said so.

I understand you to say so. You do not know that even?—I do not admit I do not know it.

Have you read any books on the subject?—I have.

Have you not seen it so stated?—I have seen it, and I take it on the book's authority, not on my own. I do not swear to the authority of the books.

I do not suppose you have ever tried the trade. I am simply asking, have you gone to all the sources of knowledge that you could to obtain information?—I could have gone there.

Why did not you before taking this out?—I did not choose.

The only source of knowledge that you are in possession of, without going there, you say you have applied yourself to?—Just so.

Yet you will not positively say whether that collected by the Greeks is better than that collected by the lazy Turks?—It is generally admitted to be so so, but I do not commit myself to it absolutely.

Tell me what you would call the amount of impurity you would expect to find in the very best virgin scammony, as imported into this country, and to be bought in the market.—Does that include flour and chalk?

If you like. All impurities foreign to the matter?—The foreign matter natural to the gum varies, but is proximately 20 per cent.

I believe, not only in this but in other drugs you take the British Pharmacopœia as your standard, do you not?—Yes.

Do not you know that the British Pharmacopœia gives as the highest standard of virgin scammony from 75 to 80 per cent. of resin?—I believe that it is so stated.

Have you not looked in your standard work?—No, I am not a Pharmaceutical chemist; I say by book knowledge the quantity is about 80 per cent.

Do you not know, as a matter of scientific knowledge, as a chemist coming here to instruct the Court, that at least 20 per cent. is almost inseparable from the article from the very mode of collecting it?—Twenty per cent.

Twenty per cent. of substances other than actual resin?

Mr. Vaughan: What the witness has said is that the 20 per cent. is fibrous vegetable tissues.

Mr. Wontner: I am perfectly willing to take that what the witness says is correct. I am endeavouring to show from the mouth of the witness, that, apart from any vegetable tissue, it is absolutely necessary, in gathering and collecting this article, that there should be a quantity of other foreign matters.

Do you not know that it is inseparable from the collection, or the obtaining, if you like, of this particular article that there should be chalk, and there should be flour, and there should be starch in it?—I do know that it is not.

You think that actually the dusty soil, the grit, could run down the side, and run into shells of this description, and that there should be none of the dust caught by the sticky substance as it is running down?—Far from it; but I said that does not amount to 20 per cent.

I ask you in addition to the 20 per cent?—You asked me whether it contained flour, and I said certainly not.

I asked you originally whether you did not know that starch was an inherent part of this very root itself?—I know flour is not.

We will take starch first. Do you know that there is a large quantity of starch in every sample?—I do.

Do you know that starch would exude with the gum?—I should say it would be scraped off, and probably some of it would exude with the gum.

Do you not know that throughout the whole body of this there is starch?—I admit it.

Do you mean to say that, as it comes out, the starch would not come out at the same time?—Probably it would.

It would come out with the gum?—A mechanical operation.

Consequently it would flow into the shells with the gum, and would become a part of the general hard substance?—That would be part of the 20 per cent.

In addition to that 20 per cent., do not you know that there necessarily must be a quantity of light chalky dust with it?—I do not admit that.

Have you the slightest doubt it must be so?—I do not say chalky dust. I say any dust is included in the 20 per cent.

Take the chalky dust?—I do not admit it is chalk.

Mr. Vaughan: If you want me to believe that this chalk is in the soil, you must produce evidence of somebody who has been there and knows this grows in chalk.

Mr. Wontner: I do not know that I can bring anyone who has been there.

Mr. Vaughan: Unless you can prove that, it is no use going into the soil.

Mr. Wontner: I will drop that part of it.

Do you not know that the British Pharmacopœia, the standard which is held up to all chemists and druggists, fixes from 75 to 80 per cent. as the highest standard of virgin scammony?—I believe it does.

You, yourself, in your report, say that there is 5 per cent of flour and 3 per cent. of chalk?—About. I have not the result of my analysis with me, but I think it is something about 12 per cent of impurity in addition to that. Rather more. I do not commit myself to that.

Perhaps I can refresh your memory:—3 per cent. of chalk, 5 per cent. of flour; so much per cent. of moisture, etc., etc.—No, that was not it. I never put my results down like that. Impurity, 5 per cent. and the starchy substances natural to the gum made about 13½ or thereabouts.

Bringing it to about 18½ per cent.?—Just so, roughly, and I should say that the starch and flour were about 5 per cent., and the chalk about 3 per cent.

Leaving upwards of 73 per cent. of pure resin?—One-tenth of one part upwards of 73 per cent.

We will take it for the purposes of this case that there was 73 per cent. of resinous scammony in this sample?—Just so.

Do you not know, of your own knowledge, that that is a percentage which is rarely found in this country?—Upon the supposition that I admit it contained 80 per cent., and I found 5 per cent. of flour and 3 per cent. of chalk, in addition to the 80 per cent., I should hold it to be adulterated; no matter the percentage of resin, if the substances are there.

I ask you whether 73 per cent. and a little over, resinous scammony is not a very large percentage of resin to find in any article of the description introduced into this country?—Not this particular variety.

Did you not tell Mr. Francis that you considered this was a very good specimen?—I told Mr. Francis I should consider it a very good specimen of the scammony of commerce.

Did you tell him you thought they had made a mistake in taking out a summons?—I told him it was a case in which I should not have recommended a summons; but a summons having been taken out, there was ground sufficient to support it.

Did you tell him you would get into very hot water with the Pharmaceutical Society?—Mr. Francis told me that.

In consequence of the summons?—No, I certainly did not do that, for I do not care about the Society.

Do you know the French Pharmacopœia?—No.

You have never seen that?—I may have seen it.

You do not know what percentage it gives of the resinous scammony?—I should think it would be about the same.

And the American the same?—I do not commit myself to that.

Do you not know, as a matter of common knowledge, that 75 per cent. is a very high percentage of scammony as introduced into this country?—75 to 80 per cent. is the quantity allowed by the Pharmacopœia.

When this sample was given to you it was moist, was it not?—No, it was about the same as flour.

Did you dry it?—Certainly. I dried it to estimate the moisture. I could not estimate the moisture without.

Then you allow 5 per cent. for the moisture, and drying is part of the process of analysis?—I do not allow it.

You charge it in your report. Without the water, would there haye been about 78 per cent? Suppose, before testing how much resin there was, you dried it first, and then tested it afterwards, would you have found 5 per cent. more?—Five per cent. more on the 73.

So that by that you would have got 78?—Yes.

So that you would have arrived at something over the standard?—I am dealing with the sample as it is sold.

Do you not know, as matter of fact, that this light powder would naturally attract a certain amount of moisture if kept in a chemist's shop?—All powders do.

Do you not know it is impossible to prevent that?—That is why I estimated it.

However careful a chemist may be, it is impossible to prevent a certain amount of moisture attaching itself?—To any powder.

So that if you take the moisture away, you get 70 per cent. of resin?—Upon the supposition that the powder was given to me perfectly dry, and contained 80 per cent. of resin, if it contained 5 per cent. of flour and 3½ per cent. of chalk, I should report it to be adulterated, not because of the presence of resin, or the absence of it, but on account of the presence of flour.

Tell me how you found the 5 per cent. of flour?—I first weighed a portion of the scammony powder. I then extracted the resin, and the residue I boiled with a little sulphuric acid, until I knew that the starch had been converted into sugar.

That is to say you formed your opinion?—I knew it as matter of fact.

That is how you knew it?—That is how I did it.

By so doing you knew it?—Yes. I estimated the amount of sugar present by a solution known as Fehling's solution.

Do you know that the gum would act on Fehling's solution?—I know I did not give it a chance, I do not say whether it would or would not.

How did you separate the gum from the starch?—As I observed I separated the resin before.

There would be gum in the residue, surely?—Certainly not, how would there be?

I ask you whether there would not be gum?—I say no.

How did you get the resin out?—By extracting it by alcohol and ether.

Is gum soluble in alcohol and ether?—Yes, gum is a general expression. Do you mean gum arabic?

You know?—There is a gum there that is soluble.

You say it is soluble in alcohol and ether?—Yes.

You pledge your reputation to it?—Yes.

The gum?—I do not say gum is soluble, for this reason, that gum is a general expression—the particular gum resin.

What is the gum?—Gum resin.

That is the gum and the resin mixed up together which you separated. What is the gum which you separated?—Gum is the substance to which I am alluding.

Is all this gum resin (referring to a specimen)?—I should say that has got about 20 per cent. of impurity.

Is not part of the impurity gum?—Do you mean gum arabic?

You say there is so much impurity?—I do not understand the question.

Mr. Vaughan: By gum you mean the gum resin?—Yes.

Gum resin and gum are the same thing?—Just so.

Mr. Wontner: When you say there is so much per cent. of resin, you mean gum resin?—I might say so.

Do you mean it?—In this particular instance I do mean it.

Do you mean it only for this particular instance. Is that the opinion formed for this particular instance, or is that what you would say on other occasions?

Mr. Vaughan: It is with reference to this scammony.

Mr. Wontner: You say you have not seen these other Pharmacopœias, the United States and the French?—I have not.

Medicinally, do you know the qualities of this?—I know it is a purgative.

You know it is a purgative, and you know nothing beyond that. Do you know that the roots themselves are actually imported and ground down, and that the resin is extracted from the dry roots?—I believe it is.

As an article of commerce in this country, and as an article of manufacture in this country?—I believe so.

Do you know that pure resin so obtained can be sold at just half the price as what you call the adulterated resin as imported from Asia Minor?—No, I know nothing about prices.

Do you know, at any rate, that it is much cheaper?—I know nothing about the prices whatever, I do not keep a shop, and am not a wholesale druggist.

I presume you made inquiries when you took out a summons of this description?—I have not taken out a summons of this description.

You know nothing about pure resin, as extracted from the dry root when imported, being much cheaper than that—than when it is imported in this way?—I know nothing of it.

Do you know, as matter of medical knowledge, whether, in the profession, scammony so obtained is regarded as not half so good as that which is condemned here?—I believe it is stated to be not so good.

As a matter of fact, have you the smallest doubt that this starch and flour that you are complaining of was introduced into this scammony in the process of extraction from the root abroad, or in the process of manipulating it abroad, and making it up for the purpose of sending home?—I have very great doubt about it.

Examined by Mr. Vaughan.

Have you ever analysed scammony before?—I have.

Have you found these foreign substances which are found here, existing in that scammony which you have analysed?—Very frequently. It is a very common adulteration.

At all events, you very commonly find these substances in the gum?—Yes.

That is, the flour and the starch?—Yes.

And in the same proportions?—No; sometimes a great deal more. Other varieties of scammony contain the third of their weight.

This in fact would be a very good sample of scammony?—I should take it to be very good.

There is nothing of course injurious in any way in these things?—Nothing injurious to health, except it is deemed so by the Act.

I observe that you say you get sugar?—It is a known chemical fact that by boiling starch with diluted sulphuric acid the starch is converted into a variety of sugar called glucose.

Could you not get it from anything else?—You can get it from many other things, but in this particular instance, there was nothing there but the starch and the flour to yield it.

You could not detect the presence of it until after you had analysed it?—The detection of the actual presence of the flour was very simple, by looking at it with the microscope.

You are quite sure it was wheaten flour?—Yes.

How do you discover the chalk?—By the examination of the residue, after extracting the gum resin. The residue is an extremely fine powder, the same as the original substance, and upon treatment of that with acids it effervesces, and there are one or two other phenomena which identify the component parts of chalk.

Not from any microscopic observation?—No, chemical experiment.

Were these experiments of such a nature as to determine positively the presence of chalk?—Yes.

You could not confound the presence of chalk with any other substance?—No, I could not have done so.

Mr. Jenkins: That sir, is my case.

Mr. Wontner: Sir, I appear in this case on behalf of Mr. Cocks, who is a chemist, having carried on business in Chancery Lane for upwards of twenty years, I believe. He is a gentleman of the highest possible respectability, and against whom, before, there has never been the slightest suggestion made that he would sell anything but what was perfectly pure. At the same time, I appear on behalf of the gentlemen who supplied him with this particular article, Messrs. Hearon, Squire, and Francis, of Coleman Street, London. I shall have to call Mr. Squire before you, and probably Mr. Francis. I may say that Mr. Squire has had, probably, the longest experience of any man in the trade of this particular article, having been upwards of forty years in the trade, and having had this article under his notice during the whole of that time. It is not of course for me to say anything with reference to the Adulteration of Food Act. No doubt is is an extremely salutary measure, and although in the case of many prepared articles, such as the mustard of commerce, and cocoa of commerce, and the tea of commerce, and other things of that description, which are manufactures long known and well understood, the legislature thinks this Act is to apply when persons perfectly *bonâ fide* dispose of articles which they believe to be genuine, which they buy as genuine, which they do not adulterate themselves, and which if they are adulterated are adulterated before they come to their hands, and without their knowledge, no doubt the legislature in so deciding is wise, and, although at a great loss to themselves, the vendors of such articles must put up with the consequences. But I say it seems to me that the Act has gone quite far enough, and before it is carried any further, at any rate, the public authorities should take the trouble to inquire respecting the articles they are about to proceed upon before they take any such proceedings; and more especially so when the persons they proceed against are persons whose characters stand as high as that of any one in the land. I think the least they could do, especially in a case of this description, when they are treading upon unknown land, is to make themselves acquainted with the subject before they attack the character and reputation of persons whose character has hitherto been above the breath of suspicion. In this case I shall conclusively show you that this summons must fail, and it ought never to have been taken out. I shall show you that Mr. Squire, one of the firm of wholesale druggists who supplied this article to the defendant, went in the ordinary way upon the market, and, having a thorough knowledge of the article, bought it from the catalogue of the broker. There were a number of consignments from Smyrna; and I shall show you that he went in the market prepared to give the best price, that he did give the best price for his article, and that the article was tested by him afterwards and found to contain 80 per cent of resin, that being the maximum amount expected to be found even by the Pharmacopœia standard, upon which the government go in regard to these matters—the standard upon which the Pharmaceutical Society of England take their stand. It was ground and dried, and in the dry state there was 80 per cent. of resin, and in that dry state we sold it to the defendant. Mr. Cocks placed it in a bottle, and, as a matter of fact, this article is not sold at all over the counter. Scammony powder is not retailed, it is not used by one person in a million; and the only adulteration that could have taken place, if adulteration it is, must have been that this article when in the hands of Mr. Cocks was put into a stoppered bottle, and the stopper perhaps did not fit quite so tight as it should, the necessary consequence of which was that it would attract a certain amount of moisture, which would reduce it probably to the 73 and a decimal which is stated by Mr. Piesse, the analyst, to be the result of his analysis, that is to say, to be the amount of resin which he found. I shall show you conclusively that, from the time it left Mr. Squire's to the time it was sold over the counter to the Inspector of the Strand Board of Works, nothing whatever was done to it, and you will have positively, on oath from Mr. Squire, that when he tested it,

he being a chemist himself, having 40 years experience, having given the best price for it, it was of the character which I have stated to you. Although the article was obtained, I may say, surreptitiously, because the article, generally speaking, would not be sold to a private individual—

Mr. Jenkins: If Mr. Wontner is not going to prove that fact, he ought not to asperse the Local Board by stating it.

Mr. Wontner: If my friend wants me to prove it, I am in a position to do so.

Mr. Jenkins: I shall call upon you to prove it.

Mr. Wontner: I have the assistant here, and I shall call him if it is necessary.

Mr. Vaughan: I do not know that that is necessary for my decision.

Mr. Wontner: So it seems to me. However, the fact remains the same, whether it was obtained by a subterfuge or whether it was obtained in a perfectly legitimate manner. The article was purchased by Mr. Squire at the highest price, it was bought as an article that had been imported from Smyrna, from which part most of this virgin scammony comes. It was sold to a chemist of high reputation and good standing, and it never left his hands until it was handed over by his assistant to the inspector. During the whole of that time not the smallest addition was made to it, either for the purpose of fraudulently increasing its bulk, which is one offence under the Act, or for putting into it anything injurious to health, which is not here suggested. The article which you have here is really and substantially the same article that was bought by Mr. Squire. As soon as it came to the knowledge of Mr. Cocks that this was to be analysed, and that an analysis had actually been made, which he really did not believe at first, he went to the gentlemen from whom he had bought it, and they went to his bottle, and took a sample from the very same bottle. I have the sample here, or a portion of it. That was taken to Dr. Attfield, Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain. He analysed it, and although the analysis varied slightly from the analysis made by the analyst who has been called here to-day, I think I may say that he made 75 per cent., whereas the analyst only made 73 and a fraction. He will be called before you, and will tell you that from the analysis he made of this sample which was given to him, and which is the same sample that was analysed by Mr. Piesse, it is a sample of thoroughly genuine virgin scammony, and as good a sample as could be obtained—that it is more than a fair average sample. You will see by a return that I will produce, if necessary, that there are a very few pounds of the best scammony collected by the Greeks, who, it appears, are much more diligent and careful in collecting it, and so manage to get it with less impurities than the lazy Turks get theirs. For instance, in scraping the bark to get what is called the cream, which, it appears, exudes, a certain portion adheres to the side—

Mr. Vaughan: You suggested in your examination that you were going to call the partners.

Mr. Wontner: I shall call them both, and shall prove by them the actual way in which it is collected, as far as knowledge can be acquired from reading books upon the subject. You will have full information from both Mr. Squire and Dr. Attfield. They will tell you, as they instruct me, that it is a necessity from the very method in which this virgin scammony is obtained, that there should be so much chalk, and so much dust in it. As to the starch, Dr. Attfield will tell you that starch is largely present in the root, that it is an ingredient in it. It is impossible to obtain the resin without obtaining a large quantity of the starch, and that he would expect to find quite as much, if not more, than is spoken to by the analyst.

Mr. Vaughan: You had better call Mr. Squire.

(*Mr. Wm. Squire, sworn. Examined by Mr. Wontner.*)

Are you a member of the firm of Hearon, Squire, and Francis, wholesale druggists, 5, Coleman Street?—Yes.

I believe Mr. Cocks, of 88, Chancery Lane, is a customer of yours, and has been for many years?—He is.

I believe you, personally, have an experience of 40 years in the trade?—Yes, I have.

During the whole of that time, with this drug called scammony?—Yes, I have.

Did you supply him with the scammony in question, which is the subject of this inquiry?

Mr. Jenkins: How can he tell that?

Mr. Wontner: You did supply him with scammony powder—my friend disputes this particular sample.

Mr. Jenkins: I do not dispute it. I said he knows nothing about it?—Yes.

Mr. Wontner: Where did you get that?—I bought it in the usual manner, I bought it on the market and had it ground and powdered, and supplied it to Mr. Cocks.

Before supplying it to him, or to any one else, did you yourself test it?—I did. After the grinding was finished, I tested that and one or two other samples.

Mr. Vaughan: Do you buy it in the root?—Not this identical powder I supplied to Mr. Cocks.

You bought the gum?—I bought the scammony in the gum.

Can you tell the way in which this is obtained?—Merely from books.

We have the books here, but, without taking time to refer to them, will you shortly tell the magistrate how it is obtained?—At a proper season of the year an incision is made transversely just at the crown of the root and then a small vessel, generally a mussel shell, at least we imagine so, because we frequently find these mussel shells imbedded in the scammony, is inserted.

Mr. Jenkins: He is not telling us this from his own knowledge. Does not it come to this, that he has heard Mr. Piesse's evidence and substantially agrees with it? The only point I raise is, whether this flour is properly or improperly in this scammony.

Mr. Wontner: We are going to show how the flour gets in.

Mr. Vaughan: The question is, whether it is introduced in this country or introduced before. People are not to be made responsible for substances which get in in the preparation or the collection of the gum in Asia Minor.

Mr. Jenkins: I think the decision in the Queen's Bench the other day, would rather lead to the inference that they were.

Mr. Vaughan: You mean with regard to the tea?

Mr. Jenkins: Yes.

Mr. Wontner: That is a different thing.

Mr. Vaughan: I do not think those cases at all go to this.

Mr. Jenkins: I submit it is really a much more simple matter than the question of tea.

Mr. Wontner: It is so simple, that if the decision should be against us, no more scammony could be sold, and you will have to bear your pains of the stomach, and have no purgatives to take. Will you go on and explain the process?—At certain intervals, say perhaps once in 24 hours, these shells are cleared and the gum is collected. It is then a soft and sticky substance, and is dried in the sun.

Mr. Vaughan: You are now giving the result of your reading?—Yes.

What authority do you quote from?—Dr. Pereira, I think, gives it.

Mr. Wontner: Here is the United States Dispensatory, which gives an account of the process?—I only go from my own reading.

Mr. Wontner then read a passage from the book referred to, which stated that it was adulterated by persons called scammony makers; the materials employed being chiefly chalk or some kind of flour, and that very little, comparatively, was exported perfectly pure.

The Witness: You will find the same thing in Pereira.

Mr. Wontner further read a passage from a paper contributed by Mr. S. H. Maltass to the Pharmaceutical Society, on November 9th, 1873.

Mr. Vaughan: Is that Dr. Pereira?

Mr. Wontner: No, this is by Mr. S. H. Maltass, who speaks from personal experience. He is dead; but Dr. Attfield is here, who heard the paper read. It gives a variety of other information, and the different per centage in different samples, from 88·2 down to as low as 10 per cent.

Mr. Wontner: You tested this scammony, and found it contained 80 per cent.?—I found it to be 80 per cent. Of course I did not go so closely into it perhaps as Mr. Piesse. I dissolved out all the matter soluble in ether, filtered it, and dried the residue, and found that it contained 80 per cent. of soluble matter.

Whilst it was in your hands, was there any adulteration?—No.

Was there anything added to it to increase its bulk?—No.

Then any adulteration, if adulteration there be, was before it came into your hands?—Certainly.

You bought it in the ordinary course upon the market?—Yes; and I think we have a fellow case here to the one I bought, from which the powder supplied to Mr. Cocks came.

Mr. Vaughan: I do not want to see that.

The Witness: I wish you would, for it is a very important matter to me.

Mr. Wontner: It is very important to the trade generally; we have a reputation of 40 years to sustain.

Mr. Vaughan: If you think it is necessary for yourself or your own reputation to produce this to me, let me see it.

The Witness: It will not take one moment. (The witness then produced a case of scammony to the magistrate, showing the state in which it is imported.)

Mr. Vaughan: Did you give the best price for it?—I did. I happen to have in my pocket the catalogue of the day's sale (producing the same). These are my remarks. The goods are on view the day before the sale, and I made my remarks as to their value and quality. Then when the sale comes you see the prices which they fetched. Here are the three lots which I bought, 30s. a pound, and they are now worth 34s. The next I valued at 22s., being second quality, and there are some others of a very common description. There are some lots of this common stuff which was here taken in at 5s., were sold without reserve from 1s. 7d. to 1s. 9d. per pound. They were bought by some German houses, and I wish the German houses luck of their bargain. That will show you the great variety in the prices of scammony.

You gave 30s. which was the highest price of the day?—Yes, and if any gentleman will bring me some, equal in quality to this, I will give him 32s. for it to day.

Mr. Wontner: Do you know, as a fact, what this white outside is?—I do not of course, I have not examined it. I should say it was farinaceous matter. I will not go so far as the analyst, and say it is wheaten flour, because I do not know that they have much wheaten flour in Syria.

Mr. Jenkins: He did not say so.

Mr. Wontner: I understood him to say so. At any rate, it is some matter put on to prevent one block sticking to the other, or to be able to press it into shape?—Yes, no doubt. Oddly enough, within the last few hours, a sample of scammony has been put into my hands to report upon. I have never in my experience seen anything like it, and I do not believe anything of the kind has ever been brought into London before. If you will examine it (handing same to the magistrate) you will see actually leaves upon it, which shows that it has been compressed within leaves in order to dry it. That is only part of a small parcel come by post within a few days. I believe it is very pure and fine scammony, but you see there is this curious fact, that the leaves are imbedded in it.

Mr. Wontner: Do you say that this sample we are upon here is a good sample of virgin scammony?—I dare say so.

As good a sample as usually can be obtained in the market?—It is, I believe, very pure.

Scammony collected by the Greeks is rarely imported into this country?—Occasionally we get a specimen. I can show you a specimen, but it is a sort of cabinet specimen.

Is it a fact that, by way of making pure scammony without any of these so-called adulterants, you import the root itself?—Yes.

Do you grind the root up, and then extract the pure scammony resin out of it?—We do.

And by doing it in that way, can you sell it at least for one half the price you sell the other?—We can sell it at one third of the price.

Do you know, as far as the medical profession is concerned, that pure scammony resin, as you call it, is not looked upon as possessing the medicinal virtues that Smyrna scammony, as imported, does?—Yes, I do. I know from my personal experience too.

So that in spite of the so-called adulterants, the scammony here complained of is considered very much better than the pure scammony which you could extract from the root?—It is very much better.

I may take it that if this were termed an adulteration within the Act it would put an end to the trade in scammony altogether, and the public would have to go without it?—Entirely, I think.

Cross-Examined by Mr. Jenkins.

How could you give that last reply, saying it would put an end to the trade altogether if this is declared to be an adulteration. Do not you know it might be sold and marked as adulterated?—Yes, but what respectable chemist would admit he sold adulterated articles.

He would not admit that he sold an adulterated drug?—He would not only not admit it, but he would say it is not an adulterated article. It comes to a question of the meaning of the word "adulteration."

Have you ever bought this drug at a higher price than you did on that day?—Yes.

At a very much higher price?—I think I have. I cannot tax my memory, but I think the highest price has been 38*s.* or 40*s.* per lb.

How much was it on that day?—30*s.*

With reference to the sample you have just produced with leaves upon it, before it is dealt with for trade purposes do you get rid of the impurities there are in it?—This is an exceptional sample I have to report upon.

Have you ever seen scammony in a similar condition to that?—Never; I think it is a unique specimen.

Have you ever seen it with leaves attached?—I have never seen scammony with leaves attached.

Have you seen any other substances attached to it?—I have seen natural scammony with small stones, and ashes and cinders.

Before that was used for trade purposes, were means used to get rid of the adulteration?—You could not do it.

It was not done?—You could not do it. I will find you in this very box of scammony, if you will permit me, a piece with cinders in it.

The adulteration alleged here with flour is only 5 per cent on the entire amount; but supposing the adulteration had been 35 per cent., would you consider that equally lawful and equally open to be sold without bringing yourself under this Act?—That is a question; I get scammony of various qualities; on the very same day that this was ground, I powdered other scammony of lower qualities—that is, of less value, and one tested 70 per cent. of resin, and another 50. We have to do with a great many different people, and if a man buys scammony of me, I say, what scammony do you want? if you want scammony, buy this, and I will be answerable for it; but if you buy anything at a lower price, you must take your chance.

Mr. Cocks buys nothing but the best, and therefore I am here to protect him and also myself.

I understand you to say there is better scammony than this sold?—No.

I thought you said at a higher price?—No, I say this scammony was formerly worth more money. Of course, the markets vary. This scammony I bought the other day is worth more money now.

Mr. Vaughan: It was the highest price of the day?—Yes, and it is now worth considerably more money.

Mr. Jenkins: You heard from the American Pharmacopœia, which Mr. Wontner read from just now, that there is such a thing as pure scammony?—Yes, there is a sample here, what I call a specimen or a cabinet sample. I believe, having examined it, that that is as pure as can be.

I have not for one moment sought to allege that you have adulterated this personally.—I am very glad to hear you say it.

Mr. Wontner: I understand you to say that pure scammony is only found in cabinet specimens, that it is not that which comes into the market as a stable commodity?—No, it is not.

(*Professor Attfield, sworn. Examined by Mr. Wontner.*)

Are you a Fellow of the Chemical Society, and Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain:—I am.

Did you, at the request of Mr. Squire and his firm, analyse a specimen of scammony:—Yes, I did.

Was that a specimen obtained from Mr. Cocks' bottle?—Yes.

Mr. Vaughan: How do you know that?—Mr. Francis told me so.

Mr. Wontner: Mr. Francis is here. He is a partner in the firm of Messrs. Hearon, Squire, and Francis.

What was the result of your analysis?—My analysis substantially confirmed that which has already been given by the public analyst. I found a little more resin than he did, not much.

You found about 75 per cent. I believe?—I found 76 per cent. of resin; that is to say, when it was perfectly dry.

You took the precaution to make it perfectly dry, as Mr. Squire did, before you tested it?—Excuse me, the resin was perfectly dry that I obtained; but I also made an analysis upon a perfectly dry powder, and from that powder I obtained 80 per cent. of resin.

From that analysis are you able to say whether the scammony was a fair specimen of virgin scammony as known in this country?—I am able to say it was a very good specimen.

Without taking cabinet specimens, it was a very good specimen of the scammony which is exported into this country, and usually known as scammony?—Yes.

We have heard of starch, chalk, and flour. Can you account in any way for the presence of starch, chalk, and flour in this production?—Yes.

From your knowledge of the matter?—First, so far as starch is concerned, the root naturally contains a large quantity of starch, and a portion of this starch may get into the juice; if the juice is carelessly collected, a large portion might get in. Then, as to the chalk, I have analysed many samples of scammony, and in every one have found earthy matter of some kind. In nearly every case that earthy matter included chalk. I have examined the earth picked out from the crevices in the root of scammony, and in that earth I have found chalk.

Do you know that, from the very process of collecting, the scammony necessarily contains a certain amount of dust of whatever description the soil may be, collected with the gum?—Certainly; I have found the earthy matter that I have got out of scammony to have a similar composition to the earth I have picked out from the roots of scammony.

Now, as to the flour?—With regard to the flour, the scammony during its drying has to be turned over, manipulated in various ways, and, to prevent the lumps from adhering, powder of some kind or other is commonly placed upon the lumps, much as a cook would dredge flour on dumplings or pie-paste, to prevent them sticking together, and this powder sometimes contains flour. It adheres firmly to the lumps, so that it could not all be scraped off or brushed off, and hence the scammony when ground naturally contains such powder.

Powder that could not be removed from the general body?—It cannot be rubbed off from the lumps of scammony.

And when ground together with the rest, it could not be separated?—That would be impossible.

You have not been to Smyrna, have you?—No.

What amount of flour and starch would you expect to find?—I could not easily ascertain the percentage of flour or starch in powdered scammony. I have heard the analyst describe the process he adopted; and I am of opinion, indeed, I am certain, that that process would not give the percentage of starch or flour.

Mr. Vaughan: Or sugar?—Starch or flour is converted into sugar by boiling with acid. So is gum, which is always present in scammony, which is natural to the scammony, and when the scammony is dissolved in ether and such liquids, what dissolves out is the resin and not the gum, the gum remains in the residue. It is not soluble in ether. The analyst said that it was. He must have made some little mistake there. I have made some hundreds of tests; I know all about it personally, from my own observation and study, and I assure you that the gum is not soluble in the ether.

Mr. Jenkins: The analyst did not understand the question. Mr. Wontner did not examine him so quietly as he is doing his own witness.

The witness: I understood the analyst most distinctly to state further that the percentage of starch was about 5. I was glad to hear the question asked as to how that was ascertained, because I should like to know how to ascertain the percentage of starch in scammony; and, when I found it was by boiling the residue with acid, thus converting it into sugar, and then estimating the amount of starch from that of the sugar, calculating backwards, I was astonished; because I know there must be in that substance which was boiled with acid some gum, and I know that would be converted into sugar, and when the analyst says he thus found 5 per cent. of starch, then I know that nearly the whole of what he did find must have been gum. But that there was a little starch of some cereal in the scammony I know from my own microscopic observation, but not 5 per cent.

Mr. Vaughan: The analyst said 5 per cent. of flour, he did not specify the starch.—I know there could not be 5 per cent. of flour. The fact is, flour contains starch.

Mr. Wontner: Do you know, as a matter of fact, what the standards of the different Pharmacopœias are—the British, French, and the United States?—80 per cent. is mentioned in the British Pharmacopœia.

As the highest to be expected?—80 per cent. is mentioned in the British Pharmacopœia, but in the American Pharmacopœia the scammony is recognised as of official strength if it has 75 per cent. of resin in it. In France the same number is taken, 75 per cent. I have the French Pharmacopœia here, and it states that the scammony should contain from 75 to 80 per cent. of resin. Then a great authority on materia medica, Dr. Pereira, says that "pure or virgin scammony should yield from 75 to 80 per cent. of resin."

And what do you, Dr. Attfield, as the Professor of Practical Chemistry to the Pharmaceutical Society, say it should yield. Do you agree with those?—I entirely agree with those authorities as to the percentage of resin found in the best scammony.

Do you say that this article we are summoned for is a genuine scammony or adulterated?—It is a genuine scammony, it is not adulterated. It contains natural impurities, but it is not adulterated.

Are those of such a character that it would be impos-

sible to get the scammony without getting the impurities?—I will not say it would be impossible. I have seen a pure specimen, but it was a cabinet specimen.

Virtually impossible?—Yes, as a commercial article.

Taking the method in which it is obtained?—Clearly, quite impossible.

Mr. Vaughan: Supposing the 5 per cent. of starch or flour were there, might it be considered to be a fair estimate of what you would necessarily expect to find in the collection of it?—Yes, I think so.

Cross-examined by Mr. Jenkins.

If you found 35 per cent. of flour present, should you consider that was an adulteration?—I should consider, if the flour were of the character I found in the scammony, that the scammony had been very badly collected.

I suppose you are perfectly acquainted with the Pharmacy Act. In your judgment, would that be an adulteration, for that Act says, "any person who sells an article which is adulterated shall, unless the contrary is proved, be deemed to have knowledge of the adulteration."

Mr. Vaughan: Are you speaking about the last Act?

Mr. Jenkins: I am speaking of the Pharmacy Act.

Mr. Vaughan: That is just the matter in issue. According to the evidence of Dr. Attfield, this is really no adulteration.

Mr. Jenkins: You said just now you thought it would be impossible to separate the impurities. Take the flour for instance, is there no means of separating that?—That amount of flour, or dust, or whatever it may be, which adheres, could not be detached.

Do you mean to tell me that if there were 20 per cent. of flour present in the powder it would be impossible to remove that?—If the 20 per cent. were in the scammony it would be impossible to remove it. If it were on the outside it could be brushed off.

In that sample is it outside (referring to a specimen)?—It adheres too tightly; try it yourself.

Will you explain why it could not be removed?—Because I have found you cannot do it.

I thought you said it could be done?—In such samples it could not be done; you would leave a little sticking to the surface.

According to the authorities, to several of which you referred, there ought to be from 75 to 80 per cent. of resin present. If that particular powder now under consideration only contains 73 and a fraction, would not that be below the standard?—That was when the moisture was out of it. Your analyst admitted there would be nearly 80 per cent. of resin in the dried scammony.

Mr. Wontner: You have the evidence of your own witness that he did not dry it.

Mr. Jenkins: There are two other summonses by the Board of Works against other vendors of this scammony powder. If your honour's decision should be against me upon this, I should be disposed to withdraw them, if your worship, having reference to the amount of alleged adulteration, should think it right that I should do so in my capacity as officer of the Board. The adulteration there is much larger.

Mr. Vaughan: I wish to ask a question of Mr. Francis.

(*Mr. George B. Francis, sworn. Examined by Mr. Vaughan.*)

You are a member of this firm?—Yes.

Where did you obtain that bottle of scammony from, that you gave Dr. Attfield for analysis?—Directly we heard from Mr. Cocks about the service of the summons, I called upon Mr. Cocks, and from the identical bottle containing the scammony we supplied to Mr. Cocks, I took that sample, and his assistant assured me that it was the same.

Mr. Wontner: The assistant is here, sir.

Mr. Vaughan: Is there any dispute about that?

Mr. Jenkins: No, sir; I do not for a moment dispute it.

Mr. Vaughan: I am of opinion in this case that there is no adulteration. The evidence of Dr. Attfield displaces the evidence that was given by the analyst with regard to the existence of the starch. The whole case now resolves itself really into the presence of the flour, and the presence also of the chalk; and after the evidence as matter of fact which has been given by Dr. Attfield, I can only come to the conclusion that the chalk has been introduced into the scammony in the way which has been suggested by him from the fact of its being a chalky soil in which the root itself has been grown. If chalk has been picked out by Dr. Attfield, from the interstices of the scammony root, it must be perfectly clear that the earth in which it has grown, if not entirely chalk, was very largely impregnated with it. As regards the chalk, therefore, it seems to me that very likely indeed it was introduced into this from the circumstance of its being collected by Greeks or Turks, or whoever they might be, who were employed for the purpose of getting at these roots. As regards the presence of flour, I think the explanation given by Dr. Attfield is a very satisfactory one. He says, this is a sticky substance, as everybody must know, and that, for the purpose of preventing the lumps from adhering one to another, there is some powder which is required to be placed between them. That powder appears sometimes to be flour, or some farinaceous substance, and I think it exceedingly creditable that no other powder of a deleterious character is employed instead of that. It appears that the quantities which are in this specimen of scammony are really such quantities as are necessarily, in fact, to be expected to be found in such a quantity as has been produced here to-day; and I think, therefore, under those circumstances, it is rather hard that a summons should be taken out against the defendant. But the summons having been taken out, I am satisfied that no adulteration is shown here. Having paid some attention to the evidence which has been produced before me in this case, I am not at all satisfied that there has been any adulteration, and I think the summons must be dismissed.

Mr. Wontner: What do you say, sir, as to the costs? Before a former colleague of yours, Mr. Arnold, a similar experiment was tried without the local authorities taking any trouble to inquire; and Mr. Arnold therefore dismisssed all the summonses, granting full costs, both of the attorney and all the witnesses, against the Board. I really think that before taking out this summons they might have looked, at least, into one or two of the standard works, and there they would have found the very explanation which has been given to you to-day. The analyst himself says that when he analysed it he thought it was a very fair sample. It is very hard to bring people here and bespatter them, without making sufficient inquiry beforehand; and I trust you will mark your sense of this case by giving costs against the Board. Although this Act is a most salutary one, it is very hard if it is to be used as a weapon of oppression instead of, as it was intended, to prevent fraud upon the public.

Mr. Jenkins: I believe, sir, your personal knowledge will tell you that the Strand Board of Works are by no means hasty in taking these proceedings. But under the Act, upon receiving the certificate of the analyst, we are bound to do so. The instructions given in this district are that the inspector shall go, without distinction, to every shop of the different kinds; and members of the Board who are in trade are treated in the same way. Having received the certificate of the analyst that an adulteration had taken place, I submit we had no option but must come here and ask your decision in the first instance. There is no favour shown in any shape or form; and I have never suggested one word against the firm, some of the members of which have been called before you to-day.

Mr. Vaughan: It is suggested that the analyst had communicated to the inspector his opinion as regards the specimen.

Mr. Jenkins: That was after the summons was taken out. The certificate was sent to us. No doubt my friend has exercised a very considerable amount of ingenuity in getting the weakest case before you first.

Mr. Wontner: I beg your pardon; it is the first upon the list.

Mr. Vaughan: I should like to have the inspector recalled.

(*Mr. F. Taylor, recalled. Examined by Mr. Vaughan*)

Were you told by the analyst that this was a very good specimen or a very fair specimen?—A very fair specimen, after the summons was taken out.

Did you communicate that to the solicitor of the Board?—No.

Why did you not?—I had no occasion that I know of.

Surely it is your duty to communicate all circumstances that come to your knowledge. The analyst gave his certificate and he communicated something to you which you ought to have communicated to the solicitor?—It was not till after the summons was taken out.

That makes no difference, because a summons may be withdrawn after it is taken out.

Mr. Jenkins: I was not aware of it till I heard it here to-day.

Mr. Vaughan: I do not know that I can impose costs, Mr. Wontner, in this case. There is no doubt the inspector ought to have communicated to the solicitor of the Board what he heard from the analyst on the subject, and then the summons could have been withdrawn. I think, for the future, when an analyst does find a fair specimen, that circumstance ought to be communicated to the Board, whether the summons has been taken out or not, because then they would be able to determine what course should be taken.

Mr. Jenkins: If I had known it, I should instantly have stopped the summons.

Mr. Wontner: The analyst told Mr. Francis, in conversation, that it was a very good specimen, and if he could have stopped the summons he would.

Mr. Vaughan: It does not appear to have been brought home to the knowledge of the solicitor.

Mr. Wontner: I do not want to press the application further.

Mr. Vaughan: I must say, in all these cases, if the quantities of ingredients supposed to be adulteration introduced into the article, is there without any knowledge to implicate the vendor, I think that circumstance ought to be taken into consideration before taking out a summons. No doubt this is a case of great hardship. I dismiss the summons, and with regard to the others I understand they are withdrawn.

Mr. Jenkins: I would just mention this before I withdraw them. The analyst certifies in one case an adulteration to the extent of 34 per cent. If you think, after that, I am justified in withdrawing the summons, I will do so.

Mr. Vaughan: I cannot tell you.

Mr. Jenkins: I was very careful just now to ask the witness whether he thought 34 or 35 per cent. would be an adulteration.

Mr. Wontner: Perhaps as *amicus curiæ* you would allow me to observe that, turning to the authorities, I find it stated over and over again that all these impurities are introduced in Smyrna by the merchants there, and the articles are sent over here with the impurities mixed up so that it is quite impossible to separate them from the article sold; and it is equally impossible for the merchant here to say that those specimens which are not so good are not scammony.

Mr. Vaughan: You must bear in mind that the facing of tea is done in China and sent over here. No doubt that is an adulteration, and I suppose there would be a difficulty in removing the face of the tea; but the question is whether that ought to be sold.

Mr. Wontner: As a matter of information, will you allow me to say that I have here the PHARMACEUTICAL JOURNAL and report, showing the different quantities imported in each year since 1866 down to 1870. In 1866 the quantity was 9886 lbs, and it has increased from that to 25,592 lbs, whereas the yielding capacity of the roots in Asia Minor remains always the same. Therefore, to satisfy the largely growing public demand, I suppose the people over there find it necessary to add something to it.

Mr. Jenkins: That is an argument in favour of our coming here.

Mr. Vaughan: It shows that the dealers in scammony should be very careful.

The other summonses were then adjourned for a fortnight.

POISONINGS BY CARBOLIC ACID, GIVEN IN MISTAKE FOR MEDICINE.

An inquest was held in the Birkenhead workhouse, on Friday, the 12th June, on the body of Patrick Richards, aged 56 years, who was accidentally poisoned on the previous Tuesday by having some carbolic acid administered to him by mistake, instead of a dose of black draught. The inquest had been adjourned for a *post-mortem* examination of the body to be made.

Meshech Boswell, an inmate of the hospital, stated that between nine and ten o'clock on Tuesday morning the deceased, who occupied the next bed to witness, asked the head male nurse, Thomas Barlow, for some opening medicine. Barlow left the ward, and immediately brought something of a dark colour in a measure, and put the half of it in a glass. When he had taken about one-half of it, the deceased said three times that it was very hot. Barlow then tasted it, and exclamed, "Oh, dear, I have given him the wrong." The doctor was immediately sent for, but before his arrival a mustard emetic was given to the deceased. Witness considered Barlow a very kind and attentive nurse.

At this stage of the inquiry, the coroner and the jury adjourned to the hospital dispensary. On the mantelpiece there were a number of bottles, containing both poisonous and harmless drugs. The bottles were mixed together, and there appeared to be no proper arrangement of the different medicines. In front of the mantelpiece there were two large blue glass bottles, side by side, one labelled "House mixture," and the other (from which the fatal draught had been taken) "Carbolic acid." The latter was also labelled "Poison" in red letters, but the word was nearly obliterated. The coroner pointed out that one bottle on the mantelpiece bore the direction "A teaspoonful of this mixture to be taken three times a day," whilst "Muriatic acid" was written on a label underneath turned upside down.—Dr. Daniels, one of the Union medical officers, who was in attendance, wished to make some explanations, but the coroner told him he must leave the jury to judge for themselves.

Dr. Henry Wilson deposed that before this occurrence he had been acting medical officer at the workhouse for six days. He attended the deceased, who had ulcerated legs. Witness had never prescribed for him. On Tuesday morning, at 20 minutes to ten o'clock, Mr. Williams, the master of the workhouse, came for witness, and asked him to accompany him to the hospital. In about ten minutes witness saw the deceased, who was then lying across the bed with his face downwards. The man had been placed in that position by the nurse and his assistant, who were endeavouring to make him vomit. Witness, on examining the deceased, found that he had lost all power of vomiting. He was comatose and insensible. Every means was resorted to to make the deceased vomit, but without effect, and death ensued 20 minutes after witness reached the hospital. Barlow, the nurse, told witness that the deceased asked him for a dose of opening medicine early in the morning, and that he had given him what he thought was black draught, and in quantity an ounce and a half, and that he had immediately discovered that he had administered instead carbolic acid. Witness had since made a *post-mortem* examination of the

body, and, from the appearance of the stomach, had no doubt death was caused by carbolic acid.—In answer to the coroner, the witness said the nurse had access to the hospital dispensary any time he pleased, the key being under his charge.—The Coroner: I suppose you have various preparations made up, and kept in different bottles as a convenience? For instance, you have black draught? Witness: Yes.—The Coroner: And it is kept in a large bottle? Witness: Yes.—The Coroner: There are other medicines besides black draught kept there? Witness: Yes; I see there is a cough mixture there. The Coroner: Does the hospital attendant supply patients who may ask for black draught, without your knowledge? Witness: So far as this case is concerned, I know nothing about it; but it is the custom in hospitals to do so if a patient asks for it. If there is a rule to the contrary, it is exceptional. Barlow had informed him that the bottle containing the black draught was kept on the mantelpiece; but he (witness) never used it. The first time witness saw the black draught was on Tuesday on the mantelpiece. The bottle containing the black draught was labelled "House mixture."—The Coroner: Did you see another bottle on the mantelpiece next to the bottle containing the "house mixture?" Witness: Yes; that bottle was labelled "Carbolic acid," and underneath was the word "Poison," with the chemist's name. The bottle containing the carbolic acid was precisely similar in size and appearance to the one containing the black draught.—The Coroner: And there were a number of other bottles on the mantelpiece? Witness: Yes; the contents of some of the bottles were harmless, whilst others were not, according to the dose.—The Coroner: Did you notice muriatic acid there? Witness: I did. The witness added that when he saw the bottle containing the carbolic acid it was so placed that the label was not visible, but the label on the bottle containing the black draught was visible. In reply to Mr. Pugh, Dr. Wilson said it was customary for the hospital attendant to administer black draught. The nurse, Barlow, told witness that when he took the bottle to pour into the glass what he supposed to be black draught the label was turned from him. On Tuesday morning Barlow had been dressing the wounds of some patients with carbolic acid, the smell of which he might retain for some time—perhaps a day. In some hospitals, the black draught was usually under the charge of the nurse; but under ordinary circumstances it was not kept by itself. It was not kept under lock and key. He considered it a very dangerous practice to keep harmless and poisonous drugs together, but in this case he considered it was unintentional. In the Birkenhead Hospital dispensary there was a want of space; indeed, there was not a shelf in the room. In witness's opinion, all bottles containing poisons should be kept distinct from other medicines. In answer to a juryman, Dr. Wilson further stated that when in the bottles the carbolic acid and the black draught appeared to be of the same colour, but when poured out they presented a different colour.

The Coroner said it would perhaps be satisfactory to the jury if Barlow made a statement, but it was a matter entirely for his own consideration.

Thomas Barlow, the nurse, then made a statement to the effect that on Tuesday morning he had been dressing the legs of some patients in No. 6 ward with carbolic acid and water. Afterwards he went into the ward where the deceased was, and dressed a carbuncle. As he was leaving the ward, Richards asked him for a black draught, as he was very much constipated. To oblige the old man, he (Barlow) went to the dispensary and brought up what he thought was a black draught, and measured an ounce and a half. When he had taken a portion of the draught, the deceased said it was very hot. He (Barlow) then tasted what was left in the glass, and, finding that it burnt his mouth, he discovered his mistake, and exclaimed, "Oh, dear, I have given him a wrong medicine." He instantly sent his wife for the doctor, and he gave Richards a dose of castor oil, which he swallowed. Mrs. Barlow also brought a mustard emetic, but the deceased did not vomit. The doctor was soon in attendance, and remained with the deceased till he died.

The Coroner, in addressing the jury, remarked that Barlow, the nurse, had made what appeared to be a very candid statement of the facts, which was corroborated by the evidence of Dr. Wilson. There could be no doubt that the deceased died from the effects of carbolic acid, administered by Barlow, the hospital attendant; and it would be for the jury to say whether he (Barlow) was guilty of gross and culpable negligence or not. If the jury thought there was a reasonable excuse for the mistake the nurse had made, then they might give him the benefit of the excuse, and reduce the case to one of excusable homicide. In order to arrive at the latter conclusion, the jury must be satisfied that Barlow exercised due and ordinary caution when he administered the carbolic acid. The case was a very serious one, not only as regarded Barlow, but as it affected the workhouse, for it might create a great prejudice against the management. With respect to the dispensary, there could be no doubt there was an immense amount of confusion as regarded the placing of the bottles. On the mantelpiece there was a large number of bottles, some of them containing deadly poisons, whilst others contained medicines of a harmless character. In an establishment of so much importance it was necessary that everything should be conducted in a correct and systematic manner; and all medicines of a poisonous character should be kept apart and entirely separate from everything else. It would be much safer and better if poisonous medicines were kept under lock and key, and that these should be in charge of the medical officer. However, it appeared to be an act of great carelessness on the part of Barlow—who, it might be supposed, could read and write—that he did not look at the labels on each bottle to see what he was taking. If the jury considered Barlow guilty of gross and culpable negligence, then they must hold him responsiblble.

The jury, after a short deliberation, returned the following verdict:—"The deceased died from the effects of carbolic acid, administered by Thomas Barlow, a nurse in the Birkenhead Union Hospital; and they further find that Barlow did not exercise due caution before administering what he considered to be a black draught. The jury add a presentment that there has been great confusion and irregularity in the arrangement of the different medicines in the hospital dispensary, and they recommend that, in future, poisons be kept under lock and key, quite distinct from medicines of a harmless nature."

The Coroner said he quite concurred in the verdict of the jury.

Upon this verdict, Barlow was discharged by the Coroner; but it was understood that he will be brought before the magistrates.

Mr. Williams, the master of the workhouse, said he hoped the unfortunate affair would not reflect any discredit on the management of the establishment, because attendance to the surgery was altogether out of his sphere of duty. He had been master of the establishment only a short time, and the matter might do him a great deal of harm.

A Juryman stated that in considering their verdict the jury never for a moment supposed there had been any mismanagement on the part of Mr. Williams; indeed, his name was never taken into consideration in the matter at all. The jury also expressed their sympathy with Barlow.

The Coroner remarked that attendance to the surgery was no part of Mr. Williams's duty.—*Liverpool Mercury.*

An inquest has been held at Gorton, on the body of Samuel Burford. The deceased hurt his thumb whilst at work, from which he suffered great pain. In order to obtain rest he purchased some chloral, and in the night he asked his wife to give him a draught of it. She went downstairs for it, but took no light, and in mistake gave her husband a draught of carbolic acid, from the effects of which he died the same night. It was stated that Mrs.

Burford had always been on the most affectionate terms with the deceased, and they had lived very happily. The jury returned a verdict of death by misadventure.—*Liverpool Mercury.*

Review.

A Treatise on Food and Dietetics, Physiologically and Therapeutically Considered. By F. W. Pavy, M.D., F.R.S. London : J. and A. Churchill.

In his preface to this work, Dr. Pavy says, "From the fact that the subject of food is one of deep concern, both to the healthy and the sick; that the information which has been obtained during the last few years has completely revolutionized some of the cardinal scientific notions formerly entertained; and that no modern systematic treatise of the kind here presented exists in the English language, I have been encouraged to think that the task I have undertaken may not be deemed superfluous. Whatever the result attained, I have steadily striven, sparing no pains for the purpose, to render the work instructive and useful." In this endeavour Dr. Pavy has completely succeeded, and he has, moreover, rendered his book exceedingly interesting; so that it may not only be studied carefully for the sake of the valuable information it contains, but may serve to pass an idle hour pleasantly as well as profitably.

It is easy to see, even although Dr. Pavy had not stated it in his preface, that much labour has been expended in collecting the numerous facts regarding foods of all sorts, their properties, uses, and employment; scattered as these necessarily are in books and periodicals of the most various sorts, and many of them inaccessable to ordinary readers.

The author commences with a brief but clear exposition of the correlation of the physical forces, and shows the necessity of food to supply energy to the organism. The origination and constituent elements of food are next dealt with; the classification, chemical relations, digestion, assimilation, and physiological uses of the alimentary principles discussed; and the use and value of each as a force-producer are stated. The difficult question of the comparative values of nitrogenous and non-nitrogenous principles in this respect is admirably treated, all the most important evidence being carefully collected and clearly placed before the reader. In speaking of the production of fat as a result of the splitting up of nitrogenous matter, however, Dr. Pavy states that although it is highly probable, we have nothing in the nature of proof. Now, Voit and Bauer's experiments on the production of fat in the organism after phosphorus poisoning do seem to furnish the proof required; for these observers found that fat was rapidly produced in the poisoned animals, although they received no food whatever, and all fat had been previously removed from the body by prolonged abstinence. The conversion of starch into sugar by the saliva is said by Dr. Pavy to be arrested in the stomach. This is true of the dog, in which the acidity of the gastric juice is sufficiently great to stop the action of the saliva; but not of man, in whom the acidity is less, so that the conversion of starch into sugar continues so long as the stomach is healthy, and only ceases when an abnormal quantity of acid is present in it. Such slight oversights as these, however, hardly detract from the value of the book; and, indeed, their slightness is a good evidence of its general accuracy. The description of food stuffs is most complete, and supplies a desideratum long felt both by medical practitioners and the general public. Nothing is more common than the question put by a patient to his medical adviser, "What shall I eat?" and not unfrequently his adviser is non-plussed, and gives a random answer. Dr. Pavy's book supplies the information wanted, and by stating the digestibility of various food, enables both practitioner and patient to select the proper sorts. Beverages of all sorts, water, tea, coffee, cocoa, alcohol, wines, etc., are fully discussed, and their proper use explained.

The injurious effects of tea in irritable states of the stomach is simply stated, but we think the author might with advantage have laid more stress on its power of causing flatulence. The description of the effect of alcohol on the system, and of its use and abuse, is exceedingly good and deserves to be read with great attention. A few pages are devoted to the preservation of food, and then follows a section on the principles of dietetics, and the rules which regulate the relations of diet to work. The next division on practical dietetics, including diet of infants and diet for training, is, perhaps, the most important in the book, and contains many valuable hints on the proper times for meals, and the quantity and quality of food to be taken at each. The book concludes with a section on therapeutic dietetics, including a number of recipes for dietetic preparations for invalids, and a list of hospital dietaries. Not the least valuable of Dr. Pavy's contributions to dietetics is the "fluid meat," which he has had prepared by Messrs. Darby and Gosden, and which is mentioned in this section. Unlike Liebig's extract, which contains merely the extractive matters of meat, which have little or no nutritive value, the fluid meat contains all the albuminous matters, artificially digested and ready for absorption, without requiring any further digestion in the body. It is, therefore, of great value when the digestive system is weakened by disease; and a similar preparation, though made by a different process, is now being employed in Germany. Dr. Pavy has omitted all mention of the curative use of diets consisting of single articles, such as the whey cure and grape cure, the omission of which we hope he will supply in another edition. It would be hardly fair to conclude this notice without mentioning the beautifnl paper on which the book is printed. Altogether the work is worthy of the author's high reputation, and we can thoroughly recommend it as one which will well repay perusal.

BOOKS RECEIVED.

Nouveaux Elements de Pharmacie. Par A. Andouard, Pharmacien, etc. With 120 engravings. Paris : J. B. Baillière et Fils. 1874. From the Publishers.

On Food : its Varieties, Chemical Composition, Nutritive Value, Comparative Digestibility, Physiological Functions and Uses, Preparation, Culinary Treatment, Preservation, Adulteration, etc. By H. Letheby, M.B., M.A., Ph.D., etc. Second Edition. London : Baillière, Tindall and Cox. 1872. From the Publishers.

Water Analysis : A Practical Treatise on the Examination of Potable Water. By J. Alfred Wanklyn and Ernest Theophron Chapman. Third Edition. Entirely Re-written by J. Alfred Wanklyn, M.R.C.S., etc. London : Trübner and Co. 1874. From the Author.

Notes and Queries.

PILLS OF IODINE IN COMBINATION WITH ALBUMEN.—In a note in *L'Union Pharmaceutique* (vol xv. p. 97), M. Collas states that iodine can be administered advantageously in the pill form in combination with albumen. As has been before pointed out by Professor Guerri, of Florence (Pharm. Journ. [3] vol. iii. p. 462), iodine combines with albumen in constant and definite proportions. The iodine is completely covered, and its presence can only be ascertained by the destruction of the organic matter. The iodized albumen may be prepared by well shaking together an albuminous solution and iodine in very fine powder, or in solution, in an appropriate vehicle. The mixture is at first of a full blackish-brown colour; but after being left in contact some hours it becomes decolorized, and no longer gives the violet colour with starch. The product is then dried with a gentle

heat, and made up into the pill form, the quantity used being such as that each pill shall correspond to 5 milligrams of iodine. M. Collas says that these pills have been found useful in the Hôpital Beaujon, and that their administration has been continued during several weeks without inconvenience.

EXTRACT OF VANILLA AND TONKA.—The following formula for an Extract of Vanilla and Tonka for flavouring purposes is given by Dr. E. P. Nichols (*Trans. Amer. Pharm. Soc.*, 1873, p. 599):—

Take of Vanilla Beans	4 ounces.
Tonka Beans	8 ounces.
Deodorized Alcohol, proof .	8 pints.
Simple Syrup	32 ounces.

Cut and bruise the beans, macerate for fourteen days in one-half the spirits, with occasional agitation, pour off the clear liquor and set aside, pour the remaining spirits on the magma, and heat by means of a water-bath to about 170° Fahr., in a loosely covered vessel, keeping it at that temperature two or three hours, cool and strain through flannel with slight pressure, mix the two portions of liquid and filter through felt; add the syrup. If a genuine extract of vanilla is desired, take of vanilla beans six ounces, omit the tonka, and proceed as above. This process so exhausts the beans that percolation is unnecessary. The loss by evaporation is very slight, if a little care is taken in properly covering the vessel, and preventing too high a temperature during the heating process. This extract is not quite as elegant in appearance as that made by percolation without heat. It could probably be made perfectly clear without any diminution of its flavouring qualities, but Dr. Nichols made no experiments in this direction.

Dr. Nichols recommends that in making the extract the long bean should always be selected, and that handsome-looking beans should not be bought when offered considerably under the market price.

CARBOLIC ACID SUPPOSITORIES OF THE "ADDITIONS TO THE BRITISH PHARMACOPŒIA."

Sir,—Mr. Pratt, of Barnstaple, would greatly oblige several of your readers by giving further particulars of his experience in making the Carbolic Acid Suppositories of the B. P. Addendum, "in a short time, with no trouble," according to the directions given.

How much powdered starch did he find to be a "sufficiency?" Did he use carbolic acid in "crystals?" It would also be interesting to know whether they were pressed into a mould, or shaped in any other way, and what he found them to weigh when finished; also the source of the powdered soap used, and whether he found it to agree with the B. P. tests, as I believe different samples of curd soap vary considerably, but although I have tried several samples of soap I have never succeeded in making the suppositories properly by following the legal form. Several friends who have tried the formula also agree that a satisfactory result cannot be obtained without some modification of the directions given; and Mr. Umney, in his well-known paper, published in the Journal of the 4th of April, states—"The Carbolic Acid and Soap Suppository does not work well, the quantity of moisture being alone derived from the carbolic acid seems to me insufficient; at any rate, it will not admit of starch being used."

Mr. Pratt's experience of the "simple directions of the B.P. Addendum," therefore, appears to be singular.

T. HOWELL WILLIAMS.

44, *Seven Sisters Road, N., July 16th*, 1874.

CASTOR OIL—DERIVATION OF ITS NAME.

Sir,—In the recent review of the 'Pharmaceutical Lexicon,' by H. V. Sweringen (June 13th) this observation occurs:—

"In one 'tracing of the original,' however, which he does give, he follows Webster and other lexicographers in saying that 'castor oil' is a corruption of 'castus oil,' the plant producing it having formerly been called 'Agnus castus.' We should like to learn whether this is fact or fancy."

The learned Dr. Paris, in his 'Pharmacologia,' has the following:—

"Castor oil will suggest itself as another example [of verbal corruption in medical botany]; this oil, from its supposed efficacy in curing and assuaging the natural heat of the body, and in soothing the passions, was called by the French 'Agnus Castus,' whence the inhabitants of St. Kitts, in the West Indies, who were formerly blended with the French in that island, called it *castor* oil."

I simply give this for what it is worth; if Dr. Paris is correct, it is, of course, a "fact;" but, should more recent authorities have found out that he was in error, then it will remain a "fancy." I, for one, should be pleased if any of your correspondents can corroborate or disprove Dr. Paris's statement.

WM. ROGERS.

HIGHER REMUNERATION FOR CHEMISTS.

Sir, Probably Mr. Fairlie would wish a chemist's prices regulated by some such method as in the following anecdote, which an "old salt" has just told me:—

"A darkey was engaged to kill a calf; when the task was completed, came the question of payment. 'How much for killing the calf, Sambo?' 'Four dollars, massa.' 'Four dollars for killing a calf! how do you make that out?' 'Two dollars for kill calf, massa, and *two dollars for know how*.'"

J. BURT.

We are glad to satisfy the expectations, and confirm the belief of our worthy contemporary, the *British Medical Journal*, by stating that Dr. Dobell was not a party to the introduction into this Journal of the notice which appeared the week before last of certain pharmaceutical novelties exhibited at the soiree lately given by him. We cannot, however, acquiesce in the opinion that "the proceeding" was, on our part, "a breach of professional propriety," or in the assertion that it "calls for energetic protest on the part of those who wish to retain a due standard of professional decorum." Of Dr. Dobell's intent or expectation in regard to this matter we cannot say anything, since we have no cognizance, and were induced to publish simply from the desire to supply our readers with information likely to be useful to them.

E. Cotterell.—Previous to the receipt of your letter we had noticed that the paper did not contain anything which had not been published before.

P. and P.—(1) Because the preparation contains a larger proportion of the active principle than the same weight of the crude drug. (2) Yellow wax has been recommended. See vol. i. of the present series of this Journal, p. 566.

"*Student.*"—You are mistaken. Dr. Redwood did not write "Syrupus Tolulani," but "Syrupi Tolutani," and therefore no correction was required.

"*G. L. Napier.*"—(1) The Juries Bill has not yet passed the House of Commons; in its present state it does contain an exemption of chemists and druggists from jury service. (2) If you refer to recent numbers of this Journal you will find full reports of the subject respecting which you ask for information.

"*Ignavus*" (who should have enclosed his name and address) will find all the details in the Calendar of the Pharmaceutical Society, which may be obtained from the Secretary, price 1*s*.

"*Elcho.*"—The triple, as imported, is, we believe, generally used.

"*Crinis.*"—Recipes for "Lime Juice and Glycerine" were given in vol. i. of the present series, pp. 658 and 716.

L. S.—The colour described is wholly due to the action of astringent matter in the Compound Tincture of Cardamons upon the Sulphate Iron. There is an Electuarium Anthelminticum in the French Codex in which the powder of Male Fern is an ingredient.

"*June.*"—It it customary to use Sp. Chloroformi.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. F. Porter Smith, Dr. Symes, Mr. Shaw, Mr. Burt, Mr. C. R. Blackett, Mr. Pittman, Mr. Fairlie, Mr. Napier, Mr. J. F. Brown, Mr. Humpage, Mr. Holdsworth, Mr. Jackson, "A Pharmaceutical Chemist," "Excelsior."

THE PURITY OF DRUGS AND PHARMACEUTICAL PREPARATIONS.

BY THE EDITOR.

THE case reported in last week's Journal of prosecution for the sale of adulterated scammony, and the letter of Mr. Urwick in the present number, as well as some other instances that have recently been made public, all tend to impress upon the retail dealers in drugs the responsibility of their business. They also tend to suggest to retailers the indispensable necessity of exercising considerable caution in regard to the quality and purity of the drugs and preparations they sell, so as to protect themselves from the consequences of prosecution under the Adulteration Act.

On a recent occasion, both Mr. Horner and Mr. Hodgkinson, in giving evidence before the Select Committee on the Adulteration Act, expressed a decided opinion that the wholesale dealers in drugs and pharmaceutical preparations, exercised a protective influence in favour of retailers. According to their view, the practice of the wholesale dealer is to take care that only drugs of unquestionable quality are supplied to those who require it. They also stated, quite as decidedly, that there was no difficulty in obtaining drugs and preparations of good quality—that in fact it was wholly a matter of price, and, for those who demanded it, there would be no hesitation in guaranteeing the articles supplied.

As an illustration of the necessity of exercising caution in purchasing pharmaceutical articles, I will mention an instance that recently came under my own observation. A manufacturer of citrate of iron and quinine was offered what appeared to be an excellent sample of sulphate of quinine, at a price much below that now ruling for either the English or foreign makes of this article. It was the produce of a well-known Continental maker, and was offered by a house of unquestionable respectability acting for him in England. The reason given for the low price, and for not selling the salt in bottles, with the maker's label, was the very plausible one, that it contained "a very trifling per-centage of cinchonidine." By accident, the sample came into my hands, and on analysis I found it to consist of—

Sulphate of cinchonidine, 60 per cent.
Sulphate of quinine, 40 "

Assuming that the 2,000 ounces of this article offered for sale had been purchased, without further inquiry, and converted into citrate of iron and quinine (?), it does not require much power of imagination to appreciate the possible consequences that might have ensued if some of that preparation had found its way into the hands of a competent public analyst; or to perceive what damage and discredit might have fallen upon the manufacturer and dispensers who had made and employed it.

NOTES ON THE MEDICINAL PLANTS OF THE SCROPHULARIACEÆ.

BY JOHN R. JACKSON, A.L.S.

This order, which is for the most part composed of herbaceous plants, is usually considered as comparatively unimportant in an economic point of view. With us this is to some extent true, the foxglove *(Digitalis purpurea)* being the only officinal plant of the group; but in other countries many species are esteemed as valuable medicines. The family is very widely distributed; its members are most abundant in temperate regions, but some are nevertheless found in other climates. Though many of the plants are acrid and bitter, their medicinal properties vary very much, as will be seen in the following consideration of the different species. Thus, in the foxglove, which is so well known that we need not describe the plant, the effects are remarkable for their varied operation, altering the frequency of the pulse, or enfeebling the action of the heart in various degrees in different persons.

In North America many of *Scrophularieæ* are used in medicine. *Scrophularia nodosa*, L., the figwort, a plant growing some two or three feet high, and found in woods and thickets over a good part of Europe, was at one time officinal in the Dublin Pharmacopœia, the leaves being used in the preparation of an ointment.

In some parts of Europe, as well as in America, they are occasionally used, as well as the roots, for making poultices for ulcers, tumours, burns, and cutaneous eruptions. The leaves have a rank, disagreeable smell and an acrid bitter taste, and the root has also a nauseous odour. The leaves of this plant were, at one time, supposed to have tonic, diaphoretic, and anthelmintic properties, and were advocated for the cure of scrofula. Farmers occasionally use a decoction of the leaves for curing scab in pigs.

The great mullein, *Verbascum Thapsus*, L., a well known British plant, in gravelly, sandy, or chalky soils, is common also in neglected fields and along roadsides in the United States. The thick woolly leaves have a mucilaginous, bitter taste, which is extracted by infusion in water. They are demulcient and emollient, and were at one time much valued not only in domestic practice but by practitioners in catarrh and diarrhœa. Sir James Smith testifies to their value in the following words: "A pint of cow's milk, with a handful of the leaves of this mullein boiled in it to half-a-pint, sweetened, strained, and taken at bed-time, is a pleasant emollient and nutritious medicine for allaying a cough or removing the pain and irritation of the piles." The leaves, steeped in hot water, are not unfrequently used by country people as poultices in hæmorrhoidal complaints. In Sweden and Norway a decoction of the leaves is given to cattle suffering from cough or pulmonary diseases. The flowers, it is said, when dried in the sun, give off a fatty substance, which is used in Alsace as a cataplasm. Porcher, in his 'Resources of the Southern Fields and Forests,' thinks that sufficient attention has not been paid to this plant as a medicine, and strongly recommends the desirability of making a careful analysis. In an enumeration of the uses to which the plant is put in North America, he states that the leaves steeped in hot water are applied externally as a feebly anodyne emollient dressing for sores, for the relief of headache and frontal pains, and are much used by the poorer classes. The leaves of this plant and the bark of the root of sassafras, in equal parts, boiled in water and concentrated, then mixed with powdered sassafras bark to form pills, are said to be valuable in the treatment of ague; and finally he refers to a report of "several cases, in which the paroxysms of intermittent fever were completely prevented by the administration of the warm infusion of the fresh root. Four ounces of the fresh root to one pint of water reduced one-half by boiling, of which two ounces

were given every hour, commencing four hours previous to the expected chill."

Other species of *Verbascum* have been said to possess similar properties to the species just mentioned.

In the genus *Veronica*, which is well known in this country as including some of the prettiest of our native flowers, we find several species have been used at various times in medicine. The well known and beautiful little plant, the germander speedwell (*Veronica chamædrys*, L.), was at one time valuable amongst the old herb-doctors as a vulnerary, and Gerarde recommends the root as a specific in pestilent fevers.

The leaves of the common speedwell (*V. officinalis*, L.) are astringent and bitter, and were, even up to a comparatively recent date, not only used as medicine in this country but also as a substitute for tea. The plant grows in South Carolina, and, though not at present included in the United States Dispensatory as an officinal medicine, it is nevertheless, after careful examination, reported to contain "in the fresh juice and an extract from the herb, a bitter principle, soluble in alcohol, but scarcely so in ether; an acrid principle, red colouring matter, a variety of tannic acid, a crystallizable fatty acid, with malic, tartaric, citric, acetic, and lactic acids; a soft, dark, green, bitter resin and mannite." The Brooklime (*V. Beccabunga*, L.), also a British species and found in moist places, was formerly valued as an antiscorbutic, the leaves and young tender stems being the parts used. In some parts the leaves are occasionally applied as a styptic to wounds, and when bruised are also applied to burns. Like the former, this species has been used in North American practice for purifying the blood.

Within the last few years, some attention has been given in America to the Virginian veronica or culversroot (*Veronica Virginica*, L.). It is a perennial plant, common in the United States in mountain valleys, and grows to a height of three or four feet. The root is the part used; it is bitter and nauseous, and imparts its active properties to boiling water. The fresh root is an active cathartic and emetic. A large teaspoonful of the root in a gill of boiling water, repeated every three hours, is said to be an efficient purgative, operating with mildness and certainty, and peculiarly adapted to typhoid and bilious fevers.

The *Gratia Dei*, so called in olden times on account of its active medicinal properties, and known also as the hedge hyssop by the herbalists, is the *Gratiola officinalis*, L. It is a perennial herb, common in moist places in the South of Europe, where it is used in dropsy, jaundice, scrofula, chronic hepatic affections, etc. In large doses, it is poisonous. "According to Vauquelin, the purgative property depends upon a peculiar substance analogous to resin, but differing from it in being soluble in hot water. Dr. Whiting has announced the existence of veratria in it, which accounts for its active properties." Though not used in medicine in this country, it is said to have formed the chief ingredient in a once famous nostrum for gout, known as "eau médicinale." In some of the meadows of Switzerland the plant is said to be so abundant that it is dangerous to allow cattle to graze in them.

In a recent American list of "Pure Medicinal Preparations prepared *in vacuo*" at New Lebanon, occurs a preparation from *Chelone glabra*, L. The plant is known as the snake-head, or balmony, and grows in damp soils. Its action is described as follows in the catalogue above referred to: Tonic, cathartic, and anthelmintic, valuable in jaundice and hepatic diseases, likewise for the removal of worms. Used as a tonic in small doses in dyspepsia, debility of the digestive organs, and during convalescence from febrile and inflammatory diseases. Fluid extract: dose, 1 dram. Chelonin: dose, 1 to 2 grains. Amongst the medicinal plants prepared by the society known as Shakers, the foliage and twigs of *Chelone glabra* are included.

In Kumaon and other parts of India, the roots of *Picrorrhiza kurroa*, Royle, are used in medicine as a tonic and antiperiodic, and are sold in the bazaars, where they occur in short brittle pieces, of a dark colour, somewhat irregular, about the thickness of a goose-quill, but tapering towards the extremities, and covered at this part with numerous small rootlets. They have a dark brown fracture when broken across, and an intensely bitter taste. This medicine is placed in the Indian Pharmacopœia amongst non-officinal articles, with the remark that "it would be desirable to have more information with regard to this root and its properties." Other Indian *Scrophulariaceæ* included in the Pharmacopœia, but not officinal, are, *Herpestis Monniera*, H.B.K., and *Celsia Coromandeliana*, Vahl. The first of these is regarded by the Hindoos as a powerful diuretic and aperient; the juice of the leaves, in conjunction with petroleum, is used as a local application in rheumatism, and the juice of the leaves of the *Celsia* is said to have been given with advantage in cases of acute and chronic dysentery.

Small quantities of the flowers of *Lyperia crocea*, Eckl., have occasionally been brought into this country from the Cape of Good Hope as a dye, but have hitherto failed to attract buyers. As imported, the flowers have somewhat the appearance and smell of saffron. Dr. Pappe, in his 'Floræ Capensis Medicæ Prodromus' says:—"This bush deserves notice as a drug, and in all probability will, ere long, become an article of colonial export. It grows abundantly in some parts of the Eastern districts, whence it has found its way into the dispensary. The flowers, which are called *Geele bloemetjes*, closely resemble saffron in smell and taste; they possess similar medical properties, and as an antispasmodic, anodyne, and stimulant, ought to rank with the *Crocus sativus*. Here they have as yet been only used with success in the convulsions of children, but they deserve a more general trial. On account of the fine orange colour which they impart, they are in daily request among the Mohamedans, who use them for the purpose of dyeing their handkerchiefs. This drug has been observed to be sometimes adulterated by the admixture of other plants of the same genus, which are less efficacious."

Amongst plants of lesser utility belonging to the same order, it will suffice to mention the eyebright, *Euphrasia officinalis*, a decoction or infusion of which is still occasionally used in some parts as a wash for disorders of the eye. It is astringent and slightly bitter. The yellow toad flax, *Linaria vulgaris*, is said to be purgative and was at one time used by the herb doctors for the cure of dropsy. *L. Cymbalaria*, some species of *Antirrhinum*, *Pedicularis palustris*, and *P. sylvatica*, have all been used by herbalists, but they are not of sufficient importance to call for further remark.

A NEW REMEDY FOR HAY FEVER AND SNEEZING.

BY HORACE DOBELL, M.D.,

Senior Physician to the Royal Hospital for Diseases of the Chest.

At this season of the year, when "sneezers" and sufferers from "hay-fever" are in the depths of their miseries, it is merciful to make public any reasonable suggestion for their relief. I have, therefore, much pleasure in being able to bring forward a little contrivance and a prescription, by the combined use of which immense comfort may be given to many sufferers.

The prescription is as follows :—

Chloral Hydrate and Camphor (of each)	16 grains.
Carbolic Acid	20 ,,
Pure Morphia	12 ,,
Oleic Acid (enough to dissolve the morphia)	20 ,,
Castor Oil (the clearest and finest) . .	7 drachms.

Rub well together to make a lotion.*

The "contrivance" is for the efficient application of the above remedy, and consists of a miniature bottle contained in a little box-wood case, so that it can be carried easily in the pocket. To the lid of the box is attached the cork of the bottle, and to the cork, in the same fashion as the spoon of a cayenne-pepper cruet, is fixed a little club-shaped rod of polished ivory, long enough to reach to the bottom of the bottle, and also to the upper extremity of the nostril. The little bottle is kept half full of the lotion above prescribed, and the little rod immersed in it. Directly the patient feels the tickle or other signal of a coming sneeze, he uncorks his bottle, withdraws the ivory club, wet with the oleaginous lotion, and gently pushes it up the nostril till it reaches the seat of the sneeze-signal ; there it should be gently pressed so as to apply the lotion to the part. After this the club is withdrawn and returned to its little bottle of fluid, where it becomes at once charged for a fresh application. As often as the sneeze threatens, the operation should be repeated. Very often one application will keep off a threatened *fit* of sneezing altogether, even though its first effect may be to excite a sneeze.

I have requested Messrs. Savory and Moore to keep this little appliance ready-made and charged with the lotion, so that it can be sent by post without difficulty or delay. It has been of so much comfort in cases within my own practice, that I am sure it is worth while for any one who has not yet found a remedy to give it a trial.

In cases accompanied by much throat irritation, it is advisable to combine with this treatment the use of the "Lozenges for Postnasal Catarrh," prepared from a prescription formerly published by me ("On Winter Cough, etc.," 2nd edition, p. 204), and always kept ready-made by Bell, Savory, Squire, Corbyn, Hanbury, and other leading chemists.

I may add that, when there is great prostration, and a tonic is required, Tincture of Eucalyptus Globulus will sometimes answer better than quinine, especially if there is much feverishness.

None of these remedies should be used without consulting the doctor in attendance on the case.

* As different perfumes affect different patients peculiarly, no scent is added in this formula ; but any one who prefers it may have it scented by the addition of whatever perfume is known to suit best.

INSECT-DEVOURING PLANTS.*

(*Concluded from page* 1001.)

Sarracenias.—In cases of insecticide, next to be considered, such evidence of intent is wanting ; but other and circumstantial evidence may be had sufficient to warrant conviction. *Sarracenais* have hollow leaves, in the form of pitcher or trumpet-shaped tubes, containing water in which flies and other insects are habitually drowned. They are all natives of the eastern side of North America, growing in bogs or low ground, so that they cannot be supposed to need the water as such. Indeed, they secrete a part, if not all, of it. The commonest species, and the only one at the north, which ranges from Newfoundland to Florida, has a broad-mouthed pitcher with an upright lid, into which rain must needs fall more or less. The yellow *Sarracenia*, with long tubular leaves, called "trumpets" in the Southern States, has an arching or partly upright lid, raised well above the orifice, so that some water may rain in ; but a portion is certainly secreted there, and may be seen bedewing the sides and collected at the bottom before the mouth opens. In other species the orifice is so completely overarched as essentially to prevent the access of water from without. In these tubes, mainly in the water, flies and other insects accumulate, perish, and decompose. Flies thrown into the open-mouthed tube of the yellow *Sarracenia*, even when free from water, are unable to get out—one hardly sees why, except that they cannot fly directly upwards ; and a microscopic *chevaux-de-frise* of fine sharp-pointed bristles which lines most of the interior, pointing strictly downwards, may be a more effectual obstacle to crawling up the sides than one would think possible. On the inside of the lid or hood of the purple northern species the bristles are much stronger ; but an insect might escape by the front without encountering these. In this species the pitchers, however, are so well supplied with water that the insects, which somehow are most abundantly attracted thither, are effectually drowned, and the contents all summer long are in the condition of a rich liquid-manure. That the tubes or pitchers of the southern species are equally attractive and fatal to flies is well known. Indeed, they are said to be taken into houses and used as fly-traps. There is no perceptible odour to draw insects, except what arises from the decomposition of macerated victims; nor is any kind of lure to be detected at the mouth of the pitcher of the common purple-flowered species. Some incredulity was therefore natural when it was stated by a Carolinian correspondent (Mr. B. F. Grady), that in the long-leaved, yellow-flowered species, the lid just above the mouth of the tubular pitcher habitually secretes drops of a sweet and viscid liquid, which attracts flies and apparently intoxicates them, since those that sip it soon become unsteady in gait and mostly fall irretrievably into the well beneath. But, upon cultivating plants of this species, obtained for this purpose, the existence of this lure was abundantly verified; and although we cannot vouch for its inebriating quality, we can no longer regard it as unlikely. No sooner was it thus ascertained that at least one species of *Sarracenia* allures flies to their ruin, than it began to appear that—just as in the case of Drosera—most of this was a mere revival of obsolete knowledge.

The Insect-destroying Process.—This was well described sixty years ago, the part played by the sweet exudation indicated, and even the intoxication hinted at, although evidently little thought of in those ante-temperance days. Dr. James Macbride, of South Carolina—the early associate of Elliott in his "Botany of South Carolina and Georgia," and to whose death, at the age of thirty-three cutting short a life of remarkable promise, the latter, touchingly alludes in the preface to his second volume—sent to Sir James Edward Smith an account of his observations upon this subject, made in 1810 and the following years. This was read to the Linnean Society

* From the *Garden*, May 23, 1874.

in 1815, and published in the twelfth volume of its "Transactions." From this forgotten paper (to which attention has lately been recalled) we cull the following extracts, premising that the observations mostly relate to a third species, *Sarracenia adunca*, alias *variolaris*, which is said to be the most efficient fly-catcher of the kind:

"If, in the months of May, June, or July, when the leaves of those plants perform their extraordinary functions in the greatest perfection, some of them be removed to a house and fixed in an erect position, it will soon be perceived that flies are attracted by them. These insects immediately approach the fauces of the leaves, and, leaning over their edges, appear to sip with eagerness something from their internal surfaces. In this position they linger; but at length, allured, as it would seem, by the pleasure of taste, they enter the tubes. The fly, which has thus changed its situation, will be seen to stand unsteadily; it totters for a few seconds, slips, and falls to the bottom of the tube, where it is either drowned or attempts in vain to ascend against the points of the hairs. The fly seldom takes wing in its fall and escapes. . . . In a house much infested by flies, this entrapment goes on so rapidly that a tube is filled in a few hours, and it becomes necessary to add water, the natural quantity being insufficient to drown the imprisoned insects. The leaves of *S. adunca* and *rubra* [a fourth species] might well be employed as fly-catchers; indeed, I am credibly informed they are in some neighbourhoods. The leaves of the *S. flava* [the species to which our foregoing remarks mainly relate], although they are very capacious, and often grow to the height of 3 feet or more, are never found to contain so many insects as those of the species above mentioned.

"The cause which attracts flies is evidently a sweet viscid substance, resembling honey, secreted by or exuding from the internal surface of the tube. . . . From the margin, where it commences, it does not extend lower than one-fourth of an inch.

"The falling of the insect as soon as it enters the tube is wholly attributable to the downward or inverted position of the hairs of the internal surface of the leaf. At the bottom of a tube split open, the hairs are plainly discernible pointing downwards; as the eye ranges upward, they gradually become shorter and attenuated, till at, or just below, the surface covered by the bait, they are no longer perceptible to the naked eye nor to the most delicate touch. It is here that the fly cannot take a hold sufficiently strong to support itself, but falls. The inability of insects to crawl up against the points of the hairs I have often tested in the most satisfactory manner."

From the last paragraph it may be inferred that Dr. Macbride did not suspect any inebriating property in the nectar, and in a closing note there is a conjecture of an impalpable loose powder in *S. flava*, at the place where the fly stands so unsteadily, and from which it is supposed to slide. We incline to take Mr. Grady's view of the case. The complete oblivion into which this paper and the whole subject had fallen is the more remarkable when it is seen that both are briefly, but explicity, referred to in Elliott's book, with which botanists are familiar. It is not so wonderful that the far earlier allusion to these facts by the younger Bartram should have been overlooked or disregarded. Fine writing was his foible; and the preface to his well known "Travels" (published at Philadelphia in 1791) is its full-blown illustration, sometimes, perhaps, deserving the epithet which he applies to the Palms of Florida—that of pomposity. In this preface he declares that "all the *Sarracenias* are insect-catchers, and so is the *Drosera rotundifolia*." "Whether the insects caught in their leaves, and which dissolve and mix with the fluid, serve for aliment or support to these kinds of plants, is doubtful," he thinks, but he should be credited with the suggestion. In one sentence he speaks of the quantities of insects which, "being invited down to sip the mellifluous exuvia from the interior surface of the tube, where they inevitably perish," being prevented from returning by the stiff hairs all pointing downwards. This, if it refers to the sweet secretion, would place it below, and not, as it is, above, the bristly surface.

Why should these plants take to organic food more than others? If we cannot answer the question, we may take a probable step towards it. For plants that are not parasitic, these, especially the Sundews, have much less than the ordinary amount of chlorophyll—that is, of the universal leaf green upon which the formation of organic matter out of inorganic materials depends. These take it, instead of making it, to a certain extent. What is the bearing of these remarkable adaptations and operations upon doctrines of evolution? There seems here to be a field on which the specific creationist, the evolutionist with design, and the necessary evolutionist, may engage in an interesting, if not decisive, "triangular duel."

ORANGE-COLOURED GLASS AS A MEANS OF PROTECTING VOLATILE OILS.*

BY WILLIAM PROCTER, JUN.

The query, What is the actual value of orange-coloured window-glass as a means of preventing the chemical action of light on volatile oils? appears to have been suggested by the use made of such glass by photographers, to prevent the decomposition of chloride and iodide of silver in the working of their processes, so as to avoid the need of being in a dark room. It is still a mooted point how far such glass will prevent the passage of actinic rays, and philosophers even disagree as to where in the spectrum, or beyond it, lies the greatest chemical influence. The question as presented above is, however, a practical one, intended to decide whether oils in colourless glass bottles, if kept in cases glazed with orange-coloured glass, will be as exempt from actinic action as though placed in a dark closet, and if so, whether orange-coloured glass is the proper material to construct glassware for this and other purposes where actinic action is to be avoided? About six months ago a closet was prepared with glass doors of orange colour, and the regular set of dispensing bottles of half-pint capacity arranged in it on shelves, to the number of about thirty distinct oils. The bottles had previously been kept on open shelving; and before being placed in the closet each bottle was emptied, thoroughly cleansed of resinous and other deposit, washed with alcohol and dried, when the clear oils were returned. At the same time two small vials were filled with oil of peppermint and two with oil of lemon, both oils being of the best quality. One of each was kept in the oil closet and the other set in a closet near the window of colourless glass. The writer was too much occupied with other matters to make corresponding experiments in and out of the closet with all the oils, and hence no result was arrived at of a character satisfactory in resolving the query *pro* or *con*. None of the oils in the closet exhibited deposition of resin, crystalline matter, or other deposit worthy of note. So far as could be remembered, their colour was but little changed; but as, in all respects except the light, they were subjected to the previous conditions surrounding them, being frequently opened for dispensing, it will be interesting to ascertain if their modified condition as regards light really retards atmospheric oxidation. The oil of peppermint kept in the closet appeared of the same colour (nearly colourless) as that kept in the light, but its odour was less marked to a perceptible degree. The oil of lemon, in both conditions, had a flocculent sediment, but was otherwise so nearly alike as to appear the same when applied to the nose, yet the oil in the vial exposed to light was evidently lighter in colour by bleaching.

A vial of (expressed) oil of orange-peel, after two months' retention in the closet, was found to have undergone the usual deterioration.

* Paper read before the American Pharmaceutical Association at Richmond, Va., September, 1873.

THE SELECT COMMITTEE ON THE ADULTERATION ACT.

At the sitting of the Committee on Thursday, June 18, the first witness examined was Dr. Hassall.

Asked as to his opinion of the effects of the Act, he said that on the whole it had been greatly beneficial in lessening adulteration; but he thought it would be an improvement if facilities were given for obtaining samples direct from the manufacturer, so as to hit directly those who adulterated or manufactured adulterated articles. The retailers were in a great measure answerable for the adulterations, for they did not pay for the adulterated articles the price which would be charged for genuine articles, and the dealer who did not desire to sell adulterated articles ought to be placed on his guard even by the price charged to him wholesale. Besides, the retail dealer could make the wholesale trader or manufacturergive him a warranty as to the genuineness of the goods bought by him; and, moreover, it would not be too hard to insist that the dealer himself should know something of the goods in which he dealt. It was witness's decided opinion that all articles should correspond strictly with the names under which they were sold—cocoa should consist wholly of cocoa, and should not be, under that name, an admixture of cocoa, sugar, and starch, as it often was; and mustard, when bought as such, should be mustard, and not, as it too frequently was, a mixture of mustard, turmeric, wheaten flour, and sometimes cayenne pepper. There might be a demand for these mixtures; but they should be sold for what they were, and not for what they were not. Questions were put relating to Dr. Voelcker's evidence respecting analysts' analyses of late and the position of the new official analysts. Witness said he thought such a position should be made one worth occupying by able men. He demurred to Dr. Voelcker's views as to the difficulty of distinguishing animal fats when mixed in butter, as stated by that gentleman when speaking of some analyses made of compositions sold as butter; and the witness declared that there is a method for analysing the fats in so-called butter, and, with all respect to Dr. Voelcker, he thought that gentleman had been rather hard upon the analysts in discrediting some of their work. Some allowance should be made, for there had been a suddenness in the demand for educated analysts; but the demand would create the supply. Referred to the adulteration of tea, the witness said he should most decidedly say that any artificial colouring of tea whatever was an adulteration, for this was practised to make a tea assume a higher quality, and to make one class of tea appear to be another; but he should not say that the usual colouring in cheese and butter was adulteration. He then read a long statement as to the definitions he would place on adulteration, and the admixtures and abstractions which might be lawfully allowed without detriment to the purchaser, such as a certain amount of salt in bread, the abstraction of a certain amount of oil from cocoa, the recognition of a certain quantity of salt and water in butter, and the like; but he made no reference (purposely, he said) to the adulteration of drugs. He thought the two acts should be incorporated, and not, as now, the one taken to read by the other, and he thought that analysts should be appointed for large districts. He was opposed to the idea of a Board of Analysts, as proposed by some witnesses, for the review of analyses, and he spoke in marked terms of the little value to be attached to the evidence of the class of men who were ready to give evidence of defence on every occasion. Moreover, with respect to the suggestion made that there should be a public laboratory at Somerset House, he pointed out that the Government analysts had enough to do to protect the revenue; but, while he was against any court of appeal, he thought the Government Inspectors were quite competent to stop the adulterated teas in bond. He thought that if tea was inspected and stopped in bond when adulterated there would be little adulterated tea in this country. In answer to Mr. Colman, the witness said that "corn-flours" were of a starchy nature, and should not be given as food except in combination with other foods, such as eggs or milk. He had lately been thinking why "corn-flours" were not made as wheaten flours were made, so as to leave in them the nitrogenous qualities of the corn (which are taken from "corn-flours"). It occurred to him that the flours would, as food, be better than they were as now prepared, if their nitrogenous properties were in them; but then they would not be applicable to the same uses to which they were now applied—their quick preparation and their uses as blanc-mange. He referred to a paper, which he was about to read, in reply to a question from the examiner, and, at the suggestion of the Chairman he put it in, and this, he said, showed the differences between butter fats and other fats, and gave the mode by which the characteristic qualities of each could be distinguished. In reply to Mr. Backhouse, he thought that one of the necessary qualifications of an analyst was that he should have a knowledge of medicine. He thought that many analysts were not sufficiently well paid to make the appointments tempting to experienced men; but the chief obstacle to the appointments being properly and efficiently filled was the liability which the analyst had of being called to a court to give evidence, for this caused him a grievous loss of time. He was not opposed to the payment by fees, but this made appointments of little value; for he held one for a place (the Isle of Wight) which had not yet sent him a single sample for analysis. In reply to Sir Charles Dilke, the witness said that at the present time a good deal of education was going on in the laboratories of analytical chemists to qualify persons under the present or any future Act. Sir Henry Peek handed the witness some samples of nutmegs, and asked if they were pure. The witness looked at them, and said that possibly they were "limed;" and Sir Henry asked, if they were, could witness say they were adulterated. The witness said he should like to see what proportion of lime there was in the nutmegs before he answered, and, of course, he allowed, logically, he ought to object to the limed nutmegs as he did to faced tea. He was not aware, he said, in answer to Sir Henry, that years ago the Dutch Government would not permit any but "limed" nutmegs to be exported, and, if that were so, then we should have to put up with it; but it should be said on the label that the things were limed. Sir Henry asked if the witness thought it was the duty of a Government to teach the people what they ate and drank; and he replied that it was the duty of the Government to protect the people, and the people should know what they ate and drank. Told a case where a person was fined because 5 per cent. of water was found in milk, he said he should not have prosecuted in such a case, but he most decidedly should in a case where 20 per cent. had been found—a point at which Dr. Tidy said he should not, and there he differed with Dr. Tidy.

The next witness was Professor Wanklyn, M.R.C.S., public analyst for Bucks, Buckingham, and High Wycombe. He said he had analysed more than 1,000 samples of milk bought in London in 1871 and 1872 (before the passing of the Adulteration Act), and had found 90 per cent. of them to be either watered or skimmed, or else both watered and skimmed. Since the passing of the Act he had not had such extensive opportunities of examining the London milk, and could not say absolutely whether or not there had been much improvement. On the subject of milk-standards, he said his standard was founded on a most laborious investigation, undertaken for the Royal Agricultural Society of Sweden, on results obtained in Switzerland and America, and on his own investigations. Milk was very constant in certain particulars. The usual yield of fat was $3\frac{1}{2}$ per cent. By high feeding the fat might be sent up to a little above 4 per cent., and, under exceptional circumstances, it might fall to 2 per cent. The very wide range given by some witnesses, he attributed to mistaking experimental error for variation in the milk. Some degree of confusion had arisen from

taking the yield of cream to represent the proportion of fat present in the milk. The lactometer was not to be depended on, because it confounded watered milk with exceptionally rich milk. He had been concerned in two butter cases at Sittingbourne wherein the dealer had been charged with selling butter adulterated with foreign fats, and wherein Dr. Wright and himself had found no signs of foreign fats. In a butter case at Liverpool, a similar charge brought against a dealer had been disposed of by Dr. Anderson of Glasgow. He did not agree with Dr. Hassall as to the possibility of detecting admixtures of common fats with butter, and would undertake to prepare such mixtures which Dr. Hassall would not be able to distinguish from pure butter; and, in answer to the chairman, said he agreed with Dr. Voelcker in this particular. In reference to tea, he said the facing of it was a perfectly legitimate practice, and was to be defended on the same grounds as the colouring of cheese, or, indeed, as the dyeing of our clothes. The facing of tea was not injurious to health, and did not add sensibly to the weight of the tea. Cocoa in its unprepared state would not be a saleable article in this country. He considered that the sale of cocoa, either simply deprived of some fat or else mixed with starch or sugar, was perfectly legitimate, the mixed cocoa, indeed, being more perfect as a dietary than the unmixed. Corn-flour he looked upon as a perfectly legitimate article of commerce. It did not, indeed, constitute a perfect dietary, but it was nutritious and wholesome, and well deserved its popularity. In reply to the question as to modifications or alterations of the Act, he proposed to insert "sensibly" or some such adverb before "increase the weight," in order to stop "fancy prosecutions." He objected most strongly to all reference to Somerset House as a final Court of Appeal in disputed cases, on the ground that the chemists at Somerset House would not sufficiently command the confidence of the general body of chemists, and that such Government sanction would practically be to license blundering. If there were no legislative interference, disagreements between analysts would rectify themselves. The main obstacle to the proper working of the Act was the backward condition of that branch of chemical analysis which related to adulteration, and this would be remedied in process of time.

The last public sitting of the Committee was held on Monday.

The first witness called was Major Donnelly, of the South Kensington Museum Department, who was told by the Chairman (Mr. C. S. Read) that the Committee had had various suggestions that it was essential, for the proper carrying out of an Adulteration Act through analysts, that those who received public appointments to make analyses should prove their capabilities by undergoing examination before some public department; and the Committee desired to know if any public department could undertake this. The witness replied that the College of Chemistry, which had been removed to South Kensington and was under Dr. Frankland, possessed everything necessary for such examinations. Some communication had been made to the Local Government Board on this subject, but nothing had been absolutely done. Asked if the Science and Art Department or Somerset House would be the better to have this responsibility, he said he could not give an opinion on that; but he thought the South Kensington laboratory was the larger. He saw no difficulty in analysts passing an examination at South Kensington, and he thought four days or a week would be ample to test a man's capabilities. He thought, too, that an examination, and the passing such under a public department, would give more confidence than was now given, and would, moreover, have the collateral advantage that there would be greater uniformity of agreement among the analysts as to what was or what was not to be considered as adulteration. In reply to Mr. Welby, the witness said there were students at the laboratory at South Kensington, and the full course of study was about two years. Some were there for trade purposes, some for training as manufacturers, and there were also some Japanese; but he did not mean that only analysts who had been brought up there as chemists should be appointed to public positions. A properly qualified chemist could go through his examination in a few days. In reply to Sir H. Peek, the witness said the laboratory was to some extent supported by the fees of students, but, of course, there was a grant of public money. Sir H. Peek asked if some of the public analysts now appointed received half the instruction given at South Kensington (the point of time was directly referred to), and the witness replied that he believed not.

Mr. Greenwell, the vestry clerk of St. Marylebone, gave evidence as to the necessity of there being corrections in the Acts of 1860 and 1872, so as to make clear the intention of the Legislature that the metropolitan local authorities should receive the penalties in aid of the expenses incurred in carrying out the law. He believed that in all parts of the country the local authorities received the penalties recovered; but that in London the Receiver of Police had claimed the penalties under the Police Act of 1839, notwithstanding that the Adulteration Act of 1860 had specially ordered that these penalties should go to the local authorities.

Mr. W. Rogers, the solicitor of the Westminster Board of Works, complained of the interpretation of the Act by London magistrates. Some of these required the analyst himself to be present to give evidence, and when this was required there was a failure of justice if he were not brought. Other London magistrates did not require to have the analyst, but took the certificate as evidence, and in that case no expenses were allowed for bringing the analyst.

The inquiry then reverted to the tea question, with especial reference to the correctness of the evidence given by Mr. Whitworth Jackson ("A Wholesale Tea Dealer," of the *Times*). Mr. Robert Jackson, the father, and Mr. William Jackson, the uncle, of this witness, stated that with the exception of some time during which he with his father carried on the Himalaya Tea Company, his experience was confined to his father's business, which was carried on at Manchester. Both denied emphatically the principal assertions made in the evidence referred to, and Mr. William Jackson said that a large part of what Mr. Whitworth Jackson had stated existed only in his own imagination and the other part consisted of exaggeration.

The witness, Mr. Whitworth Jackson, whose father had just been giving evidence against him, then advanced, and said he wished to corroborate his own evidence. He was proceeding to read a statement as to his opinion of the evidence given in opposition to his own and to disprove his, when he was stopped by the Chairman, who requested him to give any facts if he had any to give. The witness then declared that the practices to which he referred in his letter to *The Times* occurred in his father's house, and proceeded to state the reason why he had not made the statement before when under examination.

The Committee conferred together for a moment, and then ordered the room to be cleared. When the doors were again opened, the Chairman said he had been requested by the Committee to say that they unanimously declined to receive any further evidence from Mr. Whitworth Jackson.

Mr. Lumley, Q.C., the counsel of the Local Government Board, then gave evidence as to the improvements he suggested in the Acts. He suggested that the Acts should be incorporated; and he then went on to give such detailed criticisms on the Acts as to show that the need of improving their language, meaning, and purpose, was such that if carried out the statute would be altogether a different one. The witness gave a lengthy review of the law on adulterations, and stated some of the judgments which had been passed.

The Committee then adjourned *sine die*, the Chairman having previously said that this would be the last witness.

The Pharmaceutical Journal.

SATURDAY, JUNE 27, 1874.

PHARMACY IN IRELAND.

IN the present number of the JOURNAL will be found the Bill to which reference was made last week in our article on the subject of Irish Pharmacy. It turns out to be the Bill of the College of Physicians, a rough draft of which we published some weeks since.*

The second reading of this Bill was to have come on in the House of Commons last Tuesday, but it was postponed, and probably the Bill may not come before Parliament for some time. Meanwhile, it will be desirable to consider what would be the effect of its provisions, should it become law as it stands. In its present form the Bill does not, in effect, differ materially from the rough draft previously published, its leading principle being the extension of the British Pharmacy Acts to Ireland. But an important addition has been made, of a clause providing that the Pharmaceutical Society of Great Britain shall appoint examiners for Ireland, who are to conduct the Society's examinations in Dublin, just as they are now conducted in Edinburgh for North Britain.

The object contemplated by this Bill appears to be one in every way consistent with requirements that are acknowledged to be very inadequately provided for in Ireland under existing conditions. Moreover, the introduction of the Bill is but a somewhat tardy attempt to carry out the intention of the Legislature in regard to Ireland, at the time when the Pharmacy Act (1868) was passed.

However, there is reason to believe that there will be some opposition to the measure. On a former occasion we expressed ourselves unable to state what would be the attitude assumed by the Apothecaries' Hall of Ireland in regard to the Bill proposed by the College of Physicians. All we could then do was to conjecture that the body of apothecaries would not be altogether averse to it. We came to this conclusion, no less from the knowledge of the recognition by that body that the requirements of the public in regard to the dispensing of medicine were insufficently provided for, than from the views publicly expressed by the Governor and Directors of the Hall as to the maintainance of the standard of pharmaceutical qualifications.

By degrees, however, it has become apparent that there are, on the part of the Apothecaries' Hall, objections to the course proposed by the College of Physicians. During the last few months those objections have been put forward more definitely; and it is at length clear that the Apothecaries' Hall of Ireland desires to maintain, not only the standard of qualification for the practice of pharmacy, but also the monopoly it has hitherto enjoyed in granting licences to keep open shop for the sale of medicines and compounding of prescriptions.

We have, in fact, in these circumstances, another instance of the conflict between vested interests and consideration of the interests of the public. The Apothecaries' Hall bases its claim on the plea that the power and control exercised under existing statutes of the Irish and Imperial legislations were justifiable, and have proved, for nearly one hundred years, highly conducive to the public safety, by confining the compounding of medical prescriptions to persons duly educated and examined. In this respect, it is only just to admit that the influence of the Apothecaries' Hall has been eminently beneficial; and that the fact of there being a law to prevent incompetent persons from dispensing medicine in Ireland, was a good reason for not making the Pharmacy Act of 1868 apply at once to Ireland. But beyond this the argument will not stretch, and it is of no avail when urged in support of opposition to a measure intended to provide for undeniable and admitted public wants.

The truth is, that while the Apothecaries' Hall of Ireland does not itself provide an adequate supply of qualified pharmacists to satisfy present requirements in Ireland, its privileges operate as a barrier to the provision for those wants in other ways quite as well calculated to ensure competency as the licence granted by the Hall. However highly we may appreciate the wholesome restrictive influence of the Hall in times past, we cannot regard that as a reason for its action in the present being inconveniently obstructive.

It is, we think, equally illogical to object to the extension of the Pharmacy Act to Ireland, on the ground alleged by the Apothecaries' Hall, that for several years to come, registration under the Act of 1868, as a chemist and druggist, will afford very inadequate proof of pharmaceutical knowledge, or of competency to compound medical prescriptions. In regard to this point, it is urged that, in England, until the Pharmacy Act of 1868 came into operation, any person, however ignorant or incompetent, might keep open shop for the dispensing and compounding medical prescriptions. That this is a fact must, as a matter of history, be admitted as well as deplored; just as in the same sense we rejoice that a better state of things has prevailed in Ireland. But though all persons engaged in business as chemists and druggists, in Great Britain on the 31st December, 1868, were at once admitted to be registered as such under the Act, without any further proof whatever of competency, and though the oper-

* PHARM. JOURN., p. 847.

ation of the Act was only prospective as regards education and examination being obligatory, we fail to perceive what valid argument against the extension of the Act to Ireland can be deduced from those circumstances.

If it be the maintenance of pharmaceutical competency alone that is desired by the Apothecaries' Hall of Ireland, it seems to us that there are other ways of striving to attain such a desirable object besides root and branch opposition to the extension of the Pharmacy Acts to Ireland. They might well refer to the precedent afforded by the course of events in this country, and demand that the application of those Acts to Ireland should take place in the same order that they came into force here; that the licensed class should at first be the pharmaceutical chemists, as corresponding more fully with the licenciates of the Hall, in regard to competency for carrying on the business of a pharmacist. The historical interest of the Hall in the well-being of pharmacy, might well claim respect for such a demand. So, likewise, might they reasonably and consistently claim that the full extension of the 1868 Act to Ireland should not come into force until after such time as the "chemists and druggists" of the old stock, to which objection is taken, should be exhausted.

As regards the injustice to Irish chemists and druggists that it is assumed would result from an extension of the Acts of 1868, it seems that all difficulties might be got over by suitable adjustment of the period at which the Act should come into operation. There would then be no ground for complaining that Irish chemists and druggists were debarred from selling articles classified as "poisons," which they now are entitled to sell, nor would any inconvenience to the public on this score be caused in rural districts.

But perhaps the strongest reason for objecting to the continuance of the power and control of the Apothecaries' Hall of Ireland in regard to purely pharmaceutical matters is the fact that the educational system, as well as the qualification of the Hall, are essentially those of a medical institution. As we pointed out on a previous occasion, the curriculum requisite for obtaining the licence to dispense prescriptions comprises subjects wholly foreign to a pharmaceutical career; it involves an outlay of money and expenditure of time wholly unnecessary, and quite inconsistent with the growing tendency to separate the practice of medicine from that of pure pharmacy.

Since writing on this subject last week, we have received from Dr. LEET, the Registrar of the Apothecaries' Hall of Ireland, a rough draft of the Pharmacy Bill for Ireland proposed by the Governor and Council of the Hall, together with a copy of the answer to the letter of the King and Queen's College of Physicians. Most of the points referred to in that communication have already been dealt with, on the present and previous occasions; and we have in the present number printed such portions of the amended Pharmacy Bill of the Irish Hall as present any deviation from the British Pharmacy Acts.

With these data before them, and by reference to the reports of proceedings relating to Irish Pharmacy which we have from time to time published lately, our readers will be enabled to become acquainted with the main facts of the case, which will sooner or later come before Parliament for decision.

ENGLISH PHARMACY SEEN THROUGH "SILVER" SPECTACLES.

"INTELLIGENT foreigners" who visit England are apt to fancy that in a few weeks they acquire a sufficient insight into the character and customs and politics of her people to qualify them for expressing weighty judgments *de omnibus rebus et quibusdam aliis;* an opinion, however, that is usually confined to the critic. But none the less useful is it—

"To see oursel's as others see us,"

when the eyes of those "others" are educated eyes. It is therefore with pleasure that we find recorded in the *Revista Farmacéutica*, the organ of the Argentine Society of Pharmacy, the impression respecting English pharmacy produced during a recent visit to this country upon the mind of Señor JUAN J. J. KYLE, who, twenty years since, was an assistant to a present member of the Council of the Pharmaceutical Society, residing at Liverpool, but who is now the principal editor of our South American contemporary, and Professor of Chemistry in the College of Buenos Ayres.

Señor KYLE says that he had the opportunity of seeing many pharmacies, both in England and Scotland. He also visited the "celebrated School of Pharmacy in London, the property and the glory of the Pharmaceutical Society of Great Britain," and had the "pleasure of becoming acquainted with the active Secretary of the Society, Mr. BREMRIDGE, the illustrious Director of its Laboratories, Dr. ATTFIELD, and the intelligent Curator of its Museums, Mr. HOLMES." From these gentlemen, as soon as it was known that he was a member of the Pharmaceutical Society of the Argentine Republic, he received a prodigality of attention, and was conducted "through all the grand edifice in Bloomsbury Square." This establishment he considers to be a "noble, and at the same time, useful monument to the perseverance of its founders, whose sole motive was the desire to elevate English pharmacy to the rank of a profession, from the low social position it occupied not many years since." This leads to a description of the various ways by which the Society has sought this object, and an expression of opinion that "grand results have crowned its noble efforts and rewarded its perseverance." Señor KYLE says it has been a source of "great satisfaction to be able to congratulate his old friends upon having obtained so flattering a result during the years he has been absent from

England." He also appreciates "the pride they must have in possessing a museum so rich in pharmaceutical products, perfectly classified, a library the shelves of which bear thousands of scientific books, and a well-appointed laboratory."

The system of instruction in the School of Pharmacy, and the various examinations, are described by Señor KYLE with an apprehension of details which testifies that he made good use of both eyes and ears during his visit. Concerning them he says, "With a system of teaching, such as indicated, and theoretical and practical examinations like these, there can be no doubt that the new generation of English pharmacists will occupy a position in the scientific world more distinguished than had been possible previous to the foundation of the Pharmaceutical Society."

The working of the Adulteration Act in relation to chemists and druggists seems to have attracted the special attention of Señor KYLE, for he refers both to the citrate of magnesia case, and that of the sweet spirit of nitre. Respecting the latter he says: "This celebrated case showed that the application of the new law against adulteration by persons incompetent because of their small practical acquaintance with pharmacy may prove very unbearable to the pharmaceutical body." Of Dr. DUPRÉ, the chemical analyst in this case, he expresses the opinion that his "incompetence in dealing with a question of pharmacy was manifest." He then adds that, "if this analyst had been practised in the art of pharmacy, he would not have presented the sorry figure he did before the tribunal at Westminster two months since, though without doubt the decision of the magistrate in this case will exercise a salutary influence in avoiding abuses of the law, such as that sought by the Westminster Board of Health."

In the internal administrations of the pharmacy, Señor KYLE noticed an abbreviation in the hours of labour, which he covets for his own countrymen. After telling them that in a great number of establishments the doors are now closed at eight in the evening, and are only open two or three hours on holidays (*dias festivos*), he says, "When shall we, in Buenos Ayres, be able to imitate our English colleagues, and emancipate ourselves from the slavery of a system which obliges the Argentine pharmacist to stand from seven o'clock in the morning until eleven at night, working-days and holidays, at the service of the public?" The value of legs as a pharmaceutical qualification in this country is also commented on. "It is very curious to read the advertisements in the periodicals. An assistant who seeks an engagement frequently announces the number of feet and inches of his stature, and offers to remit his *carte de visite*."

One great defect appears to Señor KYLE to exist in the laws regulating pharmacy in this country. It is that the English pharmacist may keep open as many shops as he wishes, without providing for them competent superintendents. This he thinks to be a grave defect, which will lead to much abuse if not remedied.

The last extract that we shall be able to borrow from Señor KYLE's account of his visit may, we hope, be thought suitable for quotation by some of our medical contemporaries who are so ready to dilate on the duties of pharmacists. Señor KYLE says, "There exists in England an anomalous hybrid race, who are neither medical men nor pharmacists, *pur et simple*, but who, without hindrance, practice at the same time the arts of HIPPOCRATES and GALEN. These gentlemen keep a more or less complete shop, and prepare their own prescriptions in their own way without being under any inspection whatever, and without being subject to any species of regulation. Notwithstanding this, the medical men complain because in some pharmacies the pharmacist ventures to prescribe a soothing draught or purgative pill at the request of a customer who does not consider himself sufficiently unwell to consult a doctor; and they do not see the inconsistency of allowing a medical man who sells tinctures and other things, of the actual composition of which he is completely ignorant, to arrogate to himself privileges that ought to belong solely to the professional pharmacist. In this state of affairs, which undoubtedly will disappear with time, it is not strange that many pharmacists see themselves compelled to associate with pharmacy a dealing in perfumery and cigars, or to accept the post of postal or telegraph agent." We hope that our Buenos Ayres colleague's prophecy that this state of things will disappear, may some day come true, and the sooner the better!

SECOND LIST OF SUBSCRIPTIONS FOR PAINTING THE PORTRAIT OF THE LATE MR DEANE.

	£	s.	d.
Professor Attfield	1	1	0
Mr. Carteighe .	1	1	0
,, Gale . . .	1	1	0
(The above were accidentally omittted from the first list.)			
Mr. F. A. Crisp, Jun.	1	1	0
Mr. J. Good . .	1	1	0

Messrs. Bell & Co.	1	1	0

Other gentlemen desiring to join in this testimonial are requested to send their names to Mr. Sandford, 47, Piccadilly.

ON Wednesday of last week, at a meeting of the members of the Croydon Microscopical Club, under the presidency of HENRY LEE, Esq., F.R.S., Mr. HENRY LONG, Pharmaceutical Chemist, was presented with a handsome binocular microscope, in recognition of the active part he took in the formation of the club, and of his services as Honorary Secretary.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 18th June, 1874. Professor Frankland, F.R.S., Vice-President in the Chair. The ordinary business of the Society having been transacted, the papers and memoirs, of which there were a large number, were read. The first was "On the Action of Chlorine, Bromine, etc., on Isodinaphthyl," by Mr. W. Smith. Dr. Armstrong then read four communications from the Laboratory of the London Institution: No. XIII., on "Coal Tar Cresol and some Derivatives of Paracresol," by H. E. Armstrong and C. L. Field; No. XIV., on "The Action of the Chlorides of the Acids of the Sulphur Series on Organic Compounds," by H. E. Armstrong and W. H. Pike; No. XV., on "Chloro-bromo and Iodo-nitro Phenolparasulphonic Acids," by H. E. Armstrong and F. D. Brown; and No. XVI., "Note on the Decomposition of Dichloronitrophenol by Heat," by H. E. Armstrong and F. D. Brown. The sixth paper was by Mr. G. Neison, on "The Products of the Decomposition of Castor Oil:" No. III., on "Decomposition by Excess of Alkaline Hydrate," in which he has succeeded in elucidating the conflicting statements of the different chemists on this subject. The seventh was on "Hydrogen Persulphide," by Dr. W. Ramsay; the eighth, "Suberone," by Dr. C. Schorlemmer and Mr. R. S. Dale; the ninth, on "The Action of Nitrosil Chloride on Organic Bodies: Part I., on "Phenol," by Dr. W. A. Tilden; the tenth, eleventh, and twelfth, "An Apparatus for Determining the Moisture and Carbonic Anhydride in the Atmosphere," "A Method for Determining Ozone in the Presence of Chlorine and Nitric-oxide," and on "The Constitution of Urea," by Dr. D. Tommasi; the thirteenth, on "The Restitution of Burnt Steel," by Mr. S. L. Davies; fourteenth, on "The Action of Earth on Organic Nitrogen," by Mr. E. C. Stanford; and fifteenth, "Aniline and its Homologues in Coal Tar Oils," by Mr. W. Smith. This, the last meeting of the session, was finally adjourned, at a late hour, until November next.

PARIS SOCIÉTÉ DE PHARMACIE.

A meeting of this Society was held on Wednesday, June 3, under the presidency of M. Planchon. Among the papers read were a note from M. Schlagdenhauffen, on the action of permanganate of potash upon the sulphides; a note from M. Chapuis, pharmacien militaire, on the estimation of cinchonas, which was referred to the committee entrusted with this subject; and a thesis upon the elimination of arsenic.

Dr. De Vrij communicated a series of notes. The first was relative to the presence of an ammoniacal salt in normal urine, a fact that he had established long since and which had been recently confirmed. The second referred to a variety of *Cinchona*, which has been described lately under the name of *C. Hasskarliana*, and which he said was a hybrid between a sickly *C. Calisaya* and a vigorous *C. Pahudiana*. In a third he referred to the discovery of the presence of the new alkaloid, quinaminc, in a red bark, from the foot of the Himalayas, which has already been described in this Journal. He next gave a caution against a possible cause of error in the estimation of barks. He had noticed that caustic soda, which he employed, to the exclusion of ammonia, for the precipitation of the mixed alkaloids, precipitated also a product analogous to quinovic acid; he therefore recommended the employment of a great excess of soda, decantation from the precipitate, and the treatment of the latter with an acid. Finally, Dr. De Vrij rectified an error which he had committed in attributing to ozone the coloration of ether by iodides, it being due to peroxide of hydrogen.

M. Roucher described to the Society his researches upon digitalin, which he has communicated to the Academy of Medicine. He recognizes three principles: the crystallized digitalin of Nativelle, the globular digitalin of Homolle, and the soluble digitalin studied by Lefort, all three having active properties. He had found that the crystallized digitalin changed into globular digitalin under the influence of dilute alcohol, and even of pure water. Its crystals were at first transformed into globules covered with crystalline points, and then into crystalline masses.

M. Limousin said that the word globular was wanting in precision. The product of transformation was either crystalline or amorphous; there was no alternative.

M. Roucher said he had recognized the fact, but he could not explain it, and he offered to repeat the experiment of the conversion of crystallized into globular digitalin before the Society, under the field of a microscope. In reply to a question, he said that he had not been able to effect the inverse transformation of globular into crystallized digitalin.

M. Boudet reported to the Society the state of the labours of the Committee upon the International Codex, which are very advanced, and will be terminated in time for presentation to the Congress at St. Petersburg. He also requested the Society to appoint a member of the Committee as a delegate from the Society to the Congress and to vote a sum of money to cover a portion of the expense, the delegate offering to make up the deficiency of the sum allowed. The latter proposition was referred to a special committee.

M. Bussy proposed that the Committee should present a summary of its work before the departure of the delegate. It was decided that such a summary should be presented for the Society's approbation at the next meeting, under the form of a report by the delegate charged to represent the Society at the Congress.

M. Guichard reported that he had determined the nature of the crystals extracted from tolu, which he had exhibited at the last sitting; he considered them to be pure cinnamic acid. Those from benzoin were a mixture of cinnamic and benzoic acids.

PHILADELPHIA COLLEGE OF PHARMACY.

The last meeting of the session was held in the Hall of the College, on May 9th, under the presidency of Mr. A. P. Brown.

Professor Maisch presented a specimen of the flowers of *Pyrethrum roseum*, used in the preparation of insect powders. A discussion took place, during which it was stated that the powder made from the above flowers possessed a more decided and somewhat different odour from that generally seen in the United States market; and it was stated that, in powdering, large quantities of insect powder flowers were fraudulently mixed with old chamomile flowers, matricaria, etc.

Professor Maisch exhibited a sample of the leaves of *Liatris odoratissima*, which are used for perfuming tobacco, preserving cloths, etc., and according to Professor Procter contain coumarin.

Mr. A. P. Brown called the attention of the meeting to the miserable quality of the oil of sandal wood as generally furnished by the wholesale druggists. He showed a specimen of pure oil which possessed the usual persistent odour, whilst the other was of a thicker consistence, weaker in odour, and had the smell of oil of copaiba in addition.

A communication from Mr. Wilder was read, as follows:

Cudbear *versus* Cochineal.

I have often wondered why cudbear (*Lecanora tartarea*) never has been proposed as a colouring agent for elixirs, etc., instead of *cochineal*. It has at least that one good property of not reacting with salts of iron either proto-or sesqui-salts. Its only fault is that, when the alcoholic solution is largely diluted with water, it acquires a bluish (violet) tinge, very perceptible by shaking. This can, however, be remedied by the cautious addition of a drop or two o

any diluted acid. I say cautious, because, with acids, its rich carmine colour turns brick-red (which colour in itself is beautiful enough).

Thinking that the cudbear might react with some salts, so as to give a muddy or otherwise unsightly colour, I examined its behaviour to the following tests :

Ammonia.—Violet shade (gives a splendid show-colour.)

Acids.—Brick-red (according to proportion and strength; diluted acids act either as simple diluents or brighten the colour.)

Ammon. chlorid., *Potass. nitr.*, *Potass. bicarbon.*, *Sodii bicarbon.*, *Magnes. sulph.* } A bluish (violet) shade.

Alumen.—Brightens rather.

Tinct. ferri chlorid.—A coarse brick-red.

Ferri protosulph.—Nothing particular.

Zinci sulph.—Violet shade.

Potass. iodid.—Nothing particular.

Donovan's solution.—Brick-red.

Dilute tinct. iodine., *Bromine water.* } Brick-red.

Plumb. acet.—Dirty-violet.

Potass. bromid.—Nothing particular.

Water.—A violet shade.

To repeat, it ought to be preferred because of its cheapness, and because it does not react with iron salts.

After a discussion by the members on the advantage of using yellow wax in ointments, the meeting adjourned.

SOCIETY OF ARTS.

Pyrites as a Source of Sulphur, Iron, and Copper.

BY DR. C. R. A. WRIGHT, F.C.S.

(*Concluded from p.* 1007.)

In order to gain a larger yield of sulphur from pyrites various processes have been suggested; thus Gossage proposed to expel a portion of the sulphur by heat, and then to act on the residue with hydrochloric acid, whereby sulphuretted hydrogen is evolved. By the action on this of a limited quantity of air at a red heat, water is formed and sulphur set free; or by the action of sulphur dioxide, three proportions of sulphur are obtainable by virtue of the reaction—

$$2\,SO_2 + 4\,H_2S = 3\,S_2 + 4\,H_2O$$ (Duclos' process).

Dyar and Chisholm roasted the pyrites so as to obtain sulphur dioxide, and then decomposed the gas whilst still hot by hydrogen, whereby sulphur was set free and steam formed; the hydrogen for this purpose being obtained (mixed with carbonic oxide) by blowing steam through a mass of red-hot coke. Newton used either carburetted hydrogen or red-hot coke for the same purpose, and Spence proposed an improved arrangement in which the coke is contained in a vertical tube in the centre of the pyrites burner, so constructed that the sulphur dioxide formed must pass through the tube, the requisite heat being therefore generated by the combustion of the pyrites itself. It was subsequently found, however, that the same result may be more simply attained by charging an ordinary kiln with a mixture of pyrites and coal or coke. In all these processes the essential point is the separation of the sulphur from the non-volatile constituents of the pyrites by making it unite with oxygen, and the removal from the sulphur dioxide thus produced of the oxygen by means of some more powerful reducing agent.

Rodgers obtained free sulphur by blowing steam through the heated pyrites, when sulphuretted hydrogen is formed, from which the sulphur is obtained, as in Gossage's plan; and so on for other processes.

The chief commercial use of pyrites, however, so far as its contained sulphur is concerned, depends not on the extraction from the mineral of free sulphur, but on its transformation into compounds obtainable at a dearer rate from free sulphur; *i.e.*, on the use of pyrites, not as a source of sulphur, but as a cheap substitute for that substance. Several of these applications are of considerable antiquity; thus, by "weathering" (exposing to the oxidizing action of air and moisture) yellow iron pyrites, copper pyrites, galena, blende, or analogous minerals, the sulphates of the metals present are gradually formed. The formation of green, blue, and white vitriol in this way, and the production from green vitriol of Nordhausen sulphuric acid by dehydration and distillation, are manufactures of considerable antiquity in the history of chemical technology. The manufacture of alum, from alum-schist (an argillaceous rock containing a good deal of yellow iron pyrites disseminated through it) also depends on the same process. During the oxidation of pyrites, two proportions of sulphuric acid and one of ferrous oxide may be regarded as formed; of the sulphuric acid half therefore becomes converted into ferrous sulphate, whilst the other half forms sulphate of alumina by attacking the aluminous mineral in which the pyrites is imbedded. By dissolving the product obtained by gently roasting or calcining alum-schist in water, a solution of aluminium and iron sulphates is produced; and by adding to this solution chloride of potassium or ammonia, double decomposition takes place between the alkaline salt and the iron sulphate, iron chloride being formed, and potassium or ammonium sulphate, which crystallizes out along with the aluminium sulphate in the form of either potassium or ammonium alum; or sulphate of potassium or ammonium may be employed in lieu of chloride.

Longmaid's well-known process for the preparation of sulphate of soda, by heating together a mixture of pyrites and common salt, partly depends on the same principles; the sulphur of the pyrites takes up oxygen, and the two unite with the sodium of the salt simultaneously; ferric chloride and its decomposition products, produced by the action of air and moisture, ferric oxide, hydrochloric acid, chlorine, etc., are formed, the latter two escaping as gases. This process, it may be noticed in passing, is virtually the parent of a number of other methods since proposed for the manufacture of sulphate of soda, chloride of copper, and chlorine. The process of Henderson for the extraction of copper from pyrites (described below); the recent method of Robinson and Hargraves for the manufacture of sulphate of soda without the use of vitriol; and, to some extent, Deacon's chlorine process, may all be regarded as deducible from Longmaid's process, the essential reactions characteristic of these various methods taking place in their common parent-process.

The most important use of pyrites, however, as a substitute for sulphur, consists in its employment on the large scale as a means of producing sulphur dioxide, for the manufacture of sulphites, hyposulphites, sulphates, antichlors, disinfectants, etc., and principally for the production of sulphuric acid and its derivatives.

The use of pyrites for this purpose instead of sulphur, appears to have been first put in operation on the large scale in this country by Hill, of Deptford, as early as 1818. One disadvantage attending the substitution of pyrites for sulphur in the vitriol manufacture is, that to produce a given amount of vitriol, more chamber space must be allowed. When sulphur only is burnt, the resulting sulphur dioxide is diluted only with that amount of nitrogen (leaving out of consideration unchanged air) associated originally with the oxygen of the sulphur dioxide; but when pyrites is burnt, the resulting sulphur dioxide is diluted not only with this amount of nitrogen, but also with that originally associated with the oxygen taken up by the iron of the pyrites. The reactions by which the sulphur dioxide is formed are respectively indicated by the equations—

$$4\,S_2 + 8\,O_2 = 8\,SO_2$$

$$4\,FeS_2 + 11\,O_2 = 8\,SO_2 + 2\,Fe_2O_3$$

i.e., the quantities of air requisite for burning sulphur and

pyrites respectively, so as to produce the same amount of sulphur dioxide in each case, are in the proportion of 8 to 11.

Another disadvantage is the much greater degree of impurity of the acid made from pyrites owing to the volatilization and mechanical carriage of various substances from the pyrites burner to the vitriol chamber. Of these substances arsenic is by far the most objectionable, whilst iron, zinc, thallium, selenium, etc., are frequently introduced into the vitriol. For many practical purposes these impurities are not of any consequence, but the impregnation of sulphuric acid with arsenic produces as a final result the contamination of a large number of chemical products with that deleterious substance. Saltcake, hydrochloric acid, soda-ash and crystals, soap, and many other products requiring the manufacture of sulphuric acid as a step to their production, frequently contain traces and even more of arsenic derived from this source; and the widespread presence in many substances of household use, and even articles of food and medicine, of this objectionable ingredient, is in all probability not without influence on the general health of the population, besides lending additional complications in the detection of arsenic in toxicological investigations.

It is unnecessary to review in detail the various improvements made during the last half-century in the apparatus employed in the production of oil of vitriol from pyrites, and in the method of practically carrying out the manufacture. Experience shows that a slightly different form of kiln or pyrites burner is requisite, according to the nature of the sulphur ore used, in order to carry the combustion to the furthest possible extent. Slaty ores, like Wicklow pyrites, require much deeper kilns than ores containing little earthy matter, like Huelva pyrites. Ores containing more than traces of lead are very apt to flux or frit more or less, thus glazing and agglomerating the lumps, and rendering perfect combustion difficult or impossible. The same result may follow if the temperature in the kiln rise too high with certain other kinds of ores, the lower sulphides of iron first produced and the clayey and earthy matter present being frequently fusible at a sufficiently high temperature. Ores containing much earthy matter (such as Wicklow pyrites, which practically consists of a slaty mass through which pyrites is disseminated) are more difficult to burn, so as to utilize nearly the whole of the sulphur present, than ores containing little quartz or other earthy matters, such as Huelva pyrites; in any case it is practically impossible to utilize the whole of the sulphur present. On an average 100 parts of Huelva (or other analogous) ore, containing 43 per cent. of sulphur to start with, will yield, when burnt as thoroughly as is practicable on the large scale, about seventy parts of residual iron oxide, containing (besides the copper, etc., originally present) about 2·5 to 3·0 per 100 of sulphur, partly as a cupriferous kernel in the centre of each lump. Not unfrequently, however, the amount of sulphur present considerably exceeds this amount, owing to inefficient treatment during the burning of the pyrites. Hence about two parts of sulphur per 100 of original ore remain unburnt, or four parts of sulphur per 100 of sulphur originally present are not utilized. With such ores as Wicklow pyrites, containing only about 30 per cent. of sulphur to start with, a much larger quantity remains unburnt. One hundred parts of such ore, as usually burnt in the kilns, yield about 80 parts of burnt ore, containing on an average about 5 per cent. of unburnt sulphur (for the most part contained as green or unburnt mineral forming the core of the larger fragments, the smaller fragments and dust usually not containing more than 2 or 3 per cent. of sulphur, owing to the combustion being less hindered by the earthy admixtures in the case of smaller pieces). Hence about four parts of sulphur per 100 of original ore, or 13 parts per 100 of original sulphur remain unutilized. *Ceteris paribus*, the more free from earthy admixtures is the pyrites used, the less is the amount of sulphur lost by being left in the burnt pyrites. Of the portion thus left part is present as a basic persulphate of iron, part as sulphate of lime, etc., according to the nature and amount of the earthy matters present in the original ore.

The amount of sulphur left behind in the burnt ore from a given class of pyrites necessarily varies with other circumstances, such as the exact size and shape of the kilns, the methods of stoking and of removing burnt ore and of supplying green ore, and notably with the duty performed by each kiln, *i.e.*, with the quantity of pyrites passed through it in a given time; thus I have obtained the following average numbers as the results of several months' working on a uniform quality of pyrites (Huelva), 25 to 30 tons of pyrites being burnt daily—

Cwt. of pyrites per kiln per diem.	Per centage of sulphur in burnt pyrites.
5·8	2·85
6.8	2·88
7·0	3·01
7·5	3·08

The diminution in the effectiveness of the combustion as the duty becomes progressively increased is here well marked, although not very great. The following table illustrates the average composition of the burnt ore produced in the latter of these four periods as compared with that of the green ore used :—

	Green ore.	Burnt ore.
Iron	44·28	64·88
Sulphur	49·07	3·08
Copper	2·75	3·75
Arsenic	0·38	—
Quartz	2·34	2·90
Oxygen and matters not determined .	1·18	25·39
	100·00	100·00

In the process of alkali-making, the sulphur originally employed in the form of pyrites is finally rejected as a nearly valueless by-product in the form of vat-waste, consisting essentially of calcium sulphide, intermixed with oxide and carbonate, together with earthy matters. The discussion of the numerous processes proposed for the regaining of the sulphur from this source is somewhat removed from the object of the present paper. One of these, however, is sufficiently akin thereto to warrant a description; this is the method for the preparation of a factitious pyrites, patented by J. Lowthian Bell in 1852, the process utilizing not only the alkali waste, but also the burnt pyrites, which (when not containing copper) forms another by-product of little value. The process, as recently described by the patentee (*Transactions of the Newcastle Chemical Society*, 1869, p. 117), is as follows :—A blast furnace, 25 feet high, and 11 feet across the widest part, is charged with a mixture of—

	Parts.
Coke	4
Dry vat-waste (or an equivalent amount of moist)	3
Burnt pyrites	1½
Clay	2

This mixture is thus smelted in the same manner as iron ores by means of a hot-blast, heated to about 640° Fah., from 1200 to 1500 cubic feet of air per minute being forced in at the tuyeres; if the temperature rise too high, metallic iron almost free from sulphur makes its appearance, but when the operation is perfectly conducted fused sulphide of iron collects in the crucible of the furnace, and is drawn off from time to time at the tapping hole. The earthy matters of the burnt pyrites and the clay fuse together, forming a compact slag of vitreous fracture sufficiently hard to be a good road material. This retains some of the iron of the pyrites, and is hence black. Like the slag of an iron blast-

furnace, this slag is lighter than the molten metal, and simultaneously produced, and hence floats thereon, and is thus easily separated, flowing out continually at the "slag-hole." The chemical actions taking place during this operation appear to be the conversion of the peroxide of iron into protoxide, and the reaction of this on the sulphide of calcium forming lime and ferrous sulphide. In this way a "factitious pyrites" is obtained, which when freshly fractured has a deep bronze colour, and a metallic lustre with somewhat crystalline structure; sometimes, however, it has a granular appearance, and is of a darker tint. The average composition is—

Iron	65·0
Sulphur	31·0
Oxygen	4·0
	100·0

Or ferrous sulphide intermixed with a little oxide of iron. Hence the substance is, strictly speaking, not a factitious pyrites (or iron disulphide), but only a factitious iron monosulphide. This material may be employed instead of ordinary pyrites in the kilns of vitriol works, but considerable difficulty attends its utilization; being very hard and compact it will not burn readily by itself, and even when used intermixed with lumps of ordinary pyrites it is difficult to make the substance yield up more than about half of sulphur in the form of sulphur dioxide, *i.e.*, the burnt residue from it contains a large quantity of sulphur. Hence, in 1853, a slight modification of the process was patented, whereby the fused sulphide is made to flow out of the furnace into water, and a black powder or slime produced. This is then formed into cakes or bricks, which, after drying, burn much more readily than the hard fused masses. A peculiar mode of treatment is, however, requisite in order to obtain all the associated sulphur. The surplus peroxide of iron left after the burning is completed is used over again in the furnace to produce a fresh quantity of factitious pyrites.

Owing to the practical difficulties in burning the product, the circumstance that the interior lining of the furnace wears away rapidly, necessitating frequent stoppages for repairs, and the fact that the whole of the sulphur is not regained, from 3 to 5 per cent. being present in the slag on an average, it results that at the present price of pyrites this method of regaining sulphur from vat-waste is barely remunerative; nevertheless, the process is one the difficulties of which are not insurmountable, and which might possibly be worked to advantage in case of an increase of price in the natural mineral.

Modifications of Bell's process, and processes similar thereto, have been subsequently proposed, but have not yet come into use. Thus Cookson patented, in 1854, the smelting of galena by means of impure finely-divided iron, obtained by heating burnt pyrites, and carbonaceous matter; thereby lead, and a kind of factitious pyrites are formed. Pattinson patented, in 1853, the use of manganese in lieu of iron, whereby a sulphide of manganese is formed.

Several other processes have been proposed of late years for the production of hyposulphites of sulphur or of sulphur dioxide from vat-waste. Of these many have proved commercially unsuccessful; others, notably that of Mond, have met with a considerable amount of success. These processes, however, scarcely come under the head of the subjects of the present paper.

Owing to the difficulty experienced in burning off all the sulphur present in pyrites, the impure oxide of iron thence obtained in the vitriol works has not been used to any great extent as an iron ore. Occasionally, however, the burnt pyrites of the vitriol maker is used for this purpose (when free from copper), being mixed in along with other ores. It is noticeable as a curious fact that no marked increase in the amount of sulphur present in the pig-iron made appears to be occasioned by the presence of even several per cent. of sulphur in the burnt pyrites used, at any rate when clay ironstone (Cleveland ore) is smelted therewith. As stated above, in Bell's process for making factitious pyrites, metallic iron almost free from sulphur is often obtained, instead of sulphide of iron, if the temperature rise too high in the smelting process. In an iron blast-furnace, also, direct experiment shows that the great majority of the sulphur introduced into the furnace in the materials—limestone, coke, and iron ore—issues from the furnace in the slag, only a small portion being taken up by the pig-iron.

By the process for extracting copper from burnt cupriferous pyrites, described below, a peroxide of iron tolerably pure and nearly free from sulphur is obtained as a by-product. This "purple ore" is now used as a source of metallic iron to some considerable extent, partly for the production of spongy metallic iron (obtained by heating along with coal-dust or other carbonaceous matter) used for the precipitation of copper, partly as "fettling" for the beds of puddling furnaces. As stated above, an impure metallic iron, obtained similarly from ordinary burnt pyrites, was also used by Cookson as a means of reducing galena to the metallic state.

Many kinds of pyrites yield, on burning, an impure oxide of iron of sufficiently bright tint to be used as a pigment after due washing and grinding. A considerable diversity of shades can thus be obtained, and the colouring matters possess great stability.

Until a comparatively recent period, few attempts were made to extract copper from pyrites containing only a small percentage of that metal; the ordinary methods of copper smelting being only commercially applicable to substances somewhat richer in that metal. Poor cupriferous ores were occasionally smelted in a cupola furnace, whereby a regulus was obtained, which was refined in the usual way; or preferably such ores were intermixed with richer ones, and the whole smelted together; but the quantity of copper actually derived from this source did not amount to more than a very small percentage of the total annual make. Various processes for obtaining copper from such ores have, however, been used of late, and this manufacture has now attained to very considerable dimensions.

It has long been known that by exposure to air cupriferous pyrites becomes oxidized, so that a solution of copper sulphate (*inter alia*) is obtainable by lixiviating the mass; this oxidation naturally takes place in mines where copper pyrites is raised, so that the drainage water of such mines often contains an amount of copper worth saving, the process employed being very simple, viz., causing the water to flow through vats or reservoirs containing scrap iron; the iron thus acts on the copper sulphate in virtue of the reaction

$$Cu\,SO_4 + Fe = Fe\,SO_4 + Cu\,;$$

metallic copper being thrown down, and a solution of ferrous sulphate produced. Most of the processes prepared within the last 35 years for the extraction of copper from cupriferous pyrites have been based on reactions similar to that naturally taking place in the copper mines, viz., the oxidation of copper sulphide to sulphate soluble in water. Thus, in 1840, Cookson took out a patent for the production of copper sulphate from cupriferous pyrites by a process of oxidation in the dry way; the pyrites was subjected to a regulated roasting, whereby the sulphur associated with the iron was burnt off, leaving an oxide of iron, whilst that combined with the copper was left unaltered; on calcining this residue at a different temperature, the copper sulphide takes up oxygen, forming copper sulphate. The mass being lixiviated, a solution of blue vitriol is obtained, from which the crystallized substance is obtained by evaporation, etc; the purified copper sulphate may be converted into metallic copper by heating with an equivalent quantity of copper sulphide in closed vessels. Similar processes have also been proposed by several others, only differing from this in details, and not in general principles; various special roasters and calcining kilns have also been patented for this purpose.

Recently, a modification of this process has been proposed by Monier, viz., roasting cupriferous pyrites along with soda, whereby sulphates of iron, sodium, and copper are formed; on increasing this heat, the first of these is decomposed, the two other sulphates being unaltered; on lixiviation these are dissolved out, and by crystallization they are more or less separated. The crystals of copper sulphate thus obtained are dried and heated to redness, along with small coal; in this way a mixture of copper oxide and metallic copper is produced, which is reduced and refined in the usual way. It is stated by the inventor that the whole of the copper contained in cupriferous pyrites can thus be extracted readily, and with very little loss; from a ton of pyrites containing 84 lbs. of copper ($3\frac{3}{4}$ per cent.) $82\frac{1}{2}$ lbs. of metallic copper can be obtained, the loss being only $2\frac{1}{2}$ lbs; *i.e.*, the copper actually extracted is 97 per cent. of that originally present, the working loss being only 3 per cent.

Leister patented, in 1859, a process for the oxidation of the sulphide of copper left in burnt cupriferous pyrites by the wet process; viz., the conjoint action of the air and of perchloride or persulphate of iron solution obtained most conveniently by moistening the burnt pyrites with hydrochloric or sulphuric acid; the weathering is not absolutely indispensable in this process, much copper being dissolved out by merely digesting the burnt pyrites with hydrochloric acid or ferric chloride solution. From the solution of copper salt thus obtained, the metallic copper is precipitated by means of scrap iron; the resulting iron liquor being exposed to the air to peroxidize it, and used over again for a fresh batch of pyrites. In 1861, Mease, and also Hæffely patented analogous processes, the waste acid manganese chloride from the bleaching powder manufacture being used instead of hydrochloric acid; the latter inventor subjected the burnt pyrites to methodical lixiviations in tanks like those used in the alkali works, whereby the whole or nearly the whole of the copper was extracted at the end of a week. By adding soda waste to the copper liquor thus obtained, copper sulphide was formed as a precipitate, and from this metallic copper could be obtained by the ordinary processes; or the sulphide could be oxidized to crystallizable blue vitriol. This process had the merit of using up simultaneously what were thus three waste products, viz., vat-waste, still-liquor, and burnt-pyrites.

From experiments made by myself some years ago, it appears that the action of ferric solutions on sulphide of copper is of an oxidizing nature, the copper being converted into a soluble salt (sulphate and chloride), the ferric salt becoming reduced to ferrous salt; so that although at first sight such processes as that of Hæffely appear to be dissimilar in character from the natural or artificial oxidation of copper sulphide, they nevertheless really depend on the same principles. Access of air during the lixiviation of burnt pyrites with solutions of ferric salts facilitates the operation by reconverting the ferrous salt formed in ferric salt; and heating the liquor, by injection of steam or otherwise, causes the extraction of the copper to take place much more quickly than is the case in the cold. With ordinary calcined Huelva pyrites, I have found that the copper present can be readily extracted in this way, but little labour being required, and little loss of copper being occasioned; there, however, are practical inconveniences which have led to the adoption in preference of a somewhat different process, known as Henderson's.

Like Cookson's and Monier's processes, Henderson's method depends on the power possessed by copper sulphide to take up oxygen when heated; in this process, however, the conversion of the copper into a compound soluble in water, is facilitated by the addition to the pyrites of common salt; the chief result of roasting this mixture is the formation of sulphate of sodium and chloride of copper along with some chloride of iron. The whole process, therefore, simply consists in an adaptation of Longmaid's well-known process (described above) to pyrites from which the great majority of the sulphur has been removed by a sort of calcination. The following is a description of the practical working of this process, which has altogether distanced its rivals as a means of extracting copper from poor cupriferous pyrites.

The ores most suitable are those of character analogous to the Huelva and Tharsis ore, *i.e.*, containing only a few per cent. of quartz or other earthy impurities, and averaging about 3 or 4 per cent. of copper after burning. The larger lumps are broken up into pieces usually not exceeding the size of a small orange, and the dust separated by screening; the "smalls" are either made up into balls with water, clay, etc., and burnt, or are roasted separately in a special kind of kiln, analogous to a blind salt cake furnace, whilst the larger lumps are passed through the ordinary pyrites kilns, at the rate of 5 to 7 cwt. per day per kiln, according to size. The burnt ore thus produced by the vitriol maker retains from $2\frac{1}{2}$ to 5 per cent. of sulphur, according to the care and skill employed in the burning. In order to extract the copper, it is usually convenient to mix various kinds of burnt ore, or even burnt ore with "green smalls" (the unburnt smalls sifted out on breaking up the lumps), in such a way as to produce a mixture containing about half as much again of sulphur as of copper, *i.e.*, for 3 per cent. of copper, $4\frac{1}{2}$ per cent. of sulphur; to this is then added as much salt as represents about four times the copper present, the whole is then passed through crushing machines, and thoroughly intermixed.

The moderately intimate mixture of materials in coarse powder thus produced, is subjected to a roasting process for several hours, at the end of which time most of the copper has become converted into compounds soluble in water, whilst the remainder is almost wholly soluble in dilute hydrochloric acid. Some care is necessary, especially towards the end of the operation, to prevent the temperature rising too high, otherwise a good deal of the chloride of copper formed is partially decomposed and rendered insoluble in water. The temperature is somewhat moderated towards the end of the process, a dull red heat being maintained for the first two or three hours. About six hours usually suffice to work off a charge. The furnaces employed for this roasting resemble those employed for the manufacture of salt cake (blind salt cake furnaces), being heated either by a fire-place for the purpose or by the gases of a gas-generating furnace. Rotary furnaces are also in use in some works, whereby manual labour is saved; larger charges can also be worked off with this form of furnace. Throughout the roasting process the materials are stirred from time to time with a paddle. The progress of the action may be estimated by withdrawing a sample and treating it first with water, then with hydrochloric acid, and lastly (after washing with water) with nitric acid. On saturating with ammonia the liquors thus obtained, the relative tints of the blue cuprammonium-salt solutions produced afford a means of determining approximately the amounts of copper converted into soluble chloride, etc., products insoluble in water, but soluble in hydrochloric acid (basic chloride, etc.), and of sulphide as yet unchanged. Owing to the presence of traces of moisture in the air, etc., there is always a certain amount of hydrochloric acid gas formed, and in escaping, this carries with it a small quantity of copper chloride, the more the higher the temperature of roasting; the gases and vapours evolved are condensed by a coke tower, precisely similar to that used in the alkali works, the resulting acid liquor being used for the extraction of that part of the copper which is insoluble in water; inasmuch, however, as the liquor usually contains arsenic, antimony, etc., the copper obtained by its help, or that extracted directly from it, is less pure, and consequently of an inferior quality and value. The amount of copper thus volatilized is, however, only minute, when proper precautions are taken against over-heating during the roasting. According to Phillips, two tons of metallic copper only are practically regained from these liquors,

whilst 800 tons are prepared altogether, *i.e.*, the copper volatilized is only about 0·5 per cent. of the total amount.

It is practically found undesirable to treat with salt, etc., ores containing more than 6 per cent. of copper. Richer ores require a longer period of roasting, and hence more copper salts are obtained in a form insoluble in water, but soluble in acid. It is almost always practicable to work with a nearly uniform material and by a uniform process, by suitably mixing together richer and poorer varieties, and otherwise regulating the composition of the ore employed. On an average 97 to 98 per cent. of the copper actually present is rendered soluble in either water or acid, the residual oxide of iron retaining only a minute amount of copper.

The roasting being completed, the substance is placed in tanks either of tarred wood or stone, or some analogous material, and is then lixiviated with hot water, heated by injection of steam or otherwise. The aqueous liquors thus obtained are drawn off and treated separately, the insoluble portion being washed with fresh water, and the weaker liquors thus obtained being used for the treatment of a fresh batch; the lixiviation is thus methodically conducted in much the same way as the analogous process in the case of black ash, so as to obtain liquors as concentrated as possible. The insoluble portion is then again lixiviated with dilute hydrochloric acid or with the acid liquor condensed in the coke tower. From the copper solutions thus obtained, the metal is precipitated by the simple process of allowing the liquors, clarified by standing and settling, to run into precipitating tanks constructed of wood (tarred) or stone, and filled with scrap iron, steam being injected to heat the liquor and promote the action, partly by facilitating it through the increased temperature, partly by getting up a circulation and currents.

The residue left after all the copper that can be extracted has been washed out, is the purple ore referred to above; it usually contains from 0·08 to 0·20 per cent. of copper, and 0·15 to 0·25 per cent. of sulphur, and is either sold for fettling for puddling furnaces, or is reduced by heating with small coal, etc., and the resulting spongy iron employed, instead of scrap iron, in the precipitation tanks. This spongy metal is, of course, more rapid in its action than solid malleable iron or cast-iron. According to Bischof, the copper thus thrown down by means of spongy iron is much more free from arsenic than that precipitated by solid scraps, as several hours' contact is required before the arsenic it deposited, whilst copper is thrown down immediately.

The copper precipitated from the aqueous liquors usually contains 75 per cent. and upwards of metal, and only requires melting and refining to be fit for use. The impure copper thrown down from the acid liquors or from the tower liquor is frequently of an inferior character, and is often too impure to be used directly. By melting this with green ore (unburnt pyrites) or with soda waste, a copper "regulus" is obtained, which is refined in the way ordinarily practised by the copper smelter. In this way certain objections have been obviated which originally applied to the copper obtained by Henderson's process, viz., that it was apt to contain impurities of various kinds, rendering it unfit for certain purposes, *e.g.*, making brass. By treating separately the aqueous and acid liquors, the impurities present in the latter are prevented from contaminating the metal obtained from the former.

After the copper has been thrown down, the liquors contain, *inter alia*, sulphate of soda, which can be readily extracted by evaporation and crystallization.

Some varieties of pyrites contain a notable amount of silver, though insufficient to render its extraction profitable as a separate business. Most of this valuable metal can, however, be extracted by the following modification of Henderson's process, due to Claudet. The whole of the common salt used in the roasting process is not converted into sulphate, some remaining unaltered. Thus the aqueous extract first obtained is brine, containing copper, iron, sodium salts, etc., dissolved therein. Now the process that converts the copper compounds present in the burnt ore into chloride, also transforms any silver present into chloride, which salt is almost wholly dissolved out from the roasted mass by the agency of the brine, silver chloride being much more soluble in this menstruum than in plain water. Silver iodide, however, is very much less soluble in brine than is silver chloride. Hence, by adding to the aqueous liquors first obtained (before separation of the metallic copper) a soluble iodide, a precipitate is formed containing most of the silver originally present in the pyrites used in the first instance.

In practically working this process the liquors containing the silver, *i.e.*, those obtained by lixiviation with water before treatment with acid, are run into a wooden settling tank. When the suspended matter has deposited, the clear liquors are drawn off into another tank, and a solution of iodide of potassium added (crude iodide solution from kelp may be used), and the whole well mixed. After 48 hours' rest, a deposit is thrown down consisting chiefly of sulphate of lead, iodide of silver, and some copper compounds, and also containing a small quantity of gold. The clear liquor is run off and precipitated by iron to extract the copper. The deposit is washed with water and then with dilute hydrochloric acid to remove the copper compounds, and is then digested with metallic zinc, whereby the silver iodide is decomposed, metallic silver being set free and soluble zinc iodide formed. The solution of this latter salt is used over again to precipitate a fresh batch, as iodide. Most of the lead sulphate is also decomposed by the zinc, so that the resulting mass when dry has about the following composition (Claudet):—

Silver	5·95
Gold	0·06
Lead	62·28
Copper	0·60
Zinc oxide	15·46
Iron oxide	1·50
Lime	1·10
Sulphuric acid	7·68
Insoluble matter	1·75
Oxygen, loss, etc.	3·62
	100·00

From this mass the silver and the gold are separated by the ordinary process in use in the refining of these materials.

Usually the deposit of silver iodide, etc., is not removed at once from the depositing tank, but is allowed to remain in while successive batches are worked off, whereby labour is saved, the deposit being only treated with zinc, etc., at intervals as it accumulates.

The cupriferous pyrites of Spain and Portugal contain from 0·002 to 0·003 per cent. of gold and silver; from 16,300 tons of such ore, after burning off most of the sulphur in the vitriol works, 739 lbs. of silver and 7 lbs. of gold were extracted at Widnes, or about 340 grains ($\frac{3}{4}$ oz. avoirdupois) per ton. The cost of preparation of this, including 300 lbs. of iodine * consumed during the operation, was £416, leaving a clear gain of £3,250 (Claudet).

The high degree of perfection now attained by the processes in use for utilizing the valuable constituents of pyrites, and the great industrial importance of these operations thus briefly and imperfectly described, afford a proof, were any such needed, of the advantages to be gained in the arts and manufactures generally by an attentive study of the principles of pure abstract science, and the modes of thought and methods of experimental investigation associated therewith. Each new fact observed and each new principle established by the labour of purely scientific experiments, no matter how apparently far removed from manufacturing

* The price of iodine has risen considerably since 1871, when these figures were obtained.

operations, is yet of high value, not only on its own account as increasing the common stock of knowledge, but from its indirect influence on other branches of inquiry more immediately susceptible of adaptation to the wants and necessities of mankind, independently of which it can never be affirmed that even the most abstruse experimental inquiries, and those having apparently nothing whatever in common with ordinary industries, may not at a future period afford the starting-point for processes and manufactures of great commercial value. "From nothing nought comes," has long been an axiom; conversely it may be truthfully said that "nothing leads to nought," and, of all things, experimental inquiry into the secrets of Nature has the least tendency to lead to valueless consequences.

Parliamentary and Law Proceedings.

Apothecaries' Licences Bill.

The following Bill to amend the law "for the licensing and practice of Apothecaries, Chemists, and Druggists, has been prepared and brought into the House of Commons by Messrs. Errington, Blennerhassett, and Butt. It was read a first time on Wednesday, June 17th. It was set down for second reading on Tuesday, the 23rd, but was postponed to Thursday, the 25th inst.

"Whereas a great deficiency exists throughout Ireland of establishments and shops for the sale of medicines and compounding of prescriptions, and great inconvenience is thereby entailed on the public in many parts of the country, which it is expedient to remedy:

"Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

"1. *From and after the passing of this Act* every person duly qualified to practise as apothecary under the Apothecaries Act (England), fifty-fifth year of George the Third, chapter one hundred and ninety four, or as chemist and druggist or pharmaceutical chemist under the Pharmacy Acts, shall be deemed to be qualified in like manner to practise as apothecary, or chemist and druggist, or pharmaceutical chemist, and to keep open shop for the sale of medicines and compounding prescriptions in Ireland; and shall not be subject for so doing to any prosecution or penalty, notwithstanding anything to the contrary in the Apothecaries Act (Ireland), thirty-first year of George the Third, chapter thirty-four.

"2. Every person duly licensed and qualified by the Apothecaries Hall of Ireland under the authority of the Apothecaries Act (Ireland), thirty-first year of George the Third, chapter thirty-four, to practise as an apothecary and keep open shop for the sale of medicines and compounding prescriptions in Ireland, shall in like manner be deemed to be qualified to practise as an apothecary and keep open shop for sale of medicines and compounding prescriptions in Great Britain and shall not be subject to any penalty for so doing, notwithstanding anything to the contrary in the Apothecaries Act (England), fifty-fifth year of George the Third, chapter one hundred and ninety-four, or the Pharmacy Acts.

"3. It shall be lawful for the Council of the Pharmaceutical Society of Great Britain and they are hereby required to appoint fit and proper persons in Ireland, to meet at Dublin for the purpose of conducting such examinations as are provided for and contemplated by the fifteenth and sixteenth Victoria, chapter fifth-six, in the same manner as is prescribed by that Act for conducting such examinations in Scotland."

The Amended Pharmacy Bill for Ireland, proposed by the Governor and Company of the Apothecaries' Hall, Dublin.

The following are the principal clauses of a draft Bill, an early copy of which has been supplied to us by Dr. Leet, by which it is intended "to regulate the practice of pharmacy in Ireland, to institute a Pharmaceutical Society, and to alter and Amend the Act passed by the Parliament of Ireland, in the thirty-first year of the reign of His Majesty George the Third, intituled, 'An Act for the more Effectually Preserving the Health of His Majesty's Subjects, for Erecting an Apothecaries' Hall in the City of Dublin, and Regulating the Profession of an Apothecary throughout the Kingdom of Ireland.'"

"Whereas it is expedient that a Pharmaceutical Society should be instituted for Ireland, and that the Licentiates of said Society, registered under this Bill, may keep open shop for the dispensing and compounding of prescriptions of duly qualified medical practitioners; also that a register should be kept of chemists and druggists who sell poisons.

"And whereas, it is expedient and necessary that such persons should possess a competent practical knowledge of their business, and to that end, that from and after the day herein named, all persons should, before commencing such business, be duly examined as to their qualifications and practical knowledge, and that registers should be kept, as herein provided, and also that the Act passed in the Parliament of Ireland, in the thirty-first year of his Majesty George the Third, intituled 'An Act for the more Effectually Preserving the Health of His Majesty's Subjects, for Erecting an Apothecaries' Hall in the City of Dublin, and Regulating the Profession of an Apothecary throughout the Kingdom of Ireland,' should be amended:

"Be it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same as follows:

"1. From and after One Thousand Eight Hundred and Seventy , it shall be unlawful for any person, other than a duly qualified apothecary, to keep open shop for dispensing or compounding medical prescriptions in Ireland, unless such person shall be a pharmaceutical chemist within the meaning of this Bill, and be registered under this Bill.

"2. Pharmaceutical chemists within the meaning of this Bill shall consist of all persons who shall be duly examined and licensed in pharmacy, and registered as pharmaceutical chemists under the provisions of this Bill.

"3. Chemists and druggists within the meaning of this Bill shall consist of persons who have kept open shop for the sale of drugs and poisons before the passing of this Bill and of those who shall be duly registered under this Bill as hereinafter specified.

"4. The Examiners for the purpose of this Bill shall consist of four members of the Court of the Apothecaries' Hall, who examine on the subjects specified in Clause 5 of this Bill, together with not more than eight other examiners selected by members of the Pharmaceutical Society of Ireland, five to form a quorum, provided that *until* said conjoint Board be formed, the examinations may be carried on for the time being by six of the aforesaid members of the Court of the Apothecaries' Hall, assisted by six examiners nominated by the King and Queen's College of Physicians. Also of such local examiner or examiners as may be at any time appointed by the Governor and Council of the Apothecaries' Hall, or by the Pharmaceutical Council, as the case may be, to conduct in provincial towns the preliminary examination of Apprentices and Students, and the modified examination of Chemists and Druggists provided for in Clause 17 of this Bill.

"5. All such persons as shall have been so appointed to conduct examinations under this Bill shall be, and the same are hereby declared to be, fit and proper persons to conduct all such examinations as are provided for or contemplated by this Bill, and shall respectively have full power and authority, and are hereby authorized and required to examine all persons who shall present themselves for examination under the provisions of this Bill, in their knowledge of the Latin and English Languages, in Arithmetic, in Botany, in Materia Medica, in Pharma-

ceutical and General Chemistry, in Practical Pharmacy, in the British Pharmacopœia, and such other subjects as may from time to time be determined by any bye-law of the General Council of the Pharmaceutical Society of Ireland. Every candidate for the certificate of Pharmaceutical Chemist shall also furnish proof of having been engaged for a period of three years at Practical Pharmacy. Provided always that such examinations shall not include the Theory and Practice of Medicine, Surgery, or Midwifery, or any branch of Medicine or Surgery; and that the literary examinations of any other legally constituted examining body may be accepted, if approved of by the Council, in lieu of the preliminary examinations of this Board, and the said examiners are hereby empowered to grant or refuse to such persons, as in their discretion may seem fit, certificates of competent knowledge and qualification and skill to exercise the business or calling of Pharmaceutical Chemists, or Chemists and Druggists, or, as the case may require, to be engaged or employed as Students, Apprentices, or Assistants, respectively; provided, nevertheless, that in case of rejection, a rejected candidate may present himself for re-examination after six months."

6. This clause provides that the Council of the Pharmaceutical Society of Ireland shall, within three calendar months after its formation, appoint a fit and proper person to act as Registrar under this Bill, and shall have power to remove the said Registrar, or any future Registrar to be appointed under this Bill, from said office, and to appoint a new Registrar in the room of any Registrar who may die, or retire, or be removed from office, and also to appoint and remove, and pay suitable salaries to, a Treasurer and such Clerks and other Officers as may be requisite for carrying out the purposes of this Bill.

"7. For every examination and registration, and for every certificate of same, such reasonable fees or charges shall be paid as shall from time to time be fixed and determined by any by-law to be made by the General Council of the Apothecaries' Hall of Dublin, or by the Council of the Pharmaceutical Society, as the case may be; provided always, such fees or charges shall at no time exceed the fees laid down respectively in each case in Schedule (A) to this Bill annexed, and such fees shall be paid to the Treasurer, and shall by him be applied as the said Council of the Apothecaries' Hall, or of the Pharmaceutical Society, shall direct in furtherance of the provisions of this Bill.

"8. The Registrar to be appointed under or by virtue of this Bill shall from time to time make out and maintain a complete Register of all persons certified as Pharmaceutical Chemists by the examiners appointed under this Bill, also a separate Register of all persons certified in like manner as Chemists and Druggists, and also as Apprentices, Students, or Assistants, respectively; and shall keep a proper Index of these Registers, and such other registers and books as may be necessary for giving effect to the by-laws which shall from time to time be made in conformity with the provisions of this Bill."

Clauses 9, 10, 11, 12, 13, provide for the making and correction of the several Registers, and resemble the analogous clauses in the English Pharmacy Act, 1868.

"14. From and after the one thousand eight hundred and seventy , any person who not being a duly registered Chemist and Druggist, or Pharmaceutical Chemist, shall keep an open shop or wareroom for the retailing or dispensing of poisons, as set forth in the Poisons Act of 1870, 'to regulate the sale of poisons in Ireland,' or which may be hereafter added according to the provisions of said Act, provided that the exceptions therein specified, with respect to the duly qualified Apothecary, shall also apply to the Pharmaceutical Chemist registered under this Bill; or any person who, not being a duly registered Pharmaceutical Chemist, shall keep an open shop or wareroom for the dispensing or compounding medical prescriptions, or who shall take, use, or exhibit the name or title of Pharmaceutical Chemist, or Pharmaceutist, or Pharmacist, or Dispensing Chemist, or Chemist and Druggist in Ireland, or make use of any sign or title, implying that he is registered as a Pharmaceutical Chemist, or as a Chemist and Druggist under this Bill, or any Pharmaceutical Chemist who shall take or employ any person as Student, Apprentice, or Assistant, without such person having obtained the proper certificates hereinbefore directed, or who shall compound any medicines of the British Pharmacopœia, except according to the formularies of the said Pharmacopœia, each and every person so offending shall for every such offence be liable, on summary conviction before one or more Justices of the Peace, to pay a penalty not exceeding five pounds, and when recovered, such penalties shall be applied to the purposes of this Bill; but nothing in this Bill contained shall prevent any person from being liable to any other penalty, damage, or punishment, to which he would have been subject if this Bill had not passed; nor extend to, or interfere with, the business of any legally qualified Apothecary, or the lawful business of any Veterinary Surgeon.

"15. Upon the decease of any Pharmaceutical Chemist or Chemist and Druggist actually in business at the time of his death, it shall be lawful for any executor, administrator, or trustee of the estate of such Pharmaceutical Chemist, or Chemist and Druggist, to continue such business for a period not exceeding twelve months, and provided such business shall be *bonâ fide* conducted by a Pharmaceutical Chemist, or Chemist and Druggist as the case may be, registered under this Bill, provided always, that registration under this Bill shall not entitle any person so registered to practice Medicine or Surgery, or any branch of Medicine or Surgery.

"16. It shall, nevertheless, be lawful, anything to the contrary notwithstanding, for the examiners appointed under this Bill to admit to examination any Chemist and Druggist being twenty-one years of age, who shall have been in business as such in Ireland (on his own account, for a term of five years before the passing of this Bill) and who shall, within six months after it has passed into law, make application in writing for examination to the Registrar under this Bill, accompanied with a certificate according to Schedule (C) to this Bill; and every such Chemist and Druggist who shall have satisfied the examiners as to his knowledge, skill, and competency to carry on and conduct the business of a Pharmaceutical Chemist, shall receive the Certificate of Pharmacy from the said examiners, and shall be entitled to be placed on the Register of Pharmaceutical Chemists of Ireland; and the person so certified shall pay the same fees as other Pharmaceutical Chemists under this Bill; provided always that in case of rejection the rejected candidate may be re-examined after six months.

"17. Any person who has been in business as a Chemist and Druggist in Ireland before the passing of this Bill shall be entitled to be registered in the list of Chemists and Druggists of Ireland under this Bill, on producing a certificate according to Schedule C of this Bill; but any person who has not been so engaged before the passing of this Bill, shall produce a certificate of being twenty-one years of age, and shall pass a modified examination, to be determined on by the Council of the Apothecaries' Hall or of the Pharmaceutical Society, as the case may be, in order to entitle him to have his name inserted in the registered list of Chemists and Druggists of Ireland, for the purposes of this Bill; but registration in this list shall in nowise qualify or empower to compound medical prescriptions.

"18. It is hereby further enacted, that a Pharmaceutical Society shall be instituted, to be named "The Pharmaceutical Society of Ireland;" and authority is hereby given for the formation of such Society; and in order to the formation of same, it shall be lawful for every person who has been duly licensed and registered as a Pharmaceutical Chemist by this Bill, and also for every duly qualified Apothecary, upon payment of an annual sub-

scription of one guinea each to the treasurer appointed under this Bill, to become a member of said Society, and to have a voice and vote in all general meetings of the Society; and the Governor and Council of the Apothecaries' Hall of Dublin are hereby authorized and required, within one year after the passing of this Bill, to convene a meeting of all members of the Society, to be held at their Hall in Dublin, or at such other place as may be agreed on, by written or printed summonses, to be issued ten days previous to the day agreed upon for holding such meeting; and it shall be lawful for the members in assembly at such meetings to appoint a President, Vice-President, Council, and Secretary, for conducting the business of the Society; and like meetings of the Society shall be holden annually. And it shall be lawful for said Council to arrange at any time with the Council of the Pharmaceutical Society of Great Britain for a reciprocity of privileges and practice between the legally registered Pharmaceutical Chemists, and Chemists and Druggists, respectively, throughout the United Kingdom.

"19. At all general meetings of the Society, it shall be lawful for the Society to make all such By-laws and Rules for the advancement of Pharmacy and for the good government of the Society as the members present shall in their wisdom, and by a majority of votes determine, provided always, that said By-laws and Rules shall be consonant with, and not contrary to, any of the provisions of this Bill; and it shall also be lawful for the Society, at every such annual meeting, for the members present to elect from among themselves, by a majority of votes, examiners not exceeding eight in number, exclusive of provincial examiners, to be conjoint examiners with those on the Pharmacy Court of the Apothecaries' Hall, as specified in clause 4 of this Bill.

"20. It is hereby enacted that the exemption of Pharmaceutical Chemists from service on all Juries and Inquests, under the Juries Act, 1862, be applicable to the Pharmaceutical Chemist duly registered under this Bill.

"21. The parts hereinafter mentioned of the aforesaid Act of the Thirty-first of George the Third, chapter thirty-four, shall be, and the same are hereby altered and amended, that is to say, so much of the fourth section as would allow each one hundred pounds share to be subdivided into ten pounds shares, and any duly qualified Apothecary to purchase one such share; and so much of the tenth and of the twenty-fifth sections as relates to seven years' apprenticeship; so much of the twenty-fourth as would increase the Certificate Fees of Licentiates to five guineas, of Assistants to two guineas, and of Apprentices to half-a-guinea; and so much of the twenty-sixth as renders an Apothecary liable to a penalty for taking an apprentice for less than seven years, or would render him liable to a penalty for employing a duly qualified Pharmaceutical Assistant, or would subject a duly registered Pharmaceutical Chemist to a penalty for compounding medical prescriptions.

"Schedule A.

Scale of Fees for Certificates.

Chemists and Druggists	1 Guinea.
Apprentices and Students	2 Guineas.
Assistants	3 Guineas.
Pharmaceutical Chemists	5 Guineas.
The Fee for Registration	5 Shillings."

Schedule B and C relate to the form of the Register and of the certificate.

WARBURG'S FEVER TINCTURE.—ACTION FOR LIBEL.

On Saturday, June 20, there was brought before the Lord Chief Justice of the Queen's Bench and a special jury, an action for libel, by Messrs. Savory and Moore against the defendant, who is the sole maker of a tincture called "Warburg's Fever Tincture."

Mr. Powell, Q.C., and Mr. Mirehouse were for the plaintiffs; Mr. Digby Seymour, Q.C., and Mr. J. A. M'Leod were for the defendant.

An order had been given by the Government to the plaintiffs, who are the Government medical contractors, for a supply of the tincture to the troops in Africa. This came to the defendant's ears, and he, believing that the order would be for a large quantity, and knowing that there was only a very small quantity in the market, wrote to the Government official on the subject, and received a reply that a sufficient quantity of the tincture had already been supplied. He wrote again, saying that if that were the case the tincture was not his, but a spurious imitation, and asking who was the author of this scandalous fraud. This was the libel complained of. The tincture was supplied by the plaintiffs, the quantity being 50 bottles only, and it was all of the defendant's own make. There was a good deal of correspondence, and concessions on both sides were asked for. No apology was made, as, under the circumstances, the defendant said he did not feel justified in making one.

After the plaintiffs' case had been opened by Mr. Powell a discussion occurred as to the circumstances which had led to the defendant's mistake. Eventually it was agreed that the Lord Chief Justice should say what should be done between the parties, and a verdict for 40*s.* was taken, the costs to be paid by the defendant, and all imputations on both sides were withdrawn.—*Times.*

Obituary.

Notice has been received of the death of the following:—

On the 6th April, 1874, Mr. William Morgan, Pharmaceutical Chemist, of Newport, Monmouthshire. Mr. Morgan had been a member of the Pharmaceutical Society since 1853.

On the 7th May, 1874, Mr. John Joseph Baines, Chemist and Druggist, of Preston.

On the 6th June, 1874, Mr. Charles George Beale, Chemist and Druggist, of St. George's road, Brighton.

On the 18th June, 1874, Mr. Henry Bramley, Chemist and Druggist, of Knaresborough.

Notes and Queries.

[403.] BLEACHING OF CORAL.—*Incognitus* wishes to be informed as to the best method of cleaning and whitening coral.

FOWLER'S SOLUTION AND MAGENDIE'S SOLUTION.—In a paper read before the Alumni Association of the New York College of Pharmacy, Mr. John Vanderbeugle reports that having investigated the precipitate which forms when Fowler's Solution and Magendie's Solution are mixed together, he has found it to consist of pure morphia. The precipitate appears always to be formed upon the combination of these two solutions, owing to the arsenical solution being slightly alkaline. By acidulating with a small quantity of sulphuric acid the precipitation is prevented.

THE CONSTITUENTS OF FRASERA WALTERI.—The root of *Frasera Walteri*, which is sometimes called "American Calumba," has been examined by Mr. George W. Kennedy, of Pottsville (*Trans. Amer. Phar. Assoc.*, 1873, p. 635), to ascertain whether it contained berberine. He arrived at the conclusion that that alkaloid was not present. The bitter principle was isolated in crystals soluble in alcohol and water, insoluble in ether, neutral to test paper, and not precipitated by tannic acid. This Mr. Kennedy considered to be gentiopicrin, or, as he prefers to call it, "gentianin." Gentisic acid was also obtained in pale yellow needle-shaped crystals, insoluble in water, soluble in alcohol and ether, and reddening litmus paper. From the foregoing it would appear that *Frasera Walteri* contains the same active constituents as gentian, and Mr. Kennedy thinks it should be called American Gentian rather than American Calumba.

Prosecutions of Chemists and Druggists under the Adulteration Act.

Sir,—The public will be much indebted to the Bow Street Magistrate for improvement in the machinery for working the Adulteration Act, hitherto so defective that a conscientious analyst—bound as he is to testify as to *any* inconsistency he may find between the samples brought to him and the names they bear—has felt helpless to avert unjust prosecutions which are repugnant to good sense and technical knowledge, but which the ignorance of unpractical officials makes them so prone to. "For the future, when an analyst does find a *fair* specimen, that circumstance ought to be communicated to the Board." So says Mr. Vaughan. This will be appreciated by the analysts as much as by any of the parties concerned, for those, on both sides of the Thames and also the Avon will be acquitted of malevolence by all who know them personally. As to the recent case in the latter neighbourhood, it would be interesting to have a few points cleared up, for not only the report, but also Mr. Howard's subsequent explanation, is "not very clear" to me at least.

First, passing over (as accidental) the omission from the report of the name of the locality, it being sufficiently indicated I suppose by the names of Messrs. Stoddart and Tilden, when we come to the question of the alleged impurities in the Ferri et Quiniæ Citras, according to the summons resulting from the certificate—there were cinchonine and quinidine. According to Mr. Stoddart's own deposition, not only were these present (the former about ·5 per cent.), but "the salt was not wholly soluble in water;" and, as the salts of the alkaloids implicated *are* soluble in that menstruum, are we to attribute it to the dark resinous matter which Mr. Stoddart complained of, according to Mr. Howard (but not the report), and attributed to decomposition of quinine (into quinicine) by overheating? But at what period in the course of manufacturing? Simply of the quinine, according to the report, or after combination with the iron (either in solution or scaling) as Mr. Howard seems to mean?

Then comes "the precipitated alkaloid." Mr. Stoddart says the part insoluble in ether was cinchonine and quinidine, but instead of the former it was "unquestionably a trace of cinchon*idine*" according to Mr. Howard, who hints at its derivation from "most of the barks used for quinine making" "by a slight defect in manufacture," "which cannot in any way be called an adulteration." And it was submitted in defence that allowing such to be present it would not result in any pecuniary gain or other advantage to the vendor. But, Sir, has it not been the freedom from such defects in their unrivalled preparations, that has placed Messrs. Howards in the proud position they have so long occupied, enabling them to command extra *prices* for extra *care?*

The present case shows the value of a creditable name: but for that would it not be a noteworthy coincidence that these impurities (as corrected by Mr. Howard), viz. dark resinous matter (cinchonidine and quinidine) are precisely those constituting the chief part of that waste product "amorphous" quinine, obtained in the course of quinine making? The established reputation of the firm alone is sufficient to preserve them from the suspicion of having made the citrate with any such substance.

And here I should like to ask whether others have noticed, as I have repeatedly, with surprise, a decided residue (insoluble in ether) from Messrs. Howard's citrate. If the fault is in my own manipulation, how is it that what I know to be B.P. specimens do not give similar results, though subjected to exactly similar treatment, at the same time.

I should mention that in testing I use limited quantities of ether, otherwise considerable quantities of the other alkaloids would escape detection if present.

The same applies still more to Quiniæ Sulph., where the B.P. directs half an ounce of ether to 10 grains of the sulphate, just four times as much as would do if Liebig's method be followed of using only "ɱ xx. of Liq. Ammon." without any more water. With the ℥ss. ether about 16 or 18 per cent. cinchonidine might be taken up.

As for quinidine, is not its solubility in ether such that it is better to trust to its showing itself in crystallizing during slow spontaneous evaporation of the ether (*e.g.* in a narrow test tube, not a watch glass)? But does Mr. Stoddart keep to the German practice of applying the name to cinchonidine, the isomer of cinchonine ($C_{20}H_{24}N_2O$ instead of $C_{20}H_{24}N_2O_2 + 2H_2O$)?

F. P. Catford.

36, *Princes Square, Kennington.*

Where does the Starch come from?

Sir,—Would you let me ask, while the scammony question is to the front, where the starch comes from? Pereira says that virgin scammony is free from starch, and I have tested some lump virgin scammony this morning, and find it free from starch; while some virgin powder scammony I have obtained contains a large amount of the same, the highest price having been given for each.

While it is our duty to put a stop, if possible, to frivolous and catch prosecutions, it is no less the duty of every member of our body to seek for purity.

W. W. Urwick.

60, *St. George's Road, Pimlico,*
June 24, 1874.

Carbolic Acid Suppositories.

Sir,—In reply to Mr. T. H. Williams, I would state that Calvert's carbolic acid in crystal was the acid used.

The curd soap was obtained from a leading London wholesale house.

The directions of the B. P. Addendum were followed, and the suppositories readily prepared.

The mass was divided by weighing, and the suppositories finished off on a slab; I find they now weigh sixteen grains each, no doubt they have lost a trifle since they were made.

I have sent Mr. Williams a specimen per post.

Edward Pratt.

June 22nd.

Excessive Labour in Pharmacy.

Sir,—Not only regarding remuneration, but also the hours occupied, all persons, with the exception of those engaged in pharmacy, have successfully asserted their claims.

If we draw comparisons between professional and non-professional men, of every grade and class—particularly taking into consideration the time engaged each day—there will be but one conclusion, that the only slave left is the chemist and druggist; and when we consider that once round the clock does not, perhaps, in any pharmacy in England, measure the masters' or the assistants' term of daily labour—that he is on duty from twelve to fourteen or more hours a day, there cannot be a more appropriate name for the chemist than the pharmaceutical slave.

And regarding this point, none of us will readily admit that we are slaves. We seem, each and all, to be deaf to the sound of the word. We know for a certainty that in one sense, both for master and man, pharmacy means slavery, and we are at the same time indifferent to alter our state.

But why should we work so long? By excessive labour, close attention to business, confinement, want of recreation, our physical forces are daily exhausted, and result in impaired health and premature age.

And I believe we are destined not to be allowed to work so long, much longer. There are, thank God, more humane people outside the Pharmaceutical Society than in it, and it will be the outsiders who will help the few Wilberforces amongst us with a merciful hand.

And I maintain that, as a body of men, we are not humane. We work ourselves longer and harder than we should work our own horses. Acknowledging no end to the day, we are not humane to ourselves or our assistants.

Six weeks have elapsed since I had half an hour's walk. I have been unable to leave my pharmacy, on account of my staff of assistants not being complete; and I have had to fill the vacancy myself, and do double duty of master and man. More than a month I advertised for an assistant, with the small result of "three" applicants. The first, having no character, I dare not engage. The second found a more genial sphere in town. The third has come, who would not accept of any offer unless he could have three hours for recreation every other day, and do no work on Sundays. There was no alternative but to engage him, or I must continue to work myself and probably bring on illness.

And I cannot blame my new *employé*. After all, he asked nothing that a humane person should consider unreasonable. But I have put to myself this question—How is it possible to grant this with other demands? Only by closing the business earlier, say at 7 o'clock, and one afternoon a week. It is the want of assistants that will compel me to do this.

I do not expect any sympathy from our London fraternity. My tale will be most likely pooh poohed by them, for they will say that they readily find assistants. If my pharmacy were in London, where there is the central school, I should expect forty applicants to one here. The London school is the grand attraction for young men, and makes the practice of pharmacy there easy and cheap.

Were we unanimous, there would be no difficulty in closing earlier, and in having one afternoon a week. Sir J. Lubbock's Bill should be watched and supported. I admit it is a charity at any time, even in the night, to supply articles of real necessity. But every country chemist knows that as long as he keeps open his pharmacy he is abused by thoughtless people who will not obtain what they require until the last minute.

There is nothing that I see at present but Sir J. Lubbock's Bill to protect us from excessive labour, and it should be invited, welcomed, supported. A provision, however, should be made in it by which *medicines only* should be supplied after the eighth or ninth hour of duty, say at four or five o'clock each day.

Mr. Urwick's wish regarding the appointment of a country member as pharmaceutical chief will be supported by many, but we must not lose sight of the fact, that we require in our present difficulties a Jacob Bell, who will at the same time be a Wilberforce, and his staff should consist of men of nearly the same calibre. All our chieftains should be those who, by their example and self-denial, and endeavours to ameliorate our condition, show themselves worthy of the honours which are in our hands to bestow.

"Nisi Prius" seems hopeless. May I advise him to replace his hopelessness by confidence, determination, and energy, founded on just demands. I am glad of the companionship of Mr. Fairlie. Our demands deserve the immediate attention of the whole trade, for low remuneration and excessive labour are the greatest evils in our business. We may be encouraged, too, by the example of Mr. Arch, who in a few weeks effected a great change regarding the payment and labour of agricultural labourers.

A Country Major Associate.

Higher Remuneration for Chemists.

Sir,—I read with much interest Mr. Fairlie's letter on the question of prices in last week's Journal, and agree with him in thinking that no time can be better than the present for taking action thereon. It is much to the honour of the leading London establishments that they put their price on the prescriptions they dispense, and thus proclaim the amount charged, for the guidance of their brethren. Why cannot the leading man or men in each town or district do the same, and influence, if he can, his neighbours to act with him? If, however, they will not so unite, there are, I think, but few who would not agree that if a marked prescription fell into their hands they would not charge less. At all events, let them promise to mark what they charge; and then a full-priced chemist would know how to act better than he now does. I have prevailed on some in this neighbourhood so to unite, and it works satisfactorily. When the trade will co-operate as Mr. Fairlie suggests, by all means follow this plan; but where there is no disposition in the body so to act, I am satisfied that individual effort may do a great deal in bringing about an improvement. Let two or three of the best men in a large town unite as to prices, and the others will gradually come in; or if not, this limited combination will benefit their individual businesses.

Whilst writing on prices, allow me to suggest that in all mixtures when the doses exceed eight, an extra charge should be made. For example, an 8oz. mixture, containing 16 doses, should be put at 2*s.* 6*d.*; a 2oz bottle, containing 16 doses, 2*s.* or 2*s.* 6*d.*, especially noting in the bill in brackets, the number of doses or *vivâ voce*; and then a 3oz. bottle, containing 24 doses, and charged 3*s.* 6*d.* would not cause, as it sometimes now does, any surprise; and may induce the medical profession to order fewer doses. This plan has been adopted by some chemists and works well.

Turnham Green, 15th June, 1874. B. Humpage.

Hunter *v.* Freeland.

Sir,—The following subscriptions, in addition to those already announced, have been received on behalf of the fund raised to reimburse Mr. Freeland, Bathgate, for the heavy expenses—amounting to £267—incurred in defending himself in the case of "Hunter *v.* Freeland," published p. 768 of the present volume:—

Erratum.—In the list published before, p. 768, *for* R. C. Rait Parker, 10*s.* 6*d.*, *read* R. C. Rait, Partrick, 10*s.* 6*d.*

"*Non mi ricordo*," "*Apis*," *T. P. B.* and *B. T. C. A.* should bear in mind the rule as to anonymous communications.

"*Minor.*"—It is important that the specimens should be thoroughly dried, and kept in a dry place.

F. W. S.—We fear that the low standard of education, illustrated in the communication received by you, is that which obtains more generally than is usually supposed.

T. Martin.—Mr. Errington's Bill is printed at p. 1018; the fact of its introduction was mentioned last week on p. 1018.

R. H. Parker.—Bentham's 'Handbook to the British Flora,' or the 'Handbook of British Plants,' by W. Lowndes Notcutt, published at 171, Fleet Street.

"*Enitar.*"—The sample of gum appears to be a good one. We have tried it, but have not observed the gelatinization of which you complain.

H. Young.—The purchase of foreign degrees is a discreditable practice. There are persons who carry on the traffic in this country, but we are unable to furnish any information respecting it.

R. Calvert.—We have received your letter; it shall have due attention.

J. F. Brown.—The bark is that of the *Atherosperma moschata*, or Australian Sassafras, and an infusion of it is used as tea in Australia. The wood is used as timber. The specimen has been handed to the Curator of the Museums.

Theta.—No; you would have to pass exactly the same Minor examination as if you had not passed the Modified. We should be happy to furnish you with any other information, but this is really the only answer that can be given correctly.

J. T. Walker.—If you refer to Watts's Dictionary of Chemistry you will see that, according to the characters given of the borates of zinc and magnesium, borax would not be a satisfactory test.

Student.—Apply to the Secretary for a copy of the pamphlet entitled "Hints to Apprentices and Students."

Communications, Letters, etc., have been received from Mr. J. T. Walker, Mr. W. T. Martin, Dr. Leet, Mr. Pocklington, Mr. Lloyd, Mr. Young, "Minor," "A Student."
