PEPSINE.

BY CHARLES SYMES, PH.D.

There are few medicines, perhaps, which have received so extensive a trial, and yet respecting which such differences of opinion exist, as pepsine. It cannot be doubted that this arises chiefly from the fact that it has not been recognized by the Pharmacopœia, and hence no standard tests of quality exist in this country. Chemists purchase the kind they think best, influenced perhaps by the advertisements of manufacturers or the report of some experimenter who may have used very carefully prepared samples, and not the commercial article; or it might be they are guided by price, the best qualities being usually attributed to the highest priced article of its kind, and this, indeed, should be a correct guide. But I have also heard of orders for pepsine in which the only condition stipulated for was its low price. It occasionally occurs that extremes meet, and my experience indicates that they are not so wide apart as would be supposed, even in this instance. It will not be surprising, however, under such circumstances, that pepsine might mean anything possessing more or less digestive power, an appearance varying from that of decorticated liquorice to pulv. doveri, and an odour from almost nil to the strong smell of bacon. Variable as it might be, it has stood the test of time, and at last asserted its right to recognition and admission to at least the outer circle, viz., to the Appendix.

For some time past I have been conducting a series of experiments on pepsine, first with a view of ascertaining the quality of commercial specimens by different makers; and secondly, of testing the various processes which have been proposed for its preparation as a medicinal or restorative agent. My results under the first head somewhat surprised me, and might do others who have not made this subject one of experimental inquiry; one or two examples will perhaps serve as illustrations. It will be seen that I have used a minimum quantity of acid, so as to test the full peptic power of the various samples—the amount of acid often recommended in a given quantity of fluid being much larger than can possibly exist in the human stomach. In each instance, the white portion of hard-boiled eggs chopped in small pieces was used, and after digestion the undissolved portions, before weighing, were brought to as nearly as possible the same condition of dryness as they were in previously; 100 grains were introduced into each of six vials—to five of these ten drachms distilled water, ten minims dilute hydrochloric acid, and ten grains of pepsine of various kinds were added; in the sixth four drachms of the distilled water were replaced by the same quantity of pepsine wine, each drachm of which should have represented two-and-a-half grains of Pepsina Porci; all were digested under precisely the same conditions at a temperature of 100° for 12 hours. The following gives the amount by weight of undissolved albumen in each vial:—

No.	1	left undissolved	1½	gr.
„	2	„ „	2½	„
„	3	„ „	24	„
„	4	„ „	28	„
„	5	„ „	41	„
„	6	„ „	56	„

Now, the medical man who is desirous of testing the value of pepsine as a remedial agent, in one or more cases where he considers it ought to be of service, if there is any good in it, will be perfectly satisfied of its efficacy should Nos. 1 or 2 be dispensed, more or less so if No. 3; but what if No. 5? or if he should have prescribed pepsine wine, as No. 6? It might be said that this latter is largely prescribed, and also taken by invalids without prescription, frequently with good results. I can only reply that, according to the above statement, it possesses about one-half the peptic power that it should do, and that as the stomach is a laboratory whose operations are somewhat obscure even to the closest observer, in imitating its processes in a vial where we lack the vital agency, the activity of any samples operated on is almost sure to be underrated. Nevertheless, experiments conducted carefully under the same conditions are valuable as affording comparative results; and certain is it that wine or any alcoholic fluid is a most unsatisfactory vehicle for pepsine, also that, when taken with food, it unquestionably retards digestion. The above experiment was several times repeated, first with portions of precisely the same samples, and also with samples by the same makers, but obtained from different sources; the results varied slightly, but bore the same relation to each other. It was thought desirable not to obtain the samples from the manufacturers direct, informing them of the purpose for which they were required, but all were obtained from authentic sources. The pepsine Nos. 1 and 2 were both by the same manufacturer, and, as it will be seen, were of good quality, but it is somewhat anomalous that according to the dose given the former should have been about five times the strength of the latter, whereas it would appear that there is little difference between them. The catalytic action seems to be much more vigorous in the early part of the process of digestion than towards the end; therefore, had a larger amount of albumen been present in the vial No. 1, it is possible a larger amount might have been dissolved, and the residue have been but slightly greater than it actually was. Nevertheless, this could not have been

sufficient to account for the great similarity in activity of the two specimens.

Of the processes for its preparation as a medicinal agent, that of precipitating its solution by acetate of lead, and subsequent separation of the lead by hydrosulphuric acid, has probably been longest in use, but its activity appears to be more or less injured by the chemical treatment. The process of M. Brucke, consisting of solution in dilute phosphoric acid, neutralization with lime-water, re-solution in dilute hydrochloric acid, and final treatment with cholesterine, rectified spirit, and ether, yields a product possessing active peptic properties, but is more suitable as a laboratory experiment than for the purpose of manufacture on a commercial scale. Tannin and alcohol have both been proposed as precipitants for pepsine, but I am not aware of any definite process in which these are used for its preparation on a large scale. Next in order is the somewhat primitive process of Dr. Beale. It is given in the PHARMACEUTICAL JOURNAL, N.S., Vol. II., p. 684, and is as follows :—

"The mucous membrane of a perfectly fresh pig's stomach was carefully dissected from the muscular coat, and placed on a flat board. It was then lightly cleansed with a sponge and a little water, and much of the mucus, remains of food, etc., carefully removed. With the back of a knife or ivory paper knife, the surface was scraped very hard in order that the glands might be squeezed, and their contents pressed out. The viscid mucus thus obtained contains the pure gastric juice, with much epithelium from the glands and surface of the mucous membrane. It is to be spread out on a piece of glass, so as to form a very thin layer, which is to be dried at a temperature of 100° over hot water or *in vacuo* over sulphuric acid. Care must be taken that the temperature does not rise much above 100°, because the action of the solvent would be completely destroyed. When dry, the mucus is scraped from the glass, powdered in a mortar, and transferred to a well-stoppered bottle."

Several persons who have performed experiments with this (so called) pure digestive powder, including Dr. Beale himself, have spoken highly of its peptic properties ; and from their position we cannot doubt the accuracy of their experiments or statements. In my own hands, however, I cannot say the results were so satisfactory as I had anticipated. The process, too, if carried out strictly according to Dr. Beale's instructions, is a very wasteful one, more pepsine being lost than is obtained ; if, on the other hand, it is attempted to obtain a larger quantity, the quality is reduced. The mucus which is directed to be sponged off, and which is usually considerable in quantity, possesses about one-third to one-half the activity of the mucus which is afterwards directed to be *scraped* off ; then, after this scraping, a considerable amount of perspine remains, which can be demonstrated by dissolving it out.

Lastly, we have the process of Mr. E. Scheffer, the most satisfactory as regards uniformity of excellence and economy in working of any I have tried. It is detailed in this Journal so recently as May 31st, I need not therefore even recapitulate here. It can be made to answer strictly to the tests given ; it keeps well ; is soluble in an acidulated fluid, and hence might be prescribed in solution of almost any strength. Amongst other experiments one was performed in which a given quantity of the moist mucus scraped from fresh, cleansed pigs' stomachs, was divided into equal portions, one of which was retained moist, another dried in a thin layer at a temperature not exceeding 100° ; from a third portion the pure pepsine was separated by Mr. Scheffer's process, but adding sufficient sugar of milk to bring it to the exact weight of the portion simply dried.

Into each of four vials 100 grains of coagulated albumen, 10 drops dilute hydrochloric acid, and 10 drachms of water were placed ; to the first 10 grains of the dried mucus, to the second 80 grains of the moist (it requires this quantity to produce 10 grains of the dry), to the third 10 grains of the purified saccharated, to the fourth 10 grains of the same, and two drachms of the water were replaced by sherry wine. After twelve hours' digestion, at a temperature of 100°, the results were as follows :—

No.	1	left undissolved	31 grs.
„	2	„ „	22 „
„	3	„ „	12 „
„	4	„ „	52 „

From this we learn that undried mucus is more active than the same substance after drying ; that the pure pepsine diffused through sugar of milk is more active than the mucus from which it is obtained ; and finally, prove the truth of the statement before made, that wine partially destroys the activity of pepsine and is an unsuitable vehicle for its administration.

I propose, therefore, to substitute for pepsine wine an *elixir*, made by dissolving the purified moist pepsine in raspberry vinegar, so that 1 fluid drachm shall be capable of dissolving 100 grains of coagulated albumen. This keeps well, and is perfectly palatable.

THE PHARMACY OF THE UNITED STATES' PHARMACOPŒIA.

BY WILLIAM MARTINDALE, F.C.S.,

Demonstrator of Materia Medica in University College, London.

(*Continued from Vol. III., p.* 990.)

Extracta fluida.—On account of the novelty of most of these preparations, and the use of new menstrua for exhausting many of the drugs from which they are prepared, the fluid extracts have attracted a great deal of attention on both sides of the Atlantic. There are forty-six official formulæ for them, twenty-two of which are entirely new to the Pharmacopœia. The list is preceded by this head-note, which in general terms gives a model process for making them :—

"Unless otherwise directed, the fluid extracts should be prepared according to the following process :—

"The quantity of powdered material directed to be used in each of the following formulas, with one exception, is sixteen troyounces. This powder is to be moistened with a specified quantity of menstruum, and properly packed in a suitable percolator. The surface of the powder is then to be covered with a disc of paper, and the remaining portion of sixteen fluidounces of menstruum is to be poured upon it. When the liquid begins to drop from the percolator, close the lower orifice with a cork, and, having closely covered the percolator, to prevent evaporation, set it aside in a moderately warm place for four days.

"The cork is then to be removed, more menstruum is to be gradually poured on, and the percolation continued until twenty-four fluidounces have been obtained. Of these the first fourteen fluidounces are to be reserved, and the remainder, having been carefully evaporated to two fluidounces, is to be mixed with the reserved portion, and filtered through paper if necessary."

In all except two of them, sixteen troyounces produce exactly sixteen fluid ounces of fluid extract. The exceptions are, *extractum sarsaparillæ compositum fluidum*—in which the yield is slightly less—and *extractum spigeliæ et sennæ fluidum*—this is made by mixing 10 fluid ounces of fluid extract of spigelia with 6 fluid ounces of fluid extract of senna, and 20 minims each of the oils of anise and caraway.

The following table enumerates the official preparations of this class, the fineness of powder in which the drug is ordered to be used, and the proportion of glycerine in the product obtained :—

Fluid Extract of	Fineness of Powder.	Proportion of Glycerine in the product.
Belladonna	50*	¼
Buchu	50	0†
Calumba	60	⅛
Chimaphila	50	¼
Cimicifuga	80	0‡
Cinchona	80	¼

* These figures indicate the number of meshes in the linear inch of the sieve the drug must be passed through.

† The only solvent directed to be used for these is alcohol sp. gr. 0·835.

‡ Stronger alcohol, sp. gr. 0·817, alone is ordered for these.

It will be observed that for most of the drugs the quantity of glycerine used is one-fourth of the product obtained. In making sixteen fluid ounces of about one-half of these extracts, three fluid ounces of glycerine are mixed with five fluid ounces of water and eight fluid ounces of alcohol (sp. gr. 0·835), thus making the solvent the same strength in spirit as diluted alcohol. The powdered drug is moistened with one-fourth of it, packed in a percolator, the remainder of this solvent is now added, and it is macerated "in a moderately warm place for four days," as directed above. Percolation is then carried on by adding diluted alcohol until fourteen fluid ounces of percolate are obtained. This portion is set aside, and percolation continued until ten fluid ounces more of percolate have been passed. To the latter is added the remaining fluid ounce of glycerine, previous to evaporation down to the bulk of two fluid ounces. After concentration this is mixed with the fourteen ounces set aside, thus producing sixteen fluid ounces, and lastly, the whole is filtered, if necessary. The proportion of alcohol, glycerine, and water is varied to suit each particular case, thus the menstruum first used in making *extractum belladonnæ radicis fluidum*, is a mixture of twelve volumes of alcohol, three of glycerine, and one of water.

In the directions for making *extractum conii fructûs fluidum*, 180 grains of muriatic acid are ordered to be added to the second portion of percolate, along with the remaining ounce of glycerine, before evaporation, to prevent the loss of the volatile alkaloid this contains, but it is difficult to conceive that much of it will be left in conium "seed" when it has been dried and reduced to a *fine* powder. A similar addition of half-an-ounce of acetic acid is directed to be made to the second percolate in making *extractum ergotæ fluidum*. The process for *extractum ipecacuanhæ fluidum* is exceptional — one volume of water is mixed with two of stronger alcohol (why stronger alcohol should be ordered when it has to be thus diluted is not very evident), the ipecacuanha is moistened and macerated with this in a percolator for four days, percolation is then continued with the remainder of the mixture of spirit and water, and finally with diluted alcohol, until two pints of tincture have been slowly passed. This tincture is to be mixed with the glycerine, and the mixture evaporated, at a temperature not exceeding 140°, to one pint. By experiment I found that sixteen troyounces of ipecacuanha absorbed the whole of the twenty-four fluid ounces ordered for macerating and commencing the percolation—no fluid dropped through, as I anticipated by the directions given. The drug was fairly exhausted by the percolation. Half the volume of the resulting product consists of glycerine, and some difficulty is experienced in evaporating it to the required bulk at a temperature not exceeding that mentioned. It is not directed to be filtered like most of the others, and, as I expected, the preparation as made by myself is of a thick syrupy consistence and opaque brownish colour, but little or no sediment has formed in it; mixed with water it deposits, and the supernatant liquor is entirely free from colour. It mixes better with, and is more soluble in, diluted acetic acid.

The following table shows the density of the first menstruum employed—of the first and second percolates—as obtained before further treatment—of the next three fluid ounces percolated as waste, and of, generally, sixteen fluid ounces of the finished pro-

duct, in making the fluid extracts of the drugs named :—

Name of Drug.	Specific Gravity.				
	Of 1st menstruum.	Of 1st percolate.	Of 2nd percolate.	Following 3 oz. percolated.	16 oz. of product.
Belladonna.....	——	1·001	0·997	0·980	1·050
Cinchona.....	0·982	1·060	0·996	0·976	1·106
Ergota.....	0·982	1·037	0·980	0·959	1·060
Ipecacuanha.....	0·907	0·944	0·927	——	1·260
Senega.....	0·982	1·060	1·010	1·006	1·094
Valeriana.....	0·817	0·850	0·855?	——	0·878

No general conclusions can be drawn from the above table as to the approximation to complete exhaustion of the drugs of their soluble principles, because generally two solvents of different density are employed in making each preparation. When percolating with a uniform solvent, proximity to exhaustion may be judged by the fractional percolates approaching in density that of the solvent.

In making the above experiments I found a difficulty in evaporating the second percolate to the bulk of two fluid ounces, especially when it had to be previously mixed with one fluid ounce more of glycerine, on account of, in most cases, its containing so much extractive matter, and also some of the glycerine which had been used as a menstruum and had percolated more slowly than the less viscid fluid added afterwards, although in each case the percolation was carefully conducted. I am unable to explain how the second percolate of *extractum valerianæ fluidum* comes to be of greater density than the first. In evaporating the second percolate of this, as the stronger alcohol volatilized, a resinous or oily separation was found in the fluid which was not entirely dissolved when added to the first percolate. With regard to the other fluid extracts I have tried, those of cinchona, ergot, and senega much more represent the medicinal virtues of the drugs they are prepared from than any preparations I have seen. That of cinchona is excellent ; although the first percolate was a little muddy before the addition of the other portion, yet the finished product is bright and clear, and has not deposited any sediment, although it has been prepared two months. The marc of the bark also was apparently well exhausted. The fluid extract of ergot is also a good preparation ; much superior to extractum ergotæ liquidum, B. P.

As I have stated, they are all directed to be prepared of such strength that one minim should contain the medical virtues of one grain of the drug. This is done as above described, by means of fractional percolation, concentration of the second percolate, and mixing it with the first. This degree of concentration is perhaps in most cases carried further than is practically necessary. If ordered that one grain should be represented by two minims, this class of preparations would much more completely have represented the drugs they are intended. In some, too, the compilers seem to have had the desire to get out of the drug all that was soluble, rather than what alone was medicinally active, as in the case of *extractum belladonnæ radicis fluidum*, in which, probably, much merely inert extractive matter of the root is dissolved.

Careful analyses of extracts prepared from fractional percolates would yield valuable information for guidance in making these preparations. One might rationally infer that supposing the drug to be in a state of fine powder, alkaloids in combination with their vegetable acids, being probably crystallizable, would undergo liquid diffusion, and become dissolved much more quickly and readily than such colloid substances as mucilaginous, extractive, or albuminous matter, and therefore the first portion of percolate would be much the most active.

There is the same waste of alcohol in this class that I mentioned under the head of *Extracta*, the second percolates are all ordered to be *evaporated*, not distilled. Great care and skill will be required to prepare these fluid extracts well, and the manufacture of them will almost necessarily form a special trade.

Therapeutics cannot yet afford to discard these chemically indefinite Galenical preparations, else what is to take the place of such drugs as rhubarb and senna ? And although chemistry has made great advances in this direction, it has not yet either defined such active principles as veratria, aconitia, and digitaline to be simple bodies, or made them always reliable preparations. Sometimes they may be crystallized, but double and triple salts crystallized are not unknown.

(*To be continued.*)

THE ADMINISTRATION OF PHOSPHATE OF LIME.*

BY M. COIRRE.

The importance which during recent years has been attributed to the therapeutic use of the phosphates has induced the author to consider the question of the best mode of administration, with especial reference to the phosphate of lime, a compound which is too insoluble to be employed in suitable doses in most menstrua. In the stomach it is dissolved in small quantity by the hydrochloric acid of the gastric juice ; it exists also in a state of solution in the blood, urine, and other fluids of the body. When, however, it is administered in the natural state, the greater part passes into the fæces, and is lost. Satisfactory results can be obtained only by giving it in solution, and the best solvent is the one it meets with in the stomach, namely, hydrochloric acid. If chemically pure bibasic phosphate be used, a few drops of hydrochloric acid will dissolve one gram in a tablespoonful of water.

By introducing phosphate of lime into the stomach under this form, the author considers its absorption is facilitated in the highest degree, without impoverishing the gastric juice to the detriment of digestion. At the same time the hydrochloric acid aids in producing by other ways the results sought by administering phosphate of lime. It is now known, in fact, that hydrochloric acid is the acid of the gastric juice, and not lactic acid, as was long thought to be the case, and M. Coirre considers it to be a eupeptic medicine *par excellence*. Dr. Rabuteau has shown also that it is transformed in the body into chloride of sodium, the advantages of this latter agent being obtained thereby, to which fact must be attributed the remarkable results sometimes obtained from the use of hydrochloric acid in affections of the digestive canal and cases of consumption.

THE PREPARATION OF IODIDES AND BROMIDES.†

BY CHARLES RICE.

It is a curious fact that iodides and bromides, especially the former, prepared by the intervention of iron, are rather prone to develop, in the course of time, free hydracids and halogens, unless the salt has been exposed

* Abstracted from a paper in *L'Abeille Médicale*.

† *American Journal of Pharmacy*, June, 1873.

to a high degree of temperature, which is, of course, inadmissible in the case of ammonium salts. One explanation of this fact is suggested by the results observed in following another well-known process, formerly much used, and even yet practised, in the preparation of iodides and bromides, namely, to convert the iodine and bromine into hydrobromic acid and hydriodic acid by means of sulphuretted hydrogen, either in the presence of the base or its carbonate, or previous to coming in contact therewith. This process yields a product, in the case of iodine, of very feeble stability, and obstinately retaining traces of sulphur, which it is next to impossible to get rid of. In the case of bromine, the durability is longer, but decomposition frequently ensues after some time. The presence of sulphur, even in most minute proportions, appears to lead to such a result, and traces of it, present in the iron employed, are, I believe, the cause of like effects in the first-mentioned process. Photographers can make no use whatever of such iodides and bromides; the faint trace of sulphur still remaining produces at once a peculiar fogginess and spots upon the film, and there is scarcely a more sensitive test for the detection of minute traces of sulphur than the silvered collodion-film.

I annex a working formula for bromide of ammonium.

Dissolve 4 troy-ounces of bromide of potassium in 6 fluid-ounces of boiling water, and 3 troy-ounces of sulphate of ammonia in 4½ fluid ounces of boiling water. Mix the solutions while hot, and allow to cool. Then add 1½ ounces of alcohol, and set it aside for twenty-four hours. Pour off the clear liquid, wash the precipitate with a small quantity of a mixture of 1 part alcohol and 4 parts water, and concentrate to the point of crystallization. In working upon a larger scale, it is advisable to redissolve the first crop of crystals of bromide of ammonium in a small quantity of very cold water, and allowing as short a time as possible for the solution. The greater part of the accompanying sulphate of potash, which has crystallized out at the same time, will remain undissolved at first, and may be removed, when the solution may be again concentrated, until a pellicle forms. The successive crops of crystals are first drained, then dried on blotting paper laid upon porous bricks with a very gentle heat.

ANNUAL REPORT OF THE DEPUTY MASTER OF THE MINT.

The third annual report of Mr. C. W. Fremantle, Deputy-Master of the Mint, has just been issued. It states that the year 1872 has been remarkable for an extraordinary and unceasing demand for all denominations of gold, silver, and bronze coin. An idea of the magnitude of the coinage executed during the year may be gathered from the statement of the weight of metal issued, namely, gold, 119 tons; silver, 137 tons; bronze, 114 tons; total, 370 tons. The coins struck at the Mint were of thirteen denominations, and the total number of pieces struck was 52,841,048, as against 30,022,404 during 1871, and their value, real or nominal £16,426,663 10s. Of the British coins struck during the year the gold amounted to £15,111,021 10s.; the silver (of which more than half were florins) to £1,265,780; and the bronze to £47,341. The gold coinage in 1871 was £10,500,000, and in previous years averaged only £5,000,000.

Notwithstanding the unusually large amount of silver coin issued during the year 1871, and the efforts made during the first three months of last year to meet the increasing demand, the scarcity of all denominations of that coin continued to be severely felt throughout the spring and summer. But for the necessity of continuing without intermission the delivery of gold coin to the Bank of England, in order to provide against the sudden and abnormal demand which might at any time have been made upon that establishment, the Mint would have had no difficulty in issuing, in the course of a few weeks, such an amount of silver coin as would not only have met the immediate demand. As, however, the continued drain upon the resources of the Bank of England rendered necessary the maintenance of a large and constant supply of gold coin, it was impossible for the Mint to devote itself, except for occasional periods of a few days, to the coinage of silver; and, after consultation with the governors of the Bank of England, the Master of the Mint was reluctantly compelled, in the month of July, to obtain authority for the execution by contract of those processes of the silver coinage which it is impossible to carry on in the Mint simultaneously with the coinage of gold. A contract was made with Messrs. Ralph Heaton and Sons, of Birmingham, to receive bars melted at the Mint, and under the supervision of an officer of the Mint, and from them to manufacture "blanks" for a coinage of the nominal value of £1,000,000. The contract has been completed, and has been instrumental in fully satisfying not only the requirements of the home circulation, but also the numerous and heavy demands of the colonies, and in creating a fund sufficient to meet all probable demands from Scotland, Ireland, and colonial governments until a renewed withdrawal of silver coin from the Bank of England renders the resumption of the silver coinage necessary. In the rapid execution of so large an amount of silver coinage, however, difficulty has been experienced in maintaining the scrupulous examination to which all coins are subjected before they are allowed to leave the operative department, and a consequent risk incurred of issuing defective pieces.

The silver coin delivered to the public in 1872 reached the unprecedented amount of £1,238,000, of which £972,000 was issued to the Bank of England, £180,000 to Scotch banks, and £76,000 to the Colonies, besides £10,000 in threepences issued direct to the public. An extraordinary increase has taken place in the amounts of silver coin issued by the Mint to the Bank of England, from £87,000 in 1867 to £972,000 in 1872.

The nominal value of the bronze coin issued during the year 1872 was £48,000. This amount exceeds by more than £16,000 the amount issued in 1871, which itself far exceeded the average. The demand for bronze coin will appear the more extraordinary when it is considered that no issues have been made for the London district, in which a sufficient supply has existed, nor for Ireland, and that the shipments for the Colonies, with the exception of one amount of £1000 consigned to the Sydney Mint for circulation in Australia, have been inconsiderable. As in the case of the silver coinage, it has been impossible for the Mint, while engaged in the coinage of gold, to perform the operations of "rolling" and "cutting" bronze bars. These operations, therefore, have been performed by contract at Birmingham.

For the first time, a statement showing on one side the total expenses incurred in connection with the Mint during the year, and on the other the receipts of the department payable to the Exchequer has been added, in order that the general result of the transactions of the year may be seen at a glance, with the balance of profit or loss which has accrued to the public.

In the expenses of the Mint have been included the amounts paid for superannuation and compensation allowances, and the expenditure incurred by the Office of Works for repairs of buildings, coals, stores, etc., and by the Stationery Office for books and stationery, on account of the department during the year. After including these sums, the operations of the Mint for 1872 show a net gain (or excess of receipts over the total charge) of no less than £98,313. This result is due to the profit on the exceptionally large amount of silver bullion coined.

At the beginning of the year 1872 no less than 240 tons of the old copper coin, which had been withdrawn from circulation in consequence of the issue of the bronze coinage, still remained in store at the Mint. As there was no prospect that the entire amount would be used for the bronze coinage for many years, and, as the price of copper was unusually high, arrangements were made to dispose of 175 tons at its market value, under conditions

which provided for the conversion of the coin into cake copper under the supervision of an officer of the department.

The vote for the loss on the withdrawal of worn silver coin from circulation during the year 1872–73 had been raised from £15,000 to £30,000, so as to provide for the extension to other parts of the empire of the privilege, before enjoyed by England only, of returning the worn coin to the Mint at its full nominal value. The unusual demand for silver coin has had the effect of preventing the withdrawal from circulation of so large an amount of worn coin as was expected, and the sum required to make good the loss on withdrawal till the 31st of March last has been only £20,800 ; but as the demand has now been satisfied, and large amounts of worn silver coin may be expected to be sent in to the Mint, it has been considered necessary that the sum to meet this expenditure during the year 1873–74 should again be estimated at £30,000.

The work devolving upon the Mint office has been extremely heavy throughout the year, and, in recognition of the exertions made by the Mint generally, their lordships were pleased, at the close of the year, to authorize the payment of gratuities equal to two months' salary to the officers and men of the permanent establishment, with an intimation of their approval of the manner in which the duties of the department had been performed.

A quantity of worn crowns and half-crowns, weighing about 100,000 ounces, which had been withdrawn from circulation, have been subjected to the process of refinage, in order that the gold contained in them might be extracted before they were melted for re-coinage. The coins in question were known to contain such an amount of gold as might, with the present improved methods of refining, be extracted at a profit, and that it might probably be found advisable to recommend an arrangement for the extraction of the more precious metal. No refinery being now attached to the Mint, the operation was performed by Messrs. Johnson, Matthey, and Co., the well-known metallurgists, at a charge which left a margin of profit.

Before the close of the year, a communication was received from Mr. Norman Lockyer, F.R.S., on the subject of a discovery of much interest to which he had been led in the course of an investigation, by means of the spectroscope, into the constitution of the solar atmosphere. Mr. Lockyer stated that his discovery seemed likely to afford a simple and accurate method of estimating the relative proportions of the component metals of alloy, and he suggested that, as he was anxious that his method should be submitted to the test of further experiments of a practical nature, its details should be examined in the Mint, in order that it might be ascertained whether it could be applied to the assay or verification of the alloys of precious metals used in the coinage. Mr. Roberts, Chemist of the Mint, was requested to render every assistance in developing a process which might with advantage replace the methods of assay or verification in use in the Mint, and that gentleman reports rather hopefully on the results of the preliminary experiments which have been made. He says that he is satisfied that, in the examination of a series of gold-copper alloys by means of the spectroscope, differences of composition more minute than the $\frac{1}{10000}$ part can be readily distinguished. The advantage of the proposed method consists in the fact that the value of a single assay piece could be determined in a few minutes, while an assay by the ordinary method can hardly be completed in less than two hours ; but he considers that further experiments are necessary to prove whether the spectral method is sufficiently trustworthy to render it possible to substitute it for the existing method.

Mr. Roberts also reports that the amount of brittle gold set aside as unfit for working, during the coinage of more than 24 millions, was 17,000 ounces, whereas the amount of gold rejected during the coinage of £6,500,000, which was completed in July, 1871, was no less than 40,000 ounces. This diminution in the amount of brittle gold is in some measure the result of great care in the selection of metal for coinage ; but gold may be received by the Mint with a tendency to brittleness, and its unsuitability for conversion into coin may not be fully developed until the bars, into which it is melted, have been submitted to the process of annealing. It was only found necessary to employ the chlorine process for treating 9000 ounces of brittle gold, and the remaining 8000 ounces were treated by two methods found to be effectual in toughening gold which was rejected during the coinage of 1870. One of the processes adopted consists in pouring the molten metal in a thin stream into a suitable receptacle lined with borax, the metal being freely exposed to atmospheric air ; the other in the addition of chloride of copper to the molten gold.

CULTIVATION OF CINCHONA AT DARJEELING.

The following paragraph occurs in a letter from the Calcutta correspondent of the *Times*, dated June 3 :—

The cultivation of the cinchona at Darjeeling is making, comparatively, as hopeful progress as that of tea. Nine years have passed since the late Dr. T. Anderson, whom Lord Canning sent to Java to study the plantations there, removed the first nursery of cinchonas which he had formed from the northern slope of a spur near Darjeeling to a fine valley of 30,000 acres which runs down to the Teesta river. In its broad expanse and varying slope the varieties of climate are remarkable. This is Rungbee, where the Lieutenant-Governor is at this moment. I believe close to it is the Pomong garden of the Cinchona Association of Darjeeling. The *officinalis*, or grey bark variety, which had succeeded so well on the Neilgherry hills, proved a failure here. The *Calisaya*, or yellow bark, planted on a lower slope has fairly succeeded. But the *succirubra* has prospered above all expectation on the lower altitudes. The height of 4000 feet is the limit of growth, but the lower plantations are much healthier down to 1000 feet. The experiments of the government officials began to bear fruit here in 1867, when the Pomong Company took advantage of them, covering 1000 acres with *succirubra*, while the government area under that plant is 1500 acres. Last year the Pomong garden, which is worked as a commercial enterprise, yielded 36,000lb. of dry bark, and it will produce 50,000lb. this season. Its proprietors take advantage of the fact that when a five-year-old tree is cut down several shoots at once spring up, and in four years one of these is as stout as the old stem. Hence the bark which sold in the London market at 1*s.* 6*d.* a pound. Government is in a different position. It has borne the expense of all the experiments, and need run no risk for a small immediate gain. Of 3,000,000 of plants at Rungbee, more than 2,000,000 have been permanently set out. Some 200 acres of fresh soil are planted out every year. The highest tree rises to 36ft., and is 17in. in girth ; a large number of trees rise from 22ft. to 30ft. high. They are rarely touched by that canker which the Neilgherry authorities predicted would ruin them all. Dr. Henderson, who has just reported on the plantation, to which he is new, states that a trial consignment of bark, sent to England last year, realized 2*s.* per lb. Some 50,000lb. will be ready for manufacture or sale this year. A quinologist is expected from England, and the bark is being kept for his operations. But a moderate estimate gives the produce of dry bark in the next three years at 200,000lb., calculated to produce 6000lb. of quinine, and 6000lb. of other valuable alkaloids. Fever-stricken Bengal, with its swamps and malaria, will hail the boon. A sum of £50,000 has been spent on the government plantation from the first, and it costs £5000 a year now. The 400 coolies employed are Nepaulese ; but in a few years the plantation should be self-supporting. The Pomong garden, which owes its existence to it, costs £1800, and should this season pay its expenses.

The Pharmaceutical Journal.

SATURDAY, JULY 5, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE NEW EDUCATIONAL ARRANGEMENTS.

AMONG the proceedings at the last Council meeting, reported in the present number of the Journal, will be found an important resolution, embodying a series of regulations in regard to the Society's laboratory and the lectures delivered at the Society's school. As we took occasion to notice some short time since, it has been very generally regarded as unsatisfactory that so large an amount of money should annually appear on the balance-sheet as a deficit of receipts against expenditure for the professional teaching at Bloomsbury Square. The grounds of objection to this feature in the financial affairs of the Society were twofold; in the first, it was thought that such expenditure, being confined to the metropolitan school, there was some injustice done to the provinces or, at any rate, that unequal advantages were thus offered to those who could attend the Society's school in Bloomsbury Square. This view has, no doubt, some degree of plausibility at first sight, and, as our readers will be aware, it has been popular. But, like many popular plausibilities, it has not much foundation in fact; and as we have often pointed out, the advantages of the metropolitan school have always been largely shared in by the provinces. Indeed, the majority of the laboratory students have been from the commencement provincials. True, it has been argued that there was some degree of hardship inflicted on those who came to London to study in this way; but in these days of cheap and facile locomotion such hardship, in a pecuniary sense, cannot be very seriously insisted upon, and we think it might well be maintained, on the contrary, that the inducements offered by the school to make some stay in London would in the main operate advantageously. Certainly the facilities now-a-days offered in London establishments for young men to attend educational courses would tend to counterbalance any other disadvantage on the score of expense to be incurred, while at the same time there would be the opportunity for acquiring trade experience, such as is almost peculiar to the business of a London pharmacist.

However, the most serious objection to the Society's expenditure on the school was based on the ground of its inappropriateness to the existing state of things. British pharmacy is no longer in the position which the founders of the Society had to deal with. Qualification for the pursuit is no longer optional as it then was, and although the standard required may not be so high as many would desire to see, still the ordeal to be passed through in order to obtain a legal qualification to carry on the business of pharmacy is, at any rate, such as to recognize the principle that the pharmacist should have had a special education. That being the case, the means of education possess a current value which ought not to be depreciated. The new regime, inaugurated as a voluntary matter by the Society some thirty years ago, and established as a binding obligation for all by the Pharmacy Act of 1868, has now, in this latter phase, been in existence for five years, and it is natural enough that the measures originally found expedient and necessary for promoting the study of science in relation to pharmacy should now be regarded as superfluous and out of date.

As regards the Society's laboratory, the fees demanded of students have long been on a par with other schools of a similar kind, but in the case of the lectures, the fees have always been merely nominal, and it is mainly owing to this fact that the maintenance of the school has involved an output of something like £500 a-year. The new regulations will place this section of the educational establishment on a footing more analogous to other institutions, while at the same time the attendance fees are fixed on a scale sufficiently liberal to be within the means of students.

A further and perhaps still more important provision of the new regulations is the severance of the school from its former immediate connection with the Society. The feeling that this was necessary has long been gaining ground, and we congratulate the Council on having boldly taken the step of placing the school on an independent footing financially. No doubt this step may cause some shock to those who have followed the fortunes of the Society's school from its cradle, and are connected with it not only by their present interest in the advancement of pharmacy, but also by the reminiscences of their own student days. To such, Mr. SCHACHT's earnest protest against the proposed severance will need no explanation or apology, and we feel sure that even those who think his action in this respect antagonistic to progress, will respect him more than ever—if that be possible—for the course he took.

For our own part, we do not regard the new measure as being fraught with those possible evil results which Mr. SCHACHT apprehends. The school will still be the Society's school, although no longer in leading-strings, and we see no reason to fear that its establishment in financial independence will be any barrier to the creation of other schools—and let us hope rival schools—in the provinces.

Certainly there will be additional opportunity for applying the funds of the Society to an object so

eminently desirable, and since the chief aim of the Society must ever be to promote an uniform system of education of those intending to practise pharmacy, there will be more than ever scope for the efforts of those who share with Mr. SCHACHT the well-founded regret that the Society has no process by which its large surplus income can be made useful to the community who supply it.

The resolutions passed by the Council in reference to the BELL Scholarships and the PEREIRA Medal will be hailed with satisfaction by students who have felt some apprehension that they would be ineligible on account of the misunderstanding that has prevailed as to the position of persons who have passed the Major Examination. We call especial attention to the necessity of sending notice of desire to compete for the BELL Scholarship, on or before the 19th instant.

PROJECTED HERBARIUM OF MEDICINAL PLANTS.

IT is thought desirable by the Council of the Pharmaceutical Society to extend the small herbarium of medicinal plants at present in their possession, so as to include specimens of medicinal plants from every quarter of the globe, whether official or non-official, and thus render it available for reference to those who are interested in the identification of medicinal plants, or in the determination of the sources of the Materia Medica of foreign countries. The large amount of time and trouble at present necessary in order to ascertain the identity of foreign medicinal plants by comparison with the immense number of species in the collections at the British Museum and Kew—of which a comparatively small number are used in medicine—would thus be rendered considerably less. Native medicines are often brought home by medical gentlemen who have been residents in foreign countries, and who have seen beneficial results arising from their use. There cannot be much doubt that the "medicine men" of uncivilized countries have in many cases a very accurate knowledge of the medical uses of the plants around them, and that there are probably many valuable remedies used by them which are worthy of a trial in civilized countries. Of this fact *Physostigma* and *Quassia* may be quoted as instances.

The occasional failure in obtaining results from medicines used successfully by the natives of foreign countries is perhaps in some measure due to the imperfect knowledge at present possessed of foreign medical plants, and also to the limited number and poorness of the specimens available for examination by competent botanists. Of this *Sarracenia* and *Cundurango* may be instances.

The uncertainty of action attending the use of some drugs, such as aconite, probably depends in a measure upon a want of discrimination between the species which yield them. In the case of aconite, it is well known that some species, such as *A. heterophyllum*, are innocuous, while others differ considerably in power. *Pareira brava* is another instance. The roots and stems of several entirely different, though allied, plants have at different times been imported, as Pareira brava, which appear to vary widely in the amount of extract yielded by them, and in their medical properties. A specimen recently examined, which appeared identical with that described in Pereira's Materia Medica, had leaves attached which, although evidently belonging to a species of *Chondrodendron*, could not be identified with certainty by means of any of the specimens either in the British Museum or at Kew. Difficulties like these can only be overcome by a more accurate knowledge of all the plants used as medicine in the countries yielding the drugs, as there are often plants similar in habit and general appearance which grow in the same localities and are confounded one with the other by those who collect them. *Cocculus palmatus* may be quoted as an instance of this.

Pharmaceutists resident in foreign countries have frequent opportunities for increasing our knowledge of Materia Medica, and it is to them that we especially appeal to assist in carrying out this project in a manner worthy of the scientific standing of the Pharmaceutical Society of Great Britain. There is abundant provision in the museum of the Pharmaceutical Society for an extensive herbarium of medicinal plants, and the Curator will be glad to correspond with any pharmaceutists in other countries who are willing to help in making the herbarium a really useful one. It should not be forgotten that specimens of medicinal plants are rendered much more valuable when accompanied by specimens of the part used in medicine, whether root, bark, etc., and also by the fruit in a mature state when possible.

POISONING BY STRAMONIUM.

ABOUT two months since two ladies applied at a pharmacy at Pau for some leaves of soap wort. Some leaves were given them in a bottle labelled "Saponaire" by a pupil. The next day a report spread that two ladies had been poisoned by the carelessness of a pharmacien, and the physicians who were called in declared they were suffering from the effects of some poisonous solanaceous plant. The bottle was examined, and found to contain stramonium leaves. The ladies recovered, but have since entered an action against the pharmacien for an indemnity of twenty thousand francs, which sum, if they get it, they propose to give to the poor.

THE Colony of Victoria imported in 1871 drugs to the value of £21,430, on which a duty of 5 per cent. was paid, and £26,594 on which a duty of 10 per cent. was paid, besides druggists' wares amounting to £833, subject to the 5 per cent. duty, and £1458 subject to the 10 per cent. duty.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL
July 2nd, 1873.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Baynes, Betty, Brown, Greenish, Hampson, Mackay, Owen, Radley, Robbins, Sandford, Savage, Schacht, Shaw, and Urwick.

The minutes of the previous meeting were read and confirmed.

Inaugural Sessional Address.

The Secretary read a letter from Mr. Reynolds, of Leeds, stating that, much to his regret, he felt compelled, from the state of his health, to decline the honour which had been offered him of delivering the Inaugural Address in October next.

Mr. Mackay then proposed that Mr. Sandford be requested to undertake that duty, and the resolution was carried unanimously, notwithstanding a very earnest protest on the part of Mr. Sandford.

London Collector.

Mr. Mackay drew attention to an item in the accounts for commission on the collection of subscriptions in London. He did not think it was fair to put the Society to that expense when local secretaries were expected to do the work for nothing and those members who did not send in their subscriptions by a certain date had to pay a fine.

Mr. Owen said he was originally led to join the Society through being called upon by the collector.

Mr. Brown was glad this matter had been mentioned. He thought the time had long since passed when it was desirable to employ a paid canvasser to induce gentlemen to join the Society.

The Vice-President having also expressed his concurrence in the view that London members should no longer have a privilege not accorded to those in the country,

It was then resolved,

"That the employment of a collector for London and neighbourhood, in connection with the annual subscriptions, be discontinued, and that due intimation of this change be made in the Pharmaceutical Journal."

Several Members, Associates, and Apprentices, who had neglected to pay their subscriptions within the proper time, were ordered to be restored to their original status, on payment of their subscriptions and a nominal fine.

The following being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society :—

Cleaver, Edward Lawrance.....London.
Galloway, George Ross.....Inverness.
Gilmour, David.....Edinburgh.
Kirton, Christopher Henry.....Hull.
Plowman, Sydney.....Boston.
Pound, Henry William .....London.
Woods, Joseph Henry .....Warrington.
Woolldridge, George.....Birmingham.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Cleaver, Edward Lawrance ... ..London.
Plowman, Sydney.....Boston.
Pound, Henry William .....London.
Sharp, John James .....London.

Chemists and Druggists.

Buckley, Robert Clarence .....Todmorden.
Chalmers, George .....Dufftown.
Coleman, William.....Wolverhampton.
Midgley, Frank.....Padiham.
Savage, George .....Lincoln.
Shelley, Henry .....Twickenham.
Titley, Thomas .....London.
White, Timothy .....Landport.
Wright, Mark .....Wokingham.

ASSOCIATES.

The following having passed their respective examinations, and being in business, were elected "Associates in Business" of the Society :—

Minor.

Lawson, Edward James .....Whitstable.
Oliver, Frederick Bailey .....West Malling.
Otley, John .....Sheffield.

Modified.

Child, Thomas .....New Wortley, Leeds.
Storm, Elliott Baxter .....Ipswich.

The following having passed their respective examinations were elected "Associates" of the Society :—

Minor.

Adams, William .....Barnstaple.
Askew, Hugh de Bosco .....Workington.
Barry, Frederick .....Bath.
Bathe, William .....Chippenham.
Beverley, Robert Henry .....Nottingham.
Fairman, George Peters .. ..London.
Griffiths, Edwin Harpham .....Hanley.
Mason, Michael .....Salisbury.
Maynard, Henry Robert .....Brandon.
Piquet, Frederic George .....Jersey.
Slater, Elias .....Fallowfield.
Tearle, Walter .....Ilfracombe.
Thornton, Edward .....Walsall.
Tucker, William Charles.....London.

Modified.

Fenton, William .....London.
Phillips, Charles .....Birmingham.
Shaw, John .....Ashton-under-Lyne.
Taubman, Robert.....London.

APPRENTICES OR STUDENTS.

The following, having passed the preliminary examination, were elected "Apprentices or Students" of the Society —

Brick, John ....Welchpool.
Dobson, George.....Egremont, Cheshire.
Fletcher, Howard Bennett .....Leicester.
Williams, Thomas Robert .....Ipswich.

Finance Committee.

The Report of this Committee was read and adopted, and sundry payments of rent, salaries, and accounts ordered to be made.

Benevolent Fund.

The Report of this Committee, recommending that a grant of £10 be made to the widow of a deceased member, at Leeds, was received and the recommendation adopted.

Parliamentary Committee.

The Report of this Committee was received and adopted. It contained particulars of some of the cases which had been submitted to the Solicitor, and which were still under consideration. In the case of a memorial which had been sent from a provincial society, giving information of infringements of the Pharmacy Act, 1868, the Committee recommended that each of the parties offending should receive a communication from the Registrar before any legal proceedings were taken.

In another case, where a prescription containing laud-

anum had been dispensed at the shop of a person not on the Register, the compound, when submitted to an analysis, was found to contain no preparation of opium whatever.

Library, Museum, and Laboratory.

The report of several sittings of this Committee was presented, and, in accordance with some of its recommendations, the Council ordered the purchase of Jenkin's "Electricity and Magnetism" and sundry specimen bottles for the Museum.

The Society's School of Pharmacy.

The most important subject coming under the attention of the Library, Museum, and Laboratory Committee was the educational arrangements of the Society, in reference to which several meetings of the Committee had been held, the subject having been referred to them by the Council. The Committee had agreed to a report which had been submitted to and approved by the General Purposes Committee.

Mr. Schacht said he was very sorry not to have been able to attend the meeting of the General Purposes Committee on the previous evening, when this matter was discussed, but, of course, there were very many whose opinion one would like to have upon such an important change, namely, the members of the Society at large, and he sincerely hoped no decision would be arrived at on that occasion on this almost revolutionary proposition. He would venture to suggest that these regulations be published in the Pharmaceutical Journal, so that an opportunity might be given of considering them. He really was not prepared to give an opinion at the present moment. The change seemed so pregnant with importance that almost every line required a large amount of consideration. He did not mean to suggest that the matter had not received proper consideration from those gentlemen who had attended the Committee, and no doubt they had excellent reasons for everything they had said, but he should not like to hold up his hand for such a sweeping change without having much more time to think of it. He was certainly astonished at the recommendation that the ten months' course of lectures should be divided into two of five months each, for all his experience on these matters as regarded the teaching of the important sciences which they professed to teach, had gone to show that even ten months was all too short a time. A good many years ago he attended the lectures on chemistry at the Royal Institution, and chemistry in those days was not so great as it was now, organic chemistry being treated very slightly, whereas at the present time it almost swallowed up the other department. The subjects never appeared to be verbosely treated by the gentlemen who then lectured, nor did the students appear to show any lack of interest towards the close of the course. He might also refer to the system adopted by the authorities at South Kensington, where they divided the subject which was called chemistry at the Pharmaceutical Society, into three parts—namely, physics, inorganic chemistry, and organic chemistry, in each of which a student must attend at least twenty-five lectures before he was admitted as a candidate for a prize, so that in the whole he must attend something like ninety lectures. He hoped that the matter would not be pressed until an opportunity was given to enable the members of the Society to express their opinion upon it.

Mr. Mackay said the Committee had not taken action in this matter without duly consulting the professors themselves, who entirely concurred in it. It was not for him to say whether there had been any verboseness hitherto on the part of the lecturers, but they certainly stated to the Committee that they would be able to condense their subjects so as to give in a course of five months the substance of what they had hitherto delivered in the ten months' course. With regard to the laboratory, there would be no change, because the students could attend two, three, five, or ten months, as they felt disposed. He should also like it to be known that they were not quite at one with the professors on the subject of the fees, with the exception of Professor Attfield, who was quite content to let them remain as at present. Both Professor Redwood and Professor Bentley were of opinion that their fees should be a little higher; but the Committee, after long discussion, had come to the conclusion that, looking at the increased number of students who it was expected would attend, the monetary return would be greater than if their fees were raised. This matter had been mentioned on several occasions, and had been very well discussed now, and he hoped it would be decided at once. He had held for some years that this change must come sooner or later.

Mr. Betty also observed that the subject had been well discussed during the month, Mr. Schacht himself having been present at one meeting of the Committee, when the professors also attended. Professor Redwood stated his intention so to recast the subject matter of his lectures, that they may form substantially an ample course of instruction in a five months' course; as, for instance, by proving certain and scientific principles, by illustrations bearing a special relation to pharmacy. And this shorter course, whilst suiting the convenience of many students, would thus remain undiminished in efficiency. Professor Bentley also said that experience had given him the power of condensation.

Mr. Schacht said this was not really a mere matter of experiment, but it involved a very large principle, viz., whether the Society was to cease teaching or not, and he must be excused for again protesting against its being decided so hastily. He had certainly attended one of the Committee meetings, but not being a member, he had taken no part in the proceedings, and he did not then gather that it was the intention to recommend the entire separation of the Society from the province of education, for this, he apprehended was what was now going to be done. Of course, if that were so, it would be a death blow to the hopes of the provinces, for what was discontinued as a principle in London could never be urged for one moment in the country. He saw that quite plainly. Here they were giving up what had been for thirty-seven years their principle.

The President said they were not going to give up education entirely, since it was intended to endow the professorships.

Mr. Schacht said he supposed that was simply because the professors were old servants.

Mr. Mackay said that was not so. They should endow the chair, and also give accommodation for the lecturers.

The President said besides that they would still retain surveillance over the whole of the educational department.

Mr. Schacht said he apprehended they had no responsibility.

The President said they took all the responsibility, the same as before, except from a commercial point of view.

Mr. Urwick thought the course now proposed would tend to further education, as each department would now stand on its own merits, and the school would be thereby much improved. Each of the professors would now have the strongest interest in making his lectures attractive, and so more students would be brought to the school.

Mr. Sandford said he had great pleasure in embodying the Report of the Committee in the following motion:—

> "That the School of Pharmacy be no longer conducted under the immediate direction of the Council, or at the actual cost of the Society, but that in future three Professors shall be appointed annually by the Council to be called respectively:—
>
> The Professor of Chemistry and Pharmacy;
> The Professor of Botany and Materia Medica;
> The Professor of Practical Chemistry.

The endowment of each Professorship shall be £100 per annum.

It shall be the duty of the Professor of Chemistry and Pharmacy to deliver a course of sixty lectures from the beginning of October to the end of February, and a second course of sixty lectures from the beginning of March to the end of July, on three mornings of each week.

It shall be the duty of the Professor of Botany and Materia Medica to deliver a course of forty lectures from the beginning of October to the end of February, and a second course of forty lectures from the beginning of March to the end of July, on two mornings of each week. He shall, in addition, deliver a course of about twenty lectures on Practical Botany in the gardens of the Royal Botanic Society, from the middle of May to the end of July.

The Professors shall be allowed the use of the Lecture-room of the Society free of charge ; gas and fuel necessary for lighting and warming the room shall be provided by the Society, but all other expenses for assistants and materials required for carrying out the courses of lectures shall be paid by the Professors.

The Professors shall (without fee) admit the holders of the Jacob Bell Memorial Scholarships to the lectures.

That the fees for each course of lectures on Chemistry and Pharmacy shall be Two guineas, but that a student entering for two courses shall be admitted to both on payment of Three guineas, or a perpetual pupil shall pay Four guineas.

That the fees for each course of lectures on Botany and Materia Medica shall be One guinea and a half, or Two guineas and a half for the two courses. For the course of lectures on Practical Botany, One guinea. But a student entering for either of the first-named courses shall be entitled to attend the lectures on Practical Botany on payment of Two guineas at the time of entering, or perpetual admission shall be granted for Four guineas.

The Professors shall receive and appropriate all fees.

The Professor of Practical Chemistry shall have free use of the Laboratory and plant, and surrender them in good condition, fair wear and tear excepted, at the termination of his appointment.

The Professor shall receive and appropriate all fees, and pay all expenses, including gas and fuel. The fees to be on the same scale as is charged at present.

He shall admit the Bell scholars to the Laboratory, and instruct them annually without fee, but the sum of five pounds shall be paid to the Professor for each Scholar in consideration of the materials used.

In order to retain authority over the lectures and laboratory, the Library, Museum, and Laboratory Committee shall, from time to time, visit and report to the Council on the general conduct of the School. These visits may be made by the members of the Committee individually as well as by the Committee collectively.

It is not intended that the Committee shall interfere with the arrangements, the object of their inspection being simply to be assured, from time to time, that the teaching is continued in a manner conducive to the advancement of Pharmacy, and consequently satisfactory to the Council."

Mr. SANDFORD said that it was known to most present that he had for a long time considered it an anomaly that they should be both an educating and an examining body. When the Society was first established, there was no public school of pharmacy in existence, and it was, therefore, necessary to found one, and nurse it until it should be able to support itself. He believed the time had now arrived when it would support itself; at any rate with the assistance which they still proposed to give, for he thought it quite right and proper that the Society, although not an educating body should still have professors attached to the Institution, especially as they had there all the necessary means and appliances. The question of the lectures must be in some respects separate from the question of the laboratory, but it was one school. He did not adopt the phrase of there being two sessions of five months, for the whole ten months should still be considered as one session, though there were two courses of lectures delivered. The mode of distributing prizes, etc., would, no doubt, have to be further considered in detail. He did not agree with the idea that, because they gave up teaching they would be unable to assist education in the country. On the contrary, he thought they would be all the better able to assist those in the country who, like Mr. Schacht, Mr. Sutton, Mr. Atherton, and others, were doing their best to promote pharmaceutical education, as they would have more means at their disposal for so doing. With regard to the lectures, he thought having two courses of five months each would be a great improvement, as it would enable many more young men to attend. There were great numbers who could give five months to study, but who would be unable to devote so long a time as ten months. As had been already remarked also, the professors would be thrown on their own resources and thus have great inducements to make their lectures interesting and profitable, and he hoped more students would be attracted. He had felt that the proposed change was a very serious one, but as it had been so well considered, both by the Library Committee and the General Purposes Committee, on the previous evening, when there was a very full attendance, he thought the question might be decided at once.

Mr. MACKAY said he seconded the motion with a considerable amount of satisfaction, and, in doing so, wished to disabuse Mr. Schacht's mind of the belief that in agreeing to it there was the least idea of, in any way, cramping the assistance given to any provincial town in connection with pharmaceutical education ; in his belief the prevalent feeling was quite of an opposite character. They were not entirely disconnecting themselves with education, because the endowment of £100 per annum to each of the professors was a considerable item, and the use of the rooms and the laboratory would also be given them ; besides which, the Committee were still, from time to time, to inspect the arrangements, and see that everything was going on satisfactorily. He thought the provinces generally might with great advantage follow the example set them, and he spoke more positively, because of the experience of the Society in Edinburgh. Having now a place of meeting there, with specimens, and a library, it was found that a very great number of young men availed themselves of these advantages, many more in fact than was at all anticipated. They were in hopes that the same thing would continue, and he was more and more convinced, in his own mind, that if those connected with pharmacy, throughout the country, would unite and provide a place of meeting, and engage, if possible, someone able and willing to give instruction, and form something like a library and museum, the Council would be very much wanting in their duty if they did not liberally assist such endeavours. He should be the very last to propose such an alteration if it were not with the idea that it would tend to open the door wider for provincial education, rather than to close it.

Mr. SCHACHT said that he felt bound to move an amendment, not that he meant to oppose the principle or detail of the matter, for he had not really considered it, but simply because he wanted a little more time to be given before it was decided upon. He therefore begged to move, as an amendment,

"That the proposition of the Committee be published in the PHARMACEUTICAL JOURNAL, and postponed for decision until the meeting of the next Council."

Mr. SAVAGE seconded the amendment.

Mr. SHAW said he had not heard any observations from Mr. Schacht which would seem to justify the Council in postponing the matter, especially as the arrangements, with regard to fees, etc., for the ensuing session should be shortly published in the PHARMACEUTICAL JOURNAL, and the alteration ought to be made known immediately. He anticipated that this alteration would very much increase the amount of fees, and did not think it would in any way interfere with assistance being given to provincial education. They might still continue to make grants as on former occasions.

The amendment was then put and lost, only the mover and seconder voting for it.

The original motion was then put and carried.

A further resolution was passed, requesting the Library, Museum, and Laboratory Committee to arrange the details involved in carrying out the previous resolution, and to report thereon to the next meeting of Council.

THE SENIOR JACOB BELL MEMORIAL SCHOLARSHIP.

The SECRETARY read a letter received from a gentleman who was desirous of competing for the Senior Bell Scholarship, drawing attention to the fact that, under the present regulations, no one was eligible to compete, since a student who passed the Major examination *ipso facto* ceased to be an Associate.

Mr. SANDFORD said it was evidently the intention of the Council, in arranging the scholarships, that those students who were Associates and came up and passed the Major examination should be eligible to compete, and the following resolution was passed unanimously.

"That the Senior Jacob Bell Memorial Scholarship for the Session 1873-74 shall be open for competition by persons who were Associates of the Society at the time of passing the Major examination, and who are under twenty-four years of age. Candidates desiring to compete must send notice to the Secretary accompanied by certificates of age, and by testimonials from their previous employers or masters as to capability, industry, and general conduct, on or before the 19th instant."

THE PEREIRA MEDAL.

A letter was read drawing attention to the conditions of competition for the Pereira Medal, by which it would appear that only Associates who had passed the Major examination were eligible to compete. The Council considered it necessary to amend the regulation, and the following was passed :—

"That Pharmaceutical Chemists who were Associates of the Society at the time of passing the Major examination, and who have exhibited a certain proficiency in the several subjects embraced in the examination, will be placed on the list of Honors, and entitled to compete for the Pereira Medal at the end of the Session in which they passed the Major examination."

BOARDS OF EXAMINERS.

The following Reports of the Boards of Examiners were presented :—

REPORTS OF EXAMINATIONS.

June, 1873.

ENGLAND AND WALES.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	9	6	3
Minor	48	23	25
Modified	34	26	8
	91	55	36

SCOTLAND.

Examinations.	Candidates. Examined.	Passed.	Failed.
Major	2	2	0
Minor	18	14	4
Modified	3	3	0
	23	19	4

The Board of Examiners for England and Wales reported that they had considered the present system of carrying out or superintending the Preliminary examination in the provinces, and that they thought it very desirable that youths should be encouraged as much as possible to pass the examination of some one of the examining bodies approved by the Council, before entering the trade.

ELECTION OF PROFESSORS.

Professors Redwood, Bentley, and Attfield were respectively re-elected for the ensuing year, subject to the provisions of the resolution of the Council of this date.

CURATOR OF THE SOCIETY'S MUSEUMS.

Mr. Holmes was re-appointed Curator.

HOUSE COMMITTEE.

The Report of this Committee was read, recommending that estimates should be obtained for sundry repairs and for painting for the Society's house, also for replacing the existing windows with plate-glass. The Report was received, and the Committee were requested to obtain specific tenders for the alterations proposed, to be submitted to the next Council meeting.

LOCAL SECRETARIES, 1873-74.*

Aberdare	Evans, Thomas Whitty.
Aberdeen	Davidson, Charles.
Aberystwith	Davies, John Hugh.
Abingdon	Smith, William.
Altrincham	Holt, William Henry.
Andover	Madgwick, William B.
Ashby de la Zouch	Johnson, Samuel E.
Ashton-under-Lyne	Bostock, William.
Aylesbury	Turner, John.
Banbury	Beesley, Thomas.
Banff	Ellis, Bartlet.
Bangor	Griffiths, John E.
Barnsley	Badger, Alfred.
Barnstaple	Goss, Samuel.
Barrow in Furness	Sansom, Edwin.
Basingstoke	Sapp, Arkas.
Bath	Pooley, John Carpenter.
Bedford	Cuthbert, John M.
Belper	Ashton, John.
Berwick	Carr, William Graham.
Beverley	Robinson, James Mowld.
Bewdley	Newman, Robert.
Birkenhead	Nicholson, Henry.
Birmingham	Southall, William.
Blackburn	Pickup, Thomas Hartley.
Blackpool	Harrison, Joseph.
Bodmin	Williams, Joel Drew.
Bolton	Dutton, George.
Boston	Marshall, Robert.
Bradford (Yorkshire)	Rogerson, Michael.
Bridgnorth	Deighton, Thomas Milner.
Bridlington	Forge, Christopher.
Bridport	Tucker, Charles.
Brighton	Gwatkin, James Thomas.
Bristol	Stoddart, William W.
Buckingham	George, Sirett.

* Local Secretaries are appointed in all towns in Great Britain which return a Member or Members to Parliament, and in such other Towns as contain not less than Three Members of the Society or Associates in Business.

Burnley	Thomas, Richard.
Burslem	Blackshaw, Thomas.
Bury St. Edmunds	Portway, John.
Buxton	Barnett, Alexander.
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Cross, William.
Cardigan	Jones, John Edwards.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, Richard M.
Carnarvon	Lloyd, William.
Chelmsford	Baker, Charles Patrick.
Cheltenham	Smith, Nathaniel.
Chester	Mills, John.
Chesterfield	Greaves, Abraham.
Chichester	Long, William Elliott.
Chippenham	Westlake, Bernard.
Christchurch	Green, John.
Cirencester	Skinner, Thomas.
Cockermouth	Bowerbank, Joseph.
Colchester	Prosser, Evan Thomas.
Congleton	Goode, Charles.
Coventry	Wyley, John.
Darlington	Barlow, Samuel.
Deal	Green, John.
Denbigh	Edwards, William.
Derby	Frost, George.
Devizes	Portbury, George Henry.
Devonport	Dickerson, Henry.
Dewsbury	Gloyne, Thomas H.
Diss	Gostling, Thomas Preston.
Doncaster	Dunhill, William W.
Dorchester	Evans, Alfred John.
Dorking	Clift, Joseph.
Dover	Bottle, Alexander.
Droitwich	Taylor, Edmund.
Dudley	Hollier, Elliott.
Dumfries	Allan, William.
Dundee	Hardie, James.
Durham	Sarsfield, William.
Eastbourne	Provost, James A.
Edinburgh	Mackay, John.
Elgin	Robertson, William.
Evesham	Dingley, Richard Loxley.
Exeter	Walton, Ralph.
Eye	Bishop, Robert.
Falkirk	Murdoch, David.
Falmouth	Newm..., W. F.
Fareham	Franklin, Alfred.
Flint	Jones, Michael.
Folkestone	Cadman, Daniel-Charles.
Forfar	Ranken, James A.
Frome	Harvey, William Brett.

EXAMINATIONS IN EDINBURGH.

June 25th and *26th*, 1873.

Present—Messrs. Ainslie, Gilmour, Kinninmont, Noble, Tait, and Young.

MAJOR EXAMINATION.

Two candidates were examined, and declared duly qualified to be registered as Pharmaceutical Chemists :—

*Galloway, George Ross .....Inverness.
Gilmour, David .....Edinburgh.

MINOR EXAMINATION.

Eighteen candidates were examined. *Four* failed. The following *fourteen* passed, and were declared duly qualified to be registered as Chemists and Druggists :—

*Sharp, Robert Henry .....Portobello.
Morrison, William Hay .....Aberdeen.
Pendrigh, John Cuthbertson .. Sanquhar.
Equal. Carruthers, Robert Buck.....Manchester.
Equal. Duggleby, Thomas Waldby.....London.
Equal. Berry, Robert Innes.....Aberdeen.
Equal. Thompson, Mark Foggitt .....Thirsk.
Johnstone, Thomas Francis.....Dumfries.
Baikie, Peter.....Belfast.
Henderson, Andrew .....Perth.
Johnstone, Robert E. .....Edinburgh.
Cowper, David Burgess .....Edinburgh.
Robertson, John .....Inverness.
McIntyre, Ewen, Jun. .....Edinburgh.

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

Three candidates were examined, and declared qualified to be registered as Chemists and Druggists :—

Andrew, Ablett Ashworth .....Clitheroe.
Brodie, Robert .....Glasgow.
Stones, William.....Manchester.

ERRATUM.—Vol. III., p. 1041, col. i, line 23, *for* Griffiths Francis, *read* Griffith, Francis.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

Report for 1873.

The following Report for the year 1873, has been issued by the Council of the Midland Counties Chemists' Association :—

"In reviewing the proceedings of the past year, the council have satisfaction in believing that the Midland Counties Chemists' Association has steadily endeavoured to maintain its position of usefulness. It has sought, so far as lay in its power, to promote the interests of the important body of chemists and druggists residing in Birmingham and the Midland district, as well as of the younger generation of chemists, on whom the obligation of special qualifications has devolved. There are always matters of a *local* character, of commercial or scientific importance, which do not come under the cognizance of the central council in London, which very suitably claim the attention of a local organization. It is such interests as these which this council has sought to watch over.

"In July last, the council endeavoured to procure a more uniform and early closing of chemists' shops in the Birmingham district. The various members of the trade were individually appealed to, but they could not be induced to accede to an uniform hour, even though the hour was proposed to be varied in separate districts, and this well-meant endeavour was consequently frustrated.

"The council has had under its notice cases of unregistered persons who were suspected of selling poisons, in contravention of the Pharmacy Act, to the injury of the legitimate chemist. Steps have been taken to prevent offences of this kind.

"A question relating to the sale and registration of vermin killers, and the irregularity with which the law in respect thereto was observed by various chemists, has been discussed, but the subject was deferred until the annual meeting, in expectation that some practical suggestions relating thereto would be then entertained.

"The price book of the Midland Counties Chemists' Association continues to find a steady sale. The cordial co-operation of the trade generally in this district is earnestly desired, with a view to promote a healthy tariff, which shall fairly remunerate the hard-worked druggist. The responsible nature of the calling, and the increased demand for a higher scientific education, claim a corresponding standard of remuneration.

"It has been felt by this council that, in order to embrace more compactly and efficiently the various trade and other interests in this district than is even yet the case, for purposes of mutual help and benefit, some organ of communication would be helpful, which should be a medium of ready communication. The *cost* of a local magazine would be an insuperable obstacle to the establishment of a special journal, but an effort was made by this council to ascertain how far the plan of a "partially printed magazine" (to be distributed over the kingdom) would meet the wants of other associations of chemists, blank leaves being provided for recording the local affairs of each association. Whilst some of the associations cordially supported the proposal, the promises of co-operation were not sufficient to enable the scheme to be carried out.

"The rooms of the Association continue to be well frequented. The visitors' list shows an entry of 1050 persons during the year, but as many visitors fail to enter their names, the attendance must considerably exceed that number.

"Papers have been read in the rooms by the following entlemen :—

Notes on Dispensing	Mr. J. B. Williams.
Pharmaceutical Ethics . . .	Mr. W. Churchill.
,, Latin. . . .	Mr. P. Mucklow.
On Yellow Cinchon. Bark . .	Mr. H. W. Jones.
,, Iron Preparations . . .	Mr. Featherstone.

"For the information of members who do not often visit the rooms, it may here be stated that the reading room is provided with books and periodicals, specimens of materia medica, and facilities for study, whilst the accommodation the rooms afford is available for any purpose of convenience or business conference which members or their friends may desire.

"The lectutes on chemistry provided by the Birmingham and Midland Institute have been well attended by pharmaceutical students, but the number of those attending the lectures on botany has been very small. One of these few students has been in the habit of travelling from Gloucester (56 miles) to attend them. This earnestness and pressure through difficulties, in order to take advantage of the educational facilities of that noble institution, may serve to stimulate the large number of students who live in its nearer neighbourhood.

"The annual soirée of the Association took place on the 23rd of January. As on a similar occasion last year, it was held in the spacious Assembly Room of the Royal Hotel, Birmingham. It proved a most successful and enjoyable evening. Two hundred and fifty guests assembled, including chemists, a few leading medical and scientific gentlemen, and a large number of ladies. An attractive display of objects of scientific, chemical, and pharmaceutical interest, occupied several large tables in the room during the earlier hours of the evening. At half-past nine, Mr. C. J. Woodward, B.Sc., of the Midland Institute, delivered a short and brilliant lecture on "Flame." Dancing commenced about ten o'clock, and was kept up with great spirit until after two o'clock, when the company separated. This soirée will rank as one of the best of those which have distinguished the growing interests of chemistry and pharmacy in the Midland Counties.

"The council invite the members to maintain the present position of the Association by a liberal subscription list. The difficulty of providing voluntary canvassers, able to devote sufficient leisure to the collection of subscriptions, has induced the council to employ a paid canvasser, who will, in future, call upon the members for their subscriptions."

Proceedings of Scientific Societies.

CHICAGO COLLEGE OF PHARMACY.

Certificates for Display.—Portrait of Professor Attfield.

A meeting of the Chicago College was held on Wednesday, June 11, Mr. Thomas Whitefield presiding. After the reading of the minutes a question arose, which

was discussed at some length, as to what kind of certificate should be given to members of the College. One member favoured a simple form, answering the purpose of a receipt for dues. Another said the country members would not be satisfied with anything of the sort; they attached a good deal of value to their college certificates, and wished them gotten up with considerable "display style." Mr. Ebert was of opinion that the use of the showy order of certificates should be discontinued. A large number of druggists had them hung up prominently in their stores, and a great many people were led to suppose that they were diplomas. There was really a species of fraud being perpetrated by their use. The subject was finally disposed of by referring it to the board of trustees.

The financial condition of the organization having become very uncertain, through the disordered state of its records, a committee consisting of the secretary, treasurer, and former treasurer, was appointed to examine them and ascertain the present standing of the society.

Messrs. Jameson, Ebert, Patterson, Sargent, and Buck were appointed delegates to attend the convention of the American Pharmaceutical Association, to be held September 13th, in Richmond, Va.

Mr. Ebert suggested that the board of trustees should be empowered to invite the druggists of the north-west to visit Chicago during the forthcoming exposition, urging the necessity for uniting the interests of the drug trade more closely, and the prospect of being able to form an association to embrace the whole north-west.

A member doubted the propriety of committing the College to this action, and thought that the wholesale trade of the city should move in the matter. On motion, the board of trustees were authorized to act with the wholesale drug trade in event of the suggestion being carried out.

The members then arose to view a large portrait of Professor John Attfield, Professor of Chemistry to the Pharmaceutical Society of Great Britain, through whose exertions the handsome English donation to the College of scientific books and instruments was made up. The portrait was painted at the request and expense of the members of the College.

Parliamentary and Law Proceedings.

The Dishonest Dipsomaniac.

A person, giving the name of John Smith, was charged before Mr. D'Eyncourt, at the Marylebone Police Court, on Thursday, July 3, with obtaining 1oz. chloroform and one bottle of lemonade, value 1*s.* 6*d.*, under false and fraudulent representations, from the pharmacy of Mr. A. Crotch, 74, Edgware Road, on Saturday night last, June 28th. Mr. Chas. Isaacson appeared for the prisoner.

It appeared from the evidence of Mr. W. B. Fitch that the prisoner entered the shop about 10.45 p.m., and requested to be served with 1oz. pure chloroform (Duncan and Flockhart's) and one bottle of lemonade, stating that he was a medical man, that he had taken chloroform for many years for epileptic fits, and that, as he felt he had one hanging about him, he wished to be prepared for it. Witness told him it was a very unusual thing to sell that quantity of chloroform to a stranger, but still, if he was really a medical man, and required it for his own use, and would write a prescription as well as sign his name in the poison-book, he should feel bound to supply him. With this prisoner immediately complied, stating that he considered him mighty particular for such a trivial thing. After having received the chloroform, he ordered a bottle of lemonade, which was in due time opened and brought to him, when, much to witness's surprise, he found his customer with a piece of lint doubled about 6in. by 6in. saturated with chloroform and placed over his mouth and nostrils, presenting the appearance of enjoying a delightful sleep. On perceiving this, witness immediately rushed round the counter and seized the lint from him, when the prisoner, after a little time and a great deal of shaking, roused himself and drank the lemonade. When asked for payment, he stated that he received the chloroform but that witness had since taken it from him, and, therefore, he should not pay. Witness said that if he did not pay immediately he would give him into custody. After a short time, seeing a policeman at the door, prisoner said he would give his name and address, and call and pay on Monday, as he had not a penny in his pocket. The name and address given was John Lee, surgeon, 52, Eastbourne Terrace, but was found to be false; therefore, he was given into custody.

Mr. D'Eyncourt: Did you know the prisoner before this transaction?—No.

Did he appear to you to be perfectly sane?—Yes.

Do you know whether he has ever obtained chloroform before?—Yes. I find that he had obtained 1oz. of chloroform about 10.15 p.m. the same evening, before he came to me, and would not pay for it, and I am also prepared to prove four or five other cases.

Mr. D'Eyncourt: Had any person applied to you for chloroform should you have let them had it?—No, certainly not; unless I knew the parties or I received a prescription.

Mr. D'Eyncourt: I suppose had he have taken the chloroform it would have killed him?—Yes, in a very short time, and I consider him a man quite as capable of taking it as he is of inhaling it.

Mr. Isaacson: Will you swear that the defendant did not give you his name as John Reid, 22, Westbourne Terrace, instead of John Lee, 52, Eastbourne Terrace?—I will, and what is more I have it in his own handwriting twice over.

In answer to questions by Mr. D'Eyncourt, prisoner said he was in his right mind, and considered very intelligent. He had taken chloroform in this manner for about sixteen years. On his return from India, some nine years since, he had met with an accident to his arm which at times caused him great pain, and he was compelled to take chloroform to obtain rest. He supposed on this occasion, owing to domestic affairs, he took more than he really ought, for which he was extremely sorry.

At this stage of the proceedings, Mr. D'Eyncourt said he considered the prisoner ought to be put under restraint in some way, and that his friends ought to look after him. With this prisoner agreed, and, in answer to a question as to his means, said he was in receipt of 9*s.* 6*d.* a day, half-pay. After some cab fares, for which summonses had been taken out by cabmen, together with the expenses, had been paid, the prisoner was ordered a formal discharge.

The Sale of Poisons in Ireland.

Suicide by Laudanum.

An inquest was held on Monday, June 30, at the Belfast General Hospital, by Dr. Dill, the borough coroner, on the body of a woman who died in that institution on Saturday evening from the effects of an overdose of laudanum.

Evidence was given that deceased was found lying senseless on her bed. There was a great smell of creasote in the house. A bottle was found in the house having a smell of creasote. A label which was found in the house by one of the police was also handed in. On the label was the word "Laudanum," the amount to be taken as a dose, "Poison," and the name, "Hogg, grocer, 209, York Street."

A young man named Walsh, who was in the employment of Mr. James Hogg, 209, York Street, grocer and druggist, deposed, after being cautioned, that on Saturday, in the middle of the day, a woman, about fifty years of age, came into his master's shop, and purchased half-an-ounce of laudanum. The label produced was his master's. The woman appeared to be sober.

Witness, in answer to the Coroner, said that they sold arsenic, laudanum, and corrosive sublimate, in the same establishment as they sold groceries.

Mr. Hogg (owner of the establishment) : They are kept separate.

The Coroner (to witness) : What quantity of corrosive sublimate do you sell for a dose ?

Mr. Hogg : If I be permitted to interfere, it is not fair to ask this young man any questions, the answers to which might criminate him.

The Coroner : He has been cautioned, and he may answer them at his peril. If you are proprietor of this establishment, it is a most injudicious practice for a person in your position and trade to be selling such intense poisons as arsenic and corrosive sublimate.

Mr. Hogg : We do not give any of these to persons without a line from some person that we know ; some one who would vouch for the purpose for which it is intended.

The Coroner: Did you get a line when this laudanum was sold ?

Mr. Hogg : As you are aware, laudanum is in the second class of poisons, and a line is not required for that.

The Coroner: A certain dose of laudanum is just as intense a poison as any other.

Mr. Hogg : There is no Act of Parliament to bind sellers to give any particular quantity of laudanum, and of course we are not to go beyond the Act of Parliament.

The Coroner: I don't care about all the Acts of Parliament in the world ! It is a most injudicious thing for any person to be dealing in such poisons and groceries at the same time.

Mr. Hogg: It is the case with many of the druggists in town. They there give any quantity of laudanum they wish. Doctors often send to me for one ounce and two ounces, but to any one that we are suspicious of we should not give it, and, in fact, I have refused men frequently. I do not think it is fair to ask any man a question which might criminate him.

The Coroner: If we could produce a sufficient case to get an Act of Parliament modified we should be perfectly justified in doing it. We are not to kill people, even by Act of Parliament.

Dr. Calvert, House-surgeon to the General Hospital, deposed that deceased was brought under his care at half-past three o'clock on Saturday afternoon, in a state of insensibility, he believed from the effects of an overdose of some preparation of opium. She died about two hours after being brought to the hospital. Half an ounce of laudanum would produce the symptoms that she laboured under. Twenty-five drops would be a medium dose for an adult. When the stomach was pumped there was nothing in it.

The jury found that the woman died from the effects of an overdose of laudanum, taken while in an unsound state of mind.—*Belfast News Letter.*

Poisoning by a Lotion.

On Monday, June 30, the Liverpool Borough Coroner, Mr. C. Aspinall, held an inquest upon the body of John O'Brien, a painter, 44 years of age. The deceased's wife stated that he had been for some time in a bad state of health, suffering severely from rheumatism. On the preceding Friday, the doctor sent him a bottle of medicine, labelled "Two table-spoonsful three times a day," and also another bottle, containing a lotion for rubbing his foot, on which was printed in large letters the word "Poison." The deceased was in the habit of taking his medicine himself. About one o'clock on Sunday afternoon witness found him vomiting in the yard, and he told her that he had made a mistake, having taken some of the lotion in place of his proper medicine. He said his mouth felt as if it were on fire, but added that he did not think he had drunk enough to do him any serious injury. However, he seemed to grow worse, and about two o'clock she sent for a medical man, who administered an emetic, and tried other remedies, but without avail, for O'Brien died about an hour afterwards. A verdict of "Accidentally poisoned" was returned.—*Liverpool Post.*

Prosecutions under the Adulteration Act.

At the Birkenhead Police Court, on the 19th ult., a number of teadealers were summoned for selling tea which, it was alleged, was adulterated. Messrs. Robert Roberts and Co. were summoned for selling three samples of tea, which had been analysed by Dr. J. C. Brown, public analyst, Liverpool, and found to be adulterated, in one case a sample of green tea being faced with mineral matter and Prussian blue, and in the others with gypsum slightly and a trace of Prussian blue. Mr. R. B. Moore appeared to prosecute, and Mr. Segar, barrister, was for the defence. Sergeant Millington, of the County Constabulary, gave evidence of the purchase of the samples of green tea produced. He was in plain clothes at the time. He stated that the defendant's shopman told him that he would not guarantee any tea sold under 3*s.* per lb. ; the samples produced cost at the rate of from 3*s.* 8*d.* to 4*s.* per lb. Superintendent Egerton proved the delivery of them to Dr. Brown, and the latter gave evidence of the state in which he found them. He said the tea was adulterated by being faced or painted with Prussian blue and gypsum, in the proportion of from 1½ to 2 per cent. in the different samples. The substances used were not absolutely poisonous, but were injurious to health. To a weakly person they might, and probably would, be injurious, but to a strong person, not taking large quantities of the tea, he could not say decidedly that they would do much harm. In cross-examination witness said pure green tea was prepared by being dried more quickly than black ; there was some green tea which was not faced with foreign matter, and in former times there was very little of the faced or painted kinds imported. Witness produced a sample, and said, in reply to questions, "Prussian blue is not a tonic or alterative ; it is not a mineral substance at all. It does not rank among poisons, but is closely allied to them. It would not increase the bulk of the tea to any appreciable extent, though it would make a difference in the weight, say from 1 to 2 per cent. The other matters used—clay and gypsum—are not poisonous, but are used for the purpose of lightening the colour. One of the samples submitted contained as much colouring matter as any sample I have seen ; another is about the average, and the third rather better than the average of the samples that I have analysed." At the conclusion of Dr. Brown's evidence, an infusion of one of the samples was made by the magistrates, and the result was that a thick green scum floated on the surface.

Mr. Segar, in defence, argued that there had been no representation on this occasion that the tea sold was not adulterated. It was the same tea as that commonly sold in the market, and of which about ten million pounds were annually imported into this country. Samples similar to that produced had been submitted to analysis by Mr. Davies, analytical chemist, Liverpool, who pronounced the tea to be faced, but not so as to be injurious to health. Of the green tea generally sold, every bit was coloured, and every purchaser of it knew that it was not guaranteed to be pure or unprepared by any process. If a man asked for tea, he would get black, and if he wanted green, he would buy it as a fancy article, and would know he was getting something which had been doctored before it came into this country. Mr. Segar further contented that the meaning of the word "Adulteration," according to Walker's "Dictionary," was the "act of corruption by false mixture, the state of being contaminated by false mixture," and would not apply to an article which in itself remained the same, though coated with some other substance ; the painting and colouring was not, he held, adulteration. He therefore urged that the Act would not apply to a case of this kind. He called the following evidence :—

William Sharman, assistant to the defendant, said that when he sold the tea to the officer he informed him that all green tea was more or less subjected to an artificial process before it came to this country. Witness denied that this was said only after the officer had stated that the tea was intended to be subjected to analysis.

Mr. Thomas Matheson, tea broker, said that the only uncoloured green tea known was imported from Japan, and was not generally known in the market as green tea.

Mr. Davies, analytical chemist, Liverpool, said that he had examined a sample of the same tea and detected the presence of Prussian blue and gypsum, but in very minute quantities. They were inert substances and not poisonous; in small quantities, such as would be consumed, they would not be prejudicial to health. An infusion of uncoloured green tea produced by Dr. Brown was made, and the result was at once apparent,—there was no green scum, and a clear brown liquid filled the cup.

The magistrates then retired to consider their decision. On returning into court they said they were satisfied that the charge of adulteration was proved, and fined the defendants 5*s.* and costs.

Mr. Segar asked for a case for submission to the Court of Queen's Bench, as to the terms "adulterated" and "selling as adulterated." He said it was most important that these points should be cleared up by a decision of the court above.

The magistrates granted the application, and it was arranged that a number of other cases of a similar nature should stand over till the decision is given.—*Grocer.*

Reviews.

PRACTICAL MAGAZINE: an Illustrated Cyclopædia of Industrial News, Inventions, and Improvements, collected from Foreign and British Sources, for the use of those concerned in Raw Materials, Machinery, Manufactures, Building, and Decoration, etc. Vol. I. London. 1873.

Although the above title is only about half of what appears on the first page of the volume before us, it covers an exceedingly wide ground, but it is not an exaggerated epitome of the contents of the handsome volume just completed. In fact, a busy man would scarcely find time to keep abreast of the issue; and the eighty closely-printed, large quarto pages, which are published each month, would gradually accumulate like a terrible nightmare of unfulfilled duties. Subject to this qualification, the work is an admirable production. The subjects dealt with are most diverse. The textile, ceramic, and chemical manufactures, civil and mechanical engineering, metallurgy, architecture, surveying, building, are all, in their turn, the topics of valuable articles; while for lighter reading there are capital biographical and historical memoirs, sketches of the mechanism of London life, and initiation into the mysteries even of such subjects as cheap sausages. A principal feature of the work, however, is the illustration, for which the large size of the page is peculiarly adapted. Those who know what French wood-engraving is will appreciate the remark that many of the pictures appear to be printed either from the original blocks or *clichés* of engravings used in French works. Specially worthy of notice are the series illustrating an account of the dye-works of Messrs. Bontarel and Co., a drawing of an enamel cup by M. Lepec, and another of a clock in the renaissance style, which serves as a frontispiece.

But the section having special interest for the readers of this journal is an extensive series of abstracts of published articles relating to applied chemistry; and this is not the most satisfactory portion of the volume. To do such a work well requires considerable acquaintance with chemical literature, as well as vigilance in making the selection. In the first place, the quotation of authority ought to give some idea of the original source of the article. As a few out of numerous instances where this result has not been attain[illegible]y be mentioned several originally French articles that are quoted from German periodicals—for instance, Miahle's communication to the Academy respecting a neutral soap and Falière's test for bromide of potassium. Tichborne's method of filtering through parchment paper under pressure, originally published in this journal (i. 881), is quoted from the *Zeitschrift für Analytischen Chemie;* Ekin on subnitrate of bismuth (PHARM. JOURN., iii.) is attributed to the *Moniteur Scientifique;* Merrick on Cochineal (*Amer. Chemist*), to Dingler; while Mr. Consul Medhurst's information as to the adulteration of tea with willow leaves at Shanghai is quoted from the *Polytechnisches Centralblatt.* Want of vigilance is illustrated by the fact that, in the short space of six months, several paragraphs have been repeated. Thus, Girard's new method of preparing artificial alizarine is described from a German source on p. 55, and from a French source on p. 437; a similar occurrence takes place on pp. 220 and 438, with reference to a black for woollen dyeing; and on pp. 339 and 437, in reference to indigo printing; while, to conclude, but not to exhaust the list, the same method of purifying glycerine is described three times, namely, on pp. 104, 223, and 280. All the abstracts, however, appear to be ably made.

ELEMENTARY TREATISE ON PHYSICS, EXPERIMENTAL AND APPLIED, FOR THE USE OF COLLEGES AND SCHOOLS. Translated and Edited from Ganot's "Éléments de Physique." By E. ATKINSON, Ph.D., F.C.S. Fifth edition, revised and enlarged. 1872. (Longmans).

NATURAL PHILOSOPHY FOR GENERAL READERS AND YOUNG PERSONS. Translated and Edited from Ganot's "Cours Elémentaire de Physique." By E. ATKINSON, Ph.D., F.C.S. 1872. (Longmans).

Ganot's 'Eléments de Physique' is so well known to English readers by Dr. Atkinson's excellent translation that a detailed analysis of it would be superfluous. The publication of the English edition supplied a want which was keenly felt by all teachers of physical science in this country. It is, in fact, one of the few treatises in our language that give a systematic exposition of the several branches of physics; and by the clearness and exactness of its explanations and descriptions, and the excellence of its graphic illustrations, it places the facts and theories of physical science before the reader in a manner which leaves nothing to be desired. The student who has mastered it will have gained a sound knowledge, both of the principles of physics, and of the methods by which they are established.

In the present edition several useful additions of new matter have been made, among which may be mentioned the description of the apparatus invented by Helmholtz and by König for the analysis and synthesis of sounds; of the alterations produced in the spectra of gases by variations of pressure and temperature; of the discoveries of Lockyer and Janssen, relating to the nature of the solar protuberances and the methods of observing them; of Carré's dielectrical machine, Lechanché's battery Browning's regulator for the electric light, and Becquerel's electric thermometer and pyrometer. Notwithstanding these additions, and the introduction of twenty-eight new illustrations, the use of a larger page has rendered it possible to reduce the number of pages in the volume by sixty.

The second of the works which form the subject of this notice is a smaller and more elementary treatise, in which the use of mathematical symbols is altogether dispensed with. It is especially designed as a text-book of physics for the middle and upper classes of boys' and of girls' schools, and as a familiar account of physical phenomena and laws for the general reader. In range, it may, pe

haps, fairly be taken to represent the amount of knowledge required for the matriculation examination of the London University. For these purposes it is admirably adapted. The explanations and descriptions throughout are singularly clear, and the graphic illustrations are excellent. Many of these are the same in the larger treatise, but a considerable number have been made especially for the smaller one. These latter are of a striking character, well adapted to convey to young minds a vivid picture of the object or phenomenon represented,—witness those relating to the mechanical powers and the centre of gravity; the formation of images by lenses and mirrors; the camera obscura, and various optical illusions, including the diorama and ghost-scenes; and several striking experiments in electricity and magnetism. Under electromagnetism there is a clear and well-illustrated description of Morse's telegraph.

In conclusion we sincerely congratulate Dr. Atkinson on the production of two books so admirably adapted to the wants of junior and senior students of physical science.

Obituary.

Notice has been received of the death of the following :—

On the 13th June, 1873, Mr. Daniel Dixon, Chemist and Druggist, of Preston.

On the 18th June, 1873, Mr. John Mason, Chemist and Druggist, of Bournemouth.

Notes and Queries.

[345].—PRESERVATION OF SYRUPS.—I shall feel obliged by your allowing me the opportunity of making inquiry what is the best method for preventing Syr. Violæ et Syr. Rhœados from fermenting during hot weather. Re-boiling is of no *lasting* benefit. Rectified spirit tends to remove the evil, but as it would not be the right thing to use, I shall be glad to learn of a plan that will effectually cure the evil complained of.—INQUIRER.

[346].—VAPOR OLEI PINI SYLVESTRIS.—Will you kindly favour me with the formula for Dr. Morell Mackenzie's "Vapor Olei Pini Sylvestris"?—E. W.

[In the 'Pharmacopœia of the Hospital for Diseases of the Throat,' edited by Dr. Morell Mackenzie, the following formula is given for a "Vapor Folii Pini Sylvestris :"—

Oil of Scotch Pine (Fir-wool oil) .	2 fluid drachms.
Light Carbonate of Magnesia . .	60 grains.
Water to . .	3 fluid ounces.

Mix. A teaspoonful in a pint of water at 150° F. for each inhalation. A caution is given against confounding the oil ordered with ordinary oil of turpentine. The former is prepared from the leaves of *Pinus sylvestris*, and is imported from Germany as "Fir-wool Oil."—ED. PHARM. JOURN.]

[347].—ERASURE OF INK MARKS FROM PAPER.—Can any correspondent inform me what is the best process for erasing ink from paper without affecting the fibre. The usual things for linen have been tried, but without effect.—R. M.

[348.]—SPICED CONDIMENT FOR CATTLE.—In reply to this query, I should recommend the following :—

Rad. Gent. Pulv.....	℥ iv.
Rad. Ling. Pulv.....	℥ ij.
Sem : Coriand Pulv.	aa. ℥i.
Sem : Anisi. Pulv.	aa. ℥i.
Sodii. Chlor.....	℥i.

To be divided into 12 doses.—W. D.

DR. LOCOCK'S LOTION.—We are informed that the formula for this preparation, recently quoted in this Journal (iii. 779) from Cooley's Cyclopædia, is incorrect. The following, taken from the original prescription of Dr. Locock, has been kindly supplied to us by Mr T. Greenish :—

Ol. Macis	℥ ss
Liq. Ammoniæ	
Ol. Olivæ aa.	℥ ij
Sp. Rosmarini	℥ j
Aq. Rosæ	℥ ijss

M. ft. Lotio ℥ iv.

PILLS OF PROTOXIDE OF IRON.—M. Kirchmann *(Archiv. der Pharm.)*, prepares pills of protoxide of iron by mixing an equivalent of calcined magnesia with one of crystallized protosulphate of iron, and adding a small quantity of concentrated glycerine. For sixty pills he employs—

Crystallized ferrous sulphate.....	120 grams.
Calcined magnesia.....	20 „
Glycerine.....	15 drops.

These pills have a good consistence, and can be covered with sugar. If they be placed in water the sulphate of magnesia is dissolved, and the oxide of iron deposited.

TURPENTINE PILLS.—M. Lachambre *(Journ. des Connaissances Médicales)*, gives the following formula for preparing turpentine pills, which he says are promptly digested without fatiguing the stomach or causing disagreeable eructations :—

Oil of turpentine.....	8 grams.
White wax..	20 „
Essence of lemon.....	2 drops.
Powdered sugar.....	9 grams.

Melt the wax in the turpentine and essence of lemon, pour into a mortar, and when cool add the sugar and form a mass. Divide into pills of twenty-five centigrams each, which should be covered with starch and kept in well-stoppered bottles. Each pill will contain five centigrams of turpentine.

TRACING PAPER.—Tracing paper may be prepared (Dingl. polyt. J. quoted in Journ. Chem. Soc.) by mixing castor oil with three or four parts of absolute alcohol, and spreading the homogeneous mixture over paper with a brush. By washing with alcohol the oil is again dissolved and the paper restored to its original character.

CHLORINATED WATER.—Hydrochloric acid, acting on chlorate of potash, does not necessarily yield theoretically chlorine, but several intermediate oxygenated compounds are produced equal, and often superior in their medicinal effect to chlorine alone. That is why these so-called chlorine mixtures have attained such a deserved popularity. It only remains to have a uniform standard for this mixture, and the following formula attains this desideratum :

Take of Chlorate of Potash, 10 grains.
Hydrochloric Acid, 1 fluid drachm.
Water, 1 pint.

Throw the chlorate into a dry pint bottle, and pour in the acid; then let stand a few minutes, agitating occasionally, and pour in 4 fluid ounces of the water and shake; then add 4 fluid ounces more of the water and shake again. Finally, add the rest of the water, cork well, mix, and keep the mixture in a cool place.—*Pharmacist.*

Appointment.

STANSBY, Mr. CHARLES J., Pharmaceutical Chemist, has been appointed Dispenser in Charge of Stores at H. M. Naval Hospital, Bermuda.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Pharmacopœia of the University College Hospital.

Sir,—In your review of the above work last week, the reviewer wonders "what the object is of ordering both calamine and oxide of zinc in a lotion." For the information of your readers generally, I beg to state that the calamine is to give the lotion the necessary flesh colour, as it is generally used for facial acne and other skin diseases, where the diseased parts exposed would appear conspicuous if the plain oxide of zinc lotion were used. The application of *Lotio Calaminæ*, besides having a healing effect, hides the unsightly appearance of the diseased parts, which, next to complete cure, is desirable for the patient's sake. Such being the object of it, levigated calamine of the right tint—that prepared from an ore containing a little red oxide of iron—should be preferred. This is of some importance, because patients frequently complain that they do not get the lotion, when dispensed by chemists, prepared of the uniform flesh colour necessary for the purpose it is required.

Wm. Martindale.

Women in Pharmacies.

Sir,—Reading in the number of May 24th the *compte-rendu* of the annual meeting of the Pharmaceutical Society, I noticed that, in the course of the discussion which took place on Mr. Hampson's proposition, Mr. Burden said that—"In the druggists' shops in Paris you constantly saw the wife assisting her husband."

Allow me to say that the assertion of this gentleman is not quite correct. I have been now in the profession in Paris for more than twenty-nine years, and I never saw a lady at work behind the counter. I do not mean to say that ladies are not to be met with in chemists' shops, such is generally the case, but what they do is exactly the same as they can do in any other trade, that is, to receive money, give change, write bills, keep accounts, etc., etc.

E. Gallois.

Artificial Fibrin.

Sir,—In this week's journal you notice the claim which Dr. J. Goodman puts forward of having discovered a method of converting egg-albumen into fibrin. The consideration of a few obvious facts will prevent any illusion which might be caused by the statements which he makes. To prepare the artificial (!) fibrin, he directs that the shell of an egg is to be removed and the contents immersed in cold water for twelve hours or so, when it is found to undergo a chemico-molecular change, and to become solid and insoluble. This change refers, presumably, to the albumen only.

Now, it is well known to those who have made solution of albumen from eggs that a portion remains undissolved, and this, if examined under the microscope, will be found to have a fibrinous structure. This is the material which Dr. Goodman asserts is formed upon treating the egg in the manner he directs, and his statement infers that the whole of the albumen becomes thus converted by being left in contact with the water a sufficient length of time. Such, however, is by no means the case, as may be easily proved by experiment, when it will be found that the fibrinous material merely forms an envelope within which the albumen remains unaltered. If the water is then boiled, of course, there is coagulation. If the water is frequently agitated the fibrinous envelopes are broken, and the albumen gradually dissolves. Upon estimating the amount of this material it was found to be only ·75 per cent. of the fluid albumen, or 5·4 per cent. of the solid residue left on evaporating albumen to dryness at 100 C.

The formation of this egg-fibrin is nevertheless a very interesting physiological fact, and the following is a possible explanation of it:—

The ov-albumen being alkaline, or containing salts of the alkalies, retains the fibrin in solution, but when diluted with a large access of water it can no longer do so, and the fibrin is precipitated, the effect upon the viscid albumen being that the surface is acted upon first and becomes covered with a protecting envelope of the precipitate, as occurs when lumps of calcic carbonate are placed in sulphuric acid.

Thos. Garside.

Lord Street, Southport, June 16th, 1873.

A Pharmaceutical Curiosity.

Sir,—I have not the least idea where Kingswinford is, but it is evidently a locality unsuited to so erudite a gentleman as J. Bower Williams, A.P.S. Who but must sympathize with that gentleman when he pathetically exclaims, "Can ignorance go further" than to refuse to believe that "green" oil can be "black," and to hint that he had not passed his diploma because he ventured to suggest the identity of the two? He clearly has never been accustomed to *such* "green" folk as the Kingswinfordians.

But why should "our Examiners" be more flabbergasted by "Oil of Exeter" than by "Unction," "Trooper's Ointment," "Blue Butter," "Paregoric," "Salt of Wormwood," etc.? and peradventure no less virtue resides in "Oil of Cabbage" than in "Ol. Viride (Sambuci)."

I am sure we shall look anxiously for more of the promised specimens, especially if interspersed with J. Bower Williams's (A.P.S.) amusing remarks.

R. T. C. D.

Southampton.

X. Y. Z.—We do not find in the 'Directory' the name you inquire about, but a well-known "quack" lives at the address you mention.

H. Hyne.—The article is to be dipped in hypophosphite of soda solution, *after* removing it from the Javelle water.

"*Chemist and Druggist*" is referred to the rule respecting anonymous communications.

J. W.—The arrangement you complain of was one imposed upon the Pharmaceutical Society by the Legislature; but the inconvenience arising from it must cease with the lapse of time.

E. Richardson.—*Lamium album.*

G. C. Druce.—(1) *Brassica napus.* (2) *Lepidium Draba.*

X. Y. Z.—The better plan would be to consult a medical man.

A Correspondent sends us the following curious piece of news cut from the columns of a provincial paper:—

Conversazione of the Pharmaceutical Society of Great Britain.—Mr. ————, pharmacological chemist (by examination), received an invitation from the President, Vice-President, and Council of the Pharmaceutical Society to be present at the conversazione held at South Kensington Museum on Wednesday last.

Our correspondent remarks—"Could presumption and ignorance carry a man further than this?"

The following journals have been received:—The 'British Medical Journal,' June 28; the 'Medical Times and Gazette,' June 28; the 'Lancet,' June 28; the 'London Medical Record,' June 28; 'Medical Press and Circular,' June 28; 'Nature,' June 28; 'Chemical News,' June 28; 'Gardeners' Chronicle,' June 28; the 'Grocer,' June 28; 'Journal of the Society of Arts,' June 28; 'Grocery News,' June 28; 'Produce Markets Review,' June 28; 'The Practioner,' for July; 'Liverpool Daily Post,' June 28; 'Belfast News Letter,' June 28; 'Dover Chronicle,' June 28; 'Journal of Applied Science,' for July: 'British Journal of Dental Science,' for July; 'Food, Water, and Air,' for July; 'Educational Times,' for July: 'Brewers' Guardian,' July 1; 'Scientific American,' June 21.

Communications, Letters, etc., have been received from Dr. Kidd, Messrs. E. Richardson, F. R. Bessant, H. Greatrex, J. Abraham, R. M., E. W., W. S., "Nemo," "Ubique," "Euphorbia."

THE CINCHONA PLANTATIONS IN JAVA.

BY JOHN ELIOT HOWARD, F.L.S.

These plantations have just been distinguished by a great success, in having sent into the market, at Amsterdam, bark which has been sold at prices equal to from 8*s.* to 9*s.* 5*d.* (English money) per lb.; and this not simply from such accidental circumstances as will at times occur, but from the intrinsic goodness of the bark.* It was indeed time that the praiseworthy exertions of the Dutch Government in taking the lead in the introduction of the Cinchonæ into the East should be rewarded with something better than was apparent at the sale on 14th March, 1872. An "account" of the above sale, published in the PHARMACEUTICAL JOURNAL, accompanying specimens presented to the museum—apparently then copied into the 'Flora of Ratisbon,' from whence it was transferred into Haaxmann's 'Tydscrift voor Pharmacie,'—was one of the first means of conveying information to those in Java who were longing for full accounts, and who were disappointed with the silence of the pharmaceutical journals of the Netherlands. I therefore the more willingly hasten to congratulate those engaged in this friendly rivalry of nations in having taken the lead on this occasion, and having achieved that success which they merited, because in obtaining the best seeds they took the course which was calculated to lead to such a result.

I shall have to recur to this subject, as I do not say that the obtaining of the very best seed would of itself ensure success without precautions, since natural selection has a tendency *downwards* in the Cinchonæ, and the survival of the fittest is most problematical; but first I will show the importance of the results obtained, by a translation of part of the report which has reached me through Mr. Hasskarl's obliging communication, as follows:—

"Towards the middle of November the chemist for the Cinchona culture was called to his commission at Batavia, and did not return even with the closing year. As far as possible he continued his quinological studies in a chemical laboratory at Weltevreden. The distinguished quality of the *Cinchona Calisaya*, which was raised from seed gathered by Ledger in Bolivia, has been already mentioned, and has now by the examination of seven more samples been clearly set forth.

"This sort began for the first time to bear blossoms towards the end of the year (October and November), and showed in two specimens that a part of the quinine had been replaced by quinidine (Chinidin). Further experience must decide whether this phenomenon is usually present, and whether the quinidine diminishes again after the time of flowering. This will, of course, be of great importance to the bark harvest.

"To what extent this variety of C. Calisaya exceeds those before introduced into Java, will be seen by the following summary:—

	Quin.	Quinid.	S. Q.	Total Alk.
1. C. Calisaya, Java seed, medium of 8 trials	1·23	1·24	1·64	5·04
2. C. Calisaya, seed from Bolivia, Shuhkraft, med. 8 trials	2·32	0·43	3·11	4·88
3. C. Calisaya, seed from Ledger, med. of 9 trials	5·53	0·43	7·44	7·25

* I speak in general terms, resting my opinion on the analysis of M. Moens.

"This example already shows clearly *how important the chemical examination is for the choice of the sorts which are to be planted out.*" *

It also shows, as I think, the importance of not being deceived by a mere name, and led away by confounding together different sorts of Cinchonæ, which, however classified, vary to such an extraordinary degree in their produce.

I remarked, in my note on the 1872 sale above, that the Calisaya then sold had neither the appearance nor the qualities of the genuine bark, and that it was really no better than the C. Pahudiana. Mr. Moens seems to insinuate that some unworthy motive existed for depreciating the bark then sold, some of which certainly obtained extraordinary prices; but the result has been that Mr. Jobst (who is himself a quinine manufacturer), having bought the largest portion, in his published report thereon, says, that "although the external appearance of the bark has certainly improved, the alkaloidal contents *have not advanced in equal proportion*," and advises the cultivators to lay themselves out in the first place for the production of medicinal bark. We may then conclude that Mr. Jobst did not find reason to suppose that the grand object of the cultivation of the trees for the *production of quinine* had been then attained.†

He gave the following percentage as the result of his experiments:—

C. Calisaya	3·39
C. Hasskarliana	2·52
C. officinalis	3·73
C. Pahudiana	2·07

If anyone will compare these figures with the prices given at the sale, as reported in the PHARMACEUTICAL JOURNAL, they will comprehend what I have said above, and will not thereby be induced to erect a quinine manufactory—at least, not at their own expense.

Moreover, the contrast between the above figures and those given before as representing the produce of the bark from Ledger's seeds, shows but imperfectly the advantage derived from cultivating the latter sort.

In the first place, Mr. Markham has remarked on the poor and stunted appearance of the (so-called) Calisaya as it met his view in India; so contrasted, as he says, with the glorious Calisaya of the American forests. Now one obvious reason for this difference is that the seed earliest sown was of the easiest procurable kind, viz., the C. Josephiana and kindred sorts. These are mere shrubby existences, incapable of ever becoming remunerative to the planter. I have under my eye a photograph of "C. Calisaya, No. 33 plantation, Tybodas," showing both the meagre growth—spreading like a slender willow tree—and also the contortion of the roots from the volcanic soil, which had apparently conduced to bring it to its end.

I do not impute any want of care to the earliest collectors of seed. It was unfortunate that the distinctions between good and bad were not then known. I have from Mr. Hasskarl botanical specimens which show his endeavours to secure the real C. Calisaya; but none doubt the preponderance of the seed to have been such, as will be seen in our further details.

* From 'Report of the Government Bark Cultivation in Java. IV. Quarter, 1872.'

† See the *Pharmaceutische Zeitung*, 24 Mai, 1873.

If, in the place of these, the cultivators of Java have obtained from seed growing trees, capable of attaining the height (as Don Pedro Rada told me was the case of those which he felled) of 120 to 150 feet English, the prospect is very different.* That such is the case, I can well believe, since, in the interval of writing, I have measured some plants (such as I had the opportunity of showing at a meeting of the Linnean Society, May 1st of this year), proceeding originally from the same source. Mr. Broughton sent me in April, 1872, some seed of his Calisaya, raised from Ledger's seeds. I sowed these on May 22nd, 1872, and now (June 24th, 1873), the finest average about a yard in height (two are exactly one *metre* each), and the circumference at base of stem two inches. They have from four to six commencing branches, and are forming bark on the lower part of the stem. I will now give Mr. Broughton's account of his success with these at Ootacamund; he says in his report to the Indian Government, 31st July, 1871, as follows:—

"After the above kinds, the most important at present cultivated on the plantations is, undoubtedly, that of C. Calisaya. As in my former reports, the trees of Calisaya were very young, it is quite natural to find the amount of alkaloids in the bark has increased. The most remarkable point about the plants of C. Calisaya is *the great number of varieties.*

"These display ALMOST EVERY HABIT. As it was necessary to examine the bark of the trees of most marked character, in order to determine the kind most suitable for cultivation, these varieties have taken up much time. I have the honour to quote the analysis of several of these varieties. The alkaloids are given in percentages contained in dry bark.

"Trunk bark of C. Calisaya, grown at Neddivuttum:—

	I.	II.	III.	IV.	V.
Total Alkaloids...	3·95	3·93	5·28	4·16	5·36
Quinine	2·67	3·18	1·02	2·50	4·67
Cinchonidine and Cinchonine ...	1·28	0·75	4·26	1·66	0.69

"These represent fairly the different yields I have met with among the kinds of C. Calisaya raised from seed obtained from Mr. Money.† They are, as a whole, of good quality, but No. V., or *the bark of a variety with broad leaves, which are red on the under surface, and of vigorous habit, is the kind which should be propagated,* as it is the one whose cultivation can be most profitably extended. I have examined the bark of several other varieties besides those whose analyses are given above, but find them all inferior to No. V., and promising nothing remarkable in their qualities. The bark of our C. Calisaya is of excellent quality, *and is better suited for quinine manufacturers* than that of C. succirubra. I regret that a larger number of the trees has not been planted, but as the yield of bark from the present plantations will shortly be so large, I cannot now recommend any considerable extension even of this sort."*

I am unable to explain how it is that the Dutch analysis surpasses that of Mr. Broughton (*essentially*, as to commercial value, in the proportion of 5·53 to 4·67 per cent.), but the results of the recent sale at Amsterdam show that this superiority of the Dutch Calisaya is (at all events for the present) an established fact.

These results, as communicated in the way of trade, are as follows:—

		Sample.	Sold from		s.	d.		s.	d.
72	C. Calisaya ...	... A ...	110 to 120	say	1	10	to	2	0
23	„ do. ...	... B ...	130 „ 220	„	2	2	„	3	8
3	„ do. ...	... C ...	116 „	„	1	11½	„		
5	„ do. ...	... D ...	158 „ 159	„	2	6	„

35	„ Pahudiana	... P ...	120 „ 140	„	2	0	„	2	4
29	Ground Calisaya	... R ...	20 „ 35	„	0	4	„	0	7

Mr. Moens seems to object to the publication of the results of the previous sale. I hope that he will be more satisfied on the present occasion, as I think the buyers were much better aware this time than last of the real worth of their purchases; samples of the present having evidently been well tested. I do not think that any from the present sale fell into English hands, except of the last unimportant parcel; but believe that the lots of Calisaya were sold to a German quinine manufacturer, far too much experienced to be influenced by English opinion. If any one will take the trouble to compare my first table with this—looking only to the *quinine* as most essential—he will be able to discern *at once* some probable connection between the contents in *quinine*, and the price given. But to facilitate the understanding of the subject, I will present to the Pharmaceutical Society selections from the above samples, together with such opinion of them as I am able to form.

"Calisaya, sample A," I divided into five portions, thus:—

α. Bark of C. micrantha Calisayoides (grey bark).

β. Looks like bark of C. Hasskarliana, rather than Calisaya.

γ. Much like Weddell's "morada," but *more exactly* the "morada fina" of Hasskarl—C. euneura of Miquel.†

δ. Bark of C. Pahudiana.

ε. Bark of C. Hasskarliana.

"Calisaya, sample B":—

α. Probably Calisaya, resembles bark of C. nitida.

β. Compare with bark of C. Hasskarliana.

"Calisaya, sample C":—

All bark of C. Hasskarliana.

"Calisaya, sample D":—

Calisaya, but rather peculiar. I *think*, equal to E.

* A large parcel of *this* bark, coming *viâ* Para, is just now (July 8) on sale in London. The specimen of Rada's bark in the Pharmaceutical Society's museum confirms this account of the trees.

† *i.e.*, Ledger's originally.

* [With this advice I do not coincide.—J. E. H.]

† "C. euneura, Miq. sp. nov. (C. Boliviana Hsskl. hrb. non Weddell, C. Calisaya var. fina, according to Howard, in the herbarium of Hasskarl). . . . Subtus costâ argute prominente, costulisque utrinque 15-16 patulis parallelis rectis. . . . Hasskarl found it in the Province of Carabaya, on the banks of the Rio Grande, in Nov. 1853, where it is called by the inhabitants *cascarilla morada*, or *morada fina*.—Comp. Howard, in *London Bot. Congress*, p. 201."

"Calisaya, sample E" :—

Bark of Calisaya Zamba.*

H sample, C. Hasskarliana :—

Apparently very characteristic, and showing a bark intermediate in appearance between the *Calisaya* and the *Pahudiana*—probably a true *hybrid*.

S sample, C. succirubra :—

Very inferior looking. I have a botanical specimen from Java, which I think *erronously* marked C. succirubra, and more like C. pubescens; possibly this bark may belong to the sort.

O sample, C. officinalis :—

a. Bark of C. Bonplandiana, "Colorada del Rey."
β. Bark of C. officinalis, a Uritusinga.

M sample, Caloptera :†—

Contains little except Cinchonine.

P sample, Pahudiana :—

A characteristic sample of this bark.

Many of the readers of this Journal are probably not aware of the cyclone of controversy which has agitated Holland, and even found its way into both houses of legislature, respecting this sort. In my 'Nueva Quinologia' I named and described the plant after specimens and an *adumbratio* (by Junghuhn) received from Java. To this description I still adhere, as also to the accuracy of the drawing by Mr. Fitch, which I can *now* compare with five living plants in my possession. The colouring is too bright, and the minute and characteristic veining not quite done justice to, owing to the drawing being made from a dried specimen. But on the whole I congratulate myself on not having erred more widely in (to me) so new a field of definition. I then expressed my belief that this kind would prove a source of disappointment to the Dutch Government, and remonstrated against the excessive development of this particular sort (or *sorts*, for we are now informed that in part they were hybrid, and belonged to the Cinchona hybrida termed *Hasskarliana*). At all events they were then reported 408,230 of the Pahudiana, against 11,668 of the Calisaya.

An English correspondent writes me :—"If you had lauded Pahudiana to the skies, you too would have been lauded." But this was not to be. Afterwards, when it seemed to me that the kind was too much depreciated, I put in my plea against the trees being considered as "firewood."* I showed that they would in all probability yield good medicinal bark, though useless for the extraction of quinine. On this, some one accused me of "*Een meesterstuk van Verschoonenheid*," because I seemed to shift my ground, and to show that the sort was neither so good nor so bad as party spirit on the one side or the other represented. This amused much more than it annoyed me; but it was otherwise with an attack of the late Professor Miquel, written in Latin, intelligible to all the learned, published under favour of the Government, and preserved in the Belgian Archives.† Of this I am not sufficiently fortunate to possess a copy from the author, but I understand that he says of the C. Pahudiana: "Ejus cortex de quo adeo multum et *malâ fide* scriptum est." He attacks my botanical knowledge, which is unimportant: but the insinuation above ought not to have been printed.

Time generally sets things of this sort to right; and I now copy from the organ of the *Deutschen Apotheker Vereins*, (their Pharmaceutical Journal), of 24th May, 1873, the following admission of M. Moens, who writes from Bandong, Java; and, being in charge of the plantations, naturally feels some sensitiveness in respect to what is said of them; he says in reference to my observations in this Journal on the sale of Java bark at Amsterdam, 14th March, 1872:—

"I do not know what 'advice' Howard means here. Howard has only prophesied that the bark of C. Pahu-

---

* Of this sort Dr. Weddell writes thus :—"42. *C. Calisaya microcarpa* (vide tabulam), foliis oblongo-ovatis ellipticisve, obtusis, utrinque viridibus, aut in pagina inferiore nonnihil purpurascentibus, subtus pubescentibus, scrobiculis prorsus deficientibus v. parcissimis; capsulis quam in typo minoribus (8-10 *millim.* circiter longis), cæterum similibus.—*Hab.* in montibus vallis Coroico, prov. Yungas Bolivianorum, ubi vernacule *Calisaya Zamba* et *Zambita* nuncupatur.

"This variety of *Calisaya* was brought over by me in 1851, from the mountains that rise over the river Coroico, a tributary of the Mapiri, one of the most important streams of the department of La Paz. The bark gatherers (*cascarilleros*) of the neighbourhood informed me that it yielded a bark superior in quality to that of the other varieties growing in the same localities; and I confess that I was glad to find this statement of the dwellers in the wood confirmed by Mr. Howard. In fact, it was from a bark, acknowledged by him to be identical with the one just referred to, that my distinguished friend extracted the largest proportion of quinine ever found in any bark. [My largest amount (S.Q. 7·40 p.c.) was similar to that obtained by Mr. Moens, but I have since obtained 8 per cent. from the richest Calisaya.—J.E.H.] That is to say, about double the quantity mentioned by MM. Delondre and Bouchardat, as the average one of the *Calisaya*. The more or less purplish *nuance* of the under part of the leaves imparts to this variety a character of resemblance to the *C. Boliviana*. I am unacquainted with its young leaves, but it appears probable that they too must be very analogous to those of the above-named variety. Perhaps we may take for granted that it is represented by fig. 2 of the plate accompanying the article published by Mr. Howard, with regard to the barks brought over from Bolivia by Don Pedro Rada, the merchant."—*Weddell's Notes, etc.*

† C. caloptera, Miquel, sp. nov.

C. succirubra, Jung. (*non Pavon.*)

"From seed brought by Hasskarl. C. pubescens, Wedd. (Reise nicht anderer); C. purpurea, very like, according to Howard, in letters; C. pubescens, R.P. Peruv. MSS., Howard Nueva Quin., p. 74, according to Howard, London Botan. Congress, 213, in part. This has a certain resemblance to C. succirubra, and was taken for it by Junghuhn. Hasskarl compared it more rightly, as Miquel thinks, with C. cordifolia, Wedd., which it resembles in its seed, but differs in other particulars. It also stands near to C. ovata, which its bark resembles. The leaves of the specimens cultivated in Java are larger, whilst living, saturated with green and red nerves, and more pointed than those of C. succirubra—called Cascarilla naranjada by the natives."—*Hasskarl.*

A specimen given me by Hasskarl, was gathered in Nov. 1853, in the higher valleys of Carabaya.—J. E. H.

* The official reports of the transactions of the Dutch Parliament on 27th May, 1862, recorded as follows :—

Mr. Uhlenbeck, Minister of the Colonies, said: "And to show the great difference, I communicate that all the time that the Cinchona culture has been performed on a large scale there have only been planted 7804 Cinchona trees which really contain quinine, whilst in the meantime there have been planted 1,029,291 trees (Pahudianas), which are only fit for firewood."

On 2nd June 1863, Mr. Van Eck, M.P., said: "The former Minister of the Colonies stated only, the trees are firewood (*Brandhout*); we must uproot (*uitroeijen*) them."

† 'Commentatio de Cinchonæ speciebus quibusdam adjectis iis quæ in Java coluntur. Scripsit F. A. G. Miquel commentatio ex Annalibus Musei Botanici Lugduno-Batavi exscripta. Amstelodami: C. G. Vander Post. 1869.' This I understand is an abstract from the official work printed with the aid of the Government.

diana would be desired for pharmaceutical use, and that it would find buyers, *and this has certainly come to pass.* But he has also expressed his opinion that the Java Calisaya would possess no greater worth than the C. Pahudiana, and that is not correct; and so much less when it is considered that the greatest part of the plantations consist at present of C. Calisaya, which have been produced since 1867 from Bolivian seed."

So, after all, I have been right about the C. Pahudiana. Now, then, about the C. Calisaya. Turn to the first table, and we see on indubitable authority that the "Calisaya" of Java is derived from three sources.

1. C. Calisaya ("Java seed").

This table is kindly sent me by M. Hasskarl, and the paper is signed C. H. I conclude then that by Java seed the table implies that first introduced into Java, and this chiefly through his own exertions. Now, the "Calisaya of Hasskarl's sending," according to Professor Miquel, is his var. *rugosa*, of which he says, "This kind reminds through its leaves of C. parabolica and C. obovata, Pav., but *may well be a new kind*, which is, notwithstanding, *very nearly related to* the forms of Calisaya. Hasskarl found it in November, 1853, in the dale of Sandia, and the province of Carabaya, in South Peru, already in flowering condition. *The inhabitants call it Ichu-calisaya* (*itschu*, grass, straw), since it comes less on the forests than on grassy plots of ground, which are apparently the remains of earlier forests. The bark of such a tree cultivated in Java, six years old, gave Moens nearly five per cent. alkaloid, of which 2·845 quinine."

I have a specimen of the plant under my eye from Hasskarl, and, with all respect for its noble though somewhat distant relationship to the Calisaya, I venture to pronounce this Ichu-calisaya, and all derived from it, a failure.

I *predict* nothing, but look at the table!

2. Bolivia seed (Shuhkraft).

This is somewhat better, but still *not** C. Calisaya, but seed of C. Josephiana, for which latter statement I have the authority of Miquel, as follows:—

"More recently the Netherlands Consul, Shuhkraft, sent seeds of this 'C. Calisaya, Wedd. var. Josephiana, acc. ad. β.' "—*Hasskarl*, from Bolivia. "*These plants, now cultivated in Java*, bear flowers and fruit, and are not to be distinguished from the original specimens, but the plants raised from layers show always smaller leaves. The specimens brought from English India of this form stand between this kind and that next following. To this belong the specimens, brought by Hasskarl, of an old tree from the Valle Grande of Vilquebamba, in Carabaya, and also of a young tree in fruit from the same province, which grew in dry and sunny ground."—*Miquel, trans. by Hasskarl.*

I have under my eye from Hasskarl a specimen both of the young and of the old tree alluded to above, and I venture to say that *the plantations of C. Josephiana are not a success.* Again I say, *look at the table*, and understand that what is called *quinidin* has to be *deducted* from the total, 3·11 per cent.—at least, so I take it. M. Jobst does not seem to have thought the Calisaya which he bought at the previous sale much of a bargain, though he gives its produce as 3·39 per cent.

3. Bolivia seed (Ledger):—

This, I freely admit, is a great success, but (as I know from plants raised by myself) not altogether of equal quality. For proof of this I turn back to Mr. Broughton's experience; so that again we have to limit the number of genuine Calisaya trees. Out of the 2,000,000 trees said in the return to be about the number now in Java, I know not how many are of this superior kind, but I see with dissatisfaction that the "C. Calisaya *et Hasskarliana*" are enumerated *together.** Now the Hasskarliana is only a shade better than the Pahudiana, as 2·52 to 2·07,—see Jobst's analysis. In the sale we have four, or at most nine, packages of this fine bark in a total of 107 of so-called Calisaya. On the whole, I think I am not far wrong about the Calisaya.

But, if I had any doubt on the matter, M. Moens himself, in the same letter, would seem to have taken pains to relieve my uncertainty. He says:—"If we look at the cultivation of Cinchona as a speculation, people ought not to have the desire to produce bark suited for the manufacture of quinine, since, as Jobst tells us, the medicinal barks bring disproportionately higher prices than those destined for the factories, and some thousand packages of medicinal bark easily represent the value of half-a-million of guilders. The desire to produce barks rich in quinine and suited for the manufacture, has nevertheless always prevailed; but we can also point to good prospects for the quinine manufacturers. These have no need to place their hopes on the bark of C. officinalis, which in its riper age, as it appears, contains more cinchonidine and less quinine; they may place much more confidence in the culture of C. Calisaya. At all events, this sort of bark, such as has been brought into the market, contains *not so much quinine as might have been expected* from the cortex regius; moreover, the hope is not great that at a more mature age it would produce more quinine, since it has often been shown—and so again with me recently—that a handsome, very *thick bark of a ten years' old tree contains no quinine*, but very much conchinin.† But the observations of *a very large percentage of quinidine, all belong to trees which proceed from some supplied by Weddell, which were brought to Java in* 1852, and to these Calisayas, which were provided through Hasskarl's mission to South America. *Of these sorts there are about* 600,000 *to* 700,000 *trees at present, which may be cut down from time to time, and the bark of which will produce a very distinguished medicinal bark.*"

[This disposes of one-third of the two million trees in Java.]

"The larger half of the present C. Calisaya trees, some 700,000 to 800,000, proceed from trees which have been received at a later period (1864, 1865, and 1868) from Bolivia. The bark of these trees contains, so far as at present examined, no quinidine, or, at all events, very little, whether younger or older trees were tried. On the other hand, they show a very large percentage of quinine. From these trees about 270 kilogrammes will be sent to the Netherlands in the current year" (? the four packages above), "and in the next year's auction of bark, probably in March, 1873 (May), *will this sort of bark appear for the first time.* Some samples of this lot gave me 5·47 and 5·24 per cent. of pure quinine, which equals 7·05 to 6·75 of sulphate of quinine. From this people may be assured that we possess something

* According to Weddell's 'Notes,' 9, *q. v.*

* "C. Calisaya et Hasskarliana 1,235,423, total at present in the Garden." IV. Quarter, 1872.

† *i.e.*, quinidine of Pasteur.

better to found our hopes upon than the C. officinalis, and that the *main object* of the introduction of the Cinchona cultivation into Java has not failed—namely, *the obtaining a rich source of quinine.*"

This is all very good, but it does not impeach my statement about the No. 1 and No. 2 sorts of Calisaya above. This *entirely new light* shines out from *at most* "the larger half of 700,000 to 800,000 trees." I fail *exactly* to comprehend the calculation, for which the reader must recur to the original.

"In 1872 there were gathered and sent into the Netherlands 15,000 kilogrammes of bark of extraordinary goodness. Without doubt, the report of these will be more favourable than that which Jobst has given of the bark of the preceding year, and there is no reason to think that this bark will sell for less than was the case in March, 1872."

But it did sell for less, and considerably less, if I am not mistaken. Perhaps our friends will tell us why. At all events, M. Moens seems not to have present to his mind that the market may be glutted if over supplied with medicinal barks, whilst it is scarcely probable that this can be the case with *good* material for the extraction of quinine.

Let me then say one parting word to M. Moens, which I hope that he will take in good part. My advice to all cultivators of Cinchona bark is *to plant none but the very best species and to go in for high cultivation.* In so doing they will be quite independent of all courtly favour, and of all foreign competition. Success must be won by strenuous persevering exertion, for (as Schiller says of the flowers of German poetry) the Cinchona blossoms "do not expand under the sunshine of princely favour."

In this, let me say that I do not *prophesy.* I have far too much regard to a shrewd saying which imports that it is best not to prophesy till one is quite sure that what is prophesied will *certainly* come to pass.

Further, it may be a consolation to M. Moens to know that if the Dutch have erred as to excessive multiplication of the C. Pahudiana, so have the English as to the C. succirubra; and if advice has been unwelcome in the one quarter, so has it been in the other. Those who tender advice on such a subject may be content to wait till they are dead and buried before their advice will be regarded or appreciated.

I will conclude this paper with a short account of Mr. Ledger's seeds, on which so much has been seen to rest. It was while engaged in his great project of transferring the alpaca from Peru to Australia that Mr. Charles Ledger obtained the information from his native shepherds respecting the seeds of the Cinchona which he thus subsequently obtained. In the early part of the year 1865 he wrote to his brother in London that after four years of fruitless expectation the trees of the "Calisaya red bark" were reported to be in maguificent condition, and promising for seed. An Indian and his son were sent as collectors into Caupolican and returned from thence with the precious seed, which on July 22nd, 1865, was shipped from Arica to London. The autumn of the same year Mr. George Ledger sold some portion to the Consul for the Dutch Government, and after much correspondence obtained an introduction to Mr. Money to look at the box of seeds. I was asked to give my opinion, and, as I saw by the capsules that the sort appeared to be of the microcarpa kind, and as the collection was from the best district, advised that the sum named should be paid for the seeds on condition that not less than 10,000 germinated in India.

This price has since been paid by Mr. Money, and the seed, or part of it, transferred to the Indian Government. This account may be relied upon, as I have recently seen Mr. George Ledger on the subject. I cannot tell what Spanish word is translated by *red* in the above expressions. It was possibly *morada*, a term applied by the Spaniards, who are very accurate in their descriptive terms, to some of the finest Calisaya; but in looking at my plants as they are growing, I see that the term "Calisaya red bark," is still more applicable. Moreover, they are not the true *morada*, or C. Boliviana, but an undescribed sort or race. Indeed, I should not be surprised if some future botanist should define from them five or six new species, to one of which, I hope, the term *Ledgeriana* may be applied in honour of the enterprising traveller.

P.S.—I have some fifty or sixty plants now growing in the open border. They were planted out in May, and some of them bore a slight frost, but I shall have to take them up before autumn frosts set in, and I shall be glad then to give them away to early applicants.

VESICATING INSECTS.*

BY DR. FUMOUGE, PARIS.

Vesicating insects live in all the countries of the globe, and more especially the hot and temperate climates; and there is perhaps not a people which is not acquainted with their properties and knows not how to utilize them. In Europe, one kind is more particularly employed; namely officinal cantharides. It is pre-eminently *the* vesicating insect, or at least the one which holds the first rank in European pharmacopœias. And yet it would be a mistake to conclude, from its place in the Materia Medica, that it posesses vesicating properties in the highest degree: it will be seen further that it is not so. Its vesicating properties are certainly quite sufficient for the wants of therapeutics, and this explains how its use has become so prevalent; but if it is so employed in preference to other more vesicating insects, it is most especially because it is more easily gathered. Cantharides, as is well known, alight in swarms upon certain trees; it is therefore possible to collect thousands of them in a few instants, whilst this is not the case with other vesicating insects. Sometimes, as with the meloës, it is even necessary to catch them one by one, and it follows that, being thus gathered, they are far more expensive than cantharides.

Such is, I believe the cause of its almost exclusive, and I think I may say its quite exclusive, employment in pharmaceutical laboratories, as it has superseded the use of meloë and mylabris even in the countries where these were formerly employed; so that I am surprised to read, in the most recent treatises on Materia Medica, that the *Mylabris* and *Meloë Majalis* or *Proscarabœus* are employed, the former in Italy and the East, the latter in Spain. Already, several years ago, as I desired to study these insects, I asked for samples of them in Italy, Turkey, and Spain, on the strength of authors' statements; and the answer invariably was, that they no longer existed in commerce. It was with the greatest difficulty that I was enabled to procure a few pounds of *Meloë.*

There is, however, one *Mylabris*, the *Mylabris Sidæ*, better known commercially by the name of China Mylabris, which for several years has reached us from China in pretty large quantities, and may be procured in the London Docks. This insect affords on analysis as much cantharidin as cantharides; but as it is less abundant in

* From the *Practitioner.*

fatty matter, it is not, I think, as suitable as cantharides for the preparation of vesicating plasters.

The richness in cantharidin of vesicating insects is certainly very variable, and it would be very interesting to classify them according to their degree of strength, as it would be easy to do if the chemists who have had occasion to analyse them had not generally contented themselves with asserting that such and such a kind was vesicating, without stating the richness in cantharidin. This blank in the history of vesicating insects, though it is to be regretted, is, however, of slight importance for the pharmaceutical chemist, who habitually in commerce only meets with the officinal cantharides, occasionally the China Mylabris, and scarcely ever the Meloë. These are, therefore, the only vesicating insects about which he cares to be informed, as regards their richness in cantharidin.

The *Meloë Majalis* is perhaps, of all sorts, the one which contains the most cantharidin. According to my analyses, it contains 12 parts to 1000. It is, therefore, not allowable to substitute it for cantharides in pharmaceutical preparations, as this latter insect only affords 4 parts of cantharides to 1000, or only 5 at the maximum.

The China Mylabris affords, as I have said, as much cantharidin as cantharides do, but for reasons above stated it could not be used with advantage instead of cantharides in the preparation of vesicating plasters.

The pharmaceutical chemist should, therefore, not think of using Meloë or Mylabris for his preparations, and should only employ cantharides, and even that with caution, as all cantharides do not contain the same quantity of cantharidin, and may be adulterated, as happens more often than is suspected. In order to make out their proportion of active principle and not be the dupe of cheats, he has only the resource of analysis.

Researches of this kind must be made with care and promptitude, and both these conditions are, I think, fulfilled by a method of analysis which M. Mortheux and myself made known some years ago.

Though this procedure has already been described in a former publication of mine, it may be of use to give an account of it here. First, we put into a displacing apparatus 100 or even 50 grammes of the cantharides, whose strength we wish to determine, and which have been previously triturated in a mortar; then we pour on the cantharides a sufficient quantity of chloroform to immerse them entirely; and after twenty-five hours the cock of the apparatus is opened so as to let the tincture of cantharides run out. In this way the cantharides are subjected to three successive macerations, and the tincture afforded by the three macerations is distilled in the water-bath, so as to give out all its chloroform. The extract thus obtained is mixed with an equal quantity of sulphide of carbon, and then the liquid is agitated and poured on to a filter. The filter retains the cantharidin, which must be washed with a little sulphide of carbon. When thus obtained it is not entirely pure, but it is sufficiently so to enable us to ascertain the therapeutical action and commercial value of cantharides.

By analysing with this procedure various specimens of cantharides, I have been able to find out that the French Codex has adopted too high a figure in fixing at 5 per cent. the minimum quantity of cantharidin contained in cantharides of good quality. It ought to have fixed upon 4 per cent., and perhaps even upon 3 per cent, as cantharides containing only this proportion have appeared to me to be quite strong enough.

I am also surprised to see that the commission of the French Codex and authors of the British Pharmacopœia do not recommend to prepare tincture of cantharides with such a quantity of cantharides as to cause this preparation to present invariably the same proportion of cantharidin.

If the following table of mine be consulted, it will be granted that the justness of my remark is obvious on noticing that the proportion of cantharidin in cantharides may vary from 1·75 to 5 per cent.; and I have no need to insist on pointing out how untrustworthy a medicament is, prepared with a fixed quantity of a substance the active principle of which may vary in such a degree. This is a real danger when, as with tincture of cantharides, the preparations may be prescribed internally.

Origin of Cantharides.	Quantity used.	Cantharidin obtained.	Cantharidin contained in 100 grm.
	Grammes	Grm.	Grm.
1. Cantharides from France, 1866	100	0·48	4·80
2. ,, ,, ,, 1866	,,	0·275	2·75
3. ,, ,, Germany, 1866	,,	0·435	4·35
4. ,, ,, Trieste, 1866	,,	0·50	5·00
5. ,, ,, France, 1865	,,	0·375	3·75
6. ,, ,, Germany, 1865	,,	0·215	2·15
7. ,, ,, ,, 1865	,,	0·17	1·70
8. ,, ,, ,, 1866	,,	0·48	4·80

The British Pharmacopœia ought also, I think, to have indicated the minimum quantity of active principle which cantharides, employed for the preparation of blisters or epispastic papers, ought to contain. It is obvious that, if need be, cantharides containing more or less cantharidin may be used for those preparations, but only within certain limits which should not be exceeded. The epispastic papers and blistering tissues which for years have been prepared in France according to my method and by the name Albespeyres contain as nearly as possible 4 per cent. of cantharidin, and I think that this constitutes a valuable property and a real improvement in them.

Before concluding this paper it may be good to notice the trials which have lately been made with the object of replacing cantharides in the preparation of blistering plasters by cantharidin and cantharidate of potash.

The vesicating tissues prepared with cantharidin have until now been very unsatisfactory. The surface easily breaks, and they soon lose their properties on account of the slow evaporation of the cantharidin, which, as is well known, gives off vapours at the ordinary temperature. In order to prevent this last inconvenience, trials have been made of cantharidate of potash, which presents greater stability. Experience will show whether vesicating tissues prepared with the cantharidate are brittle or not; meanwhile it is quite obvious that if tissues thus prepared do not blister more quickly than those made with cantharides, there can be no advantage in using the cantharidate, which is so much dearer.

Vesicating tissues made with cantharides are at present the best agents we possess for producing vesication.

RECENT EXPERIMENTS ON OLD AND NEW ALKALOIDS OF OPIUM.*

BY A. GUBLER.

The immediate principles contained in the juice of the poppy seem to be metamorphosed at the will of each investigator, and the chemical composition of opium, already so varied, according to the analyses of Mulder, Schinler, and Bilz, has been yet further complicated, of late years, by the discovery of a great number of organic compounds.

To the old alkaloids, which were nine in number: morphine, narcotine, codeine, narceine, meconine, thebaine or paramorphine, opianine, papaverine, and porphyroxine, there are added eleven new alkaloids.

These are, in alphabetical order: apomorphine, chlorocodine, codamine, cotarnine, cryptopine, hydrocotarnine, lanthopine, laudanine, laudanosine, meconidine, and protopine.

Several, if not all, are modifications of the primitive alkaloids, produced probably by chemical operations resorted to in order to extract from opium the secrets of its magical power.

* From the *Journal de Pharmacie et de Chimie* [4] xvii. 312.

Of all these vegetable alkalies recently obtained, only two have been hitherto the object of physiological experiment, viz. *cryptopine*, and *apomorphine*. The latter, as its name indicates, seems to be, in elementary composition, merely a slightly modified form of the principal alkaloid of opium. It differs, indeed, only by the removal of an equivalent of water; its formula, according to Matthiessen and Wright (the discoverers), being $C_{17}H_{19}NO_3$; while that of morphine is $C_{17}H_{19}NO_3H_2O$. But this simple subtraction of H_2O confers on it organoleptic qualities entirely different. Far from being hypnotic and narcotic like its congener, apomorphine possesses only nauseating and vomitive properties, which are very energetic. Entering the stomach in a dose of 1 to 2 centigrammes, it produces vomiting without previous nausea in ten or twelve minutes. Subcutaneously injected, only 4 to 5 milligrammes are required to produce very powerful emetic effects, but without great depression.

Should these figures be true, we must infer that apomorphine is rapidly altered in the stomach and transformed into a substance inoffensive in contact with the digestive mucus. If it were otherwise, if there were no hindrance to the accomplishment of its topical action on the stomach, an indispensable condition of the starting of those complex movements which constitute vomiting, the latter should be produced more easily and with more intensity when apomorphine directly enters the principal passages than when, after injection, it reaches these to be partially eliminated and acts in its passage on the gastric mucus. It is thus that Drs. D'Omellas and Labbé have proved the necessity of administering by hypodermic injections much stronger doses of emetine than directly by the principal passage in order to obtain vomiting.

However it may be, apomorphine is, with reason, considered by Matthiessen and Wright as fitted to become an efficacious agent of emetic and counter-stimulant medication. It has one advantage over substances of similar action, and that is, that it is capable of being readily conveyed into the cellular tissue in sufficient quantity to produce all its physiological effects, in cases where introduction by the mouth may be impracticable, either from disease, or the patient's will.

This pharmacodynamic anomaly in the case of an immediate principle of opium merits a little attention.

And we observe, first, that the mode of action of apomorphine is exactly that of an American plant belonging to the family of Papaveraceæ, the *Sanguinaria Canadensis*, which may authorize the supposition that the active principle of this plant is the same as apomorphine. The *sanguinarine* discovered by Dana, and described also under the name of *chelerythine*, presents a similarity of composition to morphine, which warrants us in anticipating that new researches will establish its identity with apomorphine. It is, according to Gerhardt, represented by $C_{38}H_{17}NO_8$, not far removed from the old way of representing morphine $= C_{34}H_{19}NO_6\,2HO$. On the other hand, Naschold has assigned to it the formula $C_{17}H_{15}NO_4$, which brings it still nearer the new formula for morphine $C_{17}H_{19}NO_3H_2O$. In any case, the divergence between the two results is so marked as to leave some uncertainty with regard to the exact chemical composition of sanguinarine, and to justify the hypothesis of a more complete resemblance with the *dehydrated morphine* now under consideration.

In default of a rigorous quantitative analysis, always so difficult to execute, such conjectures might be tested by comparison of the *ensemble* of physical and chemical properties of the two substances. It would be interesting to ascertain if apomorphine, like sanguinarine, is soluble in amylic alcohol, benzine, sulphide of carbon, chloroform, and petroleum, and whether it communicates to its solutions a violet fluorescence.

Should experiment answer in the affirmative, it is probable that the fact would be reproduced in a certain number of similar cases, and that the profound dissimilarity of physiological action between species of the same botanical family would not imply an essential difference between the immediate principles, nor, consequently, a blow dealt to the laws of natural affinities. We might thus succeed in demonstrating that the volatile *oleiform* alkaloids of hemlock and *Œnanthe Phellandrium* are simple modifications of the essential oils of the family of Umbelliferæ; that aconitine and the neighbouring alkaloids are particular states of that volatile substance which belongs to the acrid Ranunculaceæ; that veratrine is a principle of the same origin with the toxical resinous matter which accompanies it; that picrotoxine is only a form derived from the purely bitter substance isolated in calumba, etc.

And if it were demonstrated that the same fundamental substance, submitted to changes of chemical composition apparently insignificant, may thus manifest, by turns, according to the botanical species and conditions of vegetation in each of them, the most different physiological properties, it would at the same time be established that the therapeutical or toxical virtues of immediate principles—alkaline, neutral, glucoside—are connected, not with the nature of the constituent elements, as was formerly supposed, nor even with the relative proportion of the masses of these elements, as is generally enough believed, but rather with their molecular character, or, better still, with the allotropic and dynamic states in which their elementary or compound molecules exist.

Pursuing this study, we should doubtless arrive at an explanation of the pharmacodynamic similarity of plants belonging to different groups, and the diversity in species united in the same natural family.

The second new alkaloid, of which it remains to speak, has been discovered in England by the brothers Smith, who have given it the name *cryptopia*, probably in order to denote that it was long concealed from the researches of investigators. It seems to be the least abundant of all the alkaline principles of opium, and consequently, notwithstanding its somewhat superior power to that of opium, acts efficaciously only when combined with all the others.

Pure cryptopine is colourless, and crystallizes in six-sided prisms. It dissolves readily in chloroform and alcohol, but less so in ether and in water. It combines with hydrochloric and acetic acids to form well defined salts, and is dissolved by sulphuric and nitric acids, giving a splendid purple colour with the former and an orange with the latter.

This new alkaloid has been fully experimented with by the author of the remarkable work published in London in 1869, under the title: 'The Old Vegetable Neurotics.' From his experiments on dogs and some other animal species, Dr. Harley draws the following conclusions:—

1. Cryptopine, like morphine, has two distinct actions, hypnotic and excitant, the latter consisting in the production, on one hand, of visual illusions, on the other, of convulsive phenomena. Some subjects experience simply excitation, while others are only hypnotized.

2. The somniferous effects of cryptopine are more intense and prolonged than that of the principal alkaloid of opium. A quarter more powerful than morphine, cryptopine is twice stronger than meconine and narceine.

3. Further experiments are necessary to ascertain if it presents advantages over morphine.

4. The action on the respiratory apparatus, at first stimulating, becomes depressive in strong doses, to the point of directly causing death.

5. Cardiac troubles are subordinate to respiratory disorders.

6. In considerable doses cryptopine produces pupillary dilatation.

In short, the new alkaloid ranges in the group of alkaloids of opium in which the hypnotic power predominates a little above opium, which it seems closely to resemble. It is necessary, however, to be guarded in transferring to the domain of human physiology the results obtained from lower animals. It is possible that with man, cryptopine may show itself inferior to morphine, as we have

seen to occur in the case of narceine, recognized as superior to morphine in the beautiful experiments of M. Cl. Bernard, and which the clinic finds four or five times less powerful than the old alkaloid of opium. This inequality of action, according to animal species, enables us to understand how a substance more energetic than morphine is considered by Dr. Harley as being only twice stronger than narceine. The relation indicated by this eminent observer is only true for animals experimented on by him. It may be quite different, and even reversed, in the case of man.

(*To be continued.*)

TASTELESS IODIDE AND CHLORIDE OF IRON.

The following is an extract from a letter written by Mr. Creuse, respecting the tasteless preparations of iron recently described by him,* which is published in the *American Journal of Pharmacy*:—

"If you ask me what kind of combination citrate of potassa can form with sesqui-iodide of iron, I will answer frankly that I cannot say with certitude; it is probably a combination similar to the medicinal pyrophosphate of iron or the green scales of sesquiphosphate of iron and citrate of potassa I sent you last year. That they form a combination does not admit of any doubt, for the physical and chemical changes are such as would not be presented by a simple mixture. But, be the combination what it may, I believe the new salt represents exactly the results of what happens in the stomach when protoiodide of iron is administered. Protoiodide of iron cannot be absorbed as it is, for no protosalt of iron is ever found in the animal system; when ingested into the stomach it must change in whole or in part into sesqui-iodide, which, combining with the citrates, tartrates, oxalates, malates or lactates, etc., always present in human food, becomes ready for absorption. The balance of the iodide of iron is probably eliminated, like all unabsorbed substances (I leave acetates purposely out of the list, for acetic acid is monobasic, and this class of compounds seems to be limited to the salts of polybasic vegetable acids). This explains also why protoiodide of iron is best administered just before a meal; for the food supplies the stomach with both the oxygen and the vegetable salts necessary for the digestion of the ferrous compound.

"The new iodide of iron, according to this theory, ought to be more effective and more uniformly so than the protoiodide, for it comes all ready for absorption, while the old salt, being absorbed only with the help of other variable substances, will vary more or less in its effects, besides interfering with the natural functions of the stomach.

"Experiments made by Dr. Lalanne, of this city, have confirmed this view, and have served to determine the medicinal dose of the new combination. This was necessary on account of the entirely different character of the new and the old form of iodide of iron. It has been found that from one to three grains of the salt have the same medicinal effect as an average dose of the U.S. Pharmacopœia syrup of protoiodide. As the new salt contains about 42 per cent. of iodine and 9 per cent. of metallic iron, this shows that its effects are proportionally greater than those obtained from the same substances administered as protoiodide.

"Its medical properties are, otherwise, precisely the same as those of the official iodide of iron, and its administration has always been followed by the most gratifying results; but it is not my province to speak of this, except to mention that it has found great favour among children and female patients, on account of its relatively pleasant taste and because it never blackens their teeth.

"Much of this applies also to the tasteless tincture of muriate of iron. The official tincture is still more injurious to the teeth than the syrup of protoiodide of iron; it not merely blackens them but destroys them when used long enough. I have heard some dentists speak very strongly on the subject.

"In regard to the quantity of citric acid needed for one fluidounce of tincture of muriate of iron, I have found from recent experiments that it requires from 90 to 95 grains of citric acid, neutralized by 180 to 190 grains of crystallized carbonate of soda to transform that quantity into the tasteless compound. It seems singular at first sight that the more acid is the solution of muriate of iron, the more citric acid it requires; but it is easy to account for that apparent anomaly: for, any excess of muriatic acid decomposing a corresponding quantity of citrate of soda, more of that salt is needed in proportion to the free acid present."

* See PHARMACEUTICAL JOURNAL [3] vol. iii., p. 953.

ESSENCE OF ALAN-GILAN (YLANG-YLANG).*

Unona odoratissima.

BY H. GAL.

In a paper presented to the French Academy the author has recorded the results of an investigation of the principal properties of the essence which for the last few years has been known in commerce as Ylang-ylang or Alan-gilan. It is a product obtained by distillation from the flower of the *Unona odoratissima*, an anonaceous tree growing in the Antilles and Jamaica.

The essence has a density of 0·980, at a temperature of 0·15° C. A column five centimetres long rotates a beam of polarized light 14° to the left. It passes over entirely in distillation without leaving any carbonaceous residue, but within very extended limits of temperature, ebullition commencing at about 160° C., and the temperature continuing to rise till beyond 300° C.

The essence is insoluble in water, but entirely soluble in ether; alcohol only partially dissolves it. The insoluble portion taken up in ether appears after the evaporation of that solvent as a semi-fluid, transparent mass. About one fourth of the essence yields this product.

Nitric acid attacks ylang-ylang with great energy, intense vapours being disengaged in the cold, and by the addition of water a resin is obtained presenting a great analogy with that which is formed by oxidation of benzoin by means of the same reagent. Bisulphite of soda is without action upon this essence. Potash, on the contrary, when sufficiently concentrated and used at a suitable temperature, gives rise to a kind of saponification. If the alkaline portion be removed, and a fresh quantity of potash added, and the treatment be repeated until the essence is no longer attacked, a substance is left which is insoluble in water. The aqueous portion, upon the addition of hydrochloric acid, deposits a solid body having a crystalline aspect. This dissolves with facility in boiling water; the solution, being filtered to separate a small quantity of resinous matter, yields upon cooling white pearly plates. This body melts at about 120° C., it volatilizes very readily, and is deposited upon the cool sides of the vessel in shining needles, and boils regularly at about 245° C. These are the physical properties of benzoic acid, and this substance has also its chemical properties. In fact if a small quantity be heated in presence of an excess of lime, an oil is separated which is insoluble in water, and possesses the odour and properties of benzine. Treated with perchloride of phosphorus, an energetic reaction takes place, and the piquant and characteristic odour of chloride of benzole becomes manifest. A few drops of this latter body with alcohol yielded benzoic ether. For greater certainty M. Gal submitted some of this acid to analysis. 0·276 of matter, ignited by means of oxide of copper, gave 0·126 of water and 0·696 of carbonic acid.

	Found.	Calculated.
C	68·7 ...	68·8
H	5·0 ...	4·9

It is, therefore, quite evident that the acid abstracted

* *Comptes Rendus*, June 16, 1873.

from the essence by saponification is none other than benzoic acid. The author believes this to be the first essence which has yielded a like result, that compound having been, hitherto, only met with in balsams.

The part insoluble in potash was distilled with water, and then separated from the water which passed over with it into the receiver. After drying over chloride of calcium, this oil distilled at from 170° C. to 300° C., very nearly as the natural essence. With so great a range of temperature, it was useless to expect to separate from this matter definite products with a constant boiling point; M. Gal, therefore, attempted to ascertain the nature of these bodies, which might be supposed to consist of carbides of hydrogen analogous to those so often met with in essences.

The product was treated with anhydrous phosphoric acid; a vigorous reaction took place, and a liquid was collected which no longer possessed the odour of the essence. Iodide of phosphorus also reacted upon it with great energy, and a liquid was distilled more dense than water, and possessing a piquant odour. These reactions showed that it was an oxygenated substance—or rather a mixture of oxygenated substances—resembling the alcohols in chemical properties.

M. Gal considers it probable that the acid referred to may be considered as forming in the essence benzoic ethers with these alcohols. On the one hand, the acid does not exist in the essence in a free state; and on the other hand, he was unable to obtain any alcohol soluble in water by distillation of the essence in the presence of potash.

THE USE OF TARTARIC ACID IN SOLUTIONS OF MAGNESIA.*

BY E. LEGER.

Since the introduction of citrate of magnesia into therapeutics several attempts, more or less successful, have been made to replace the citric acid, in consequence of its relatively high price. When ordinary tartaric acid is used in combination with magnesia, the solution, at first limpid, quickly becomes turbid, and deposits the greater part of the salt formed. In seeking to overcome this difficulty, and render the solution stable, the author tried successively the various modifications of tartaric acid which are formed under the influence of heat, and found that the use of metatartaric acid leaves nothing to be desired.

When tartaric acid is heated to 170° C. it quickly melts and is transformed into metatartaric acid, which, dissolved in water, is no longer susceptible of crystallization. It forms with magnesia a very soluble tasteless salt, the purgative action of which is more energetic and more constant than that of the citrate, which in many cases is uncertain.

The method of preparation which M. Leger adopts is to heat over a gentle fire a small quantity of tartaric acid in a porcelain capsule,—or, better still, a silver basin,—until it melts, carefully stirring it from time to time. Small portions of fresh acid are successively added, in such a manner as not to cool the mass too much, which might cause it to solidify and burn. The additions are stopped when the vessel is two-thirds full, and the same temperature is continued until the mass which at first is pasty and puffed up becomes completely liquid; large bubbles are formed and burst on the surface; the acid takes a slight amber colour and is then completely modified. The basin is removed from the fire and the contents allowed to cool until the acid can be manipulated without adhering to the fingers; it is then pressed into cakes, quickly cooled, and put into well stoppered bottles, it being very hygroscopic.

In the preparation of the purgative magnesian solution three-fourths of the quantity of water to be used is poured, cold, on the mixture of acid and carbonate of magnesia. The reaction is very brisk, and in less than ten minutes the solution is complete. It is necessary to avoid the use of heat; for the modified tartaric acid brought into contact with water at the boiling temperature repasses immediately to the state of ordinary tartaric acid, and the tartrate of magnesia is precipitated.

The respective proportions of modified tartaric acid and carbonate of magnesia required are two parts of acid to one part of magnesia.

When the acid has been completely modified the solutions will keep for several weeks without alteration. The action of the tartrate of magnesia is much more certain than that of the citrate, and is nearly equal to that of the sulphate. The author believes that this new salt will take high rank in therapeutics, and that this form of tartaric acid will to a great extent replace citric acid.

* *Répertoire de Pharmacie*, June 25, 1873.

ALCOHOLS FROM FLINT AND QUARTZ.*

BY DR. J. EMERSON REYNOLDS,

In appearing before you this evening to lecture on "Alcohols from Flint and Quartz," you will permit me at the outset to explain, and even materially to extend, the title of my discourse.

I do not propose to show that spirits can be extracted from flint and quartz by mechanical processes; but I hope to satisfy you that by indirect and purely chemical means we can obtain from these familiar and widely-diffused minerals, and from native silicates, bodies resembling in chemical action, and even in appearance, the well-known alcohol of wine.

Carbon has hitherto been considered the sole alcohol-forming element; but we shall see that the chief constituent of flint and quartz, namely, silicon, must now be admitted to share in this power, and likewise in the ability to form other remarkable compounds.

In selecting this subject, I have done so in part because this most promising field of research, opened up by the labours of Wöhler, Buff, Friedel, Crafts, Ladenburg, and others, has hitherto been but little cultivated in this country; and also because we find in this new branch of chemical investigation most interesting illustrations of the advantage we may derive from the cautious use of the argument from analogy.

As a preliminary to the inquiry I propose, we may consider very briefly the chemical nature of flint and quartz.

The word "flint" is of very ancient origin, and was often used to indicate any particularly hard rock. In this sense it is employed several times in the Old Testament—first, in the Book of Deuteronomy, viii., 15, and in Psalms, cxiv., 8, where the rock struck by Moses is said to be "of flint." We now use the term to distinguish a well-known uncrystalline mineral, which can be easily shown to be a chemical compound of two so-called elementary forms of matter—oxygen and silicon.

Flint is identical in chemical composition with quartz or rock-crystal, though physically different. The common name of "silica" is given to the chemical compound, and the terms flint, agate, quartz, rock-crystal to the forms in which we meet with this substance in nature.

Having cleared our ground so far, we have to find how the oxygen may be separated from any of those forms of silica, and the element silicon may be obtained. This cannot be directly accomplished, but by indirect means we can obtain the desired results. I have here a quantity of finely-divided flint, mixed with some powdered fluor-spar; when I pour oil of vitriol on the mixture, and apply heat, a colourless gas is obtained, which, when passed into water, produces a highly acid and gelatinous liquid. The gas is a compound of the element fluorine with silicon—the tetrafluoride of silicon—and this, when brought in contact with water, produces an acid called hydrofluosilicic and a quantity of gelatinous hydrate of silica.

* Lecture delivered at the Royal Institution, Friday, May 2, 1873.

The clear acid liquid, when treated with caustic soda, yields this white salt, the fluosilicate of sodium, from which we directly obtain the silicon, as you see, by simply heating with some metallic sodium. In this case, the sodium replaces the silicon, the latter separating, as you observe, in the tube as a dark-brown substance.

Having thus prepared silicon from flint, we are in a position to compare it with carbon, to trace out the analogies which subsist between them, and then to show that some of the alcoholic and other *compounds* of carbon have their strange and interesting analogues in a silicon series.

First, then, we shall compare the elements themselves.

We meet with nearly pure carbon under the well-known forms of charcoal, graphite, and diamond.

We can easily prepare the corresponding varieties of silicon—the amorphous, the graphitoidal, and adamantine. With the aid of the phengascope, I shall now project on the screen images of specimens, in order that you may compare the varieties side by side. I have also on the table a very fine specimen of crystallized silicon, for which I have to thank Messrs. Hopkin and Williams. [The lecturer showed a greatly magnified image of a fine crystallized diamond on the screen; a number of other specimens were exhibited in the same way.]

As might be anticipated, the specific gravity of carbon is lowest in charcoal and highest in diamond. Corresponding differences in specific gravity are observed between the varieties of silicon. The two elements also correspond remarkably in variations of specific heat, with different states of aggregation. The specific heat of the diamond is lower than that of graphite, and the specific heat of adamantine silicon is lower than that of the graphitoidal variety.

We are familiar with the fact that carbon burns in oxygen, producing, in an excess of that gas, the well-known gaseous oxide of carbon, commonly called carbonic acid; charcoal and coke burn readily in oxygen, while graphite is consumed with considerable difficulty, and the diamond is still more difficult of combustion. Amorphous silicon burns as easily in oxygen as charcoal, and forms the oxide silica, the same oxide that we find as flint or quartz.

In this way we can reproduce, so far as composition is concerned, the substance from which we originally obtained the silicon for our experiments. Now, though amorphous silicon is easily burnt, the graphitic and adamantine varieties of the element resemble the corresponding forms of carbon in difficult combustibility. Crystalline silicon may be raised even to a white heat in oxygen gas without burning.

Unlike carbon, silicon in any of its forms easily combines directly with chlorine, producing the liquid chloride which I have in this tube. This is a very volatile body, boiling at 50° C., and is half as heavy again as water. It can also be prepared from silica by heating to full redness the finely-divided oxide and carbon in a current of chlorine. In composition this chloride is the silicon representative of tetrachloride of carbon.

In addition to this chloride of silicon, the discovery of which we owe to Berzelius, another has very recently been obtained by Friedel, which corresponds to a well-known carbon hexachloride.

We next pass to a compound of silicon with hydrogen. It may be prepared in a pure state by means of a rather complex reaction I shall have presently to refer to; but we can easily obtain the impure gas by Wöhler's method, in treating a compound of silicon and magnesium with hydrochloric acid. We thus obtain a colourless, spontaneously inflammable gas, which burns with a bright light on contact with the air. In its pure condition siliciuretted hydrogen is not spontaneously combustible at ordinary pressure, but in a slightly rarefied atmosphere it easily inflames. The compositions of these silicon and carbon compounds are shown in this table:—

SiO_2.	Oxides.	CO_2.
$SiCl_4$.	Chlorides.	CCl_4.
Si_2Cl_6.	,,	C_2Cl_6.
SiH_4.	Hydrides.	CH_4.

The siliciuretted hydrogen is evidently the chemical analogue of marsh-gas, the tetrahydride of carbon.

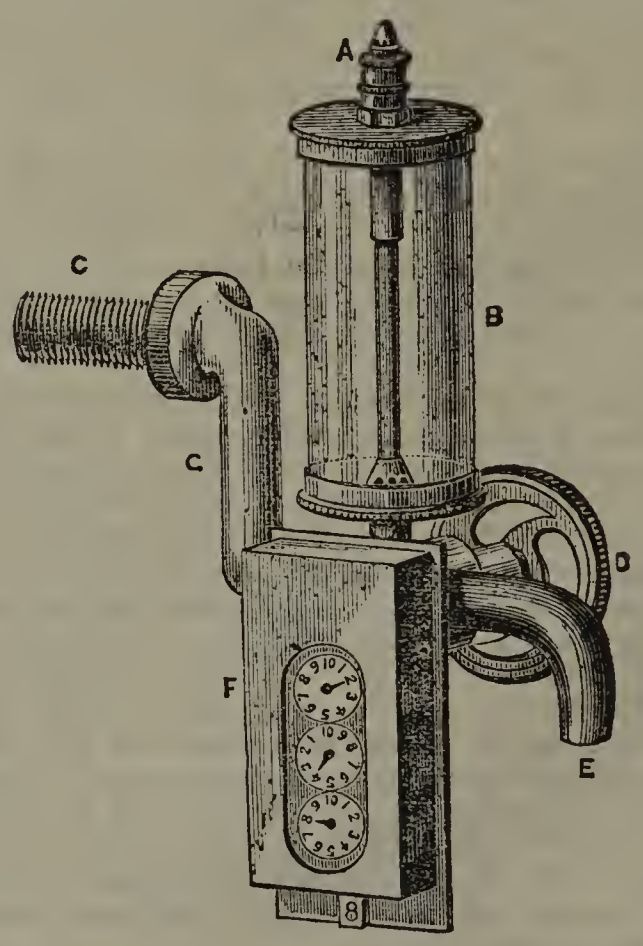
It is usual to regard marsh gas as the typical carbon compound from which some alcoholic series may be supposed to spring, and, in fact, all the alcohols belonging to the group of which the well-known wood-spirit and spirit of wine are the the chief members are commonly regarded as derivatives of marsh-gas, in which a part, or all, the hydrogen has been replaced by one or more compound radicals, such as hydroxyl, methyl, ethyl, propyl, etc. In these cases carbon of the marsh-gas is the grouping element of the compound, or that constituent which serves to bind together the different materials of which the molecular edifice is constructed. In the same way the silicon in siliciuretted hydrogen may be shown to be the nucleus round which can be grouped hydroxyl, methyl, ethyl, etc., so as to form alcohols. Several of the less complex terms are still wanting, but their existence is rendered highly probable by the occurrence of bodies bearing the same close relation to the unknown alcohol that marsh-gas bears to wood-spirit, or the acid of vinegar (acetic acid) to common spirit of wine. As we ascend in the series, however, we meet with the true alcohols, in which silicon takes the place of carbon as the grouping element.

It must be here admitted, however, that no well-defined alcohols have yet been discovered in which silicon acts in any other way than as the nucleus of the compound; carbon radicals in all these cases playing the subordinate parts. But we have every reason to expect that complex alcohols containing silicon only will yet be obtained.

(*To be continued.*)

SELF-REGISTERING MEASURING TAP.

The accompanying woodcut represents a useful improvement in measuring taps. By means of an arrangement similar to that adopted in gas meters, every discharge from the tap, whether it be in ounces or drachms, or any other fixed quantity, according to the size of the measuring glass, is registered on the dial. A check is thus kept on the quantity drawn, and that which remains in the barrel or tank. The contrivance has been registered by Messrs. Dows, Clark, and Co.



The Pharmaceutical Journal.

SATURDAY, JULY 12, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE DRUG TRADE.

THE statistics which refer to our drug trade and its collateral branches during the past thirty years—a commercial period most important to this country—possess features of the greatest interest. They are, too, more especially interesting to chemists and druggists as showing how goods in which they deal in the every-day course of business have progressed as a distinct branch of trade, or whether they have progressed at all. We have before us the statistics giving the exports and imports of drugs, so far as the United Kingdom is concerned, during the past thirty years—say from 1840 to 1870—and we propose to give the most salient points which these figures bring to light. We first begin with our exports of "drugs and chemical products unenumerated," which is the official classification given to these goods in the Government returns. In the year 1840 the declared value of these goods exported was £142,902, which gradually increased until the amount was, in the year 1850, no less than £363,142. From this time the increase was still more rapid, the amount being in 1853 £538,616, and subsequently the trade appears to have increased and expanded with remarkable rapidity. The exports were in 1864, £900,402; 1865, £919,256; 1866, £1,011,506; 1867, £1,068,114; 1868, £1,049,277; 1869, £1,287,453; and 1870, £1,382,786. It will thus be perceived at a glance how remarkable has been the modern development of this branch of our commerce. In the year 1840, as we have shown above, the value of the drugs, etc., exported from this country was only £142,000 in round numbers, whereas in 1870—thirty years after—the amount had increased to no less a sum than £1,382,000—an augmentation of considerably over a million pounds sterling! Probably it may surprise many of our readers, and even those who are more directly concerned in the shipment of drugs, to know that the trade has achieved such rapid progress in modern times as is here shown—a progress as remarkable as it is gratifying. While upon the subject of our exports we may appropriately glance at the export trade in soda alkali, and here again we find a no less astonishing progress than is recorded above. In the year 1840 this article was exported from the United Kingdom to the value of £47,045; in 1850, £375,351; in 1860, £965,348; and in 1870, £1,485,596; and we thus see the results of thirty years' commerce in respect to this commodity. The increase in the trade here shown is certainly astonishing, and amounts to over a million pounds sterling as a clear gain in this branch of the business during the three decades under notice. The subject of the rapid development of England's foreign commerce of late years was eloquently alluded to by Mr. GLADSTONE in a recent speech; and such facts as we here show, concerning as they do comparatively minor goods, bear out the truth of the Prime Minister's observation that our trade is not increasing gradually and slowly, but by "leaps and bounds." In respect to drugs and chemicals, this is specially the case, and must be an interesting fact to the readers of this Journal.

The statistics giving the exports of opium from this country during the past thirty years are well worthy of passing notice. Here again the inevitable law of increase appears to go on, testifying to the indomitable principle of British commerce. In the year 1840 our exports of opium only reached the small total of 35,848 lbs.; in 1850 they were 87,451 lbs.; in 1860, 98,072 lbs., and in 1870, 150,414 lbs. Thus it will be seen from these few figures that the export trade in opium has grown into much greater importance in present times than as compared with what it was formerly. From 35,000 lbs. to 150,000 lbs. is not a bad increase to have occurred in such an article during a period of thirty years, and is a sufficient refutation of the erroneous arguments of those who assert that the commerce in this article is entirely stagnant, and quite unsusceptible of improvement. Speaking in a comparative sense, this trade is, of course, small; but, speaking again comparatively, the increase shown above is certainly noteworthy. It is a fact also that, while the declared real value of the exports of opium from the United Kingdom was in the year 1860 £91,125, it was in the year 1870 £196,165, an augmentation which places the progress of the trade in this article in a yet clearer light. Indeed, it is worthy of remembrance, amongst the notabilia of the chemist and druggist, that the exports of opium from this country are now annually worth something like two hundred thousand pounds sterling and that during the past thirty years the amount has been more than quadrupled. Before finishing our exports of drugs, it may be well to state that in 1840 the exports of Peruvian bark amounted to 1058 cwts., while in 1870 they were 12,785 cwts. The declared value of these exports was in 1856 £110,695, and in 1870, £123,375.

We must next turn to the figures relating to the imports, from which we learn how the trade has gone on in the importation of saltpetre and cubic nitre. In the year 1840 saltpetre was imported to the amount of 304,817 cwts.; in 1850, 271,139 cwts.; in 1860, 329,206 cwts., and in 1870, 295,538 cwts., a diminution thus being apparent. With regard, however, to the imports of cubic nitre, the

case is widely different, as will be seen from the following statistics of the importation: — 1840, 33,000 cwts.; 1850, 257,873 cwts.; 1860, 745,559 cwts., and 1870, 1,132,647 cwts. The augmentation in the imports of this last named commodity is very great, in fact astonishingly so. In 1840 the amount imported was 33,000 cwts., which, as contrasted with the large total of the imports of the year 1870, shows the great rapidity with which this branch of the import trade has progressed and expanded.

WHAT IS A MEDICINE?

What is an adulteration? is a question which has somewhat perplexed many British pharmacists, and it still remains without a satisfactory answer. Our brethren across La Manche are also just now experiencing the truth of the saying that nothing is so difficult as a definition, the all important question to them now being, What is a medicine? The French law confining the sale and dispensing of medicines to pharmaciens has recently been enforced in several cases, but it has been difficult sometimes for the Court to discriminate between articles of medication and those of alimentation. Discussions have taken place at the meetings of various societies, and opinions have been volunteered to assist the judges in coming to a decision, but apparently without securing unanimity, for while the court at Paris has decided that cod-liver oil is a medicine, and has fined unqualified persons for selling it, the court at Douai has decided that it is an article of grocery. To add to the ludicrousness of the position, it has been pointed out that the same law which confines the sale of drugs to the pharmacien also limits the dealings of the pharmacien to drugs, and therefore if cod-liver oil be an article of food its sale in a French pharmacy is interdicted.

THE ROYAL BOTANIC SOCIETY'S FETE.

On Wednesday evening last the Royal Botanic Society gave a grand fête in their gardens at Regent's Park. Unlike the fête of last year, the pleasure of which was marred by a violent thunderstorm, the present reception was a great success every way.

About eight thousand invitations were issued—the fellows themselves numbering between two and three thousand—and the result was a sight which for gay beauty has been seldom surpassed. The gardens were illuminated by one of Gramm's patent lights placed on the anemometer tower; and several other electric lights were displayed from prominent parts of the grounds. Thousands of coloured lights were scattered in every direction, and at intervals the whole was further illuminated by magnesium lights and various coloured fires.

A BOTANICAL FEATURE OF KHIVA.

The Prussian correspondent of the *Times*, in a recent letter describing the physical characters of the steppes and deserts surrounding Khiva, gives the following account of one of the plants indigenous to this district:—

"Excepting one extraordinary plant, as uncanny in its appearance as the character of the entire region, there are no shrubs or trees to be met with even in summer. This plant, the queen of the melancholy family of the *Chenopodiaceæ*, which prevails in the steppe, is the well-known Saxaul (*Anabasis Ammodendron*). A sort of willow, sometimes growing to a height of fifteen feet, and forming whole woods on rivers and lakes, it is probably the most lugubrious-looking tree in the world. It has no leaves, but only small excrescences of a livid hue; it has no ramifying branches, but only thin boughs coming immediately from the stems; last, not least, it does not grow erect, but laboriously struggles up in zig-zag curves, as though it longed to return to the earth, whence it sprang up with such painful effort. Compared to a wood in more favoured climes, a Saxaul copse is an assemblage of hunch-backs and consumptives, wearing mourning for their deceased relatives, whose footsteps they expect speedily to follow. Still the tree makes excellent fuel, and is an inestimable blessing in a country in which there is no other material to kindle a fire. Until lately the Russians heated their steamers on the Aral and Sir Daria exclusively with Saxaul."

RHEEA OR CHINA GRASS.

An advertisement in the *Times* of July 10th, signed by the Under Secretary of State for India, states that an opportunity having presented itself of obtaining the Rheea—"China Grass," or "Ramie"—plant in its fresh state, persons wishing for a supply for the purpose of experiment should apply to the Reporter on Indian Products, at the India Office, without delay. Inventors in this country will thus for the first time have an opportunity of experimenting with the Rheea plant in its green state.

INDIAN OPIUM.

The poppy being exclusively grown for the Supreme Government of India in Benares and Behar, the permission of the Lieutenant-Governor of Bengal has been sought and obtained on the subject of improving its cultivation. The opium manufactured in the Himalayas contains 50 per cent. more morphia than that of the plains of India. This fact was placed on record in the *Journal of the Agri-Horticultural Society of India.*

LIEBIG'S SUCCESSOR AT THE FRENCH ACADEMY.

We learn from the *Moniteur Scientifique* that at the sitting of the French Academy, on Monday last, Sir Charles Wheatstone was elected as a Foreign Associate of that body, in the place of the late Baron Liebig.

MANNA, ETC., FROM PALERMO.

From the consular reports we find that the shipments of manna from Palermo were 1345 cwt., valued at £8189, in 1870, and 2530 cwt., valued at £14,642, in 1871. Most of this goes to France. The trade in essences and essential oils also shows a large increase, having risen from 8890 lbs., valued at £1252, in 1870, to 49,800 lbs., valued at £6620, in 1871. There are five manufactories of concentrated lemon juice and essences in that city which turn out 400 pipes annually.

Provincial Transactions.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

The district round Northampton is not a good one for botanical specimens, the land being cultivated to the exclusion of wild flowers, while the absence of commons and chalky uplands renders it comparatively unproductive; but, though great varieties are not to be discovered, a fair variety of plants may with diligence be found. One of the most favoured spots, perhaps, is Yardley Chase, about eight miles from the town, and this was after a due amount of discussion chosen for the botanical ramble of the above Society.

Accordingly, the few favoured ones who were able started on the 27th ultimo under most discouraging circumstances, the sky being overcast and the horizon covered with nimbus of a most lurid tint, denoting their full charge of electricity. Candid friends had given their various opinions: all arriving with extraordinary unanimity to the fact that the worst possible day had been chosen; but, despite the prophecies of ill weather, it was determined to go, and the company proceeded by rail to Castle Ashby, where the ramble proper commenced, along a road leading to the seat of the Marquis of Northampton, who had kindly given permission for the members to go over the park and gardens. Several spring flowers were gathered, including *Geranium dissectum* and *G. pusillum*, the little *Erodium moschatum*, with its extraordinary long carpophore—whence its common name, stork's bill—being especially abundant. The view to the rear was extremely pretty across the Nene valley, with the old church of Earl's Barton a prominent object in the landscape, and the Nene winding its sinuous course through the numerous mills that impede its progess. By the time the entrance gate of the Comptons was reached the sky had begun to clear, and those members who had with provident foresight brought umbrellas and mackintoshes began to make overtures of business. The mansion was soon in sight, and a gentle walk conducted to the terraces, round which were stone letters for a fence, forming the text: "Consider the lilies of the field," etc.; on which, in striking juxtaposition, some peacocks were displaying their beauties, in vain trying to outshine the floral treasures contained within. The entrance to the old garden having been effected, the enthusiasm and delight of all was aroused by the sight of plants which are but too commonly thrust out to make room for the everlasting rows of pyrethrum, lobelia, and geranium, placed with mathematical exactitude—plants such as comfrey, whose use in bone-setting is sanctioned by Squire; *Chelidonium majus*, the cure for warts; fumitory, hogweed, holy thistle, and large bunches of borage which, with comfrey explained so well the definite inflorescence of a scorpioid cyme; while in the herb garden such old monkish legacies as henbane, angelica, lambs' lettuce, herb burnet, and tarragon were growing luxuriantly.

Down the long walk were masses of *Rheum* in flower, forming a very effective plant; and by the path

> "Foxglove and nightshade, side by side,
> Emblems of punishment and pride."

Solomon's Seal was pointed out as the plant yielding the rhizome sometimes in request after those sweet interchanges of courtesy with which alley life abounds, while its near relation, lily of the valley, recalled vividly Lodore Falls to one at least of the company. Then came the visits to the ferneries and conservatories, and neither few nor far between were the objects of interest and beauty. *Chœmerops*, with its straight-veined variety of parallel venation, the spiral phyllotaxy of the screw-pine, the beautiful passion and trumpet flowers, the giant-leaved banana, the *Citrus Limetta*, *Limonis*, and *Aurantium*, characteristically showing buds, flower, and fruit, on the same plant; the Hoya, which carried back to one's memory a diagram of Bentley, showing the filled up cell by secondary deposits, the stag-horn fern, with an epiphytian mode of existence, the fragrant orchids, graceful tree-ferns, showy azaleas, and fantastic palms, all holding out, and not in vain, some inducements to linger. And then under glorious old trees, sycamores, limes, and birch, under which the rose of sharon was displaying its multifarious stamens, and the rhododendrons made a magnificent show.

Dinner having been partaken of, the following toasts were heartily drunk:—"Success to the Northampton Pharmaceutical Association," "The President, Mr. Hester," "The Secretary," "The Pharmaceutical Society of Great Britain: its late and present President," "The Pharmaceutical Journal and Dr. Paul," "The Principals," and "The Marquis of Northampton." The company then proceeded through the long avenue (three miles) to Yardley Chase, soon separating to search after *Paris quadrifolia*, helleborine, *Habenaria bifolia*, *Listera ovata*, and other desired floral treasures, the way leading through an old quiet forest, over the springy turf, by sedge-lined ditches and primrose-covered nooks, on through fields and pastures, till a group of oaks attract attention and excite curiosity as to which is the Yardley oak, immortalized by Cowper. There, beyond all doubt, is the one, so gnarled, distorted, and hollow, so completely weather-worn, yet putting forth as if in the prime of life leaves so abundantly. Then on, passing Cowper's house and through country as redolent of him as the Trosachs are of Scott, in the distance the River Ouse, with its white water lilies, Weston Underwood, and Clifton Church, Olney's long street and church spire—all interesting and attractive by his aid. Reluctantly at Olney was the ramble completed, long to be remembered for its pleasures, longingly looked back to for its enjoyment and forward for its renewal. By the kind invitation of P. Jeyes, Esq., the members of the Association breakfasted at Holly Lodge on the following Tuesday and Thursday, a very happy morning being spent in looking over the gardens and conservatories, croquet and archery however competing with botanical attractions. Many hearty thanks were given to Mr. and the Misses Jeyes for their kind and graceful hospitality, and to the principals for the extra time allowed.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture I.

Introduction—Inter-relations—Units of Measurement, etc.

"Imponderables," as a technical term, was in the last century a name given to those fluids which were supposed to convey electricity, light, heat, etc.; and because these fluids could not be isolated and weighed, all that men received through their agency were also named "imponderables." These phenomena are now regarded as being due to motions in ponderable matter, and they are considered rather as forces causing motion in this matter than either as a fluid, or as that which can be conveyed, *i.e.*, carried, by fluids. The term is, however, retained as a brief mode of expressing the subject of this course of lectures, especially as no one can confidently assert that it may not again be reinstated in the position it once occupied.

The "energies of the imponderables," then, is a phrase comprehending all results of those unseen, unknown, and by man unweighable powers which pervade space. By

* Cantor Lecture, delivered February 3.

such powers the very sun, and planets, and stars are so influenced that they move in harmonious union or oneness, and, therefore, the name universe is applicable. With this extensive view of the influences and actions of the imponderables these lectures are not to be concerned. The bounds of them are, however, easily defined. This earth and that which man can utilize upon it are our limits. Even when thus "cabined, cribbed, confined" to the earth and the handiwork of men, still, those who have perused and thought over the title, viz., "The Energies of the Imponderables, with especial reference to the Measurement and Utilization of them," may have commented upon it in spirit, saying, "Fools rush in where angels fear to tread." When body, form, and fashion were first given to the scheme of this course, that great was the presumption, and that great, therefore, would be the failure, were not unknown feelings.

The causes of such views are simple and easily made clear. The energies of the imponderables have in one form or another occupied the attention of the most thoughtful as well as the most practical men in every age. They may not have given this name to the subject of their investigation, but, call it what you will, the ultimate source of all power that nature gives to man is to be found in the energy of one or more of those unknown agents to which the name of imponderables has been given. To dwell upon this now would be to anticipate the series of lectures. It may suffice to state that the object of the course is to bring before you illustrations of the modes in which men have been led—or are now being led—to define not only the ways and varieties of ways in which each imponderable acts, but also to estimate by those measurements to which men appeal in material things, the amount or value (if the word be preferred) of that work in material things done by these imponderable elemental powers. To do this involves references, perhaps, in few words, to conclusions at which a life of self-devotion to one cause may have arrived, that life, too, being aided by the very highest of cultivated mental intelligence and the capability of employing such powers of scientific research, the very alphabet of which is beyond the attainment of the majority of men.

Whilst thus frankly, and at the outset, admitting how high a class of mind is required for these original investigations, it must not be overlooked that the principles which have governed the researches of these men, and the conclusions at which they have arrived, may be appreciated by many minds.

When the late Mr. Faraday was discoursing "On the Conservation of Force," he made a statement in relation to an observing and a mathematical mind which will have more weight by your generalization of his words than by my dilution of them. Hence this quotation :—

"It may be supposed that one who has little or no mathematical knowledge should hardly assume a right to judge of the generality and force of a principle such as that which forms the subject of these remarks. My apology is this :—I do not perceive that a mathematical mind, simply as such, has any advantage over an equally acute mind not mathematical in perceiving the nature and power of a natural principle of action. It cannot of itself introduce the knowledge of any new principle. Dealing with any and every amount of static-electricity, the mathematical mind can and has balanced and adjusted them with wonderful advantage, and has foretold results which the experimentalist can do no more than verify. But it could not discover dynamic-electricity, nor electro-magnetism, nor magneto-electricity, or even suggest them; though, when once discovered by the experimentalist, it can take them up with extreme facility. So, in respect to the force of gravitation, it has calculated the results of the power in such a wonderful manner as to trace the known planets through their courses of perturbations, and in so doing has discovered a planet before unknown. There may be results of the gravitating force of other kinds than attraction inversely as the square of the distance, of which it knows nothing, can discover nothing, and can neither assert nor deny their possibility or occurrence." *

Influenced by such views as these, it seemed that no disrespect to the highest intellect could accrue from an attempt to make clear, even to the lowest, a few of the fundamental principles from which important truths have been evolved. It must be borne in mind that to illustrate the modes by which these energies have been measured and utilized, and not to make any attempt at measuring them, is the leading principle which, thus early enunciated, may prevent misconceptions of the title.

The very words, "Energies of the Imponderables," are to some minds terms and not realities—symbols, like political watch-words, serving only to classify their professors—things for *savans* to discourse upon—provinces in that intellectual dreamland in which natural science is supposed to dwell. To the majority of men, to those who toil for their daily bread, and with all their toiling find but scant supply, the monastery of science, in which her monks live apart from the world and all its vulgar cares, seems a paradise in which is no unrest. Such is only one of many thousand delusions. Within the thinly-peopled world of those who investigate the laws of nature there are all the pleasures and pains which meet the labourer with his spade, the mechanic with his tools, the merchant in his office, or the statesman in his cabinet. It is because students and investigators of nature's laws live much alone —because they cultivate a species of clanship—because there is amongst them a kind of Hindoo caste—that they are seldom in contact and companionship with the toilers in material things. This is much to be regretted. Although both parties are losers, yet the toilers in material things are by far the greatest losers.

Such men as these are the true pioneers of the human race, and that army is ill-directed which allows the work of preparation done by its pioneers to be so far in advance that the mountains they had levelled were again piled up, the rivers they had dried were again flowing, and the thorns once cleared from the desolate prairies were again rendering the ground unfertile. The men of science are they who give the sap of vitality to the tree of commerce. Society plucks the fruit and seldom waters the plant. Such has been, and such still is, the case with investigators of natural science, if the men amongst whom they live take the fruit and care neither for the gardeners nor the garden.

Look at the world! the beautiful glass in some of our stained windows is a lost art. Look at the temples in India, illustrations of which the photographs so truthfully reproduced in this room a few weeks since. Civilized Europe and self-satisfied England cannot, either by their St. Peter's at Rome or those recent productions which we are bound to recognize as the highest attainment of national architecture — the Albert Hall and adjacent memorial—approach even at a distance. These temples of a religious profession, with which we are not even acquainted, and of which no records remain, abound in an architecture with which neither in its conception nor in its detail have we aught to compare. And of the materials the men of that age used, we may say the stone is stone still; the sharpness of the carvings is sharpness still.

Is all our dolomite a bastard dolomite? Why are we in England obliged to seek for Italians to form our moulds—to pour in the clay, and to sculpture the marble? Why do we go to Germany for our draughtsmen, our science, and our music, and to France for our adornments and our designs?

One illustration of the neglect of obviously social gain from want of scientific attention cannot, in this room, be out of place?

The Society of Arts was founded in 1753, and when the scientifically practical and theoretical minds of Count

* P. 364, 'Proceedings of Royal Institution,' on 27th Feb., 1857.

Rumford and others considered on what basis and why the "Royal Institution of Great Britain" should be founded, they expressed the objects of thus founding a Society, which should supplement the work of the Society of Arts, in the following title-page to the charter of 1800 :—

"Royal Institution of Great Britain, for Diffusing the Knowledge and Facilitating the General Introduction of Useful Mechanical Inventions and Improvements, and for Teaching, by Courses of Philosophical Lectures and Experiments, the Application of Science to the Common Purposes of Life."

In reference to the necessity for so supplementing the work done here by our predecessors, in order to "advance the applications of science to the common purposes of life," the then managers state that "the giving of premiums to inventors, was done by a most respectable society (the Society of Arts), but to diffuse knowledge needed another incorporation."

Whilst admitting how nobly the Royal Institution has done good work, and how generations yet unborn will look back with reverential gratitude to the boons which those who have laboured within its walls have conferred upon men, it is curious to mark how the views of its founders, and the one great purpose of its formation in 1800, are being realized by the Society of Arts in 1873.

In 1800 the managers of the Royal Institution, as their first act, constituted fourteen committees, for the following purposes :—

1. To investigate the various processes used in making bread, with a view to their improvement.
2. To investigate means for producing cheap and nutritious soups for feeding the poor.
3. Improvement of cottages and cottage fireplaces.
4. Improvements in the construction of stoves for warming dwelling-houses.
5. Improvements in kitchen fireplaces and kitchen utensils of private families.
6. Improvements of the most useful articles of household furniture.
7. To ascertain, by experiment, the effects of various processes of cookery upon the food of cattle.
8. Improvement of kitchen fire-places and kitchen utensils used on shipboard.
9. Improvement of lime-kilns.
10. Ascertaining the effects of mixing clay, etc., with coal-dust and cinders, in forming fire-balls and combustible cakes.
11. Improving the composition of mortar and cements.
12. To ascertain the best method of building cottages and farm-houses with earth rammed together.
13. A committee of mechanics for the improvement of useful machines of all descriptions.
14. A committee for improving the various processes necessary in producing iron from its ores, and in working and refining of iron and steel.

Thus did one noble foster-child of this Society prescribe its own duty, and, child-like, neglect that particular duty, and now that the child has attained the age of threescore years and ten, the nursing mother, by gold medals and money rewards, steps forward to complete the work begun by her foster-child, and further, by these annual Cantor Lectures, she now does that which, not being done in 1800, led to the formation of the "Royal Institution of Great Britain."

This comes of the people of a country allowing the science of a country to dwell alone. All advances are first suggested by men who observe and think; they are extended by men who reason and test; they are utilized by men who act.

The pioneers of an army are not the fighting men; sailors navigate the ship; marines do the warfare.

The men who investigate the laws which govern the energies of the imponderables are not the men to utilize and apply them. The practical knowledge—the stimulus of interest—the capital of the manufacturer, are wanting to the philosopher; while the manufacturer, on his part, is equally in want of the general information and accurate reasoning of the man of science. When the commercial element enters, and another object of regard is set up for worship, the man of science cannot serve two masters; he cannot serve science and mammon. The more earnestly and heartily he serves the former, the less he bows to the latter. The service of natural science has within itself far more ennobling mental rewards than mammon can confer.

Longfellow, in his letter to Agassiz, on his fiftieth birthday (28th May, 1857), after alluding to the sacrifice he made of his country and his home, for the cause of natural history, well expresses what he feels who, single-minded, teaches men to read what is still unread in the manuscripts of God. Agassiz is described as—

"He who wandered away and away,
With Nature, the dear old nurse,
Who sang to him night and day
The rhymes of the universe."

And then comes a reward more welcome than money or honours—

"For whenever the way seems long,
Or his heart begins to fail,
Nature sings a more wonderful song,
Or tells a more marvellous tale."

This course of Cantor Lectures, in relation to the energies of the imponderables, is to be an attempt to occupy the border-land between pure scientific research and the ministration to social needs; to tread, in fact, upon neutral ground, to launch our boat upon the Rubicon which divides the provinces of science from those of commerce. It does not aspire to any claim on the nests of science; they who build them are welcome to the imagined and worthless immortality of a name. It does not propound to commerce new modes of amassing wealth. They may keep their wealth who can. But it does seek to bring before those whose daily bread and daily luxuries are derived from science, illustrations of some of the truths on which our daily labour rests. It will try to do this in plain and simple form, divested of those higher studies through which these truths have been in some measure attained, and in a thousand ways extended.

That the work is one worthy of all human intelligence may be inferred from the official document given by the authorities of that incorporation of men who are the real rulers of the earth, properly so-called. Statesmen and politicians may influence the minds and bodies of men, but engineers influence all material things.

The Institution of Civil Engineers, established in 1818, long before passenger railways, telegraphs, etc., etc., were known, and now numbering among its members men in all parts of the globe, clearly and aptly defined the objects of their incorporation in words well fitted to the purposes of our present consideration. They then (in 1818) defined the object of their association to be, "The acquisition of that species of knowledge which constitutes the profession of a civil engineer, whereby the great sources of power in nature—*i.e.*, the energies of the imponderables—are converted, adapted, and applied, for the use and convenience of man."

It may be said, and with some show of reason, when the comprehensive title of these lectures is considered, a little well or completely done is better than much ill or very partially done. As a principle in education this is a truism which the Committee of Council on Education and our various School Boards would do well to adopt and illustrate; but these Cantor Lectures are not to be scholastic lessons; they may teach, but the primary object of them is rather to be suggestive of thought—to give the minds of hearers and readers food for reflection, material for development, to arouse inquiry, to provoke investigation; to leave, in fact, an unsatisfied impression that there is more than the lecturer has expressed—and there is much for hearers and readers to consider. If thus they only lay in the foundations of knowledge, and in rough

and sketchy outline show the superstructure, they will have done good service — they will have stimulated research, and so led to the acquisition of knowledge and a habit of mind more valuable far than any which can be given from this platform to you who sit at ease on those cushioned seats, willing to rest for a while under the delusive spell that the Society of Arts has thus found a right royal road (and perhaps a pleasant one) to learning. Such an unsatisfied feeling in relation to the energies named, and the measurement and utilization of them, it is the object of this course to endeavour to create. If this result be attained, then in those future years, when by individual labour present difficulties are overcome, and light shines where thick darkness now overspreads, there will be cause for thanks, where, perhaps, when these lectures end an unsatisfied longing may alone be found.

Men need but watch the progress of science truths for a few years, or read the development, stage by stage, of any branch of investigation, to be satisfied of this, that with whatever pertinacity and show of reasoning any theory is propounded and established, it rapidly wanes. Astronomical and geological truths and facts, how often and again have they been satisfactorily (?) explained, and yet how soon and how rapidly has one explanation been so crushed out by another, that the first, which by its authors was applauded, is by the upholders of the second ridiculed.

The theories of the imponderables, with which we must occasionally deal or allude to, but with which we are in no degree further concerned, are, day by day, in a transition state. Like the cause of solar heat, or the rotation of the moon, they are a bloodless battle-field, on which, with our increasing love of talking and our decreasing love of working, words may war with words.

A triumphant victory to-day in science theory may be the prelude to an ignominious defeat of the same theory to-morrow. Subject, doubtless, to many dissentient views, the belief that he who propounds theory, and uses theories solely as means or ways by which to convey ideas of how such and such facts may perhaps be brought about, and not of expressing a conviction that the way described is the actual plan in operation, he is the truly wise man. Those who allow themselves to dwell upon the conception and the development of theories, who build theory upon theory, who sometimes pile Ossa upon Pelion, and sometimes Pelion upon Ossa, are not unlike those whom Milton describes—

> . . . . "Who reasoned high
> Of providence, foreknowledge, will, and fate,
> Fixed fate, free will, foreknowledge absolute,
> And found no end, in wandering mazes lost."

Thus it is that the decisions of one age and one day differ from those of another age and another day. Theories, we must remember, are but opinions; with opinions, as such, this course of lectures is not concerned. The facts of nature, so far as they have yet been made apparent, or may be in process of being so, are our province. They change not. To those who have appealed to nature direct, and brought from her exhaustless stores of knowledge some truths that men may utilize, is due the information which is to be brought before you.

The mode by which they have won this knowledge is exactly that pursued in our courts of law and equity, to arrive at the truth on one point and on one point only. Look how long and tedious legal investigations seem, and yet in how few words the result is declared. Guilty or not guilty—Verdict for the plaintiff or verdict for the defendant. One or other of these very brief phrases records the conclusion or the judgment of many days of patient labours and searchings for truths.

To not less careful questioning by men in years past, as well as now current, we owe all we know of the energies, the measurement and utilization of which is to be a feature in these lectures. That cross-questioning of the keenest and clearest kind has been essential, may be inferred from the fact that these energies are so co-related —so mutually convertible—that they merge and change, Proteus-like, one into the other so instantaneously, that no one energy can be conveniently retained alone and in operation. They thus pass and interchange without (to our eyes) a signal from any magician's wand.

The transmutations of the imponderables are accomplished in a way that would have gladdened the eyes of the most profound alchemist, could he have seen as great transmutations in some of the material things in which he worked. For example, whenever energy is lost by resistance heat is produced,* *i.e.*, when the resistance is perfect and complete, admitting of no intermediate state. *E.g.*, if a wheel in machinery does not move easily, the consequence is heat, manifested on the shaft.

If, however, that energy can be converted into an intermediate state, then this state may be assumed—much as light from gas is an intermediate state between chemical affinity and heat. Do what we may, that from which energy results can neither be created nor destroyed.

In the case of blows by impact, as in the tongue of a bell, or the hammer on an anvil, or a clock, or a piano, or on a drum-head, or on a gong, then, whilst doubtless some part of this checked energy is converted into heat, yet a large portion is spent in the production of vibrations in matter, appreciable to our senses, and suggestive of vibrations in molecules, which our senses, aided by physical appliances, have not yet made visible, but which chemical changes, and what to the minds of science theorists of the present day, is conclusive evidence, seem to point as similar vibrations in the invisible molecules and atoms of which it is assumed that bodies consist.

These remarks may suffice to explain that, whilst to speak of estimating an "energy" is easy, yet to estimate that "energy" is an employment which tasks the keenest and most watchful faculties of the human mind, as well as claiming from human hands the production of some of their most exquisite and refined work.

(*To be continued.*)

* In reference to this sentence, Mr. Highton, in a letter published in the *Journal of the Society of Arts* (June 27), says:— "This, of course, is a simple matter of fact and observation; but if such a matter be mis-stated, or imperfectly stated, at the threshold of a science, all its conclusions become erroneous, or, to say the least, only partially true. Now what are the real facts as proved by experiments? The destruction of energy may produce heat, or cold, or neither; that is, it may produce an equal quantity of both, so that in the result there is no variation of temperature. Thus a weight falling on a mass of metal produces heat; if its fall be checked by elastic wires it produces cold; If the two be combined, equal quantities of heat and cold may be produced. Conversely, a weight falling on a lump of india-rubber produces cold; if its fall be checked by an elastic string of india-rubber it produces heat. If its fall condenses air it produces heat; if it be so contrived that it expands air it produces cold; if it compresses water above 42° F. it produces heat; if below 42° F. it produces cold; if at 42° F., it produces neither heat nor cold, or perhaps equal quantities of each. An electric current passing through wires usually produces heat, but the wires through which it passes may be so arranged that it shall produce cold.

It is quite plain that if a true science of energy is to be built up, the whole of the facts must be taken into consideration. Partial facts can be the foundation of only a false science. The experiments on which only a true theory can be built have hitherto been comparatively few and one-sided. If the theories of Joule, Sir W. Thomson, and other great men, as they undoubtedly are, have been too hastily accepted in their completeness, and too wide generalizations drawn from partial facts, it is the part of true scientific greatness to pull down a too hastily constructed building, and to lay fresh foundations in more numerous experiments. The scientific world ought to be looking forward with interest to the time when the Committee of the British Association appointed to report on this subject will at length break their long silence of three years and a-half, and either give us a theory which will bear full investigation, or at least confess the imperfeetion of the present theories."

HOUSE OF COMMONS.

Trades Marks' Registration Bill.

On Monday evening Mr. Gladstone stated that it was not intended to proceed any further with this Bill during the present session.

Juries Bill.

The second reading of this Bill has been again postponed until Friday, July 11.

Shop Hours' Regulation Bill.

This Bill is set down for second reading on Thursday, July 10.

Poisoning by Arsenic.

An adjourned inquest on the body of Henry Charles Horner, an errand boy in the employ of Mr. Lewis, chemist, High Street, Portsmouth, was held before W. H. Garrington, Esq., at the Hospital at Landport, on Wednesday, July 2. From previous evidence it had appeared that about three weeks ago Mr. Lewis heard what he supposed was a rat behind the drawers of the counter, and having taken out one drawer, a packet of Chapman's Wheat Flour, the corner of which had had been opened, was found. A morning or two afterwards Mr. Lewis handed the packet to the deceased, his errand boy, directing him to throw it away. The lad, however, took it into the kitchen and asked the servant girl to boil some for him. She did so, and the boy took about three spoonfuls. The girl also partook of some; and both noticed that the flour was "hot to the taste." Shortly afterwards they were taken seriously ill. Emetics were administered, and the boy, who was the worse of the two, was taken in a cab to the Hospital, where, after remaining a few days, he died. The girl recovered. It appeared that Mr. Lewis's predecessor (Mr. Pasmore) had some twelve months ago put arsenic into a packet of corn-flour in order to kill the rats with which the house was infested; and though he states that all which was not eaten was subsequently removed, the evidence suggested that Mr. Pasmore must have been mistaken. Mr. Pike, surgeon, who made a *post-mortem* examination, expressed his belief that death had been caused by some irritant poison, which had produced inflammation of the stomach and bowels, but he was unable to state positively whether that poison were arsenic. The inquest had been accordingly adjourned, in order that an analysis of the contents of the stomach might be made.

Mr. William Royston Pike, surgeon, said since the adjournment of the inquest he had made an examination of a small quantity of the contents of the intestines, and an organic analysis of the stomach, liver, and intestines. In the stomach and intestines, and contents of the latter, he found no traces of arsenic; but the organic analysis of the liver afforded abundant evidence of the cause of death. Arsenic had undoubtedly been taken and absorbed into the system. Examination by the microscope also showed numerous crystals of arsenious acid in the liver. He was not assisted by anyone in the analysis; but the crystals had been seen by the house-surgeon, Dr. Wilson, and others. He had no hesitation in saying from the symptoms before death, the appearances after death, the *post-mortem* examination, and the analysis, that death arose from taking white arsenic, or arsenious acid.

The father of the deceased asked if the Coroner thought it necessary to examine Mr. Pasmore?—The Coroner thought nothing hung on his testimony, and that he would not be justified in putting the borough to the expense of sending for him from Exeter. It was not likely Mr. Pasmore put the parcel where it was found purposely to poison the deceased; and if he came, he would not be bound to answer any questions. He (the Coroner) thought they might assume that this packet was part of the one put behind the drawers, while Mr. Pasmore had the business; but he could have had no *animus*, and could not see into futurity. This was one of those unfortunate events which did sometimes occur.—The father: If you are satisfied, I am.—The Coroner: I am satisfied; and I am anxious that you and the public should be.

The jury eventually returned a verdict that deceased was accidentally poisoned by taking arsenic. The jury also unanimously agreed to an addendum to the verdict, stating that not only was no blame attributable to Mr. Lewis, but that he was much to be commended for the promptitude and discretion with which he administered the emetics, whereby probably the girl's life had been preserved. —*From the Hampshire Telegraph.*

Prosecutions under the Adulteration Act.

The Sale of Cocoa.

At Marylebone Police Court, on Thursday, July 3, several grocers were summoned by the Vestry of St. Pancras, before Mr. D'Eyncourt under the 3d section of the Adulteration of Food Act for selling cocoa adulterated with sugar and sago. Mr. Cooper, solicitor, prosecuted; Mr. Willis, barrister, and Mr. Haynes, solicitor, appeared for the defendants. Evidence of the purchase of the cocoa was given, and the certificate of Dr. Stevenson, the analyst, put in. Mr. Willis contended that the cocoa was not mixed with the sugar and sago for the purpose of increasing its weight or bulk, but to render it what was called soluble, and give it a quality which it would not otherwise possess. Mr. Charles Stevens Reynolds, a partner in the firm of Barry and Co., mustard manufacturers, etc., of Ropemaker Street, Finsbury, was then called. He said there were three kinds of cocoa—nibs, flake, and soluble. There was a much greater quantity sold in the soluble form than in the nib, the proportion being fifty tons of the former to one ton of the latter. The sugar and sago were not added to the cocoa for the purpose of increasing its bulk, but to produce an article that the public would more readily buy and drink. Mr. D'Eyncourt remarked that although the defendants had not conformed strictly with the Act of Parliament, yet he was of opinion that the sugar and sago had not been added to the cocoa for the purpose of fraudulently increasing its weight. The summons would therefore be dismissed.—*Times.*

Adulterated Mustard.

On Monday, July 7, Mr. Edmund Shemeld, a grocer, carrying on business at 160, Westminster Bridge Road, was summoned to the Southwark Police Court by Mr. Roffey, the Vestry Clerk of Lambeth, under the third section of the Adulteration of Food Act, for selling adulterated mustard. Mr. Coxhead, one of the sanitary inspectors, said that on the 13th ult. he purchased of defendant, at his shop, a quarter of a pound of mustard, for which he paid him 4*d.* Witness told him he intended to have it analysed, when the defendant said it was not genuine, as the public would not like genuine mustard. Witness told him he had not declared it mixed. Dr. Muter, after analysing the mustard, certified it to be mixed with turmeric and inferior flour. However, it was not injurious to health. The defendant said that all cheap mustard was mixed, and he generally put a label on, "This article is sold free from any injurious mixture." Mr. Partridge told him that would not do, and fined him 40*s.*, and 4*s.* 6*d.* costs.—*Times.*

PAPERS PRESENTED TO PARLIAMENT.

International Metric Commission at Paris.

A report to the Board of Trade upon the formation and proceedings of the International Metric Commission at Paris, 1869–1872, made by the Warden of the Standards, one of the delegates from the United Kingdom, has been presented to Parliament by command of Her Majesty.

The objects of the appointment of the International Metric Commission at Paris were wholly and exclusively of a scientific character. They consisted of the construction and verification, with all the best appliances of modern science, of new international standards of the metre and kilogram ; together with a series of authoritative copies of those standards, uniform in construction and identical in value, for the use of the several countries who have adopted or contemplate the adoption of the metric system ; thus establishing it anew upon a scientific basis, and affording the means of making it by the common accord of all the countries interested a *de facto* uniform system of international weights and measures.

The first meeting of the French section of the Commission took place on the 9th of November, 1869, and their meetings were continued weekly until the end of May, 1870, when a general meeting of the Commission was called together on 8th of August, 1870.

In the meantime, war was declared between France and Germany, and although there was a numerous meeting of the delegates from the several countries on the day appointed, the German members were necessarily absent. The Commission was then inaugurated. The veteran M. Mathieu, who had been secretary to the Metric Commission of 1812, was appointed president of the Commission ; MM. Struve, Miller, Henry, and Herr, vice-presidents, and MM. Hirsch and Tresca, joint secretaries. Under the existing disturbed state of affairs at Paris, it was at once decided that no definitive resolutions should be adopted until the whole Commission could assemble at a more favourable period. Nevertheless the members held several meetings, and fully discussed the principles upon which the new standards were to be constructed and verified, as a preliminary study. This discussion was much facilitated by the results of the previous labours of the members of the French section, who had laid the foundation of future operations by experiments in metals and their alloys, for ascertaining the best material for the new standards, and in the preparation of new instruments and apparatus for their comparisons.

The *Procès-Verbaux* of the meetings of the French section were laid before the Commission, and the French members were requested to continue their valuable labours and investigations. A committee of preparatory researches was appointed by the Commission, consisting, in addition to the French members, of some of the representatives of other countries, who were the most practically conversant with the various technical details of the comparison of standards. This committee was requested to examine into the best methods of carrying into effect the objects of the Commission, and to make all the necessary preparatory arrangements for the meeting of the Commission so soon as circumstances would allow their being called together. The Commission adjourned on 13th August.

After the conclusion of the war, and when a calm had been re-established at Paris, the French section of the Commission resumed their labours on 1st December, 1871. They continued their weekly meetings until the end of March, 1872, when the committee of preparatory researches was called together for the purpose of completing all the preliminary arrangements for the general meeting of the Commission.

This committee met on 2nd April, 1872, and sat daily until 13th April. The printed *procès-verbaux* of these meetings fill ninety 12mo pages. After a full discussion of the several subjects which would require to be decided by the Commission, it was resolved that a general meeting of the Commission should be called together in September following, and the questions to be proposed for deliberation and decision were formally drawn up under twenty-three separate heads.

Of the questions so formulated, 1 to 14 related to the new international metre ; 16 to 23 to the new international kilogram, whilst 15 had for its object the creation at Paris of a permanent international bureau of weights and measures, under the direction and control of the International Metric Commission.

The meeting of the International Metric Commission took place as proposed, on 24th September, 1872, and was very fully attended. Meetings were held daily until 12th October. The twenty-nine countries who took part in this scientific commission, and their fifty representatives, were as follows :—Germany (Professor Förster ; including, also, for Bavaria, Professor de Jolly, and for Wurtemburg, Dr. Steinbeis). Great Britain (Sir G. B. Airy, K.C.B. ; W. H. Miller, F.R.S. ; H. W. Chisholm). Argentine Republic (M. de Balcarce). Austria and Hungary (for Austria, Dr. J. Herr and Dr. Von Lang ; for Hungary, E. de Krusper, and C. de Szily). Belgium (H. Maus, M. Stas, and M. Heusschen). Chili (C. Gay). Columbia (T. el Caïcedo). Denmark (M. Holten). Spain (General Ibañez). United States of America (Professor J. Henry and Mr. Hilgard). Republic of the Equator (A. y Montufar). France (M. Mathieu, General Morin, M. Le Verrier, M. Faye, M. Fizeau, M. H. St. Claire Deville, General Jarras, E. Becquerel, M. E. Peligot, and H. Tresca). Greece (M. Soutzo). Italy (Marquis Ricci and M. G. Govi). Nicaragua (Michel Chevalier). Holland (M. Stamkart and M. Bosscha). Peru (Don P. Galvez and Dr. E. Bonifaz). Portugal (General Morin). Russia (M. de Jacobi, Otto Struve, and H. Wild). Papal See (Padre Secchi). San Salvador (T. el Caïcedo). Sweden (Baron Wrede). Norway (M. Broch). Switzerland (Dr. A. Hirsch). Turkey (Husny Bey). Uruguay (Don M.M. Cervantes). Venezuela (Dr. E. Acosta).

A resolution was at once unanimously adopted by the Commission for constructing the new international metre, the *mètre des Archives* in its existing state to be taken as the point of departure. Considering, too, that the simple relation established by the originators of the metric system between the unit of weight and the unit of volume is represented by the actual kilogram in a manner sufficiently exact for ordinary uses, and that the exact sciences have not the same need of a simple numerical relation, but only of a determination of such relation as perfect as possible ; and, considering also the difficulties that would arise from a change in the actual unit of the metric system, it was decided that the international kilogram shall be derived from the *kilogramme des Archives* in its actual state.

Several of the questions were decided at once, and the remainder were referred to separate committees, each composed of ten members of the Commission, selected as being more particularly conversant with the several subjects, who were to report to the Commission the mode and form in which in their decisions might most properly be made. One of these committees was charged with the duty of examining the defining ends of the mètre des Archives, to ascertain whether or how far the defining surfaces of the metre were altered by contact of instruments in the frequent comparisons made not only during its construction in 1797, but subsequently, or by other circumstances.

The apparatus consisted in the first instance of an excellent microscope, mounted on an iron carriage, with rectangular movement, and having a micrometer for measuring fractions of a *micron* or a thousandth of a millimetre. A simple magnifying glass was also used, as well as the telescope of a cathetometer. Photographs of the ends of the metre were also taken, considerably enlarged.

The mètre des Archives is of forged platinum, no method of fusing platinum having at the time of its construction been known. The bar appeared to be straight, and to have no appreciable flexure round its longitudinal axis. The ends had evidently been finished off, and polished, by an ordinary lapidary's wheel, charged with fine emery and tripoli, the concentric marks of which were left on each surface, showing a radius of curvature of about six centimetres. Around the middle of each end the metal was brighter and of a higher polish, owing to the pressure of contact pieces during comparisons, and it was considered important to ascertain if any sensible

alteration of the length of the measure had thus occurred. But it was found that even here the marks of the original finishing off were still visible, and no perceptible depression could be proved. There was also nothing to show that this higher polish might not have been caused during the original verification of the metre, and consequently that the subsequent scientific comparisons of other metres were made with the mètre des Archives in its existing state. On the whole, it was found that there was no ground for believing that any material alteration had occurred in the length of the metre, and it was believed that its original length could at the present time be determined with certainty from untouched points in the end surfaces.

The material for constructing the metre was the subject of report by another Committee. The material required is one that shall, as far as possible, be unalterable by the action of air, fire, or chemical agents; and that will resist mechanical forces applied to it by friction, compression, or sudden shock. It ought to possess physical properties invariable with time, and be subject to no molecular or spontaneous modifications dependent upon change in the surrounding physical conditions, such as temperature, atmospheric pressure, terrestrial magnetism, etc. To satisfy these requirements, a non-oxidizable material is needed which shall be insensible to the action of ozone, sulphur, chlorine, sulphuretted hydrogen, ammonia, water including sea water, and even some acids and alkalies. It should be capable of resisting the red heat of ordinary fires, and not be acted upon by such heat, so as to anneal it or temper it; in fact, that it should experience no change either in its dimensions or its composition. It ought to be hard enough for the surface not to be easily scratched; its elasticity should be so great that considerable pressure applied to it will produce no permanent change of form; its cohesion should be sufficient to prevent any fracture from even a violent blow; its polished straight surface should render any modification of its normal form at once evident to the eye. The material, if amorphous, should not crystallize spontaneously; and if crystallized, it should be of a regular system, and not liable to a change of crystalline form, which is equivalent to a change of density, and consequently of its length. In order to lessen the influences of the sources of error arising from variations in temperature during the comparisons, a material is required that has a very small co-efficient of expansion. To provide for the international metres being as nearly as possible identical in their material, they should all be produced from one mass, all the parts of which shall be perfectly homogeneous.

After laying down these essential conditions, the first material considered was *quartz*. This satisfied many of the requirements, though its fragility and want of power of resistance to fire rendered it objectionable. But the difficulty, if not impossibility, of finding a sufficiently large and homogeneous piece of quartz, perfect in its axis of crystallization, even for a single metre, much less for the whole number of metres required, constituted an immediate and fatal objection to its adoption.

The objections to glass, in addition to some of those attaching to quartz, were its being affected by moist air tarnishing its surface, and more particularly by changes of temperature altering its molecular and crystalline composition as a tempered body. These changes affect the constancy of its density, dilatation, and even length; a glass metre, like a steel metre, becoming shorter by time.

Only two of the metals satisfied the requirements for invariability in the material of the metre, gold and platinum. All other metals were rejected, from being injuriously affected by air more or less pure or charged with moisture. Gold was evidently too soft. The choice of platinum might be justified by the state of preservation of the original metric standards. This old hard platinum, however, was not pure, but was mixed with rhodium, palladium, and particularly iridium. It also probably contained arsenic. On the other hand, the new platinum of commerce was too soft for the purpose.

Few alloys when fused and cooled afford a homogeneous ingot, from the difference in density and fusibility of their component metals; in solidifying when cooling, there is a want of uniformity in the molecules of their several superincumbent strata. This constitutes an objection to brass, bronze, and all alloys of copper, zinc, and tin, which also are too dilatable by heat. The sole alloy answering all the conditions is that of platinum and iridium. Not only have these two metals the same system of regular crystallization, and the same density, 21·15; but this is also the case when platinum is alloyed with 10, 20, or 30 per cent. of iridium; and these alloys produce a perfectly homogeneous material. They are the two metals which of all others dilate the least by heat, and it has been proved that the co-efficient of dilatation of platinum containing 10 per cent. of iridium is as nearly as possible identical with that of the mètre des Archives, and that it remains unchanged after great alternations of temperature and lapse of time. Platinum-iridium has been also proved to be extremely hard and rigid, and its co-efficient of elasticity to be considerable, as well as its cohesion or resistance to fracture. It is easily cut with a diamond, and lines $\frac{3}{1000}$ of a millimetre apart, even when magnified from 300 to 600 times, are perfectly regular. If the proportion of iridium is conveniently fixed, the malleability and ductility of the ingot is such that it may be laminated by the hammer, or by pressure into any form required. Platinum is very easily rendered quite pure, and so is iridium. Sufficient quantities of these metals can be readily obtained for all the standards required, the price varying from 700 to 1000 francs (£28 to £40) the kilogram.

It was consequently proposed by the Committee that for the material of the metres, an alloy shall be used of 90 per cent. of platinum with 10 per cent. of iridium; that the measuring bars shall be constructed from one ingot produced at a single casting, and that these bars should be annealed for several days at the highest temperature.

After full discussion by the Commission, and particularly as to some objections which had been raised by Sir G. B. Airy against the employment of platinum, and in favour of the bronze used for the English standard yards, these resolutions were unanimously adopted. It was also decided, for similar reasons, that the material of the international kilogram should be the same, but that kilograms of quartz should be constructed for such countries as required them.

A third Committee reported on the Form and Support of the Metre, the problem being to determine upon a form of bar that with a given quantity of material should possess great rigidity, both in a vertical and horizontal direction, readily take a uniform temperature, and allow other division lines to be marked, if required, between the extreme defining lines.

Another Committee, entrusted with the subject of Thermometers and Dilatation, held that for determining the temperature with a degree of precision exceeding 0°·1 C., recourse must be had to an air thermometer. In all mercurial thermometers, the dilatation of the glass which envelops it being about one-seventh that of the quicksilver renders the reading of the best calibrated thermometers liable to an error of some tenths of a degree. On the other hand, the air thermometer was considered to be an instrument too complicated in construction and difficult of use. The Committee therefore recommended that every international metre be accompanied by two detached mercurial thermometers, carefully compared with an air thermometer, and verified with it from time to time.

On the recommendation of the Committee considering the Normal Temperature of the Metre, and the Weight of Kilogram in a Vacuum or in Air, the Commission resolved that the international metre shall have the length of a metre at the temperature of 0° C., and that the international kilogram shall be determined with reference to its weight in a vacuum.

For the determination of the weight of a cubic decimetre of water, of the methods hitherto adopted it was decided the best was that by the accurate measurement of the external volume of a solid body, and the subsequent determination by hydrostatic weighings of the weight of the water displaced by the immersion of the body in this liquid, that the cylindrical form is that which affords the greatest facilities of construction, if made of sufficiently large dimensions, and that for the definite determination a cylinder of sufficiently large volume be chosen (of 10 litres for instance), so that the condensation of liquid upon the surface shall have less influence on the result.

Among the propositions submitted by the committee on balances and the mode of weighing to the Commission, and subsequently unanimously adopted, was one that a new balance to be constructed so as to give results of the greatest precision, and another that in weighing, both the method of alternation of the weights and that of substitution, with counterpoise of a similar material, shall be employed.

The Commission decided to elect from its body a permanent committee whose functions shall continue in force until the next general meeting of the Commission : this committee, which is to be composed of twelve members, all belonging to different countries, is to direct and superintend the execution of the decisions of the International Commission relating to the comparisons amongst themselves of the new metric standards, as well as the construction of the comparateurs, balances, and all other auxiliary instruments required for these comparisons.

An election having taken place for the members of the permanent committee, those having the majority of votes were found to be as follows :—Messrs. Förster (Germany), Ibañez (Spain), Bosscha (Holland), Herr (Austria), Wild (Russia), Baron Wrede (Sweden), Hilgard (America, U.S.) Morin (France), Chisholm (Gt. Britain), Broch (Norway), Stas (Belgium), Husny Bey (Turkey).

The International Commission also urges upon the several governments interested the great utility of founding an international bureau of weights and measures, having its seat to be at Paris, and maintained by common contributions from all countries who shall be parties to the treaty to be entered into by the governments interested in the creation of the bureau.

The first step in progress since taken has been for the French government to communicate diplomatically with all the other governments interested, and to inquire how many of the new standard metres, either *à traits* or *à bouts*, and kilograms, will be required for each country, in order that all necessary arrangements may be made as soon as possible for their construction. The cost of each platinum-iridium metre, to be repaid to the French government, is estimated at about 4000 francs, or £160, and of a platinum-iridium kilogram at 1500 francs, or £75. The metric standards required for the Standards Department of this country are a platinum-iridium *mètre à traits*, *mètre à bouts*, and a kilogram.

Obituary.

Notice has been received of the death of the following :—
On the 2nd July, 1873, Mr. Stanley Wood, Chemist and Druggist, of Arlington Street, Salford.

THE HALF-YEARLY ABSTRACT OF THE MEDICAL SCIENCES. Being a Digest of British and Continental Medicine, and of the Progress of Medicine and the Collateral Sciences. Edited by WILLIAM DOMETT STONE, M.D., etc. Vol. LVII. January to June, 1873. London : J. and A. Churchill.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

A WARNING.

Sir,—I wish to avail myself of the columns of the PHARMACEUTICAL JOURNAL to put my brother chemists on their guard against a Frenchwoman travelling the country with "a little lamp, without a wick," for sale. This lamp is perfectly worthless, as any one may ascertain who will watch its operation but for a short time.

Madame is very specious; she talks of the chief chemists (mentioning their names) who are her agents in various towns, and states her intention to confine the sale to chemists alone, having been advised that that is the best course to pursue. You soon ascertain, however, that every grocer, ironmonger, and huckster in the district has been visited, and the same tale told. Of course, no less quantity than the third of a gross of the useless article can be supplied. She must be reaping a rich harvest by her venture, my own neighbourhood being deluged with them, but I trust this word of caution will prevent my *confrères* in those towns she is about to visit being victimized by her.

ONE OF THE BITTEN.

[*** In compliance with the request of our correspondent we publish the foregoing as a warning, although lamps without wicks are rather far removed from pharmacy.—ED. PHARM. JOURNAL.]

J. Bower Williams.—We are unable to comply with your request, and cannot say whether the writer of the letter signed "R. T. C. D." would do so. Having marked your letter "private," we are unable to forward it to him unless you so desire it.

P. H. W.—(1) The precipitate is sesquioxide of manganese, resulting from the reduction of the permanganate. This reaction may be due to the presence of organic matter, but it also takes place when water contains other reducing substances, such as nitrates. The presence of organic impurity or sewage contamination in water cannot be determined by means of permanganates. (2) Wanklyn's 'Water Analysis,' or Sutton's 'Volumetric Analysis.'

"*Inquirer.*"—Your prescription would have been dispensed in London without much hesitation. Perchloride of mercury *is* sometimes given in quarter grain doses, and it is milder in its action when decomposed into mercuric iodide held in solution by an excess of iodide of potassium, as in the formula sent.

W. S.—Apply to the Secretary of the Pharmaceutical Society, 17, Bloomsbury Square.

R. J. M.—No, it is *Erigeron acris*.

"*An Assistant*" (Cardiff), is referred to the regulations respecting anonymous contributions.

"*One that has been Bitten*" writes to inform us that an assistant, whom he had engaged with good references, has suddenly left him in an unsatisfactory manner, but we cannot publish the details as reported. Probably, the proper way would be to seek redress through the hands of the police.

"*Euphorbia.*"—(1) Thlaspi arvense. (2) Ononis arvensis. (3) Sisymbrium officinale. (4) Matricaria Camomilla. (5) Euphorbia Peplis. (6) Stachys sylvatica.

"*Inquirens.*"—"How Crops Grow," published by Macmillan and Co.

"*A Pharmaceutist.*"—(1) We know of no satisfactory work on Adulterations. (2) Wanklyn's 'Water Analysis,' and Sutton's 'Volumetric Analysis.'

F. R. Bessant.—The person mentioned is eligible according to the terms of the Pharmacy Act, and the Council of the Society has thought fit to place him on the list of candidates. The statement accompanying the name will enable each elector to judge the merits of the case and vote accordingly.

B. J. Clarke.—Your complaint has been handed to the Secretary. On referring to the paragraph relating to the issue of the Journal, you will see that once a month its publication takes place on Saturday.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. A. W. Bennett, Pocklington, Harper, "Inquirer," "M. P. S.," E. H.

THE CINCHONA PLANTATIONS IN JAVA.

BY JOHN ELIOT HOWARD, F.L.S.

I did not receive till last Friday a pamphlet called 'A Contribution towards the Knowledge of the Cinchona Culture in Java. By K. W. von Gorkom. Translated from Dutch into German by C. Hasskarl.' This paper, which may be considered official, helps greatly towards the understanding of the very important question, "From whence arises the superiority of the Dutch Calisaya tree, proceeding from Ledger's seed, over those raised from the same seed in British India?" I do not say that we have quite a definite answer, but that we are on the way to it, and shall soon, as I hope, get to the bottom of the business. I feel some responsibility to accomplish this, as in reply to an official letter of inquiry from her Majesty's Secretary of State for India, in January, 1872,* I ventured to recommend the cultivation of these superior kinds of Calisaya, and specially of No. V. Calisaya (Broughton).

There is a contrast *now* pointed out between the plants from British India and those which have been raised in Java. "In 1866-7 there were raised 3000 plants of C. Calisaya, from seed obtained from British India. These have *quite an irregular type*, so that their identity with the remaining Calisaya plants may be called in question. Almost all the Calisaya plants raised since 1868, and thus planted out in the open, since 1869-70 proceed from the trees obtained from Bolivian seed. They show themselves *by an unchangeable type and a high percentage of quinine*, so that from this source in a few years distinguished bark for the manufactories may be expected."

The cultivators in Java, having obtained *the real sort*, have been careful to propagate it by cuttings, not trusting to the variable results of the seed. And what is this typical sort? Of this we shall doubtless be informed from Java. At present I can only say that the appearance of the small portion of the bark which I have seen is that of the *Zamba* (as I have said), and its contents in alkaloid, 7·44 per cent. of sulph. quinine, against 7·40, my best among many trials† of this sort, confirms me in this view. At the same time there are so many kindred kinds that we must wait distinct specimens of the flowers, fruit, and leaves from Java. From British India we shall, I hope, receive similar specimens of *their* variety, which for convenience' sake I shall call "*Calisaya red bark*." The botanical specimens which I have from Ootacamund are all *C. Josephiana*. The one plant remaining from those I raised from Ledger's seed is C. Calisaya of a good type.‡ The present paper so completely confirms what I have written that I might have saved myself much trouble if I had received it sooner. It seems that on July 1st, last year, there were altogether 1,507,079 cinchona trees in Java (exclusive of C. Pahudiana). Of these there were 1,090,797 trees of C. Calisaya, including 80,000 C. Hasskarliana. The amount of good Calisaya was, at the very utmost—"1200 plants planted out in the open in 1865-6, in 1866 about 20,000 plants of like origin (obtained from Mr. Ledger) and in 1869 again more than 5000 plants. The first and last sending of the seeds were through Mr. Schuhkraft, at La Paz, in Bolivia,"—so that if my arithmetic is right, there were then 984,597 plants of poor and so called Calisaya against 26,200 real and good trees. I sincerely hope the proportion may be reversed, and this speedily.

Of these inferior sorts Mr. Von Gorkom says: "The old original varieties of Calisaya show a remarkably varying percentage of alkaloids and must consequently be considered more as medicinal barks."

But though of little account for the production of quinine, some of these trees contain (according to Mr. Moens) a *large* amount of *conchinin* (quinidine of Pasteur). This fact, which separates them widely from the genuine Calisaya, turns out most fortunate for the success of the plantations. There is no alkaloid (unless it be aricine) so sparingly produced by the Cinchona as this *conchinin* (whilst *cinchonidine* on the other hand is the most abundant), and, as it happens to be much sought after, it may *soon* reach a price in the market near to that of quinine.

I refer to the original paper for much interesting information, and also for confirmation of what I have written, especially about the C. Pahudiana, which has been planted out in the wild forest, and (as Mr. Von Gorkom justly observes) "what has been obtained from these forest plantations is clear gain. From the C. Pahudiana planted out in the open ground since 1863-4 we have gathered about 5000 kilogrammes of bark." The maximum price in 1872 sale was 5*s.* 4*d.*, and the minimum price in May, 1873, was 2*s.* The whole may then represent at least £1500 already saved from destruction, and I will further add that this tree, "which has now become historical,"* is not unlikely to *improve much with age*, whilst the reverse is pretty sure to be the case (owing to the cinchotannic acid) with the C. succirubra.

* See PHARM. JOURN., March 9, 1872.

† My 8 per cent. trial was from the bark of a *very large Calisaya tree* of I know not exactly what type.

‡ I cannot identify it either with the Zamba or the red variety.

* The following is from Mr. Von Gorkom's account of the Pahudiana. "This sort of Cinchona soon raised a violent contest. Miquel defined it as the worthless *C. Carabayensis*, and remained of the same opinion. Howard examined it carefully and described it as a new kind, to which he gave the name of C. Pahudiana, in order to do honour to the statesman to whom, without contradiction, the paternity of the Cinchona culture belongs. The value of this C. Pahudiana was so strongly called in question, that the Indian Government, moved by the higher authorities, forbade by a decree of 11th Sept., 1862, its further extension." [It increased notwithstanding from 324,343 in 1862 to 909,155 in 1866.] "But whatever may be said of this now historical plant, it has shown that it can be useful in Pharmacy, and that its product can be sold for a considerable price in Europe. In alkaloidal contents it stands certainly near our other barks."

THE PHARMACY OF THE UNITED STATES' PHARMACOPŒIA.

BY WILLIAM MARTINDALE, F.C.S.,

Demonstrator of Materia Medica in University College, London.

(*Continued from p.* 4.)

Glycerita.—Four out of the five formulæ for these are new to the American work, and are taken from the British Pharmacopœia, but the most useful of our preparations of glycerine—*glycerinum amyli* is not inserted, and, shade of Bishop Berkeley! there is not only tar-water—*infusum picis liquidæ*—but there is a glycerite of tar. This is made by mixing tar, first with carbonate of magnesia, treating with two successive portions of a mixture of glycerine, alcohol, and water, and finally it is of course—percolated!

Infusa.—Thirty-one of these are official; they are

generally *macerated*, as it is termed—that of rhubarb is *digested*—with water, boiling or cold, during periods varying from ten minutes to two hours; *infusum quassiæ*, with cold water, stands twelve hours, and *infusum picis liquidæ*, also cold, stands twenty-four hours. The following cold infusions—*infusum angusturæ*, *infusum calumbæ*, *infusum cascarillæ*, *infusum serpentariæ*, and *infusum valerianæ*, may be made by percolation, or alternative processes are given by which they can be made by maceration; *infusum krameriæ* and *infusum pruni virginianæ* are made by percolation only. The infusion of calumba is ordered to be boiled after straining to coagulate and separate by again straining the albuminous matter which calumba contains; this undoubtedly makes the infusion keep much better. *Infusum cinchonæ flavæ* and *infusum cinchonæ rubræ* are directed to be percolated with one fluid drachm of aromatic sulphuric acid and water q. s. to obtain a pint. *Infusum digitalis* is two and a half times stronger than the B.P. preparation, it also contains some tincture of cinnamon. *Infusum gentianæ compositum* is our *mistura gentianæ* made by percolation. There are also infusions (not official in B.P.) of capsicum, thoroughwort, juniper, sage, spigelia-root, tobacco, dandelion, and ginger, all made with boiling water.

Linimenta.—Nine formulæ. *Linimentum aconiti* is made by percolating eight troyounces of finely powdered aconite root with alcohol sp. gr. 0·835 till thirty-two ounces of tincture are obtained, distilling and evaporating this down to seven fluid ounces, and adding a fluid ounce of glycerine. It will be a little stronger than the British Pharmacopœia liniment, and glycerine will be a much more advantageous addition to it than camphor for use as a liniment. *Extractum belladonnæ radicis fluidum* is, I think, intended to represent our *linimentum belladonnæ*. *Linimentum calcis* is eight fluid ounces of solution of lime mixed with seven troyounces of flaxseed (linseed) oil; it is, in fact, the original Carron oil. *Linimentum cantharidis* is prepared by digesting one troyounce of cantharides in half-a-pint of oil of turpentine and straining. In making *linimentum saponis* the soap is first ordered to be dissolved in the water and the other ingredients mixed with this; thus made it will gelatinize at low temperatures, which is a disadvantage in its use on account of the difficulty in getting it out of the vessels containing it.

Linimentum plumbi subacetatis is three troyounces of olive oil mixed with two troyounces of solution of subacetate of lead. *Linimentum terebinthinæ* is made by melting twelve troyounces of resin cerate and adding half-a-pint of oil of turpentine. The other liniments have little interest pharmaceutically. One point in these formulæ for liniments is worthy of notice and imitation—fixed oils are ordered to be weighed, not measured.

Liquores.—*Liquor gutta-perchæ* is prepared by dissolving gutta-percha in purified chloroform, agitating with finely powdered carbonate of lead to separate the mechanical impurities, and decanting the clear supernatant liquor after it has deposited.

Liquor morphiæ sulphatis.—The only official solution of morphia is one grain of the sulphate dissolved in an ounce of distilled water. *Liquor plumbi subacetatis dilutus*—*syn.* Lead Water—contains no spirit. *Liquor ammoniæ acetatis* is ordered to be prepared at the time of use, and it will thus be slightly effervescent. The other official liquors possess more chemical than pharmaceutical interest.

Mellita.—Three preparations, *mel despumatum*, *mel rosæ* and *mel sodii boratis*. A tincture of red rose petals is prepared by percolation and concentrating by evaporation the second portion of percolate to a small bulk, the two are then mixed with clarified honey to make *mel rosæ*.

Misturæ.—Eight preparations. Assafœtida is emulsified with water to make *mistura assafœtidæ*. *Mistura chloroformi* is prepared by dissolving sixty grains of camphor in half a troyounce of purified chloroform, triturating them with the yolk of one egg and gradually adding six fluid ounces of water. *Mistura potassæ citratis*—*syn.* Neutral Mixture—is prepared by neutralizing lemon juice with bicarbonate of potash. *Mistura glycyrrhizæ composita*—*syn.* Brown Mixture, "an exceedingly popular cough mixture" in America,—has the following composition—

Take of—		
Liquorice (commercial extract) in fine powder,		
Sugar in coarse powder,		
Gum Arabic, in fine powder, each	½ troyounce.	
Camphorated Tincture of Opium	fl. ℥ ij	
Wine of Antimony	fl. ℥ j	
Spirit of Nitrous Ether	fl. ℥ ss	
Water	fl. ℥ xij	M.

Mistura cretæ contains glycerine in place of syrup and *mistura ferri composita* spirit of lavender in place of spirit of nutmeg.

Mucilagines.—Four formulæ. *Mucilago acaciæ* is prepared by dissolving four troyounces of gum arabic in eight fluid ounces of water. *Mucilago sassafras medullæ*, principally used as an eye lotion, is prepared by macerating sassafras pith, 120 grains, in a pint of water and straining. *Mucilago tragacanthæ* is made by dissolving tragacanth in boiling water. As I have shown,* it is much more easily prepared by moistening the powdered tragacanth placed in a dry bottle first with a little rectified spirit, adding the requisite quantity of water and shaking briskly till in about two minutes a homogeneous mucilage is obtained. *Mucilago ulmi* is simply an infusion of slippery elm-bark prepared with boiling water.

Olea destillata.—Twenty-four of these are official. The following general tests and mode of preparing them are given in a head note—

"The Distilled Oils, when dropped on paper, produce a greasy stain, which entirely disappears on exposure to a moderate heat. When shaken with water in a graduated tube and allowed to separate, they are not diminished in volume. Dry acetate of potassium, or solid chloride of calcium, is not liquefied on being agitated with them.

"Most of the Distilled Oils are prepared by the following general formula.

"Put the substance from which the Oil is to be extracted into a retort, or other vessel suitable for distillation, and add enough water to cover it; then distil by a regulated heat into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it."

The following not contained in the British Pharmacopœia are official, viz.:—*oleum chenopodii* (wormseed), *oleum erigerontis canadensis*, *oleum gaultheriæ*, *oleum hedeomæ*, *oleum fœniculi*, *oleum monardæ* (horsemint), *oleum origani* (true), *oleum sassafras*, *oleum succini* (in materia medica list), *oleum succini rectificatum*, *oleum valerianæ*, and there is also a pyroligneous oil of tobacco.

Oleoresina.—Six formulæ, viz., those of capsicum cubeb, fern, lupulina, black pepper, and ginger.

* Pharmaceutical Journal, Vol. ix., 2nd series, p. 521

These preparations, as their name implies, consist "of oils, either fixed or volatile, holding resin and sometimes other active matter in solution. Their preparation is very simple, consisting in the exhausting of the medicine employed with ether, by means of percolation, and the subsequent evaporation of the menstruum."* In preparing the oleoresin of capsicum the fatty matter that separates is ordered to be removed, as is also the piperin from that of black pepper and of cubeb. *Oleoresina filicis* corresponds, of course, to our *extractum filicis liquidum.*

Pilulæ.—For these there are nineteen formulæ, which are headed by this note :—

"The practice of sugar-coating pills is approved in reference to pills which are expected to be slow in their operation, but is of doubtful propriety in regard to those intended to act quickly, as the coating retards the solution of the pill matter in the liquids of the stomach."

In fourteen of the formulæ the quantity of ingredients are ordered to be divided into twenty-four pills, two only are ordered to be kept in the mass—*pilula saponis composita* (the same as B.P.) and *pilula ferri carbonatis*—the same as Vallet's Ferruginous Pills. The formula for this is an excellent one, and the preparation much superior to either *ferri carbonas saccharata*, B.P., which is not official in the United States' Pharmacopœia, or to the pill bearing the same name in the British Pharmacopœia. The carbonate of iron is ordered to be precipitated in a weak syrup, and carefully freed from the sulphate of soda, formed in double decomposition, by washing the precipitate also with a weak syrup. It is then collected, mixed with sugar and clarified honey, and evaporated in a water-bath to a definite weight, in which state it will be suitable to form pills. In this process the carbonate will not be so liable to oxidation as in making *ferri carbonas saccharata*, B.P. In the U.S. Pharmacopœia there are also *pilulæ ferri compositæ* : they are nearly the same as the old London preparation, and contain myrrh, etc. *Pilulæ aloes* contain two grains each of socotrine aloes and powdered soap made into a pill with water, q. s. *Pilulæ aloes et assafœtidæ* contain equal quantities of socotrine aloes, assafœtida, and powdered soap, with water, q. s. *Pilulæ aloes et mastiches*—the old Lady Webster's dinner pills—find a place : socotrine aloes, 48 grains, mastic and powdered red rose petals, of each 12 grains, with water, q. s., are divided into twenty-four pills. *Pilulæ aloes et myrrhæ* have aromatic powder in place of saffron in their composition. Plummer's Pills made into a mass with molasses are called *pilulæ antimonii compositæ.* One part of powdered soap with three parts of assafœtida form *pilulæ asssfœditæ.* The following is the formula for

Pilulæ Catharticæ Compositæ.

℞. Compound Extract of Colocynth, 32 grains.
Extract of Jalap, in fine powder.
Mild Chloride of Mercury (calomel), each 24 grains.
Gamboge, in fine powder, 6 grains.

Mix the powders together, then, with water, form a pilular mass, and divide into twenty-four pills.

Copaiba is made into pills by the aid of magnesia recently burnt. *Pilulæ ferri iodidi* are prepared to resemble Blancard's Pills, as nearly as possible ; care is directed to be taken in forming the solution of the iodide of iron, and, in concentrating this, that the iron shall not get oxidized, or the iodine liberated. A little reduced iron is mixed with the solution and incorporated with the mass, which also contains sugar, powdered liquorice root, powdered liquorice (commercial extract), and gum arabic. The pills are ordered to be varnished with an ethereal solution of balsam of Tolu. They should be "devoid of the smell of iodine ; and distilled water rubbed with them and filtered, does not colour solution of starch, or gives it only a slight blue tint." *Pilulæ hydrargyri* are much the same as ours. *Pilulæ opii* have 1 grain of powdered opium in each, made into a mass with powdered soap and water. *Pilulæ quiniæ* contain 1 grain of sulphate of quinine in each, made into a mass with inspissated clarified honey. *Pilulæ rhei* have in each 3 grains of rhubarb and 2 of powdered soap, with water, q. s. *Pilulæ rhei compositæ* have rhubarb, 2 grains, socotrine aloes, 1½ grains, powdered myrrh, 1 grain, and oil of peppermint, one-eight of a minim, with water, q. s., in each pill. *Pilulæ scillæ compositæ* are much the same as the corresponding B.P. preparation.

The proportions in these formulæ have been simplified, and, as compared with our own pharmacopœia, they are not complicated with a quantity of inert matter as, for example, our compound rhubarb pill is, nearly one-third of its weight being treacle. It is generally a desideratum to make pills as small as possible. In the U.S. Pharmacopœia compound rhubarb pill is the only one which contains an essential oil. Powdered soap, as will be observed above, is freely ordered as an excipient, sometimes where quite unnecessary, as, for example, in *pilulæ opii* ; it is rather too chemical in its action to be compatible even with aloes.

(To be continued.)

* Wood and Bache's 'Dispensatory,' 12th edition, p. 1259.

CRYSTALLIZED PROTOIODIDE OF MERCURY.*

BY P. YVON.

In a note presented to the French Academy, the author states that crystallized protoiodide of mercury may be obtained by heating in a sand bath a flask containing mercury and iodine, the latter being enclosed in a small tube suspended in the centre of the flask. With this arrangement, the mercurial vapour being in excess, the crystals obtained have been always contaminated by it ; the first analyses having yielded 64·2 and 64·3 per cent. of mercury instead of 61·16 per cent.

This excess of mercury may be removed by washing the crystals with dilute nitric acid, analysis having given 61·64 and 61·76 per cent. Upon prolonging the action of the nitric acid the crystals become orange red, and that without change of composition.

The process by which the crystallized protoiodide of mercury may be produced in a regular manner is by heating in a sand bath, in a sealed flask, iodine and mercury in the proportions indicated by their equivalents. The temperature should not exceed 250° C. Upon removing immediately the flask from the sand bath, it will be found that the upper part is hung with crystals of a very beautiful red colour, which become yellow upon cooling. The crystals so obtained are well defined, yellow or slightly orange

* *Comptes Rendus*, vol. lxxvi., p. 1607.

and attain sometimes a pretty considerable size, especially when they unite to form spangles, some of which measure 15 to 18 millimetres long. The smaller of these spangles are flexible.

These crystals, submitted to analysis, gave as a mean of three operations

	Found per cent.	Theory per cent.
Mercury	61·17	61·16
Iodine	38·76	38·83

Their crystalline form belongs to the orthorhombic system. Examined by the monochromatic light of sodium these crystals appear to be a clear brilliant green.

Submitted to the action of heat the crystallized protoiodide of mercury becomes red, the change of colour commencing at about 70° C., and the tint deepening more and more, until at 220° C. the crystals are of a magnificent garnet red colour. Upon cooling they reassume their primitive hues. It is curious to compare this phenomenon with that—exactly the reverse—presented by the biniodide.

If heated with precaution the crystallized protoiodide sublimes entirely without decomposition. The sublimation commences at about 190° C.; but at 220° C. the crystals soften, and at 290° C. they melt in a black liquid which commences to boil at about 310° C. If, on the contrary, the protoiodide be heated suddenly, it is decomposed into metallic mercury and a rather clear yellow sublimate. It might have been supposed that this body would be an iodide richer in iodine; but it is not. The following results are given by the author under reserve, in view of the difficulty of obtaining a pure body. The direct valuation of the quantity of mercury abandoned through the sudden sublimation of the protoiodide may be fixed at 8 per cent., this and the following figures being the mean of a great number of sublimations, all of which varied within the limits of 1·5 per cent. The sublimed iodide would therefore contain very nearly $61{\cdot}16 - 8 = 53{\cdot}16$ per cent. of mercury; but 58 per cent. was found. The following are the centesimal proportions of its composition, showing that the sublimate was an oxyiodide corresponding to the formula—

$$Hg_{12}O_6I_7 = 6HgO, 7HgI$$

	Found.	Theory.
Mercury	58	58·11
Iodine	40	39·74
Oxygen (by difference) .	2	2·14

This oxyiodide, soon after its preparation, is of a fine clear yellow colour, and occurs in brilliant crystalline spangles; but these rapidly, and especially in the light, become orange yellow, and at length brick red. They also diminish much in volume, the spangles bend back upon themselves, and then assume a pulverulent appearance.

PREPARATIONS OF WILD CHERRY BARK.

(*Prunus Virginiana.*)

Infusion of Wild Cherry Bark forms the subject of a paper by Mr. J. B. Moore, published in the *American Journal of Pharmacy* for June. He considers that water extracts but a meagre proportion of the bitter tonic principle of the drug, and that an infusion made according to the U.S. Pharmacopœia formula represents only the sedative properties. He says that glycerine is one of the best solvents for the bitter principle of the bark, and associated with water, forms a menstruum admirably adapted for extracting its entire medicinal virtues. He proposes the following formula, which he has found to give satisfactory results:—

℞. Powd. Wild Cherry Bark, No. 60,	℥ss, troy
Glycerine	f ℥ ij
Water, temp. 86°,	
Water,	each a sufficient quantity.

Moisten the bark with six fluid drachms of water, at the temperature of 86°. Allow the mixture to stand for two hours in an air-tight vessel, at about the same temperature. Then pack it firmly in a glass percolator. Mix the glycerine with ten fluid ounces of water at the temperature of 86°, gradually pour the mixture upon the bark, and when it has all passed from the surface continue the percolation with water until one pint of infusion is obtained.

As prepared by the above formula, the infusion is stated to be much darker in colour than as made by the officinal process, and much more bitter; the taste, however, is modified and rendered more agreeable by the glycerine it contains. The hydrocyanic acid odour is also strongly marked in it.

Mr. Moore thinks that the formula might be still further improved by doubling the strength of the infusion; that is, using one troyounce of bark to the pint of infusion instead of half a troy ounce as is now employed. It would greatly lessen the bulk of the dose, which might then be reduced from two or three fluid ounces to two or three tablespoonfuls.

A sample made by the above formula kept without apparent change for about ten days, with the exception of very slight turbidity and a little deposit of resinous or other insoluble matter. The characteristic hydrocyanic acid odour remained apparently undiminished for that period, after which there was a gradual loss of that odour, with an increased cloudiness and deposit; a sample made with double the proportion of the bark kept without visible change, beyond a slight cloudiness and a little deposit, for about sixteen days, retaining its characteristic odour and taste but very slightly diminished for that time. A sample made in strict conformity to the officinal formula, with water alone as the menstruum, exhibited in a very short time a cloudiness, which rapidly increased, and the hydrocyanic odour was entirely lost in four or five days, while the infusion became entirely spoiled and unfit for use in less than a week.

The glycerine not only contributes to its preservation, but also forms a better and more potent menstruum for the solution of the virtues of the bark, and affords a much more active and efficient preparation. The sweet taste of the glycerine also serves to conceal in a measure the bitterness of the infusion, and renders it more agreeable to the taste. Glycerine itself, possessing alterative, nutrient and demulcent properties, is useful in almost all cases in which the infusion of wild cherry bark would be employed; while in no case can there be any possible objection to its use.

The two hours' preliminary maceration in the above process may with advantage be prolonged to five or six hours, time will thus be given for the necessary reactions which develop the sedative properties of the bark to become more complete.

The temperature of the water with which the bark is moistened preparatory to maceration should never be below 86° to 90°, and the maceration should be conducted at about the same temperature, as this temperature serves to promote the reactions referred to above. But care must be exercised not to allow the temperature to much exceed that point, otherwise there will be more or less loss of hydrocyanic acid.

An elegant and valuable combination of the properties of tar with those of wild cherry bark may be formed in the following manner:—

℞. Tar, pure	one pint.
Infusion Wild Cherry Bark .	four pints.

To the infusion, in a suitable bottle, or other air-tight vessel, add the tar. Set it aside to macerate for two or three days. Stir the mixture well with a stick, and shake it vigorously frequently during the maceration. Then filter through paper. The *stirring* is an important part of the process, as it breaks up the tar and thus presents a larger surface of it to the action of the solvent, which enables the liquid to more thoroughly and more quickly exhaust the tar of all that is soluble in it; whereas, if the mixture is simply shaken the tar will often remain in an impermeable mass, the interior of which is entirely inaccessible to the menstruum. When prepared as above directed, and filtered, this infusion is quite a handsome preparation, and, to those who have not an aversion to the taste of tar, it is not an unpleasant one. Glycerine being a good solvent of the medicinal virtues of tar, this compound infusion possesses the properties of the latter in a high degree. It may be administered in the dose of from one to two tablespoonfuls every two or three hours, as required.

This infusion is not so liable to spoil as the simple infusion of wild cherry bark. Being impregnated with the antiseptic properties of tar, it will keep for a long time unchanged, if kept in a cool dark place.

In the late revised edition of the U.S. Pharmacopœia, the Committee of Revision have substituted a "fine powder" of wild cherry bark for the "moderately coarse" one employed in the edition of 1860. This Mr. Moore considers a judicious change.

In a paper on the preparation of the fluid extract of wild cherry bark of the United States Pharmacopœia (*American Journal of Pharmacy*, July), Mr. H. W. Porter proposes to reduce the bulk of material used for developing the latent hydrocyanic acid by depriving the almonds of their fixed oil, which amounts to more than one-half their weight (54 per cent.), and of other matters insoluble in water, amounting in all to nearly three-fourths the weight of the almonds; or, in other words, by extracting from the almonds all that is requisite for developing the hydrocyanic acid represented by the amygdalin of the bark, namely, a nearly pure emulsin.

He prepares a smooth paste of almonds, and mixes with it sufficient benzin to make a fluid mass, transfers it to a long cylindrical percolator and treats with benzin until the drops falling from the percolator contain no fixed oil. The powder remaining in the percolator is then turned out, and laid by to dry in a warm place, where the temperature does not exceed 100° degrees, until the odour of benzin has entirely disappeared. One troy ounce of almonds, when treated in this manner, yielded 160 grains.

The powder is next treated with water by percolation. It is soon exhausted, as the drops from the percolator soon fail to give a precipitate when added to alcohol. A dense solution results, which consists largely of emulsin, and contains small portions of gum and sugar. This dense aqueous solution is then added to some properly concentrated fluid extract of wild cherry, and put aside for twenty-four hours. It is then filtered, and finally sugar or glycerine added.

The final filtration is easily made, the small portions of emulsin and the gum, which are precipitated by the tannin of the fluid extract, do not clog the filter in the least appreciable degree. The use of benzin instead of ether is simply a matter of economy.

The formula Mr. Porter has worked by is as follows: Take of wild cherry bark, in fine powder, sixteen troy ounces; glycerine, eight fluid ounces; stronger alcohol and water, of each a sufficient quantity; sweet almonds, two troy ounces; benzin, a sufficient quantity; moisten the bark with eight fluid ounces of alcohol, and pack carefully in a percolator; add alcohol until three pints of tincture is obtained, from this distil two pints and a half of alcohol, mix the residue with twenty fluid ounces of water, evaporate to twenty-two fluid ounces, pour into a bottle, and add the solution of emulsin prepared from two troy ounces of almonds by the process above described. Allow the mixture to stand for twenty-four hours, filter through paper, and add the glycerine.

ALCOHOLS FROM FLINTS AND QUARTZ.*

BY DR. J. EMERSON REYNOLDS.

(*Continued from page* 30.)

In 1857, Buff and Wöhler obtained a volatile fuming liquid on heating crystalline silicon nearly to redness in a current of dry hydrochloric acid gas. The precise nature of this liquid was unknown until 1871, when Friedel and Crafts published the results of their admirable researches upon Buff and Wöhler's liquid, and showed that it was a mixture of chloride of silicon with a new body, which proved to be the strict chemical analogue of our well-known chloroform, silicon replacing carbon.

$SiHCl_3$. Chloroforms. $CHCl_3$.

This body is a colourless, mobile, and very volatile liquid, boiling at 35° C. I have a quantity of it in this tube. One of its most remarkable properties is that of exploding with great facility when its vapour is mixed with air. I shall now show you the experiment. Ordinary chloride of silicon does not afford an explosive mixture when its vapour is mingled with air.

When this remarkable body is made to unite with anhydrous alcohol, a colourless, ethereal liquid is obtained on distillation, having an agreeable odour, and a boiling-point at 134° C. This body is strictly analogous in composition to a substance obtained by Williamson and Kay, by acting on ordinary chloroform with sodium alcohol.

These ethers may each be regarded as derived from a glycerine or triatomic alcohol, as shown below. Neither of these alcohols has as yet been isolated.

$Si\begin{cases}H\\OC_2H_5\\OC_2H_5\\OC_2H_5\end{cases}$	Formic ethers (tribasic).	$C\begin{cases}H\\OC_2H_5\\OC_2H_5\\OC_2H_5\end{cases}$
$Si\begin{cases}H\\OH\\OH\\OH\end{cases}$	Glycerines.	$C\begin{cases}H\\OH\\OH\\OH\end{cases}$

By the action of sodium on the silicon ether just referred to, we can obtain siliciuretted hydrogen in a state of purity. This is the only known mode of obtaining the pure compound.

Returning to the silicon chloroform, about whose chemical nature we can now have little if any doubt, we next have to inquire in what direction, and how far, we can pursue the analogy between the great pain-killer, discovered almost simultaneously by Soubeiran and the illustrious chemist of Giessen, who has so recently passed away from amongst us, and the curious body that we can obtain indirectly from flint or other form of silica in the manner I have described.

Ordinary chloroform is well known to be closely allied to common wood-spirit, or methyl alcohol, in a way that will be evident on comparing the formulæ. In fact, chloroform is easily obtained by treating wood-spirit with bleaching-powder. We cannot in any simple way reverse this process and prepare wood-spirit from chloroform, but we can do something in this direction, for we are able by the action of caustic potash to obtain from chloroform formic acid, a body which is one of the most remarkable products of oxidation of wood-spirit. The relation of formic acid to the alcohol is shown in the table which follows; and it is there further pointed out that this formic acid should yield an anhydride—a body capable of producing the acid by union with the elements of water. This anhydride is not known, but the importance of suggesting its existence will appear in a moment.

* Lecture delivered at the Royal Institution, Friday, May 2, 1873.

$Si\begin{cases}H\\H\\H\\OH\end{cases}$	Methyl alcohols.	$C\begin{cases}H\\H\\H\\OH\end{cases}$
$Si\begin{cases}H\\O\\OH\end{cases}$	Formic acids.	$C\begin{cases}H\\O\\OH\end{cases}$
$Si\begin{cases}H\\O\\O(SiOH)\end{cases}$	Anhydrides.	$C\begin{cases}H\\O\\O(COH)\end{cases}$

Regarding silicon chloroform from the same point of view, analogy would lead us to look for a simple silicon alcohol similar to wood-spirit or methyl alcohol; but we would not expect the silicon chloroform easily to yield this alcohol directly, though we would be justified in hoping that an acid, corresponding to formic acid, might be obtained. As a matter of fact, no such alcohol has as yet been prepared, even indirectly; but a corresponding acid is very readily produced, and more than this, for the anhydride at present wanting in the carbon series is found in that of silicon. If I pass the vapour of silicon chloroform into water nearly ice-cold, a white solid body is obtained without any evolution of hydrogen, and an acid liquid produced. The white solid then collected, washed, and dried at a low temperature, forms a white, inflammable powder, which was first described by Buff and Wöhler. Friedel and Ladenburg have shown that this remarkable body is the anhydride of the silico-formic acid. According to the results of my own investigations, the acid liquid to which I referred just now contains, in addition to hydrochloric acid, the true silico-formic acid—a body possessing nearly as energetic reducing properties as the corresponding acid derived from wood-spirit. I shall now demonstrate these facts. [The lecturer then exhibited the experiments referred to.]

It will naturally be asked whether the silicon chloroform is capable of acting as an anæsthetic, like ordinary chloroform. But it is only necessary to bear in mind the fact that it is very easily decomposed by water into gelatinous matter, and highly corrosive hydrochloric acid, in order to understand that its inhalation would be attended by the speedy destruction of the lungs of any person persisting in the experiment. Starting from silicon chloroform, then, we have been led, by analogical reasoning in the first instance, to infer the existence of a simple silicon alcohol precisely corresponding to wood-spirit. On testing this induction by experiment, we have obtained answers which are, so far as they go, altogether favourable to the view just stated. In fact, the results are as satisfactory as they can be short of the discovery of the silico-methyl alcohol.

I shall now endeavour to strengthen this position by showing that the existence of three higher members of the alcoholic series has been rendered highly probable by the discovery of closely related bodies, though the alcohols themselves have not been isolated; and, finally, I shall show that the alcohols of still higher terms have actually been obtained.

In the course of their elaborate and able investigation of silicon compounds, Friedel and Crafts discovered that chloride of silicon easily acts upon common alcohol, as I have already mentioned, producing a body which Friedel and Ladenburg have recently shown to be easily attacked by a mixture of sodium with a curious substance contained in this tube—zinc-ethyl. The product, when treated with caustic potash, yields a body which bears the same relation to silico-propyl alcohol that formic acid does to wood-spirit. This relationship is shown in the formulæ—

$Si\begin{cases}C_2H_5\\H\\H\\OH\end{cases}$	Propyl alcohols.	$C\begin{cases}C_2H_5\\H\\H\\OH\end{cases}$
$Si\begin{cases}C_2H_5\\O\\OH\end{cases}$	Propionic acids.	$C\begin{cases}C_2H_5\\O\\OH\end{cases}$

This silico-propionic acid is in this tube, and is a white combustible powder, like the silico-formic anhydride I have already shown to you. It is soluble in warm caustic potash, but not in caustic soda; by which character it can be distinguished from silica. It is only necessary to state that it can be obtained in aqueous solution, and in the pure state, by Professor Graham's valuable dialytic process.

In the amyl term, neither alcohol nor acid are yet known; but by the action of zinc-methyl on chloride of silicon we can obtain a light, colourless, and very volatile liquid, which is silicon-methide, a body that may, for reasons which will presently appear, be fairly considered to stand in the same relation to silico-amyl alcohol that marsh-gas does to wood-spirit. Thus—

$Si\begin{cases}C_4H_9\\H\\H\\H\end{cases}$	Amyl hydrides.	$C\begin{cases}C_4H_9\\H\\H\\H\end{cases}$
$Si\begin{cases}C_4H_9\\H\\H\\OH\end{cases}$	Alcohols.	$C\begin{cases}C_4H_9\\H\\H\\OH\end{cases}$

The researches of Friedel and Crafts have made us acquainted with a body which may also probably be regarded as the hydride corresponding to silico-hexyl alcohol. This compound is prepared by the action of zinc-methide and zinc-ethide in chloride of silicon.

$Si\begin{cases}C_5H_{11}\\H\\H\\H\end{cases}$	Hexyl hydrides.	$C\begin{cases}C_5H_{11}\\H\\H\\H\end{cases}$
$Si\begin{cases}C_5H_{11}\\H\\H\\OH\end{cases}$	Hexyl alchohols.	$C\begin{cases}C_5H_{11}\\H\\H\\OH\end{cases}$

Having, therefore, stated the grounds for inferring the existence of silico-propyl, silico-amyl, and silico-hexyl alcohols, I shall now pass at once to the second-class of evidence, and show that the alcohols of still higher terms can actually be prepared.

In referring to the preparation of silico-propionic acid, it was stated that when chloride of silicon acts upon absolute alcohol a body is obtained which, on treatment with zinc-ethyl and sodium, yields an ethereal product from which silico-propionic acid can be obtained by treatment with caustic potash. If, however, instead of using the caustic alkali we continue the action of zinc-ethyl and sodium, decompose the products with water in sealed tubes, and distil, a liquid is obtained which contains one of the "alcohols from flint" we are in search of. In this tube I have a small quantity of the alcohol, and here you will find its composition stated—

$Si\begin{cases}C_2H_5\\C_2H_5\\C_2H_5\\OH\end{cases}$	Heptyl alcohols.	$C\begin{cases}C_2H_5\\C_2H_5\\C_2H_5\\OH\end{cases}$

You will observe that it is the silico-heptyl alcohol precisely corresponding to a simple carbon alcohol recently discovered by Nahapetian, both being *tertiary* alcohols. We owe to Ladenburg the discovery of this lowest known term of alcohols containing silicon. As you can observe it is a colourless liquid, not unlike the ordinary alcohol of wine. It is insoluble in water, but easily dissolved by spirit and ether. Chemically it acts just like any of the other alcohols, producing ethers, and dissolving the alkali metals to form sodium or potassium alcoholates. When common spirit burns you are aware that its flame is nearly colourless, but I shall now burn some of our alco-

hol from flint, and you will find, particularly when we feed the flame with oxygen, that a bright light is emitted.

Clearly defined though this alcohol is, it does not stand alone, for at least one other compound of the same order is known. It was suggested in 1870, by Friedel and Crafts, that silicon ethide, a body easily prepared by the action of chloride of silicon on zinc ethide—might be regarded as the hydride of silico-nonyl, and should stand in the same relation to an alcohol that marsh-gas does to common wood-spirit, or ethyl hydride to ordinary alcohol. This happy idea, when put to the test of experiment, was fully justified by the result, for, on treating silicon ethide in essentially the same manner that we should adopt in preparing wood-spirit from marsh-gas, a colourless liquid, lighter than, and insoluble in, water is obtained. The boiling-point of this body is 190° C. It yields an ether with acetic acid, dissolves sodium, forming an alcoholate, and, in fact, conforms to the general habits of the alcohols of the series to which common spirit belongs. The compositions of these bodies are thus represented—

$$Si\begin{cases}C_8H_{17}\\H\\H\\H\end{cases}\qquad \text{Nonyl hydrides.}\qquad C\begin{cases}C_8H_{17}\\H\\H\\H\end{cases}$$

$$Si\begin{cases}C_8H_{17}\\H\\H\\OH\end{cases}\qquad \text{Alcohols.}\qquad C\begin{cases}C_8H_{17}\\H\\H\\OH\end{cases}$$

It is thus shown to be precisely similar to the nonyl alcohol prepared by Pelouze and Cahours from American petroleum.

Ladenburg has very recently advanced even beyond the point we have now reached, and has shown that the chloride of silicon can be made to yield two ethers, which correspond, as I may suggest, to silico-nonyl diatomic and triatomic alcohols. Thus—

$$Si\begin{cases}C_2H_5\\C_2H_5\\OC_2H_5\\OC_2H_5\end{cases}\quad\text{or}\quad Si\begin{cases}C_8H_{17}\\H\\OH\\OH\end{cases}$$

$$Si\begin{cases}C_2H_5\\OC_2H_5\\OC_2H_5\\OC_2H_5\end{cases}\quad\text{or}\quad Si\begin{cases}C_8H_{17}\\OH\\OH\\OH\end{cases}$$

In all the preceding compounds it will have been noted that but one atom of silicon is present, and though, as I pointed out in the earlier part of this lecture, the silicon in these cases occupies the chief position as the grouping element, we should much like to see silicon uniting with silicon, and forming a more condensed compound with hydrogen. Happily, however, very important evidence, even upon this point, is forthcoming, for Friedel and Ladenburg have discovered corresponding hexa-chloride, iodide, and bromide of silicon, and treatment of the hexa-iodide with zinc-ethyl enables us to obtain the ethide whose formula is given in this table—

Hydride.	Chloride.	Ethide.
Si_2H_6	Si_2Cl_6	$Si_2(C_2H_5)_6$

It is not improbable that in the last-named compound we have the starting-point of a new series of still more complex bodies, analogous to derivatives of olefiant-gas rather than to those of marsh-gas.

I trust you will now admit that the case I proposed to lay before you has been made out—namely, that we can obtain some alcohols indirectly from flint or other form of silica, and that we have solid ground for inferring the existence of many others.

A rich and beautiful field for chemical research appears to lie before us in tracing out the analogies between the compounds of carbon and silicon, and recognizing the chemical representatives of many of the most complex "organic compounds" in the native silicates which form so large a part of the crust of this earth.

Hitherto in this lecture I have avoided reference to subjects not directly connected with the matter in hand, but, before concluding, I would refer, necessarily in a very few words, to some inquiries in this department of chemistry which have been carried on in the laboratory of the Royal Dublin Society. First, however, allow me to perform an experiment. I have here a glass jar filled with dry ammoniacal gas; when I drop into it some chloride of silicon, a white compound is obtained. This body was discovered by Persoz in 1830, and the composition he assigns to it would, as ably suggested by Dr. Hofmann, represent a mixture of sal-ammoniac with the hydrochlorate of silicon-guanidine. If this white body be ignited strongly in a closed vessel, an infusible white substance remains, which has been examined by Deville and Wöhler, who have shown that it contains silicon and nitrogen, and that the same or similar body can be produced by intensely heating crystalline silicon in an atmosphere of nitrogen.

My examination of this curious body has led me to the conclusion that it is the silicon analogue of cyanogen—a well-known compound of nitrogen with carbon, and the chief constituent of the deadly poison prussic acid. This body, though little affected even at a very high temperature, in the absence of moisture is easily decomposed by steam—silica, ammonia, and hydrogen resulting. A similar decomposition is effected by heating with soda-lime. I may add that, when this singular compound is fused with a small quantity of carbonate of potassium, cyanide and silicate of the metal are produced; in this case, carbon appears to displace silicon.

If, in the experiments with ammoniacal gas, we substitute silicon chloroform for the silicic chloride, a body is obtained from which this compound of silicon and nitrogen can be easily extracted. Now we know well that when ordinary chloroform is heated with ammonia gas, chloride and cyanide of ammonium are obtained, and that under certain circumstances a body called *para-cyanogen* is also produced. Analogy would lead us to anticipate that silicon chloroform would react in a similar manner, and the facts I have hitherto observed justify this inference.

It would be out of place to pursue this subject here, as the results of the inquiry referred to have not yet been published. I have, therefore, now simply shown to you one of the chief bodies to which interest belongs, and ventured to point out the relationship I believe it to bear to some of the well-known and remarkable compounds of carbon with nitrogen.

In concluding this lecture, I need simply remind the audience I have the honour to address that the practical value of scientific research is rarely apparent at first. Who could have suspected that the benzole discovered by the venerable philosopher whose name is so inseparably connected with this Institution would have proved, in the able hands of Perkin and of Hofmann, the chief source of many of the exquisite dyes now largely manufactured in this country? Yet in this, as in a hundred of other instances, the small and apparently useless scientific seedling has gradually expanded into the strong tree, yielding its rich store of useful fruit. Let us hope that a similar future awaits some of the alcohols from flint which have been referred to this evening, and that, in pursuing our studies of the silicon analogues of the more complex carbon compounds, we may be led to appreciate more fully than we have hitherto done the admirable economy and harmony of Nature.

THE ACTION OF WATER ON LEAD.

BY SIR ROBERT CHRISTISON, BART.

The most general results of the author's former inquiries are—1. That the purest waters act the most power-

fully on lead, corroding it, and forming a carbonate of peculiar and uniform composition. 2. That all salts impede this action, and may prevent it altogether, some of them when in extremely minute proportions. 3. That the proportion of each salt required to prevent action is nearly in the inverse ratio of the solubility of the compound which its acid forms with the oxide of lead.

The effect of certain inorganic and organic ingredients of water in modifying the prcservative power of the salts the author did not investigate. This has been made the subject of numerous inquiries and observations by others, chiefly, however, of a desultory nature, some of them much too succinctly described, and some, also, of questionable accuracy.

It has been denied that water acts by reason and in the ratio of its purity ; and it has even been alleged that distilled water itself does not act if really quite pure. The author has, however, invariably found the reverse to be the case, and can assign no other explanation of these statements, except some error in manipulation. For example, a very pure spring water was sent to him from the south of England, with the assurance that it had been found incapable of attacking lead ; but, on making trial of it, he found it to act with an energy not inferior to that of distilled water.

It has also been stated that ordinary distilled water is apt to contain a trace of nitric or nitrous acid, from nitrates incidentally present in the water subjected to distillation ; and that such water, if distilled after the addition of a little potash to fix the acid thoroughly, yields a distillate which has no action upon lead. But when the author prepared distilled water in this way, with great care to prevent the access of impurities from other sources, the only result was that the action was even stronger than that of the ordinary distilled water of the laboratory, and greater, indeed, than he had ever before observed.

An interesting statement has been made by Dr. Nevins, to the effect that some salts appear to allow of a certain action going on when they are present in water largely, although their influence when they exist in very small quantities is to act as preventives. This result the author has sometimes obtained, and has found the action such as might prove dangerous. But its limit requires to be defined ; and there is reason to suppose that the proportion required to *permit* action will be found to be greater than is ever likely to occur in the instance of waters applicable to household use.

It has also been said, but in general terms and without experimental proof, that the presence of carbonate of soda, even in a hard water, takes away the preventive influence of the other salts, and enables the water to dissolve lead. There appears to be some foundation for this statement ; but here, too, it is necessary to fix what is the limit to such influence before its importance can be valued. Moreover, as bicarbonate of soda appears to have no such effect, and this is the usual form of the carbonate in natural waters, the practical importance of the fact is inconsiderable.

The corrosive action of water upon lead has often been confounded with other causes of corrosion, and the water has borne the blame. Thus the true action has been confounded with the corrosive action of potent agents accidentally coming in contact with the metal in the presence of water, as, for example, when a lead pipe has been led through fresh mortar, which is frequently or permanently kept moist, or when lumps of fresh mortar have been allowed to fall upon the bottom of a lead cistern.

The true or simple action of water has not unfrequently been confounded also with the effects of galvanic action. Thus, if a lead pipe or cistern be soldered with pewter solder and not with lead, erosion takes place near the line of junction of the solder with the lead. The presence of bars of other metals crossing lead, or bits of them lying on it, will also develop the same action ; and some facts seem to point to the same property being possessed in a minor degree by some stony and earthy substances. This observation may explain the local erosion sometimes observed in cisterns containing hard water ; since, if galvanic action be excited, it will be increased by the fact of saline matter existing more largely in these waters than in soft or comparatively pure water.

Lastly, some observers have contradicted former statements, because under certain circumstances, which led them to anticipate no action, they nevertheless found lead in water, but only in extremely minute and unimportant proportion. The test for lead, hydrosulphuric acid, when employed in the way now usually practised is so delicate as to detect that metal when dissolved in ten million parts of water, or even more. Facts, however, warrant the conclusion that the impregnation must amount to at least ten times this quantity before water can act injuriously on man, however long it may be used.—*Iron.*

HOMŒOPATHIC PILULES.

With a view of throwing some light upon the question whether the beneficial results sometimes reported as following the use of homœopathic medicines were due to imagination or to the action of a powerful drug, some experiments have been made with the variety of preparations known as pilules, and these are described in the April and July numbers of the *Practitioner*. Pilules are different from globules ; they are about as large as No. 5 shot, and obviously might contain a powerful dose of any energetic substance. The dilution chosen was that known as the second. Each pilule, the average weight of which was 0·6 grain, should accordingly contain 0·00006 grain of the drug. This quantity, in the drugs chosen, is fairly within the reach of analysis.

Sulphate of Copper Pilules.—First sample, no copper could be detected in 100 pilules ; second sample, no copper could be detected in 200 pilules. The quantity of sulphate of copper in the above pilules should have been 0·006 and 0·012 grain respectively. If even as little as 0·0001 grain of the sulphate had been present it would have been detected. These samples therefore contain much less of the drug than they should have done (120 times less in the second sample), and in all probability no copper at all was present.

Corrosive Sublimate Pilules.—It was just possible to detect mercury in 200 of the pilules. The amount was, however, less than corresponds to 0·0005 grain of corrosive sublimate, whereas 0·012 grain of this salt should have been present.

Nux Vomica Pilules.—No strychnine could be detected, even when 300 pilules were employed. Three hundred pilules should have contained about $\frac{1}{10000}$ grain of strychnia. Now, so small a quantity as $\frac{1}{70000}$ grain of strychnia is well known to give distinct reactions to chemical tests, but no reaction could be obtained in the present case.

Aconitum Napellus Pilules.—First sample : no aconite could be detected in 100 of the pilules (weight 80·85 grains). Second sample : same result (weight of the 100 pilules, 96·40 grains). Comparative experiments showed that had these pilules contained as small a quantity even as $\frac{1}{8000}$ of a grain of aconite, it would have been detected with certainty. This corresponds to about the 160th part of a grain of the extract of aconite ; the quantity which should have been present is from $\frac{4}{5}$ to nearly 1 grain, or more than 100 times more.

Belladonna Pilules.—First sample : no atropine could be detected in 100 pilules (weight 80·39 grains). Second sample : same result (weight of 100 pilules, 81·00 grains). Comparative experiments showed that by means of chemical tests alone, as little as $\frac{1}{6000}$ of a grain of atropine would have been detected with certainty. This corresponds to about $\frac{1}{30}$ of a grain of the extract of belladonna, whereas as much as $\frac{4}{5}$ of a grain, or 24 times as much, should have been present.

The Pharmaceutical Journal.

SATURDAY, JULY 19, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

POISONING BY CARBOLIC ACID.

THE numerous cases of poisoning that have occurred, either from design or accidental misuse of carbolic acid, unfortunately constitute too decisive evidence that the application of this material to various purposes connected with daily life is not accompanied with such precautionary measures as are desirable and necessary for preventing accident.

Our readers will find at page 56 the report of another case of this kind, which will serve as an example in support of the view here expressed, and a perusal of the proceedings at the inquest will probably be useful in leading many to observe somewhat of the same caution in selling carbolic acid that they do in selling other materials which are by law regarded as poisons, and therefore must be sold only under certain conditions.

In this case we have another instance of the tendency of popular opinion to read the provisions of the Pharmacy Act, 1868, in regard to poisons, in a much wider sense than is customary among members of the drug trade. As in many previous instances we find here again that the CORONER'S attention was mainly attracted by the 17th clause of the Act, and although reminded that poisons are legally poisons only if included in the two schedules appended to the Act, he still held that from a legal point of view it is absolutely unlawful to sell any poison, no matter whether mentioned in the schedule or not, without labelling it "Poison," and in expressing this as his "decided opinion" he referred to the phrase, "or may hereafter be added thereto," apparently suggesting that if any poisons sold by druggists were not in the schedule, they ought to be put there.

Regarding this part of the Pharmacy Act as a measure for the benefit of the public, it would be unreasonable to deny that there is some cogent reason for the view taken by the CORONER in this case. But we should at the same time be sorry to see the poison schedules of the Act so amplified, and although it is no part of our province to interpret the law, we believe, as we have many times stated already, that the wide reading of the term "all poisons," irrespective of the existing schedules, is an error in point of law. But, nevertheless, the jury appears to have adopted even still more strongly than the CORONER the foregoing opinion, and expressed in the verdict regret that poisons of the kind should be sold without the word "Poison" being written on the bottles containing them.

It is true, the report published in the *Bucks Herald* states that it was generally understood the verdict did not reflect in any special manner on Mr. TURNER, and we are glad to find this publicly stated. But at the same time it would be folly to shut our eyes to the possible damage that may be done to the business of any one who is so unlucky as to have his name connected with such a case. Whether the censures of coroners' juries be well-founded or not, we feel sure that from this point of view every one must desire to be exempt from the penalties they may entail, and on the principle of self-preservation it will be well to consider whether there be not some facile means of attaining such immunity.

In the present case, for instance, it came out in evidence that the purchaser of the carbolic acid "was not aware of the mixture being of so deadly a nature. Had it been labelled 'Poison' he should not have left it where he did." This is highly important, and although, on the other hand, Mr. TURNER pleaded the "custom of the trade" as a justification for not attaching a "Poison" label, that plea—well-founded as it was—did not suffice to command recognition by the jury. Mr. TURNER, no doubt was quite right in thinking he was not bound by law to label carbolic acid "Poison," but as regards his interests, it was a question of human nature rather than of strict law which had to be considered. Would it not, therefore, be desirable for druggists to make a freer use of the "Poison" label, and thus protect themselves from the disagreeable consequences arising from misuse of articles they have sold? The precaution is a simple one at least. As to the argument against the use of the "Poison" label, that it might deter people from having anything to do with articles so labelled, we do not think it is altogether competent for the vendors of such articles to urge that consideration, for the spirit of the Act which gives them an exclusive licence to sell poisonous drugs has unquestionably in view the safety of the public as a primary matter.

We think, therefore, that in the sale of such potent articles as carbolic acid it would be desirable for druggists to make it a "custom of the trade" to attach the "Poison" label. Moreover, we would recommend that in the sale even of such articles as paregoric they should, in the exercise of their knowledge and discretion, sometimes adopt a like course, or at least some similar precautions against accidents in the use of mild opiates for children, such as we have often had occasion to report. By adopting such a course they would, we think, protect themselves, and would also establish some reason for demanding that the sale of drugs should be restricted to those competent to carry it on with due regard to public safety.

SOUND PHARMACY.

In this country it has long been the prevailing opinion among those who best understand the subject that safety in dispensing must always depend mainly upon the intelligence and training of the dispenser, rather than upon such aid as may be obtained from the use of labels and bottles of various shapes and colours. Even when discussion was at its height concerning regulations for the dispensing and keeping of poisons, which the present Government attempted to make compulsory, it was generally conceded that the value of all such contrivances was but slight compared with an intelligent and practical acquaintance with the drugs manipulated on the part of the person handling them. Mr. Haselden, while President of the Pharmaceutical Society, called attention in these columns to the importance of every apprentice having an opportunity of becoming practically acquainted with the Pharmacopœia processes, and suggested that it was the duty of every employer—and not an unprofitable one—as far as possible to practise pharmacy in the laboratory as well as in the shop.

A series of unfortunate accidents in France—such as the substitution of arseniate of potash for the sulphate, of sulphate of zinc for sulphate of magnesia, and acetate of baryta for sulphovinate of soda—has turned the attention of French pharmaciens in the same direction, and some of the opinions uttered during the discussion of the subject have been as applicable to circumstances in this country as those in France.

In a paper on precautions against accidents through the substitution of one medicine for another, M. Baudrimont, Professor of Pharmaceutical Chemistry at the Paris School of Pharmacy, has pointed out that the majority of such accidents as those indicated above have had their origin in mistakes committed outside of the pharmacy. He therefore insists that it is incumbent upon every pharmacist scrupulously to examine every chemical before receiving it into stock, in order not only to identify it, but to recognize any products of alteration or substitution which may be present in it. As to the Galenical preparations, such as the powders, tinctures, extracts, syrups, etc., he considers that every principal of a pharmacy should hold it to be a point of honour never to employ any that he has not manufactured himself, rejecting absolutely preparations of this kind found in commerce.

But M. Baudrimont has other safeguards. Bottles with sharp angles and rugged sides are to appeal to the fingers of the possibly ignorant or inattentive dispenser, and should the spurring of one sense not be sufficient, brown glass, and earthenware painted bright red, red paper, red bags, red drawers, red labels, and a list of poisons drawn up on red paper are to appeal to another. This flaunting of scarlet is to be supplemented by a danger mark to be placed on the prescription by the prescriber, and the keeping of all dangerous substances apart. These expedients, not altogether new, and not altogether neglected in well-conducted pharmacies, M. Baudrimont thinks would render an error practically impossible.

As might have been expected, the programme of M. Baudrimont has elicited criticism which has not always been favourable. The reporter of a committee of the Bordeaux Pharmaceutical Society, M. Martin Barbet, with a frankness scarcely French, expresses an opinion, which he would probably tolerate from no other nationality, namely, that it is to the decadence of French pharmacy, to the insufficient instruction, notorious incapacity and idleness of French pharmacists that the uninterrupted series of accidents has been due. His remarks are worth quoting :—"Where," he asks, "are the pharmaciens who pre-"pare their own distilled waters, their extracts, their "powders, alcoholates, tinctures, etc ?" "Read," he continues, "the remarkable prospectuses of all the "new houses, you will see that they consider them-"selves to be responding to an undisputed want, and "you will find in every line the irrefutable proof of "the degradation into which the profession has "fallen. Under the fallacious pretext of coming to "our aid, while in them it is the bait of lucre, they "sell you fluid extracts for fear you cannot make "them to dissolve ; titrated solutions in case you "cannot calculate ; concentrated products of all sorts, "for the preparation of simple and compound syrups, "alcoholates, etc., because you are no longer apt to "make either infusions or decoctions, or manipula-"tions of any sort. It would not be surprising to see "before long a means for sparing the trouble of "making pills and draughts. And thus we have "allowed the pharmacist to be turned into a mer-"cantile man without initiative and without value."

Beneath the irony of this language there lies a substantial layer of truth, and truth that is at least as applicable, and probably more so, to the pharmacy of this country as to that of France. Of course it will not do to deny the advantages attached to the conducting of some operations upon a large scale. But it will be politic in the pharmacist not to lose sight of some of the most important duties of his calling, and thus sink to the rank of intermediary between the manufacturing druggists and the public. Such must be the natural consequence in proportion as practical pharmacy is discarded from our pharmacies. As a matter of business, each manufacturer will try to attach some special repute to even the pharmacopœia articles of his production ; prescribers will exercise their whims and fancies as to the ingredients entering into their prescriptions ; and more often than now—though now it occurs much too often—the laboratory man will have to be converted into a swift-footed messenger to range over half a town before a mixture can be made up. Those who think this is to be an exaggeration should study the discussions which continually take place

in the American pharmaceutical societies upon the sale of elixirs. Under such a system—the pharmacist being often ignorant of what he is handling—uncomfortable bottles and startling labels might take first rank as educational appliances. But we believe with M. BARBET that the welfare of the pharmacist, as well as the safety of the public, will be best secured by an adherence to healthier pharmaceutical traditions, and the relegation of these expedients to their proper place as mere complementary safeguards.

REPORTS ON THE OLIVE OIL TRADE.

SEVERAL reports upon this subject have been published, from which we glean a good deal of information with regard to the olive oil trade. The British Consul, writing from Corfu (Greece) on the trade and commerce of the past year, states that the export returns of olive oil, the staple product of Corfu, convey no idea whatever of the actual yield of the season—the approximate amount of which is only to be ascertained from the valuation of the exports—which must by law precede the gathering of the olives, and by which the quota of oil payable by the tenant to his landlord in name of rent is fixed and determined. As the present is not a year of crop no estimate has been made. Before the cession of Corfu to Greece, those estimates were returnable to an officer of the government, whose duty it was to enter them in a register kept for the purpose, and to which reference was to be had in the event of any dispute between landlord and tenant. But since the cession this system of collective registration has been discontinued, and has been transferred to the judges of the district courts, with whom the returns are deposited, and by whom the record is kept. The annual exportation of olive oil from Corfu amounts to over 5500 tuns, the greater portion of which goes to Trieste and to English ports. The tun is reckoned to contain sixteen Ionian barrels of sixteen imperial gallons each. The average price of oil during the year varied from 10½ to 11¼ Spanish dollars, or from 45*s.* 6*d.* to 48*s.* 9*d.* per barrel. At the close of the year 600 tuns of the stock-in-hand remained for exportation. From Palermo we learn that the olive oil trade has undergone considerable fluctuation of late. The export of the oil rose from £61,842 in 1868, to £111,908 in 1869, fell in the following year to £39,523, but recovered itself in 1871, advancing to the large figure of £155,900. This, however, is described as a product of most uncertain character, the crop varying greatly according to the season, and rarely continuing good for two consecutive seasons. Olive oil is one of the principal articles of produce available for exportation from the Island of Cephalonia (Greece), and adds materially to the prosperity of the inhabitants. The trade is usually a brisk one. The yield of an average crop is estimated from 30,000 to 35,000 Ionian barrels of 16 imperial gallons. The value of olive oil exported from the Island during the past year was over £15,000. Consul PATON (Ragusa, Austria), writing in reference to the olive oil crop of last year, describes how in a great measure it has been displaced by the advancing popularity in the market of petroleum. He states that the olive pluck of Ragusa last year was a failure, partly from the worm, and partly from the extraordinary deluges of rain which occurred in November and December. Eleven inches of rain, or about one-third of the average total rain of the year, fell on one day in the middle of December, the consequence being that terraces were broken down, trees uprooted, and a large part of the yield not plucked from the tree, but picked up out of the mud. The price has been, moreover, low—viz., 44*s.* a barrel. The fact is, remarks the Consul, that petroleum is now amongst all the populations of the south of Europe doing so much that was formerly done by olive oil, that it is only the extraordinary demand for oil for the purposes of machinery that keeps up the price. This is certainly a significant remark as showing the difference in the progress made respectively by petroleum and olive oil.

SHOP HOURS' REGULATION BILL.

IT will be seen upon reference to p. 56 that the Shop Hours' Regulation Bill has met with the fate to which its native absurdity fully entitled it, and has been withdrawn before it had been discussed in Parliament. This result has been doubtless due as much to the general opposition it has evoked,—in which the Pharmaceutical Society, by its Council, has taken an active part,—as to the late period of the session.

THE TEACHING OF NATURAL SCIENCE IN SCHOOLS.

THE following remark by Professor AGASSIZ on the teaching of natural history in schools is quoted by *Nature* from the *University Monthly*:—"I am satisfied that there are branches of knowlege which are better taught without books than with them; and there are some cases so obvious that I wonder why it is that teachers always resort to books when they would teach some new branch in their schools. When we would study natural history instead of books, let us take specimens—stones, minerals, crystals. When we would study plants let us go to the plants themselves, and not to books describing them. When we would study animals, let us observe animals."

THE USE OF ENAMELLED IRON VESSELS.

M. STANISLAS MARTIN reports that having used an enamelled cast-iron vessel in making a preparation containing citric acid, he was surprised at the end of the operation to notice that the entire surface of the metal had been laid bare. Upon investigation he found that the enamel was composed almost entirely of carbonate of lead.

Proceedings of Scientific Societies.

CHICAGO COLLEGE OF PHARMACY.

An adjourned regular meeting of the College held June 11th, 1873. President Whitfield called the meeting to order. The question of engraving and re-issuing the fire-destroyed certificate of membership was, on motion, referred to the Board of Trustees with power to act.

The Committee on Finance, failing to make a report, on motion, an investigating committee, consisting of the Secretary, Treasurer, and ex-Treasurer, were appointed to examine the accounts.

The following were appointed delegates to the Richmond meeting of the American Pharmaceutical Association, and to the convention of teaching colleges, with power to fill vacancies: Thomas N. Jamieson, Albert E. Ebert, George Buck, E. H. Sargent, and Theo. H. Patterson.

A motion prevailed empowering the Board of Trustees to co-operate with any movement that may be made for holding a convention of pharmacists of the North West during the October Exposition in this city.

The committee on the revision of the bye-laws reported the following changes, which, being separately acted upon, were adopted. The initiation fee and annual dues were each raised from 5 dols. to 10 dols. Life membership to 100 dols. Associate membership to 5 dols. annually, or 50 dols. if paid in one payment.

After making other minor changes in the wording of the bye-laws the business committee moved that a complete list of all the donations received by the College since the fire be published in the *Pharmacist* as soon as an inventory of the same is made.

Mr. E. H. Sargent, in behalf of the committee on the Attfield testimonial, presented to the College an oil painting representing Professor J. Attfield, of London, with the following remarks:

"Mr. PRESIDENT: In behalf of several of our fellow-members, I have the honour and pleasure to present, in their name, to the Chicago College of Pharmacy this work of art, as a fitting memorial of events ever to be remembered—the destruction and re-establishment of this school of pharmacy. And not alone, sir, nor chiefly, does this work of art remind us of events in our own narrow sphere, for the inspiration which gave rise to it had its birth beyond the seas.

"In this picture we present to you, sir, and to our associates, a faithful portrait of one who has for all time endeared himself to each one of us as the benefactor of this College, Professor Attfield, who stands to us as the representative of that noble band of English pharmacists who so generously and so promptly came to our aid, in the time of our great adversity. I cannot, sir, with any words at my command, adequately express the admiration excited by the prompt and effective generosity of our English friends. We owe to their endeavours the present condition and means of usefulness of this College; may we not be sure that so important a result will, in view of the good to be accomplished, compensate in a great measure the generous givers, and prove, more than any words which we may utter, the value and our appreciation of their gift. May we and our successors be ever reminded by this portrait that we have a duty to fulfil: that in receiving we pledge ourselves to bestow, not alone in kind, but in all ways that will aid the unfortunate, nourish the needy, or educate the ignorant. Thus only can we prove ourselves worthy of the confidence and generosity bestowed, or properly use the trust confided to us.

"In conclusion, let us hope that our benefactor and his co-labourers may each receive the reward of the generous giver, and long live to witness the growth of their grateful recipient.

"In placing this truthful portrait of our valued friend upon these walls, let us, with one voice, echo the motto with which we are greeted, '*Concordia soll ihr Name sein*,' and add 'ESTO PERPETUA.'"

The President, Mr. THOS. WHITFIELD, on behalf of the College, accepted the testimonial, responding as follows:

"Sir: As the presiding officer of this College, I have the honour to accept in its behalf the very life-like and handsome offering which you have so appropriately presented.

"In accepting this portrait for the College, I should be doing injustice to those whom I have the honour to represent, and also to my own feelings, were I to pass over in silence the generous action of those who, prompted by the generosity of our transatlantic friends, caused the production of this, to us, touchingly eloquent memorial.

"The College, I am sure, desires to return its grateful thanks to those of its number who were instrumental in honouring it with this portrait of one who must ever occupy a large place in the heart of its every member. Wider spread, better planned or executed, and less ostentatiously displayed benevolence was never known than is represented in these halls, expressing at once the sympathy of our English friends at our calamity, and their appreciation of our efforts in the education of our profession, in a form so tangible that every beholder must be at once struck with admiration. Now we are called upon to accept this the fitting finale, the very counterpart of the originator of this outpouring from our fellow-workers in pharmacy in Great Britain.

"I believe that this College as a body is alive to the importance of the trust reposed in it, and knowing this I feel fully warranted in assuring you, sir, and through you our English as well as our home friends, that it will not prove recreant to the important trust or incompetent to the discharge of its duty.

"We are told that a pebble cast into a body of water causes a displacement co-equal with the water's surface, only limited by its banks. Also, that the vibration communicated to the atmosphere does not die, but 'keeps circling on through infinite space for ever.'

"Now, sir, if these statements are true in relation to causes so minute, who shall dare attempt to measure the influence which this munificent donation—the instigator of which we recognize in this portrait—shall exert on the education of the pharmacists of the present not only, but of the future, throughout endless generations."

It was voted that the portrait of Professor Attfield be placed on exhibition in the Art Gallery of this city, bearing a suitable inscription.

SOCIETY OF ARTS.

ON THE ENERGIES OF THE IMPONDERABLES, WITH ESPECIAL REFERENCE TO THE MEASUREMENT AND UTILIZATION OF THEM.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture I.

Introduction—Inter-relations—Units of Measurement, etc.

(*Continued from page* 36.)

The difficulty of the task results not so much from a solution of the simple problem which the words "estimate that energy" convey, as from the incompetence alluded to of isolating and continuing the special energy and noting its operation. For no one of nature's energies, be they ponderable or imponderable, is alone. Solitariness in the unseen, as well as in the seen, is no part of nature's plans.

Faraday seemed to have realized this view in great intensity when he wrote:—"If, as I believe, dualities are essential to the forces, are always equal, are mutually dependent, that one cannot appear or exist without the other; the proof of this would lead to many consequences of high importance to the philosophy of force generally."†

* Cantor Lecture, delivered February 3, 1873.

† 'Proceedings of Royal Institution for 1854,' p. 6.

This interlacing of energies—this correlation, as it is called, of physical forces, whilst it knits in harmonious union energies which are nominally distinct, baffles the investigator who wishes to assign to each its share in any specific work. For example, the energy of gravity operates everywhere, and our fundamental principle in hydraulics, that fluids press equally in all directions, may be granted as a postulate. The experiments by which it can be confirmed may be and are very clearly described, but no one has ever made or can make them. Gravity never ceases to impress upon fluids a downward tendency, and so prevents an equality of pressures in all directions being established.

It may be in the interest of the Moslem faith to assert that, without visible means, Mahomet's coffin rests between earth and heaven; but, assuming the truth of the tradition, or of the fact (whichever it be), we know well that gravity operates in all its wonted intensity, and that the coffin is held there (if held at all) by the introduction of some counteracting energy, as that of magnetism.

The energy of electricity is ever passing into heat—that of heat into electricity or light. Electricity, again, appears to assume the form of vitality; and then, again, it totally fails to fulfil the vital conditions. In some animals the exhaustion of their muscular energy is consequent upon the exhaustion of their vital energy, and no electrical appliance can restore the vital energy, even though it seems to restore the muscular. Take affinity. This passes, by means unknown to us, into electricity and heat.

There is also this peculiarity amongst these energies. The work of one energy, estimated by any means known to us, gives no indication of the work of some other energy, resident or potential, in the same matter.

For example, the estimation of a drop of water by gravity standards—to speak of it as weighing so many grains—gives no indication whatever of its ability to promote affinities— to absorb and convey heat—to decompose light. And if even all these were known, there would still be no indication that upon an electrical standard of measurement, its destructive effects are equal to that of a flash of lightning.

The only energies that may be said to be non-interchangeable are those of gravity and vitality. The former is enduring—the latter fleeting. The character of the one is persistence and constancy, that of the other, change and variety. Gravity may be said to be quietly resident in matter; vitality shows its presence by growth or motion.

Gravity is an energy pervading all nature, as intense in grains of sand as in the mountain; in a drop of water as in the river or the ocean. Disregarding alike the vitality of the plant or the animal—for gravity treats them as though they were as inert, indifferent, and unconscious of its presence as the soil of the garden or the mineral under the earth—thus this energy, which is to occupy our chief consideration on Monday next, is alone, and yet we shall find how that it has been left for recent times to tabulate its measure, to report and utilize, under the guidance of ordinary arithmetical and mathematical rules, the scientific and social consequences of the measure so established.

The other energy, that of vitality, which is to occupy our attention a fortnight hence, can hardly as yet be said to have been measured. The time, however, is very near when the hope will be realized that the energy of vitality —the mechanical, the statical, the dynamical, and absolute energy, of course, is meant—may be reduced to as exact a science as those of light, heat, and electricity have recently been.

All who have questioned Nature are well aware how simply and truthfully she replies. It must, however, be steadly borne in mind that this truthfulness applies to the question and answer in their mutual relations. If the question be so put that Dame Nature has to answer in respect to the combination of two elements, and so is called upon to give a reply which is in truth the aggregate of the two, she does so. It behoves the questioner to frame his question with the utmost care, in order to eliminate what is extraneous to his purpose. All must have observed how difficult it is to frame a question which cannot be misread or admit of a reply evidently based upon a view which the questioner never contemplated. For example, if the question relate to gravity, caution is needed to exclude the buoyancy and even viscosity of the air and the centrifugal effects of the earth's rotation.

If it relate to electricity, caution is needed to exclude the most infinitesimal alloy of a metal—even a metal itself.

If it relate to vitality, caution is needed to exclude the effects of temporary exhilaration or prostration.

If it relate to affinity, caution is needed to exclude the complication of phenomena by variations in gaseous pressure or atmospheric temperature.

If it relate to heat, caution is needed to exclude peculiarly constituted substances, in their unknown and varying effects on heat from their atomic or rather molecular condition.

Although, for purposes of classification and the general distinction of the phenomena, the energies found in nature are arranged under the general headings which are prefixed to the respective lectures of this course, yet it must be borne in mind that these are verbal rather than emphatically actual distinctions. They are merely the terms recognized at the present day, and in a few years may be dismissed. The convertibility of energy just now alluded to is a phrase which conveys a clear meaning, but this convertibility is a process that cannot be followed. At one time in the science world a general principle seems to have been established in relation to it; again and again the hope fades, the principle is on no secure basis, whilst the convertibility is ever active. It may not inappropriately be asked which energy is the source of the others —which, in fact, seems to have the highest claim to be classed as *the one*. Doubtless, as a question of sequence, in time gravity must claim the first place, but, so far as our powers of utilizing the energies of the imponderables are concerned we are not able to appeal very hopefully to gravity. We cannot obtain the other energies from it. Gravity refuses to be converted; its political principles are of the type which permits no change. Nature's No. 1 must be gravity; man's No. 1 affinity. For example, oxygen and hydrogen manifest their affinities in obedience to some inexplicable law. They enter into what is called combination, and in so doing manifest one form of energy to which the name of the "energy of affinity" is given. But in the transition state—in the act of obeying the very imperfectly known laws of affinity —another energy of a different name and character appears, viz., heat. Evidence of the power of this energy—heat—is furnished to tests very different to those which may be applied to the energy of affinity. The heat presented to the thermo-electric pile, and that a great change in the mode of its energy has taken place is obvious from the results it produces at a distance; to this new form of energy we give the name of electricity. By a species of magic, electricity has called forth an energy to which is given the name of magnetism. Suitable circumstances being presented to this new energy, there is a machine propelled and capable of doing mechanical work. We now call it mechanical energy.

Thus, by change superposed on change, the energy of an imponderable has been converted into that energy of the ponderable to which we are indebted for all, or nearly all, of arts, manufactures, and commerce.

The two imponderable energies into which chemical affinity cannot be converted are vitality and gravity. These two may, as we shall hereafter find, assume the form of the others—the others cannot assume their forms —at least not in any plain and honest sense. Except in these two, physical energy is a visible reproduction of the invisible doings of chemical affinity.

Simple as this process of transformation may appear, and convenient and useful as the suddenness of the change may be, it cannot be denied that to the investigator it is perplexing. Men, however, labour on, each perhaps winning a little from the unknown, and adding it to the

known. Thus, although "hills peep o'er hills, and Alps on Alps arise," yet men of varied resources and patient perseverance have won those invaluable treasures of measurement and utilization from the imponderable and unseen, which give the title to this course of Cantor Lectures.

Even Livingstone has not shown a more noble resolve "to conquer or to die" than have those to whom we are indebted for all we know touching the modes of measuring the energies of gravity, vitality, affinity, electricity, light, and heat.

As illustrations of the difficulties of the tasks before them,. it may suffice, in this introductory stage, briefly to observe that :—

Galvanic currents may escape notice unless the intensity of terrestrial magnetism be neutralized.

Dimagnetism and the magneto-electric spark escape notice, unless a large number of galvanic cells or their equivalent is used.

What was called the "smell of electricity" led Schonbein to the discovery of " ozone," a remarkable product, and one whose energies are yet unknown, although being slowly but surely developed.

That a vibrating magnetizing needle came to rest sooner in the neighbourhood of a copper plate, now called a damper, than when the plate was away, led to the discovery of the induction of electric currents by Faraday.

Opinion from telescopic appearances of the size of the stars led to an idea that their discs differed; the phenomenon has been found to be due to the diffraction of light.

The velocity of sound was calculated, making due allowance for the direction of the wind ; in recent years it has been found that the heat developed by one particle of air striking another must be taken into account.

We are indebted to "energy" for all we have, and all that men have won. For, example, this building and all that it contains is an example of one of the energies of gravity. The lightning, with its thunder, is an example of the energy of electricity. Power of hearing and of speaking are examples of the energy of vitality. The bread eaten and the wine drunk are assimilated and become ours by the energy of affinity. It is owing to the energy of light that vision can be had; and to the energy of heat that railways and locomotion can be utilized.

The word "energy" itself, which has in these days, phœnix-like, risen from its ashes, and which plays so important a part in the title to this course of Cantor Lectures, may properly claim some notice.

The word has been adopted, rejected, and revived. It seems to have been first used by Lucretius, a Roman philosopher, who was born B.C. 95 and died B.C. 55. The word had been forgotten or laid in oblivion until Dr. Young, in his lectures at the Royal Institution in 1807, explained what he meant by energy,* and illustrated his meaning by the impact of an ivory ball or balls upon a line of suspended balls.

Here are several ivory balls suspended so as to touch each other. If the end one be raised a little, and then allowed to fall, the ball at the other end will be driven away. The motion in the last ball resulted from energy expended in the raising of the first ball, and this first ball was raised by the energy of vitality. When, however, vitality no longer puts forth energy, then the energy of gravity operates, and causes the ball to fall. Such a simple experiment revived the word "energy," which has thus been reintroduced, and bids fair to hold an important place in science annals for some years.

Energy is from two Greek words ἐν, within, and ἔργον, work; used in its true sense, it means the work "that is within." Whenever, then, we find that a power to do work exists, we may say, "there is energy." It needs not that the work be done, it is immaterial how long it has lain dormant, or whether it be in man's estimation great or small, we only need the assurance that there is the capacity to do. A loaded gun need not be discharged to assure us that in that which is in the gun is energy, and yet to ascertain or measure the energy the discharge must take place. When that has happened, we may say, within the gun is no energy. The gun itself is merely a contrivance by which certain combinations may be induced to exercise their energies ; it has nothing to do with the communication or even introduction of the energy utilized. When the energy is within the barrel, and inoperative, we handle and play with the gun, disregarding the thought of energy, but when the energy of quiescence is to become energy in action, it behoves us to play with the gun no longer.

But how can the gun be again a means or an agent through which some one or other energy may remanifest itself. Clearly by another group of quiescent energies being introduced. This illustration of an expended and a reintroduced energy may suffice to give a character to an element in respect of all the energies, viz., their expenditure and reintroduction or re-creation. Either through the innate operation of natural causes or through the agency of vital energy, there must be a restoration. These restorations are effected in ways to which the name of legion may be applied. For example, a weight requires energy to raise it, a spring requires energy to bend it, air in a gun requires energy to compress it, before any of these can be said to have energy in possession. The water in a mill-pond has been raised by the energy of the sun. The chemical affinities in a galvanic cell are innate. A labourer and a horse require food that they may work. So with many similar illustrations. In all these is a dormant or quiescent energy. Once let it loose and the Arabian Nights story of Sinbad and the Giant, or that boast of Owen Glendower, that he could

> "Call spirits from the vasty deep,"

would not be met with Hotspur's taunt,

> "Why, so can I, or so can any man ;
> But will they come when you do call for them?"

These energies always come when rightly summoned.

Observe, energy presents itself in two forms—energy in quiescence, and energy in action. To these forms technical names have been given. Energy in quiescence is called potential energy ; and energy in action is called kinetic energy. In this weight, suspended as pendulum, these two energies may be illustrated. If the weight be struck from its lowest position, then the kinetic energy of vitality, as manifested through muscular action, sets it off. But if the weight be elevated and simply let fall, then the potential energy stored up in the act of lifting becomes kinetic energy, through the influence of what we call gravity.

To sum up. Belonging or attached to all that is material are certain powers or influences which cannot be separated and so weighed, hence these powers or influences are said to be "imponderable." Since these powers or influences affect the motions of bodies they are called forces, for force is that unknown influence which causes, retards, stops, or accelerates motion.

Again, when by such arrangements as nature calls into play, or men can contrive, these forces manifest themselves in action, they are said to be energetic.

Now, since we can plan to some extent how and when each force should manifest its energy, and obtain or retain the results, these results are called work. This may be measured or weighed, and it is through such work alone that a value can by men be placed upon the forces of the imponderables, which, by their energy, have done work.

The measurement, therefore, of the energies of the imponderables resolves itself into a measurement of the

* In Lecture 8, Young wrote:—" The term 'energy' may be applied with great propriety to the product of the mass (or weight) of a body into the square of the number expressing its velocity." This is not "energy" according to modern usage, but, for reasons which need not at present concern us, it is double of that to which in these days the term "energy" is applied.

work they do. It is, therefore, very essential that the measurement of work should be by means easily reproducible, scientifically accurate, of universal application, beyond all question and all cavil, admitting of no elements which, under any circumstances, could vitiate or falsify a conclusion.

Three elements only are needed to fulfil these conditions, viz., the *mass* of the body moved, the *space* through which it moved, and the *time* during which, by the operation of some force, it was being moved. These three elements being known, all others or varieties can be derived from them; hence all others are called *derived* measurements. Reasoning thus, a pound weight from which mass may be deduced, a two-foot rule by which space may be measured, and a clock by which time may be noted, are all that we require in England in order to determine measurements of work. But very clearly these three sources of fundamental units must be of an irreproachable character. Speaking generally, who dare venture to say that the pound weight he has, or the clock he has, or the two-foot rule he has, is more to be relied upon than the corresponding instrument in the possession of his neighbour. 'Tis amusing to listen to the pleadings of the owners of watches and two-foot rules, and scales and weights, as to the wonderful accuracy of those they possess.

Where lies the appeal? Who shall decide whether the second ticked by the watch which cost thirty shillings or that ticked by the chronometer which cost one hundred pounds is to be the true second? Who shall decide the inch and the pound when the owners disagree? The answer to these questions, doubtless, raises in your minds forms of difficulties not easily solved.

It may suffice, for this evening, to glance at one or two of these difficulties, in order that we may not think it a trifling with important interests in what, perhaps, seems a kind of childish quibbling, to suggest as a difficulty in such common affairs as a pound weight, a second, and an inch. Let us first see that from these can be had all we use as measures.

When we say of anything it measures ten, twenty, thirty or forty, we may add the words inches, feet, yards, or miles. These words must be in some way related. The measurement thus expressed consists of two parts, a numerical and a denominational one. The numerical is absolute and independent of the denominational one. This latter is, for a special case, the unit of measurement; hence there may be a great variety of units, all, however, by their interrelations, capable of being resolved into one. This one, this original, this is the difficult one to decide, and to it a portion of the lecture on Monday next must be given.

So far, then, for the unit of space. Now as to time. Let anyone attempt to measure time by the repetition of a unit derived from any ordinary source, and he will soon find himself in a labyrinth of doubts. All our measures of time are derived from astronomy. Of the unit of this our future grain there is the compound measure which some may say is put beyond the reach of such disparaging remarks, viz., that invaluable measure in all commercial transactions, the pound weight. Time is our own; we waste it as we please; we do not pay for it. Space is our own; we can walk where and as we please; but as to our food, that is ours by purchase, and we buy it by the pound weight.

Well, "truth," the proverb says, "is mighty and must prevail." The pound weight is quite worthless as a scientifically accurate and universal measure. There is really no such thing as weight for a universal measure, and yet nobody ever bought a pound of sugar without thinking he was getting at one time the same quantity as at another. That is not the case. Weight, speaking accurately, is a most variable measure, and is, therefore, one on which no reliance is to be placed in scientific investigation. What we do measure, scientifically speaking, when we speak of weight, is mass, and an endeavour shall be made to show you the difference between mass and weight.

First, weight is not at all to be relied upon. Here is a jar of water balanced on a scale-beam, but so as to hardly equal the weights on the other side. If I put my finger in the jar, the jar overbalances the weights. But why should the scale pan sink when one simply touches the water with the hand? It is not pressed down. The hand is merely put into another atmosphere, water, instead of air. Lest anyone should think that the jar is pressed down, let a weight hanging by a string, which sustains the weight, be suspended in the water, still the scale pan in which the jar of water is descends. Therefore, the weight appears to be altered—there seems something or other about it which is not altogether correct. The matter presents itself again in this form. Here is a scale-beam with a block of wood at one end and an exactly balanced weight at the other. Now, as the weights pass from one atmosphere to another they change in their relationship; and whilst the mass or quantity of matter contained in this block of wood and in this counterpoising weight remains the same, yet the relation of the weights does not remain the same. Some may say that if the matter undergoes no change, then the weight undergoes no change. It is the weight which undergoes a great change, but the matter undergoes no change. At present both are in an atmosphere of air, and you see that the beam is in exact equilibrium; but now let each be immersed in an atmosphere of water, and you see at once how the relationship to each other is changed; they no longer balance. The mass of wood is the same as before, and, therefore, as far as moving from one atmosphere to another is concerned, masses must be considered, and not weights; therefore, where the atmosphere changes, there we must give up the idea of weight. There is another cause why weight will not act as a standard unit. Weight results from the action of gravity; it is not a property of matter at all. If we change the force of gravity which tends to pull a mass down, we then change the amount of pressure that the mass exerts on a spring. If we take a mass of matter at one of the poles, it is nearer to the centre of the earth than if it were at the equator, and in consequence it will be pulled down with greater force, so that what would weigh (say) $1\frac{1}{2}$ lb. by a spring balance at the pole, would weigh (say) $1\frac{1}{4}$ at the equator. Therefore, if we ordered a quantity of goods to be sent from some place near the poles towards the equator, and they were weighed by a spring balance, they would not weigh so much on reaching their destination as they did when they were shipped; and yet the quantity of matter would be exactly the same.

Observe, it is a spring balance, and not a scale-beam, that is used. A spring balance measures force only, viz., in this case the depressing or pulling down force of gravity at the place where it is used. With a spring balance a gravitation experiment is made. If a scale-beam be used, then as the change of gravity effects the weight in each scale pan equally, the relations between them will not be affected, and the scale-beam will be in equilibrium when the contents of the scales are influenced by the varying force of gravity.

You saw, a short time ago, that weight varies by taking the mass into an atmosphere denser than that in which we live, and now you shall see the same result by changing the atmosphere for one more rare. Here is a glass beaker, suspended bottom upwards by a hook, so as to exactly balance a weight at the other end of the cord; the system is now in equilibrium. I will change the atmosphere within the beaker by admitting some ordinary coal gas into it, and you see the weight changes at once; the beaker appears to be lighter. These illustrations show that, dealing with weight, we deal with that which is variable in all parts of the earth, and, owing to atmospheric changes, variable at the same time almost in the same position. Doubtless all of us who have attained years of discretion, have been asked the question, in our

earlier days, which was the heavier, a pound of lead or a pound of feathers. Here, in a glass case, is a bag of feathers (eiderdown), and a weight exactly balancing them. Call the weight a pound of lead, and then, truly, the pound of lead is balanced by the pound of feathers. Now, the scale-beam is a delicate one, and accurately poised. By this pipe is admitted hydrogen gas into the case, the upper part of the case is closed, the hydrogen ascends, the air gradually escapes at the bottom, the scale-beam loses its equilibrium, and the bag of feathers descends, and is evidently heavier than the pound of lead.

This must for the present suffice to satisfy you that weight, as such, must not be considered an accurate measure, and that, somehow or another, a measure for mass must be obtained and used in the place of that which we call weight. These three units, then,—mass, space, and time—are sufficient for all purposes of measurement, and when reliable data have been furnished from whence these can be deduced, determined, and (if lost) restored, we shall be in possession of all that is required for the purpose of recording every measurement requisite for estimating and comparing the work done by the energy manifested by any one or more of the forces derived from the "imponderables."

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Shop Hours' Regulation Bill.

This Bill was withdrawn on Thursday, July 10th.

Weights and Measures (Metric System) Bill.

On Wednesday, July 16th, Sir T. Bazley, in the absence of Mr. J. B. Smith, through illness, moved that the order for the second reading of the Weights and Measures (Metric System) Bill should be discharged. The motion was agreed to and the Bill was withdrawn.

Juries Bill.

The further consideration of this Bill in Committee is fixed for Thursday, July 17th.

Poisoning by Carbolic Acid.

An inquest was held at the Star Inn, Aylesbury, on Monday, July 7th, to inquire into the circumstances attending the death of Thomas Keen, aged 22.

It appeared from the evidence that the deceased had been playing at cricket, and adjourned to the Star to have a glass of ale with his companions. Whilst they were there, one of the party took up a three-parts emptied bottle of carbolic acid (which had been used for destroying ants, and was standing on the tap-room mantel-piece) smelt it, and said, "Here is some physic." Keen said, "Oh, I can do with a dose of it," and, just glancing at the bottle, put it to his lips, and drank about a tablespoonful of the liquid. In about ten minutes afterwards he sank into a swoon, from which he never rallied.

Wm. Green, the landlord, said that about a fortnight before, he had sent a man in his employ to Mr. Turner's shop to get some mixture to destroy ants with. He did not get the mixture the first time, but he brought it back with him the second. It was carbolic acid. Sells said that the young man who had served him had told him that he did not know that it would kill the ants, but it would certainly drive them away.

The Foreman inquired whether the mixture in question was not of the nature of a disinfectant?

The Coroner—Yes, it is especially sold for that.

Witness said he used a little of the contents according to the directions, and some of it was used for white-washing the walls. As nearly as he could judge, half the bottle-full was used in this way. The bottle was afterwards placed on the tap-room mantel-piece. He did not see the deceased take any of the carbolic acid. He was only fetched into the tap-room when deceased had taken it. Deceased was sitting up, and witness asked him how he was. Deceased said, "Oh, I am all right." He (witness) had been sent for because it was thought the case was serious. He sent for a medical man directly, and in the meantime gave deceased some salt and water with the view of making him vomit. Deceased went out into the back yard, and was afterwards brought into the house. He did not speak after being brought in. He (witness) was not aware of the mixture being of so deadly a nature. Had it been labelled "Poison," he should not have left it where he did.

In answer to a juror, witness stated that deceased was not in the least intoxicated.

Edward Sells said he worked for Mr. Green, and recollected going to Mr. Turner's. He asked for some stuff to kill ants with, and the boy in the shop said he had not got anything he could give him excepting carbolic acid. The boy said it was very nasty smelling stuff, and if he put it against his fingers it would take the skin off. He came out and told his master, who said they ought to have some, and he accordingly went and fetched 3*d*. worth. The bottle on the table was the one he fetched. He used some of the mixture next day for killing the ants.

In answer to the Foreman, witness stated that when he went to Mr. Turner's shop, the junior apprentice, who served him, went up to the elder one to ask how much the bottle would be, but neither of them gave him any sort of intimation that it contained a strong poison. [It should be stated that at a subsequent period witness was re-called and admitted that he could not be quite certain that nothing was said about "Poison."]

Henry Mayne said he was with deceased on Monday night from five o'clock up to the time of his death. Deceased was quite sober. While they were in the tap-room one of the young men who were with them said he smelt something, and took a bottle off the mantel-piece to see if that was what smelt. He was just putting it back on the mantel-piece with the remark that it was medicine, or something of that sort, when deceased took it up, saying "Then it will do me good," and drank some of it. Deceased simply looked at the bottle for a moment, and then put it up to his mouth and drank. Witness did not notice how much there was in the bottle, or how much Keen drank. After that a young man named Quest said, "You have not drunk that stuff, Keen, have you?" and he said, "No, I have not swallowed it." Afterwards somebody said, "I should not wonder if you are not a 'stiff 'un' in two or three hours." Deceased said, "It won't much matter if I am." Deceased made no remark about the mixture tasting strong, but about five minutes afterwards he complained of feeling ill, and said he should like to have a drop of brandy, but everybody said the best thing he could have was some salt and water. Deceased took the salt and water, and shortly afterwards went out into the back yard, and fell down on a dung-heap.

In answer to the jury, witness said that he saw tears come into deceased eyes when he had drunk the mixture, as though it had burnt him. He afterwards took up the cue to strike at a bagatelle ball, but pitched on to the side of the table, and then he went into the yard. It might be seven minutes from the time of his taking the mixture that he fell down in the yard. He could read the label on the bottle very well, as he was a good scholar.

To the Coroner—Nothing had fallen from the deceased during the course of the day showing that he was in low spirits. When deceased said he should not mind if he was a "stiff-'un," he thought it was evidently only intended as a joke.

F. E. Ballard said he was an apprentice to Mr. Turner, chemist, of Aylesbury. He recollected the witness Sells coming to Mr. Turner's shop, and asking for something

to kill ants with. He told Sells that he would have to be very careful with it, for it was a very strong poison, and he might blister his hands with it.

To the Jury: He was quite sure he told Sells it was poison. Sells came in subsequently, and brought a bottle for some of the carbolic acid. The other boy in the shop served him. He (witness) knew that the carbolic acid was poison.

Mr. Turner, who was present in the room, then said that there was nothing in the schedule to the Act regulating the sale of poisonous substances which said anything about carbolic acid.

The Coroner: The Act says it shall be unlawful to sell any poison, either by wholesale or retail, unless the box, bottle, vessel, wrapper, or cover in which such poison is contained be distinctly labelled with the name of the article, and with the word "Poison," and the name and address of the seller of the poison. The words in the Act are very wide.

Mr. Turner: The two schedules to the Act specify what are poisons.

The Coroner: But the Act says "or may hereafter be added thereto." My opinion, from a legal point of view, decidedly is, that it is absolutely unlawful to sell any poison, no matter whether mentioned in the schedule or not, without labelling it.

Mr. Turner admitted that it would have been better for a label with the word "Poison" to have been affixed to the bottle, but as the article in question was almost entirely used as a disinfectant, it was not the custom in the trade to label it "Poison," although he (Mr. Turner) frequently did so. Still, he always received the carbolic acid without a poison label from the wholesale houses, who were bound to put one on as much as he was. Neither in the addenda to the schedules, nor in the schedules themselves, was carbolic acid mentioned as a poison coming under the operation of the Act, although at the time the Act was passed it was known that it was a poison.

The Coroner thought that that decided the matter, as the Act included any "known poison," and it was admitted that carbolic acid was a known poison.

Mr. Turner: So is "paregoric" a poison, and raw rum. The Pharmaceutical Society had decided that more harm than good would result from labelling paregoric "Poison," as it would deter people from taking a very useful medicine.

The Coroner thought there was a difference between poisons made up into medicines and poisons such as carbolic acid.

The Foreman thought that the whole spirit of the Act, as read by the Coroner, was exemplified in the words "all and every," and that neither the Pharmaceutical Society nor any other society could supersede an Act of Parliament.

Mr. Turner still thought that if carbolic acid had been intended to come within the provisions of the Act it would have been mentioned in the schedule. He was as sorry as anyone could be that the accident had occurred.

The Coroner: What Mr. Turner says is, that the trade have never considered it necessary to put "Poison" on these bottles. They are accustomed to have articles sent in very large quantities containing precisely the same ingredients with the word "Poison" altogether omitted, and, therefore, that he has done nothing more than is done in the course of trade by other persons.

The Foreman thought that if it was practised by the whole trade it was a mistake.

Mr. Turner was then formally sworn, and deposed that he was a pharmaceutical chemist practising at Aylesbury. He sold every kind of poison. In selling carbolic acid and other disinfectants it was not usual to put a label with the word "Poison" on. It was thought that the other directions on it were sufficient. He always sold it with the words "carbolic acid" on it, and sometimes added "Poison" as well, but that was not done in this particular case. He produced a bottle of Calvert's carbolic, which was the acid he received in its wholesale form. That had not "Poison" on it. He could not understand how anybody in his senses could take a bottle like that and drink it blindly.

The Coroner: Everyone does not know that carbolic acid is poison.

Mr. Turner: I do not consider that I am bound by law to label these disinfectants as poison, or that these disinfectants come under the provisions of the Act.

Mr. C. Hooper, surgeon, said, that between nine and ten o'clock on the night in question he was sent for to the Star Inn. Upon his arrival he found the deceased upon his hands and knees in the back yard, apparently retching, and covered with a profuse sweat. He had him brought into the inn, and when he found what deceased had been taking, he immediately set to work with a stomach pump, and pumped two or three quarts of fluid in and out for the purpose of washing out the stomach. Deceased was insensible all the time, and never recovered his senses. Witness used the stomach pump for an hour or two. From five to ten drops of carbolic acid would have been enough to destroy life. A tablespoonful would certainly have done so. He made a *post-mortem* examination of the body on Tuesday, and found the internal organs very much congested, and the blood more fluid and darker coloured than was natural. The local effects of the caustic were not very marked. The absorption of the acid into the system was the cause of death. It acted as a narcotic poison.

Mr. Turner asked whether deceased had not been subject to fits?

Mr. Hooper replied that there could be no doubt the carbolic acid was the cause of death, as the blood, the brain, and all the internal organs were strongly impregnated with the smell of it. Deceased never showed the slightest signs of rallying from the time he (witness) saw him till the time of his death. If he had rejected the poison the instant he had taken it, he might have recovered. There were no convulsive movements in deceased's body at all suggestive of a fit.

The jury, having deliberated, returned a verdict "That the deceased died from misadventure, caused by his taking carbolic acid without being aware of the effect it would produce. The jury regret that poisons of this kind should be sold without the word 'Poison' being written upon the bottles which contain them."

It was generally understood that this verdict did not reflect in any special manner on Mr. Turner, who had only complied with the custom of the trade.—*Bucks Herald.*

Poisoning by a Strychnia Vermin Killer.

An inquest was held at Broadmead, Bristol, on Thursday, July 10, on the body of Maria Rich, who it was supposed had committed suicide by taking some vermin powder. Evidence was given that deceased was seen to drink something out of an egg cup and that directly afterwards she was taken ill.

Eliza Stacey, a servant in the deceased's house, said that the deceased sent her for two pennyworth of mice powder; she went to Matthews's, but they said she was not of age, and would not give it to her. She informed deceased, who was very cross about it. She went out again, and obtained some powder at the bottom of West Street, at Mr. Bennett's shop. She was not known at the shop, but she put a cross to a book, and she was asked her name and address. She gave the poison to Mrs. Rich, and did not see it afterwards.

Joseph Bennett, chemist, Lawrence Hill, deposed to letting the girl Stacey have the vermin powder, which contained from 1½ to 2 grains of strychnine.

Dr. Challacombe said he was called in to see the deceased, and found she had died from poison. He had made a *post-mortem* examination of the body. The symp-

toms undoubtedly pointed to strychnine as the cause of death. From half a grain to two grains would kill a person. There were traces of powder on the egg glass. There were no marks of violence about the body. The coroner summed up, and the jury returned a verdict of "Temporary insanity."—*Bristol Times.*

Poisoning by Prussic Acid.

At Stoke-upon-Trent, a youth, named Ash, a druggist's assistant, who had been apprehended on the charge of neglect of service, committed suicide in the police-cell. He told some persons in an adjoining cell that he had taken poison, and he was dead before any assistance could reach him. A large quantity of prussic acid was found concealed upon the body.—*Daily Telegraph.*

A Disputed Case under the Adulteration Act.

At the Lambeth Police-court, on Thursday, the case of the Vestry *v.* Henry Mason came on for hearing. It was a summons which had been adjourned on two previous occasions, charging the defendant, a grocer, 149, Kennington Lane, under the Adulteration Act, with selling an article, to wit, "Tea, containing exhausted leaves mixed with stalks and fragments of foreign matter, such as husks, scorched tea, buds, etc., the said adulterants being added to increase the weight and bulk, but although deteriorating the value, these adulterants are not such as are dangerous to health." At a previous examination, Mr. Douglas Straight, M.P., who appeared for the defendant, contended that there was no case: the Vestry analyst, Dr. Muter, plainly stating that there was nothing deleterious to health in the tea sold; that exhausted leaves were present could not be proved, and was emphatically denied; that the stalks mentioned in the certificate were tea stalks, and the buds so-called tea seeds, both integral portions of rough tea such as the defendant offered for sale at 1*s.* 4*d.* per lb. Professors Campbell and Harkness, who had analysed the tea for the defendant, were in court and prepared to swear its purity; but Mr. Roffey, the vestry clerk, who appeared for the prosecution, objected to the analysis of the two professors on the ground that the sample which had been handed to them had not been identified with the tea sold to the informer. A portion of the latter sample was produced in court in a sealed packet, and was referred by the bench for a joint analysis by Dr. Muter and Dr. T. Stephenson on behalf of the prosecution, and Professors Campbell and Harkness on behalf of the defendant. The joint analysis took place at the laboratory of St. Thomas's Hospital on Monday, the 7th instant. When the case was called on in court on Thursday, Mr. Poland, who had been retained by the Vestry, asked leave to withdraw the summons, the analysis of Dr. Stevenson being found in accord with those of Messrs. Campbell and Harkness as to the purity of the tea, and differing entirely from the original certificate of Dr. Muter, the Vestry analyst, upon whose evidence the charge had been founded. Mr. Gush, for the defendant, asked for full costs. His client had been subjected to a groundless and vexatious prosecution hanging over him for five weeks. The loss to his business was considerable. It was necessary to have the highest professional skill to rebut the evidence of the public analyst, and such witnesses must and ought to be well paid. Mr. Ellison, the presiding magistrate, said he thought the Vestry were not to be intimidated in their endeavour to carry out the Adulteration Act by any heavy claims for expenses where the prosecution broke down. At the same time, it was quite clear that the prosecution were not in this instance well advised, and that the defendant left the court without a stain on his reputation. He should allow six guineas for expenses.

A summons against Mr. Theodore Smith, of Kennington Lane, was then called. Mr. Roffey, on behalf of the Vestry, said that this was a similar charge, and he was not prepared to proceed after the result of the last case. This summons was therefore also dismissed, with costs against the Vestry, £2 2*s.*—*Grocer.*

Reviews.

Les Plantes Médicinales et Usuelles de nos Champs, —Jardins,—Forets. Par H. Rodin. Ornéde 117 Vignettes. Paris: Rothschild. 1873.

M. Rodin enjoys a high reputation among French botanists, not only for his knowledge of the vegetable kingdom, but for his powers as an expositor, whether by tongue or pen.

Twenty years' experience as *chef d'Institution* has convinced him that, in spite of the excellent treatises placed in the hands of young students in botany; in spite, moreover, of the admitted attractiveness of the study, very few cultivate it except for a temporary purpose, so that it is rare to find, in town or country, many students of it over thirty years of age. This premature abandonment of the pursuit M. Rodin ascribes to the technical form in which botanical treatises are cast, addressed as they usually are to students of medicine or pharmacy. He thinks that, while retaining all that is scientifically important, a treatise may yet be popular and inspire a taste for the study which will survive its temporary purpose.

His little work will be found to combine both conditions. To make sure that nothing necessary from a scientific point of view was left out, he submitted his manuscript to the professors of the Jardin-du-Plantes and of the École de Pharmacie, trusting to his own powers to convey his matter clearly and popularly. The result is one of the most charming little volumes ever devoted to the exposition of a science. Starting from the thesis that many of our indigenous plants would acquire an enhanced value in the eyes of physicians and their patients if they grew on the mountains of the Cordilleras or in the forests of Australia, he shows that it is by no means necessary to go so far afield for vegetable agents quite equal in therapeutic value to many imported from abroad. He gives an interesting account of the preparation of simples as it appears in the 'Capitularia' of Charlemagne, and after proving that the rude pharmacy of the Middle Ages is still practised in the case of our indigenous plants, he shows that more skilful processes can educe from these plants a number of virtues of which they were not even suspected. The succeeding chapters treat of "emollient plants," "temperant plants" (by which he means those that modify the activity of the organic functions), "stimulant plants," "astringent plants," and so on till he has constructed a complete medical flora out of the fields and forests of France. The chapters on expectorants, diuretics, purgatives, narcotics, and febrifuges are really excellent, and reveal an amount of *materia medica* indigenous to French soil which few *pharmaciens* have dreamt of. A practical chapter on "dangerous plants" is also a valuable feature in the volume. The illustrations are well chosen and well executed, and materially enhance the attractiveness of a book which cannot fail to have many readers.

Manual of Chemical Analysis as applied to the Examination of Medicinal Chemicals. By Frederick Hoffmann, Ph.D., Pharmaceutist. New York: D. Appleton and Co. 1873.

Associated as pharmacy is with therapeutics, it is important that the materials employed by the pharmacist should be pure; perhaps nothing would so much tend to that end, as all pharmacists becoming conversant with analysis, providing that they used the knowledge in testing their own medicinal chemicals.

Mr. Hoffmann's 'Manual' is a work written essentially for pharmaceutical chemists and manufacturing druggists. It comprises within its range the chief medicinal chemicals, giving their synonyms, their properties, and the tests by which impurities may be recognized. It has been compiled with special reference to the fifth decennial edition of the United States' Pharmacopœia, the latest British Pharmacopœia, and the Pharmacopœia Germanica, 1872, and the latest additions to these works are included and dilated upon. The book is excellently printed; the indices are copious; and as it is mainly a qualitative work, the inconvenience of the American system of weights and measures is not felt.

The strength of the test reagents and the outlines of qualitative and volumetric analysis are given as prefatory matter. The section on qualitative analysis is the weakest part of the book, which is good otherwise. In the scheme of analysis, after the separation has been effected by sulphuretted hydrogen, the analyst is not told to vary his method in the event of phosphoric acid being present; nor is even such a provision mentioned as being requisite, although, as is well known, it is essential, if phosphoric acid has been detected after the passing of sulphuretted hydrogen, to precipitate with ammonia and ammonic chloride, then add ammonic sulphide to the filtrate; and, finally, after mixing the two precipitates, decompose the phosphates with ammonic sulphide; the presence of phosphoric acid as ammonic phosphate in the filtrate showing that phosphates decomposable by ammonic sulphide are present. The usual analysis for phosphates should then be followed with the precipitate. If ammonia, ammonic chloride, and ammonic sulphide were added at once, as the author gives it, the analyst would not be able qualitatively to examine bases in combination with phosphoric acid. Again, the method given for separating manganese and zinc from iron, aluminium, and chromium is based on the solubility of the hydrates of manganese and zinc in ammonic chloride and ammonia. This is imperfect. Invariably, if only small quantities be present, the hydrates of manganese and zinc are carried down by ferric hydrate, and would escape detection. In this part we also notice that on heating the substance under examination on charcoal with *sodic carbonate* fusion into the coal is said denote *alkalies*. Certainly the impurities treated of might be detected by the schemes given; but we hold that outlines are fallacious, inasmuch as chemical analysis without completeness is a myth, and it is to be hoped that those for whom the work was compiled will not study analysis superficially. It were best, therefore, to have had this part thorough or to have omitted it altogether, leaving the analyst to rely on more comprehensive and special works on analysis. If the former suggestion had been adopted the numerous repetitions of tests now inserted after each substance might have been dispensed with. The reader is continually being reminded of the tests for the common acids, especially that for arsenic, after the classification of the properties of the compound in which these impurities may occur. Much time and labour could have been saved by presuming that after a test for an impurity had been indicated it would be remembered and acted upon by the student, excepting only when special methods are requisite. These are, for the most part, trusty ones; but there are certainly some crude tests given. Ammonia in water is said to be indicated by the white turbidity given by sodic carbonate and mercuric chloride, quite ignoring the delicate Nessler test; the organic matter is to be estimated from the amount of potassic permanganate required to colourize a certain quantity of the water. The author seems not to give pharmaceutical chemists credit for being able to perform the higher grades of analysis. Take, for example, that to estimate the moisture in sodic chloride ten scruples are directed *to be allowed to stand for several days* in a tared beaker, at nearly 100° C.

The section on medicinal chemicals and their preparations is full of utility. But it is to be regretted that the author considered a want of unanimity in expressing the constitution of chemical compounds a valid reason for omitting entirely symbolic notation. Each compound is described in the old and in the new nomenclature, *e.g.*, "Cupri sulphas," cuprum sulphuricum; ferri phosphas, ferrum phosphoricum, ferrum oxydulato-oxydatum phosphoricum; followed by the English equivalents. The properties are then given in detail. Under the head of examination the impurities liable to be present are given, and the tests for them. On this part we have already expressed our opinion. In some cases there follows a rough quantitative estimation. Iodoform, chloral, benzoate, bromide and iodide of ammonium, etc., lately added to the American Pharmacopœia, are fully described; the same with the alkaloids and their salts in detail yet succinctly. A good method of estimating the alkaloids in cinchona barks is also supplemented with Stoddart's chemico-microscropic test. Altogether the examination of the medicinal chemicals from their properties is complete, although there is little new matter in this part, nor does the author pretend to have more than gathered facts coming under his title.

In a future edition, to make the work adequately to serve its purpose, attention is required to the imperfections here pointed out, as well as to a careful revision; for there are several errors, vagueness in style, and others, arising, we charitably presume, from haste in compilation, but quite unpardonable in a "Manual." The idea of technical manuals is a happy one, and in these days of progress, when technical compendia are required more than aught else, we should welcome a good work of this kind to pharmaceutical literature.

POSOLOGICAL TABLES. Being a Classification of the Doses of all Officinal Substances for the Use of Students and Practitioners. By W. HANDSEL GRIFFITHS, Ph.D., etc. Dublin: Fannin. London: Baillière, Tindall, and Cox. 1873. Second Edition.

This is a second edition of the sheet-table of doses noticed in these pages a short time since. In the present issue the names of substances and preparations of which the doses are very small or exceptional have been printed in red ink. Should the compilation reach a third edition it would be well to remove eyesores like E. Au*th*emidis and I. Dulcamar*a*. It would also be easy to avoid making the nominative form do duty for the genitive in ammonium, potassium, and several other instances.

Obituary.

Notice has been received of the death of the following:—

We regret to have to announce the death of Mr. John Holliday Thomas (of the firm of J. H. Thomas and Son, Pharmaceutical Chemists, Boston, Lincolnshire). The deceased was one of the early founders of the Society, having joined it in 1842. He died on June 24th, at Hampstead Heath, aged 66 years, greatly respected by a large circle of friends.

Notice has also been received of the death, on the 19th May, 1873, Mr. Henry Blacklock, of Bournemouth, Pharmaceutical Chemist. Mr. Blacklock joined the Pharmaceutical Society in 1852.

Notes and Queries.

OLEATE OF MERCURY.—("*Inquirer*").—The following is the formula for "Ung. Hydrargyri Oleatis" (20 per cent.), given in the Pharmacopœia of the University College Hospital, just published:—

"Precipitated peroxide of mercury . . 2 drachms.
Oleic acid . . . . . 10 „

To the oleic acid, kept agitated in a mortar, sprinkle in the peroxide gradually, and triturate frequently during twenty-four hours, until the peroxide is dissolved, and a gelatinous solution is formed."

The School of Pharmacy.

Sir,—Although it is scarcely likely that the purpose of my motion at the last Council meeting has anywhere been misunderstood in consequence of the error, I should still be glad if you will kindly correct your report of its wording, as given in the Pharmaceutical Journal of July 5th, page 11.

My resolution was, "That the proposition of the Committee be published in the Pharmaceutical Journal, and postponed for decision until the next meeting of Council" —that is, until *next month*, and *not*, as your reporter has it, "until the meeting of the next Council," which would have meant until about this time *next year*.

My hope was to gain just so much time for the general consideration of the important changes suggested, as is wisely provided for in that section of the bye-law, which runs—"It shall be lawful for the Chairman to postpone or adjourn to the next meeting any motion whereof notice in writing has not been given at a prior meeting."

It is right I should add that no notice of this motion had been given.

Clifton, July 15th, 1873. G. F. Schacht.

Poisoning by Carbolic Acid.

Sir,—I have forwarded to you *per* same post a copy of the *Bucks Herald* of to-day, containing an account of a case of accidental poisoning by carbolic acid at Aylesbury. I think that no member of the trade can read it without seeing and feeling what an unfortunate position any of us may be placed in, at any moment, through the misinterpretation of the Pharmacy Act by a coroner, combined with the stultity of a country jury.

Really, after some consideration, I begin, with many others, to imagine that this Act, instead of being the boon to the trade we thought it would, will eventually turn out a curse. Here is a case to the point.

Mr. Turner (or rather his assistant), local secretary to the Society at Aylesbury, retails 3*d.* of impure carbolic acid to a man for destroying ants, placing on the bottle a large label (three inches by four), bearing in bold type the words "Carbolic acid," with full directions for use as a disinfectant, etc., at the same time cautioning him as to its corrosive nature. Would any one ever dream of a man being such an idiot as to pick up a bottle and instantly drink off crude carbolic acid. (No doubt it was done in a spirit of bravado.) Would not the result have been the same had it contained nitric or sulphuric acid?

Yet it is all the chemist's fault. He ought, says the jury, to have labelled it "Poison." He has infringed the Pharmacy Act, insinuates the Coroner.

As reported in the local papers, the Coroner does not do Mr. Turner the justice to read that portion of the Act (Clause 2) which states:—

"All the articles named or referred to in the appended list, both in Part I. and Part II., *are poisons within the meaning of the Pharmacy Act of* 1868,"

But he goes on to read Clause 17 of the Act:—

"It is unlawful *to sell any poison*," etc.

I do not find myself that Messrs. Calvert, or any other makers, label their acid for retailing "Poison."

It seems to me as if the public expect that when a chemist sells an article of at all a virulent nature that he must march about with it to see that no one is poisoned thereby.

I think myself if we are to be subjected to these annoyances (which may happen at any time to any one of us) the sooner this preparation and many others of a similar nature are added to Part I. or II. of the schedule the better. In this case the jury did not wish a censure to be passed on the chemist; at the same time it seems hard that a chemist in a country town should have his reputation and trade damaged by the remarks of a coroner who apparently does not quite understand the Act, and the foreman of a jury who speaks of the Pharmaceutical Society with contempt. I must apologize for thus trespassing on your space, but it seems to me a case of great importance to the profession, and a subject that ought to be ventilated, in the hopes of finding a remedy for it. I enclose my card and remain,

July 12th, 1873. A Country Chemist.

Another correspondent writes in reference to this case, to say that no doubt it will cause numbers to label carbolic acid "Poison" who, otherwise, would not do so, and thus prevent their names being brought forward so prominently a Mr. Turner's was, if any such accident were to occur within their district.

A Difficulty in Dispensing.

Sir,—The following prescription was dispensed by me.

℞. Potass. Bicarb.	ʒ v
Liq. Strychniæ	ʒ iss
Inf. Gent. Co. ad.	ʒ viij

ʒss. ter in die.

The patient took more than one-half of the mixture, and left off taking it for more than a fortnight, then finished it with the exception of two doses, and took the remainder in a fortnight afterwards. The consequence was that the mixture was not so clear as when first sent out. When the patient took the last two doses the mixture had a sediment. The patient in the last dose (and to a slight degree in the dose before) suffered from the effects of an over-dose of strychnia, all the symptoms appearing in a very marked degree. My object in writing is to ask the probable cause of this result. The mixture when it left my hands was clear, and contained not a visible particle of strychnia in the "liquor."

It had been made up before elsewhere, but at no time was it kept for such a length of time as on this occasion.

Rothesay, July 15th, 1873. W. K. H.

[*** The result was no doubt due to an overdose of strychnine, for the quantity of water in the mixture was insufficient to dissolve the whole of the strychnine, which would be set free by the reaction of the potass. bicarb. on the liq. strychniæ. The actual quantity of strychnine thus precipitated would be likely to escape notice when the mixture was first made up, but when deposited as sediment might cause serious results. It may be assumed the prescriber intended the strychnine to be in solution, since he ordered the liquor, but it would also seem that he did not take into account the action of the alkali prescribed with it, since he did not order a "Shake the bottle" label to be used. Of course, in the absence of such a direction, it would have been advisable for the dispenser to attach such a label, although the direction to do so is properly the duty of the prescriber.—Ed. Ph. Journ.]

T. E. B.—(1) You would probably be able to obtain some lessons from a practical dentist for a consideration. (2) See Pharmaceutical Journal, 3rd series, vol. i., pp. 457, 557; ii., 637, 878. (3) We cannot undertake to recommend any dealers in preference to others.

Mr. G. Hick is thanked for his information. The communication to the Secretary was not lost sight of, but it was necessary to communicate with the Registrar of Deaths, which caused a little delay.

"*Inquirer.*"—(1) See p. 59. (2) We believe the particular tree mentioned no longer exists. It was not the only one of the kind, but was supposed to be the oldest.

A. E. J.—According to the terms of a letter written by direction of the Commissioners of Inland Revenue, and printed in the issue of the Pharmaceutical Journal for October 26, 1872, p. 327, "no licence is required for the sale of quinine wine, if made according to the receipe in the British Pharmacopœia, and not sold as a proprietary or patent medicine."

"*An Assistant*" (Cardiff). The case is one more suited for the consideration of a medical man.

M. P. S.—We are at a loss to perceive why there should be any restriction such as you refer to. If a candidate passes in such a manner as to entitle him to honours, it appears quite immaterial whether he has failed previously or not.

N. O. T. Bright, writing from the Pons Asinorum (which side is not stated), is referred to the rule respecting anonymous communications.

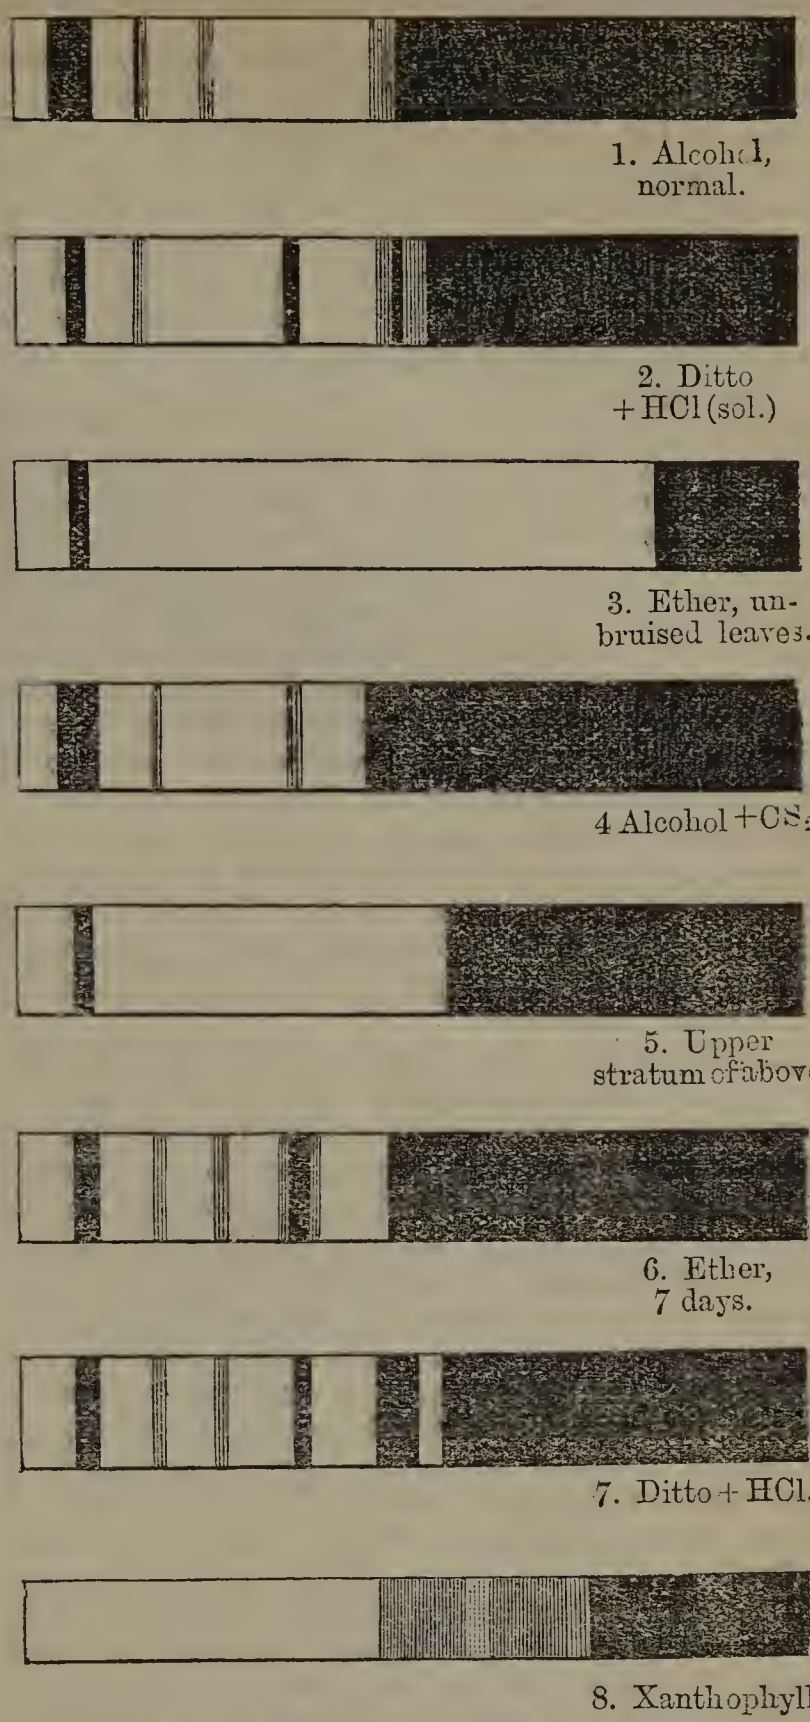
Communications, Letters, etc., have been received from Messrs. Orme, Gibbs, Upsilon, H. P., T. E. B., W. B. B.

M. CHAUTARD'S CLASSIFICATION OF THE ABSORPTION BANDS OF CHLOROPHYLL.

BY HENRY POCKLINGTON.

M. Chautard's interesting memoir, translated in the PHARMACEUTICAL JOURNAL for June 21st (p. 1014), goes a very little way towards completing our knowledge of the various chlorophyll compounds and other colouring matters of leaves. It is to my mind very doubtful whether an English reader will find much that is new in it, and still more doubtful whether the author's classification of bands will give place to Mr. H. C. Sorby's tentative classification* of the colouring matters that produce them. Mr. Sorby, as many of my readers may be aware, forms the following five great families of colouring matters, each of which he places in one of three groups, according as their absorption is removed or not when the solution is alkaline with ammonia, or, if not removed by ammonia, is removed by addition of citric acid, or, finally, when not removed even when it is acid with citric acid. The *first* of these families is the chlorophyll family, distinguished by being insoluble in water, soluble in alcohol and in bisulphide of carbon. Of these there are several species, giving well marked spectra, with several narrow, dark absorption bands, one or more of which occur at the red end of the spectrum. The spectrum of the chlorophyll of nettle—selected because it is the one specially mentioned by M. Chautard—is shown in Fig. 1, and the spectra of elm, elder and privet are figured in my paper on "The Colour of Cantharides,"† recently published in this journal, and show the more characteristic of these absorption bands.

The second family is the *xanthophyll* family, containing several distinct species, of which the more common two are found in the inside and outside respectively of the common carrot. They are insoluble in water, but soluble in alcohol and in bisulphide of carbon, more soluble in the former than the latter, and also, as Herr Krauss ('Archives des Sciences,' noticed in *English Mechanic* for May 23rd) has shown, more soluble in alcohol than in benzine. Mr. Sorby's method of procuring a tolerably pure xanthophyll is the one generally adopted by myself, though I am disposed to prefer Krauss' in the case of deep green leaves, where the xanthophyll family are less fully represented than in the more yellow-green leaves. It is this. Digest the leaves for some time in considerably less alcohol than would dissolve the whole of the xanthophyll. This removes the greater part of the unchanged chlorophyll (more rapidly soluble in alcohol than xanthophyll), and on digesting the "leaves in fresh alcohol, and agitating with bisulphide of carbon, or on evaporating to dryness and dissolving in it, a tolerably pure preparation may be obtained." The spectra of the xanthophyll family are distinct from those of the chlorophyll family, and show two rather indistinct bands at the blue end,



1. Alcohol, normal.

2. Ditto + HCl (sol.)

3. Ether, unbruised leaves.

4 Alcohol + CS_2

5. Upper stratum of above

6. Ether, 7 days.

7. Ditto + HCl.

8. Xanthophyll.

Explanation of Chart.

1.—Is the normal alcoholic spectrum made rapidly from purified bruised leaves of Urtica dioica.

2.—The same with hydrocholoric acid added.

3.—Spectrum of an etherial solution made in twelve hours from unbruised young leaves in perfect condition.

4 and 5.—Lower and upper strata of alcoholic solution, treated with acid and agitated with bisulphide of carbon. The non-acidulated solution gives similar results without the 3rd band of No. 4.

6 and 7.—Ethereal solution of seven days, with and without the addition of acid.

8.—Xanthophyll of same leaves.

* "On the Colour of Leaves at Different Seasons of the Year," *Quarterly Journal of Microscopical Science*, vol. xi., N.S., pp. 214, *et seq.*; "On the Various Tints of Autumn Foliage," *Quarterly Journal of Science*, xxix., pp. 64-77, and in various other papers in *P. R. Society*, *Monthly Microscopical Journal*, *Chemical News*, etc.

† PHARMACEUTICAL JOURNAL, vol. iii. pp. 950. The specific band of the chlorophyll of elm has been partially removed, and a xanthophyllic absorption band substituted. This family is identical partly with the cyanophyll group of Herr Krauss. This family is impure, however.

but the red-yellow and yellow-green rays are freely transmitted. To see these bands, tolerably concentrated solutions in thin strata should be used and the slit carefully adjusted.

The *third* family is the erythrophyll family, and is a large and perplexing one. Its members are soluble in water, alcohol, ether, but not in bisulphide of carbon. To procure it, Mr. Sorby recommends that the reddest leaves be digested for a few hours "in as much cold ether as will dissolve all

their contained water. If the plant be very succulent and too little ether used, the water is displaced and sinks to the bottom with nearly all the colour in solution, and the ether is left almost free from erythrophyll." (The leaves of the red camellia manifest this phenomenon very well.) "On agitating the ethereal solution in a test tube with water it sinks to the bottom with nearly all the erythrophyll, whilst the chlorophyll and xanthophyll are left in the ether at the top along with a considerable part of the colours of the chrysotannin groups." It is probably some one member of this family that produces the red chromule-like substance when deoxidized by metallic potassium, sodium, or by pyrogallic acid with *liquor potassæ*, referred to in my paper on Cantharides, and which also gives the lovely bloom to the leaves* of *Cinchona Calisaya*, and other leaves, when modified by the chrysotannic series. It is also a member of this group, modified by one or more (probably two) others, that produces the "accidental" in the red described by M. Chautard, to which I shall refer presently, merely remarking now that the method adopted by M. Chautard of particularizing the *locale* of his bands renders it difficult to identify them, and that it is unfortunate that he appears not to have made any attempt to distinguish the colouring matters concerned.

The *fourth* family is the *chrysotannin* family, s metimes (and often) confused with a sub-class, the chrysophyllic. The former are to be identified by their action upon the persalts of iron. Neither usually give any absorption bands, but a more or less complete absorption of the blue end of the spectrum when not oxidized or otherwise modified. This family, in its modification (quinotannic, etc.), is a very large one, and enters into union with the preceding and the following to a very great extent, so that it is frequently difficult to say to how great an extent either of the three may be concerned in any colour, or change of colour. They are soluble in water, alcohol, and ether, but not in bisulphide of carbon.

The *fifth* and last family is the *phaiophyll* family. These are more or less brown, insoluble in bisulphide of carbon, and of very varying solubility in alcohol and water, and are usually in a maximum state of oxidation.

To return to M. Chautard's memoir. It will be observed that he recommends the solution to be made with *dilute* alcohol. This is, in fact, nearly essential to his results, as I soon found in working over his ground, and will account probably for the fact that other observers, who, like myself, chiefly operate on stronger and purer solutions, have not described the "accidentals." It is, perhaps, best in discussing this question to take the purer alcoholic solution of the colouring matters first, and compare the results thus obtained with M. Chautard's. If an alcoholic solution be rapidly made, after having purified the leaves by a few minutes' immersion in boiling water, having bruised them (Sach's method), its spectrum will be found to consist of a broad, well-defined band in the red, extending from $\frac{7}{8}$ to $2\frac{1}{4}$, full, a shaded band also in red, or rather orange, at $2\frac{7}{8}$ to $3\frac{1}{16}$, shaded somewhat at $3\frac{1}{4}$ to $4\frac{1}{4}$, full and general absorption of the whole of the violet and blue. (This is as nearly as possible a purely normal chlorophyll spectrum). The addition of hydrochloric acid produces an extra band in the green at $5\frac{1}{4}$ to 6, bare, and the solution changes to olive-green, with, if the method of Sach's be not followed, a considerable amount of turbidity and partial absorption of the extreme red. If bisulphide of carbon be added, and the mixture agitated and then allowed to subside, it will carry down with it nearly all the colouring matter, leaving only a modified xanthophyll, giving an indistinct band in the blue-green part of the spectrum, the bisulphide solution giving a band at $6\frac{1}{4}$ to $7\frac{1}{2}$, by reason of the removal of a portion of the xanthophyllic absorption from the blue.

The bold band in the red is split into halves by the addition of strong ammonia, and the bisulphide of carbon removes from a pure alcoholic solution a colouring matter or matters giving a band similar to the normal "specific band," but leaving in the alcohol a narrow band exactly corresponding to the centre of the normal broad band, and to the narrow strip removed by ammonia. This band is probably due to some form of erythrophyll, and is not of universal occurrence. For example, the green leaves* of *Cinchona Calisaya* do not contain the chlorophylloid to which I suppose it is due when they are fresh, but the dried leaves of *Cinchona succirubra* do contain it. On the other hand, the "red" leaves of *C. Calisaya* do contain this particular substance, as also do the leaves of our English elm. Figs. 4 and 5 show the position of the band referred to. It must be borne in mind in examining this chart that, as Sorby has shown (in his paper on "Aphideine"), the bisulphide of carbon has the property of shifting the absorption generally towards the red end of the spectrum, and that, therefore, the true position of the alcoholic band may be nearer the least refrangible end, as compared with the lower, bisulphide, spectrum. On the other hand, it is to be noted that it exactly corresponds in position with the band given by a rapidly made, pale-coloured solution in ether or alcohol from unbruised leaves, and there is, therefore, reason to believe that it is due to some substance or other selectively soluble in ether and alcohol, less soluble in bisulphide of carbon, and readily acted upon by ammonia.

So far, dealing as we have done with the purer chlorophyllic solution, we have found nothing analogous to the "accidental" bands of M. Chautard. If, as I have already said, we follow his method of preparing the tincture we shall meet with substantially his results. This led me to examine an aqueous decoction (hot and cold, rapidly made in each case), and I found that carefully made solutions, either with hot water or (slightly more prolonged in operation) with cold water, gave, when treated with the acid, the extreme red absorption and obscure bands to which our author refers, and that the solution so treated with hydrochloric acid was sparingly soluble in alcohol and ether, but very soluble in water. Further examination showed that the aqueous solution contained the following groups of colouring matters, of which it is difficult to name with certainty the one actively concerned: one or more of the *erythrophyll* family, a *chrysotannin*, darkening with persalts of iron, and a peculiar *chrysophyll*. Taking some solution, prepared according to our author's plan, I added an excess of ether, and allowed the mixture to

* The colouring matters of these leaves are, however, specially complex, and it is hard to say what particular family or group is most implicated in any colour change.

* For bountiful supplies of these leaves, fresh and dry, my thanks are due to J. Eliot Howard, Esq.

separate. The upper or ethereal solution gave the spectrum referred to by M. Chautard as the normal spectrum; the lower, a spectrum with the "specific" band lowered towards the red end, and behaving, with hydrochloric acid, partially the same as M. Chautard's solution—not entirely, for one constituent (probably a xanthophyllic product) is selectively soluble in ether. The aqueous solution and the diluted alcoholic alike deepen in colour under the action of any deoxidizing agent, and lose their colour again under any oxidizing agent.

To sum up my conclusions very briefly, the shifting of the specific band to the red is probably due to the removal of the more purely chlorophyllic absorption from the violet side of the specific band, and the production of a new absorption band due to an erythrophyll-chrysotannic product on the red side of it, and the introduction of a new, more or less general, absorption at the extreme red end, due to a chrysotannic compound.

The spectrum of an ethereal solution allowed to remain long in contact with the leaves (several days) is worth notice, and is charted in figs. 6 and 7; the former being the spectrum of the unacted upon solution; the latter, on the addition of hydrochloric or diluted nitric acid. The appearance of the fifth band has been previously referred to as following the addition of hydrochloric acid, and frequently appears spontaneously, in cases where the xanthophyll group is sparingly present, and has been figured by myself, and probably by others, as so occurring.

The addition of pyrogallic acid and liquor potassæ, or of metallic sodium, or potassium, to the water-ether solution, precipitates a red colouring matter similar to that previously referred to. But space will not permit anything like a complete discussion of the highly complex colouring matter of this homely leaf. Many of them will come again under consideration, in another connection, very shortly and may be deferred; and others are as yet, so far as I know, imperfectly understood. I have probably said enough to show that these colouring matters are more complex than is generally believed, and to indicate the way in which their study may be conducted. In conclusion, it is but just, though unnecessary, to acknowledge my indebtedness to Mr. Sorby's articles for much that I have said.

P.S.—Since the foregoing was sent to press Mr. Sorby has reviewed Herr Krauss' book (*Academy*, July 1st), and takes very similar ground. Mr. Sorby has also communicated a paper to the Royal Society on a "Comparative Vegetable Chromatology" giving the latest results at which he has arrived.—H. P.

NOTE ON THE EXHIBITION OF RESIN OF COPAIBA.

BY A. W. GERRARD,

Dispenser, and Teacher of Pharmacy, University College Hospital.

The above resin has been recently introduced to the notice of the medical profession by Dr. Samuel Wilks as possessing therapeutic advantages over the balsam, and likewise as being more agreeable for the patient to take. In a letter to the *Lancet* of June the 21st, Dr. Wilks, in reply to numerous inquiries that had been made as to the best method of dispensing it, gave the following formula, which had been recommended by me, and was used in the dispensary of Guy's Hospital:—

Take of—

Resin of Copaiba	180 grains.
Rectified Spirit	5 drachms.
Spirit of Chloroform	1 „
Mucilage of Acacia	2 ounces.
Water to	12 „

Mix according to art.

These ingredients, when mixed in their proper order, form a mixture which, although it contains the resin in a fine state of division, I did not consider altogether satisfactory, as after standing a day or two the resin collects at the bottom of the bottle, forming a semi-compact mass which is shaken apart with difficulty. With the view of overcoming this objection, I made experiments with various other substances and obtained the best result in the following:—

Take of—

Resin of Copaiba	15 grains.
Compound Powder of Almonds	30 „
Water to	1 ounce.

Rub the resin with the powder until well incorporated, then add the water after the manner of forming an emulsion.

This forms a cream-coloured emulsion of a very satisfactory character, having but a faint odour of copaiba. This may be removed by the addition of compound tincture of lavender, which at the same time imparts an agreeable pink tinge.

The emulsifying power of the powder of almonds is undoubtedly due principally to the fixed oil it contains, which acts as a solvent of the resin; the action is also assisted by the gum and sugar. For the use of hospital dispensers and others who may have frequent occasion to dispense it, it may be kept in a concentrated form, 1 = 4.

EFFERVESCING SOLUTION OF TARTRATE OF SODIUM.

A formula for this preparation is published in the *American Journal of Pharmacy* for July, which has been devised by Mr. Joseph Landschütz, of Philadelphia, who states that he has for some time dispensed it, and that his customers decidedly prefer it to the popular solution of citrate of magnesium.

The merits claimed for the solution of tartrate of sodium are that it is more pleasant to the taste than even citrate of magnesium, while it is more reliable and efficient in its action as a purgative, with less tendency to produce tenesmus. Another decided advantage is the fact of its forming a permanent solution, from which no precipitate settles down, and last, though not least, its much greater cheapness, costing only about one-fourth as much as the magnesium citrate. The present high price of citric acid seems to offer peculiar temptations to cheaper sophistications, such as sulphate of magnesium.

Mr. Landschütz's formula for filling fourteen of the ordinary twelve-ounce citrate bottles, is as follows:—

Dissolve 9 oz. crystallized tartaric acid, and 17 oz. crystallized carbonate of sodium, in about one quart of cold water.

Provided the acid is not moist, and the carbonate not effloresced, the above solution will be nearly

neutral. In general, it is best to test it, and neutralize it, if necessary. Then dissolve in it 28 scruples bicarbonate of sodium. Filter, and add sufficient water to make the entire quantity measure 147 fluid ounces.

Make a syrup from

21 oz. best crushed sugar,
14 drachms crystallized tartaric acid,
10 oz. water. After cooling, add
1 drachm essence of lemon and mix thoroughly.

Measure 1½ fluid ounces of this syrup into each of the fourteen bottles. Then pour in slowly the first solution, carefully avoiding an admixture with the syrup; cork and tie each bottle as soon as filled. When this is carefully managed, but very little carbonic acid gas will escape.

Each bottle so prepared will contain about seven drachms of dry tartrate of sodium, which is a fair adult dose.

DETERMINATION OF POISONOUS VEGETABLE SUBSTANCES FOR FORENSIC INVESTIGATIONS.*

The writer proposes chloroform as a very important and easily applicable test reagent for distinguishing between the various vegetable alkaloids. From solution in sulphuric acid the following substances are gradually withdrawn by repeated agitation with chloroform:—caffeine, theobromine, colchicine, thebaine, papaverine, narcotine, and picrotoxine. From the same solution, after neutralizing with an alkali, chloroform withdraws immediately and completely in the cold strychnine, chinine, chinidine, cinchonine, caffeine, theobromine, emetine, atropine, hyoscyamine, aconitine, veratrine, physostygmine, narcotine, codeine, thebaine, nicotine, coniine; and, more slowly, brucine, colchicine, and papaverine; sabadilline only when warmed; and narceine in smaller quantities. Morphine and solanine are not withdrawn by chloroform from either an acid or alkaline solution.

In order to apply the alcohol test, the object is cut up, warmed to 75° C., heated with water containing sulphuric acid, and the solution digested at that temperature; the insoluble residue is pressed off, and repeatedly extracted with warm water. The acid extracts thus obtained are nearly neutralized by bicarbonate of soda till only a slight acid reaction remains, and then evaporated in a water-bath to a thin syrup. This is mixed with four times its volume of 90 per cent. alcohol, and, after twenty-four hours, warmed to 40° or 50° C., filtered off, and the residue extracted with alcohol. From the alcoholic extract the alcohol is then completely distilled off. The residue of distillation is filtered, chloroform added, and then ammonia, till there is a distinct alkaline reaction, and the solution is then repeatedly agitated. The chloroform solution is then separated, and the alkaline fluid extracted with fresh portions of chloroform, until no residue is left on evaporating a small portion of the liquid. The alkaline fluid is in the meantime placed aside, and all the chloroform solutions several times agitated with fresh portions of water containing sulphuric acid. The chloroform is separated from the sulphuric water, the latter neutralized with ammonia, and then shaken again several times with chloroform. The chloroform solution now obtained is passed through a filter moistened with chloroform, washed with chloroform, and evaporated. The residue that remains behind is tested for all those alkaloids which have been mentioned above as being extracted from an alkaline solution by chloroform. The alkaline aqueous fluid that was placed aside is treated with a fresh quantity of chloroform and dilute sulphuric acid till it becomes acid, again agitated with chloroform, and the chloroform separated and evaporated. Any picrotoxine that may be present and the remainder of the colchicine remain in the residue. On the now acid aqueous fluid is poured a stratum of amyl-alcohol, the solution made alkaline with ammonia, and shaken, the amyl-alcohol taken off, filtered, and evaporated; all the morphine, digitaline and solanine, and the greater part of the remainder of the sabadilline, narceine, and picrotoxine will be found in the solution; in the residue, after evaporation, a small quantity of the narcotine, caffeine, papaverine, theobromine, digitaline and colchicine. The first extract with chloroform is now evaporated, the residue repeatedly extracted with warm water containing sulphuric acid, the acid fluid neutralized with ammonia and agitated with chloroform. The remainder of the substances will remain, after evaporation of the chloroform.

Dr. Nowak also gives the following reactions resulting from the application of concentrated sulphuric acid :—

Of the poisonous substance of which an analysis is required a small quantity is placed on a watch-glass, and one or two drops of chemically-pure sulphuric acid added. The results obtained may classify the substances into six groups, as follows :—

1. The substance remains colourless : chinine, cinchonine, morphine, strychnine, caffeine, theobromine, codeine (coniine, nicotine), atropine.

2. A yellow colour of different shades ensues : chinidine, colchicine, emetine, narcotine, aconitine, picrotoxine, solanine, veratrine, sabadilline.

3. The substance becomes rose-red : brucine.

4. It becomes first red, but is very soon dissolved with a yellow colour : thebaine.

5. A violet colour results : papaverine.

6. Various shades of brown are produced : delphinine, narceine, digitaline.

The paper includes also instructions for a variety of other useful tests to determine the presence of the particular alkaloids.

* Abstract of a paper by Dr. Joseph Nowak in the 'Sitzungsberichte der kais. Akademie der Wissenschaften' of Vienna.

THE SANITARY VALUE OF FLOWERS.

The following is quoted by the *Gardeners' Chronicle* from a new American publication, *Hygiene: a Journal of Sanitary Science* :—

"Wordsworth sings that

'Every flower
Enjoys the air it breathes;'

whilst the chemist adds (as far as the leaves are concerned) that, by its breath, it purifies the air for the service of man. Not content with this, modern chemical research is engaged in determining other and unsuspected uses for what have hitherto been considered, in their forms of grace, their various hues and fragrance, to minister only to the æsthetic wants of mankind.

"When these researches, two or three years ago, first began to attract the attention of those interested in sanitary science, the writer, then connected with the health department of a large city, found a fitting field in the low, swampy surroundings, filling the air with malaria, and in the neighbourhood of the numerous slaughter-houses, reeking with animal exhalations, in which to test the value of their deductions. Here, in the vicinity of some of the most beautiful natural scenery in the world, rendered almost uninhabitable—as at Staten Island, at numerous points along the Hudson and elsewhere—by the presence of malaria, there is abundant incentive for urging the speedy carrying out of a measure of reclamation at once inexpensive, attractive, and effectual—namely, the cultivation of odorous and aromatic plants and shrubs in all regions where either animal or vegetable miasms abound.

"That our readers may be able to judge of the probable

effectiveness of such a measure, we present the following *résumé* of the researches above referred to, as well as the collateral evidence of the long-recognized hygienic and sanative value of perfumes in general. . . . . .

"It is to the investigations of an Italian *savant*, Professor Paolo Mantegazza, of Pavia, that we are indebted for the information that this great atmospheric purifier (ozone) is generated in larger quantities by certain plants and fruits possessing spicy aromatic odours than it is by the action of electricity upon the air, the potent influence of which in purifying the atmosphere we all recognize and are grateful for after a thunderstorm. This ozone is developed in some plants by the direct rays of the sun, whilst in others, the action, once commenced in solar light, is continued in darkness; cherry-laurel, clove, lavender, mint, lemon, fennel, narcissus, heliotrope, hyacinth, mignonette, etc., as well as some perfumes, as eau-de-cologne, oil of bergamot, extract of millefleurs, essence of lavender, and some aromatic tinctures, all produce ozone largely on exposure to the sun's rays. Mantegazza has further pointed out that the oxidation of the essential oils, such as turpentine, nutmeg, aniseed, thyme, peppermint, etc., under the influence of light and air, is a convenient source of ozone, as they, even in small quantities, ozonize much of the atmospheric oxygen.

"He finds also, that while the ozonigenic properties of flowers reside mainly in their perfumes—the most odoriferous yielding the largest amount of ozone—certain others, possessing no particular perfume, have extraordinary ozonigenic power; as, for instance, the sun-flower, broad belts of which were planted by the late Commander Maury around the grounds of the National Observatory at Washington, and to the effect of which he attributed the after immunity of his family from intermittent fevers, previously quite prevalent in that neighbourhood. Dr. Cornelius Fox also states in his work on ozone and antozone, that the cultivation of this gaudy plant in malarious districts has been especially urged, as it is said to possess the property of purifying the air laden with marsh miasm, and of exhaling ozonized oxygen.

"Professor Mantegazza demonstrates in his report on the action of essences and flowers in the production of atmospheric ozone and their hygienic utility, that the instructions of Empedocles, in the second book of his didactic poem on Nature, to plant aromatic and balsamic herbs as preventives of pestilence, were founded on a close observation and shrewd, though empirical, insight. The historian Herodian relates that, in a plague which devastated Italy in the second century, strangers crowding into Rome were directed by the physicians to retreat to San Lorenzo, then called *Laurentum*, from the bowers of laurel which surrounded it, that by a cooler atmosphere and by the 'odour of laurel' they might escape the dangers of infection.

"The practice of burning aromatic woods and herbs, as well as odorous gums, spices, etc.,—not to speak of the use of tar-smoke, the antiseptic properties of which are attributed to carbolic and other acids,—as a means of arresting the spread of, and extinguishing epidemics, is of the highest antiquity. Numerous instances are cited of the extinction of the plague by means of fires of odoriferous wood, green laurel, wormwood, chamomile, etc., in the market places, and even in the houses both of the healthy and the sick. Their efficacy, it is now claimed, was due to the production of ozone, by which the pestilential constitution of the atmosphere was purified.

"Within the limit of these pages it is only possible to hint at the sources of information, and this only to give weight and authority to the practical suggestions of measures affecting the great problem of the prevention of disease and the preservation of health. These suggestions, in the present case, are obvious, and will, in some degree, supplement the recent recommendations of Dr. Stephen Smith concerning the cultivation of shade trees in the streets of cities as a means of diminishing the high mortality of summer by modifying the temperature, and by purifying the atmosphere.

"What we would here urge is the cultivation of plants and flowers possessing these desirable ozonigenic properties, alike in city and country, within doors and without; in cities because the air of cities always contains less ozone than the air of the surrounding country, and the denser parts of cities less than the more sparsely built, or than the air of parks and squares; in the country, because very few regions are entirely free from malarial taint.

"They should be cultivated in and around schools and all other places where animal exhalations abound, especially in the districts where slaughtering and kindred occupations are carried on, and in graveyards and cemeteries. The swamps and flats and 'meadows' of Staten Island, those around Jersey City and Hoboken, in the vicinity of Brooklyn and in the upper part of Manhattan Island, should be made to blossom as the rose.

"Aside from the poetical and æsthetic aspects, the florist and the nurseryman and the seedsman may put in a plea for consideration on purely utilitarian grounds. Instead of such disinfectants as those that have been described as chiefly of value because 'they smell so badly that people open the windows and let the fresh air in,' they will furnish us each

> 'Daintie flowre and herb that growes on ground,
> To bud out faire and throw swete smels around.'

And it may yet come to pass that he who makes two flowers to blossom where only one bloomed before shall receive the encomium Dean Swift suggested for the successful corn or grass grower."

SPECTRA OF POLARIZED LIGHT.*

BY WILLIAM SPOTTISWOODE, ESQ., LL.D., M.A.,

Treas. R.S., Sec. R.I.

Some apology is, perhaps, due to you on my part for proposing that you should come together for such elementary experiments as those which I have to offer you this evening; but the growing importance of the subject of polarization, both in general and in astronomical physics, and the increased instrumental means at our command for the study and the exhibition of the phenomena, all seem to indicate that an hour may be not unprofitably spent in trying to obtain a clearer insight into the fundamental parts of the subject.

The object which I propose on this occasion is to verify experimentally the explanation furnished by the wave-theory of the colours produced by crystal plates when submitted to polarized light. Not because the wave-theory or its conclusions need in themselves any verification, but because the line of argument ought to be continuous throughout,—not like an electric current which leaps from one part of a broken conductor to another. Each line, whether theoretical or experimental, should be complete and continuous from one end to another.

Having this object in view, I propose to reproduce, by way of memorandum, a few of the phenomena in question so as to bring them and their analysis in as close juxtaposition as possible; and for this purpose I have arranged two electric lamps, each furnished with a complete polarizing apparatus, but the second having in addition a pair of dispersive prisms, forming, in fact, a spectroscope. In the first arrangement I would draw your particular attention to a Nicol's prism or polarizer, superior in respect of size, and in the opinion of those best capable of judging, not inferior in quality to any hitherto constructed. We have, in fact, before us, first the pair of Nicols constructed by Mr. Ladd, which accompanied Professor Tyndall in his journey to the United States; secondly, a larger one made

---

* Lecture delivered at the Royal Institution, Friday, May 23, 1873

for him by Mr. Browning; and thirdly, the largest of all, by Messrs. Tisley and Spiller. And lest it should seem that in thus proceeding from large to larger we have been aiming merely at indefinite size, I may explain that my object has always been a strictly definite one, viz., to obtain a polarizer large enough to transmit the entire beam which issues from the lantern; in this I have now completely succeeded.

Now it is well known that if a plate of selenite sufficiently thin be placed between two such Nicol's prisms, or, more technically speaking, between a polarizer and an analyser, colour will be produced. And the question proposed is, What is the nature of that colour? Is it simply a pure colour of the spectrum, or is it compound, and if so, what are its component parts? The answer given by the wave theory is in brief this: In its passage through the selenite plate the rays have been so separated in the direction of their vibrations and the velocity of their transmission, that, when re-compounded by means of the analyser, they have in some instances neutralized one another. If this be the case, the fact ought to be visible when the beam emerging from the analyser is dispersed by the spectroscope; for then we have the rays of all the different colours ranged side by side, and if any be wanting, their absence will be shown by the appearance of a dark band in their place in the spectrum. But not only so; the spectrum ought also to give an account of the other phenomena exhibited by the selenite when the analyser is turned round, viz., that when the angle of turning amounts to 45° all trace of colour disappears: and also that when the angle amounts to 90° colour reappears. not, however, the original colour, but one complementary to it.

You now see in the spectrum of the reddish light produced by the selenite a broad but dark band in the blue; when the analyser is turned round the band becomes less and less dark, until when the angle of turning amounts to 45° it has entirely disappeared. At this stage each part of the spectrum has its own proportional intensity, and the whole produces the colourless images seen without the spectroscope. Lastly, as the turning of the analyser is continued a dark band appears in the red, the part of the spectrum complementary to that occupied by the first band; and the darkness is most complete when the turning amounts to 90°. Thus we have from the spectroscope a complete account of what has taken place to produce the original colour and its changes.

It is further well known that the colour produced by a selenite, or other crystal plate, is dependent upon the thickness of the plate. And, in fact, if a series of plates be taken, given different colours, their spectra are found to show bands arranged in different positions. The thinner plates show bands in the parts of the spectrum nearest to the violet, where the waves are shorter, and consequently give rise to redder colours; while the thicker show bands nearer to the red, where the waves are longer, and consequently supply bluer tints.

When the thickness of the plate is continually increased, so that the colour produced has gone through the complete cycle of the spectrum, a further increase of thickness causes a reproduction of the colours in the same order; but it will be noticed that at each recurrence of the cycle the tints become paler, until when a number of cycles have been performed, and the thickness of the plate is considerable, all trace of colour is lost. Let us now take a series of plates, the first two of which, as you see, give colours; with the others which are successively of greater thickness the tints are so feeble that they can scarcely be distinguished. The spectrum of the first shows a single band; that of the second, two: showing that the second series of tints is not identical with the first, but that it is produced by the extinction of two colours from the components of white light. The spectra of the others show series of bands more and more numerous in proportion to the thickness of the plate, an array which may be increased indefinitely. The total light, then, of which the spectrum is deprived by the thicker plates is taken from a greater number of its parts; or in other words, the light which still remains is distributed more and more evenly over the spectrum; and in the same proportion the sum total of it approaches more and more nearly to white light.

These experiments were made more than thirty years ago by the French philosophers, MM. Foucault and Fizeau.

If instead of selenite, Iceland spar, or other ordinary crystals, we use plates of quartz cut perpendicularly to the axis, and turn the analyser round as before, the light, instead of exhibiting only one colour and its complementary, with an intermediate stage in which colour is absent, changes continuously in tint; and the order of the colour depends partly upon the direction in which the analyser is turned, and partly upon the character of the crystal, *i.e.*, whether it is right-handed or left-handed. If we examine the spectrum in this case we find that the dark band never disappears, but marches from one end of the spectrum to another, or *vice versâ*, precisely in such a direction as to give rise to the tints seen by direct projection.

The kind of polarization effected by the quartz plates is called circular, while that effected by the other class of crystals is called plane on account of the form of the vibrations executed by the molecules of æther; and this leads us to examine a little more closely the nature of the polarization of different parts of these spectra of polarized light.

Now, two things are clear; first, that if light be plane-polarized, that is, if all the vibrations throughout the entire ray are rectilinear and in one plane, they must in all their bearings have reference to a particular direction in space, so that they will be differently affected by different positions of the analyser. Secondly, that if the vibrations be circular they will be affected in precisely the same way (whatever that may be) in all positions of the analyser. This statement merely recapitulates a fundamental point in polarization. In fact, plane-polarized light is alternately transmitted and extinguished by the analyser as it is turned through 90°; while circularly-polarized light remains to all appearance unchanged. And if we examine carefully the spectrum of light which has passed through a selenite, or other ordinary crystal, we shall find that, commencing with two consecutive bands in position, the parts occupied by the bands and those midway between them are plane-polarized, for they become alternately dark and bright; while the intermediate parts, *i.e.*, the parts at one-fourth of the distance from one band to the next remain permanently bright. These are, in fact, circularly polarized. But it would be incorrect to conclude from this experiment alone that such is really the case, because the same appearance would be seen if those parts were unpolarized, *i.e.*, in the condition of ordinary lights. And on such a supposition we should conclude with equal justice that the parts on either side of the parts last mentioned (*e.g.*, the parts separated by eighth parts of the interval between two bands) were partially polarized. But there is an instrument of very simple construction, called a "quarter-undulation plate," a plate usually of mica, which thickness is an odd multiple of a quarter of a wave length, which enables us to discriminate between light unpolarized and circularly-polarized. The exact mechanical effect produced upon the ray could hardly be explained in detail within our present limits of time; but suffice it for the present to say that when placed in a proper position, the plate transforms plane into circular and circular into plane-polarization. That being so, the parts which were originally banded ought to remain bright, and those which originally remained bright ought to become banded during the rotation of the analyser. The general effect to the eye will consequently be a general shifting of the bands through one-fourth of the space which separates each pair.

Circular-polarization, like circular motion generally, may of course be of two kinds, which differ only in the direction of the motion. And, in fact, to convert the circular polarization produced by this plate from one of these kinds to the other (say from right-handed to left-handed, or *vice versâ*), we have only to turn the plate round through 90°. Conversely right-handed circular-polarization will be changed by the plate into plane-polarization in one direction, while left-handed will be changed into plane at right angles to the first. Hence, if the plate be turned round through 90° we shall see that the bands are shifted in a direction opposite to that in which they were moved at first. In this, therefore, we have evidence not only that the polarization immediately on either side of a band is circular, but also that that immediately on the one side is right-handed, while that immediately on the other is left-handed.

If time permitted, I might enter still further into detail, and show that the polarization between the plane and the circular is elliptical, and even the positions of the longer and shorter axes and the direction of motion in each case. But sufficient has, perhaps, been said for our present purpose.

Before proceeding to the more varied forms of spectral bands, which I hope presently to bring under your notice, I should like to ask your attention for a few minutes to the peculiar phenomena exhibited when two plates of selenite giving complementary colours are used. The appearance of the spectrum varies with the relative position of the plates. If they are similarly placed, that is as if they were one plate of crystal, they will behave as a single plate, whose thickness is the sum of the thicknesses of each, and will produce double the number of bands which one alone would give; and when the analyser is turned, the bands will disappear and reappear in their complementary positions, as usual in the case of plane-polarization. If one of them be turned round through 45°, a single band will be seen at a particular position in the spectrum. This breaks into two, which recede from one another towards the red and violet ends respectively, or advance towards one another according to the direction in which the analyser is turned. If the plate be turned through 45° in the opposite direction the effects will be reversed. The darkness of the bands is, however, not equally complete during their whole passage. Lastly, if one of the plates be turned through 90° no bands will be seen, and the spectrum will be alternately bright and dark, as if no plates were used, except only that the polarization is itself turned through 90°.

If a wedge-shaped crystal be used, the bands instead of being straight will cross the spectrum diagonally, the direction of the diagonal (dexter or sinister) being determined by the position of the thicker end of the wedge. If two similar wedges be used with their thickest ends together, they will act as a wedge whose angle and whose thickness is double of the first. If they be placed in the reverse position they will act as a flat plate, and the bands will again cross the spectrum in straight lines at right angles to its length.

If a concave plate be used the bands will dispose themselves in a fan-like arrangement, their divergence depending upon the distance of the slit from the centre of concavity.

If two quartz wedges, one of which has the optic axis parallel to the edge of the refractory angle, and the other perpendicular to it, but in one of the planes containing the angle (Babinet's Compensator) the appearances of the bands are very various.

The diagonal bands, beside sometimes doubling themselves as with ordinary wedges, sometimes combine so as to form longitudinal (instead of transverse) bands, and sometimes cross one another so as to form a diaper pattern with bright compartments in a dark framework, and *vice versâ*, according to the position of the plates.

The effects of different dispositions of the interposed crystals might be varied indefinitely; but enough has, perhaps, been said to show the delicacy of the method of spectrum analysis as applied to the examination of polarized light.

PRECAUTIONS AGAINST THE INFECTION OF CHOLERA.

The following precautions against the infection of cholera are recommended by Dr. Simon, the medical officer to the Local Government Board. The value of the suggestions and the importance of the subject to which they refer fully justify their reproduction here.

1. As Asiatic cholera is now prevailing in parts of the continent of Europe, and may probably extend (or perhaps has already extended) to places which are in frequent and rapid communication with England, it is not unlikely that, within the next month or two, cases of the disease may be brought into the ports of this country.

2. The order, now about to be issued, of the Local Government Board will give power to local sanitary authorities to deal with any such cases, if they arrive, in a way to protect the population, as far as practicable, against surprise. But as cases of choleraic infection have widely-different degrees of severity, it is possible that some such cases, slightly affected, will, notwithstanding the vigilance of local authorities, be landed without particular notice in English sea-board towns, whence then they may advance to other, and perhaps inland, places.

3. Former experience of cholera in England justifies a belief that the presence of imported cases of the disease at various spots in the country will not be capable of causing much injury to the population, if the places receiving the infection have had the advantage of proper sanitary administration; and, in order that all local populations may make their self-defence as effective as they can, it will be well for them to have regard to the present state of knowledge concerning the mode in which epidemics of cholera (at least in this country) are produced.

4. Cholera in England shows itself so little contagious in the sense in which small-pox and scarlatina are commonly called contagious, that, if reasonable care be taken where it is present, there is almost no risk that the disease will spread to persons who nurse and otherwise closely attend upon the sick. But cholera has a certain peculiar infectiveness of its own, which, *where local conditions assist*, can operate with terrible force, and at considerable distances from the sick. It is characteristic of cholera (and as much so of the slighest choleraic diarrhœa as of the disease in its more developed and alarming forms) that *all matters which the patient discharges from his stomach and bowels are infective*. Probably, under ordinary circumstances, the patient has no power of infecting other persons except by means of these discharges; nor any power of infecting even by them, except in so far as particles of them are enabled to taint the food, water, or air, which people consume. Thus when a case of cholera is imported into any place, the disease is not likely to spread unless in proportion as it finds locally open to it certain facilities for spreading by *indirect infection*. In order rightly to appreciate what these facilities must be the following considerations have to be borne in mind:—*first*, that any choleraic discharge cast without previous thorough disinfection into any cesspool or drain, or other depository or conduit of filth, infects the excremental matters with which it there mingles, and probably, more or less, the effluvia which those matters evolve; *secondly* that the infective power of choleraic discharges attaches to whatever bedding, clothing, towels, and like things, have been imbued with them, and renders these things if not thoroughly disinfected as capable of spreading the disease in places to which they are sent (for washing or other purposes) as, in like circumstances, the patient himself would be · *thirdly*,

that if by leakage or soakage from cesspools or drains, or through reckless casting out of slops and wash-water, any taint (however small) of the infective material gets access to wells or other sources of drinking-water, it imparts to enormous volumes of water the power of propagating the disease. When due regard is had to these possibilities of indirect infection, there will be no difficulty in understanding that even a single case of cholera, perhaps of the slightest degree, and perhaps quite unsuspected in its neighbourhood, may, *if local circumstances co-operate*, exert a terribly infective power on considerable masses of population.

5. It might be supposed that, under those provisions of the Sanitary Acts which relate to precautions against dangerous infections of disease, security could be taken, as regards the infective discharges of cholera, against various kinds of personal conduct which would be dangerous to the public health: above all, that, under those provisions or otherwise, the universal disinfection of such discharges could be enforced. Undoubtedly everything possible in this direction ought to be done, wherever a case of cholera is known to exist: too much importance cannot be attached to the precaution of thoroughly disinfecting, without delay, all discharges from the stomach and bowels of persons suffering under the disease, and of disinfecting or destroying all bedding, clothing, towels, and the like, which such discharges may have imbued: and of course neither choleraic discharges, nor any slops which may contain traces of them, should ever (even when supposed to be disinfected) be cast into any position from which they may get access into drinking-water. But, although the duty of observing those precautions is one which ought never to be neglected, populations cannot prudently stake their lives on the chance that it will be completely fulfilled for them. Apart from all questions of negligence, the degrees of cholera are too many, and the slight and incipient cases far too apt to escape observation, for any such defence against its infection to be more than partial. And therefore the main object for endeavour must be, to secure everywhere such local circumstances that the infective material, though not disinfected, would be unable to spread its influence among the population.

6. The dangers which have to be guarded against as favouring the spread of cholera-infection are particularly two. First, and above all, there is the danger of water-supplies which are in any (even the slightest) degree tainted by house-refuse or other like kinds of filth; as where there is outflow, leakage or filtration, from sewers, house-drains, privies, cesspools, foul ditches or the like, into springs, streams, wells or reservoirs, from which the supply of water is drawn, or into the soil in which the wells are situate: a danger which may exist on a small scale (but perhaps often repeated in the same district) at the pump or dip-well of a private house, or, on a large and even vast scale, in the source of public water-works. And secondly, there is the danger of breathing air which is foul with effluvia from the same sorts of impurity.

7. Information as to the high degree in which those two dangers affect the public health in ordinary times, and as to the special importance which attaches to them at times when any diarrhœal infection is likely to be introduced, has now for so many years been before the public that the improved systems of refuse-removal and water-supply by which the dangers are permanently obviated for large populations, and also the minor structural improvements by which separate households are secured against them, ought long ago to have come into universal use.

So far, however, as this wiser course has not been adopted, temporary security must, as far as practicable, be sought in measures of a palliative kind.

(*a.*) Immediate and searching examination of sources of water supply should be made in all cases where the source is in any degree open to the suspicion of impurity: and the water both from private and public sources should be examined. Where pollution is discovered, everything practicable should be done to prevent the pollution from continuing, or, if this object cannot be attained, to prevent the water from being drunk.

(*b.*) Simultaneously, there should be immediate thorough removal of every sort of house-refuse and other filth which has accumulated in neglected places; future accumulations of the same sort should be prevented: attention should be given to all defects of house-drains and sinks through which offensive smells are let into houses: thorough washing and lime-washing of uncleanly premises, especially of such as are densely occupied, should be practised again and again.

(*c.*) Disinfection should be very freely and very frequently employed in and round about houses, wherever there are receptacles or conduits of filth; wherever there is filth-sodden porous earth; wherever anything else, in or under or about the house, tends to make the atmosphere foul.

In the absence of permanent safeguards, no approach to security can be got without incessant cleansings and disinfections, or without extreme and constant vigilance against every possible contamination of drinking-water.

8. In view of any possibility that the infection of cholera may again be present in this country, it is desirable that in each locality the public should ascertain to whom it practically has to look, in case of need, for its collective safety against such dangers as the above. The responsibility is, in a large proportion of cases, mixed. The most critical of all its branches, the responsibility of providing for the unpollutedness of water-supplies, is, in many very important places, in the hands of commercial companies; and it is to be hoped that these companies, informed, as they must be, of the calamitous influence which some of their number have exerted in previous epidemics of cholera, will remember, if the disease shall again be present here, that each of them, in its daily distribution of water, has hundreds, or even thousands of human lives in its hands. But, except to that extent, the responsibility for local defences against cholera, both as regards water supply and as regards local cleanliness and refuse-removal, is vested in the local sanitary authorities, urban and rural. These authorities are all, by law, so constituted as to represent, in their respective areas of jurisdiction, the will of the local rate-paying population; and each such population has had almost absolute means of deciding for itself whether the district which it inhabits should be wholesomely or unwholesomely kept. It is greatly to be wished that the former of these alternatives had, from long ago, been the desire of every local constituency in the country; and it may fairly be believed that, in considerable parts of the country, conditions favourable to the spread of cholera are less abundant than at former times of visitation. But it is certain that in very many places the conditions of security are wholly or almost wholly absent; and it is to be hoped that in all this large class of cases the authorities, under present circumstances, will do everything which, in the remaining time, can be done to justify the trust reposed in them by the Legislature for the protection of the public health.

9. It is important for the public very distinctly to remember that pains taken and costs incurred for the purposes to which this memorandum refers cannot in any event be regarded as wasted trouble and expense. The local conditions which would enable cholera, if imported, to spread its infection in this country, are conditions which day by day, in the absence of cholera, create and spread other diseases: diseases which, as being never absent from the country, are, in the long run, far more destructive than cholera: and the sanitary improvements which would justify a sense of security against any apprehended importation of cholera would, to their extent, though cholera should never reappear in England, give amply remunerative results in the prevention of those other diseases.

The Pharmaceutical Journal.

SATURDAY, JULY 26, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACY IN THE SERVICES.

OUR readers have lately had an opportunity of learning something of the position held by the pharmacists connected with the French army, and a letter published in the present number (p. 79) affords means of comparing with that the conditions under which our own military authorities require the services of dispensers to be performed.

The comparison is not satisfactory either as regards the status of the pharmacist or as regards the interests of those who may require the services of the military dispenser. Looking to the terms of the advertisement referred to by our correspondent—which appeared in this Journal on the 7th June last—we cannot but agree with him in thinking that its natural purport is a demand for competent pharmacists already qualified for undertaking the duty of dispensing medicines. The heading of the advertisement with the word "Dispensers" is apparently in itself sufficient to justify such an impression, which is moreover, consistent with the regulations relative to the appointment of dispensers in naval hospitals, requiring candidates to possess the Pharmaceutical Society's certificate of qualification, according to the duties they have to perform.

It appears, however, that so far as the army is concerned, the only path by which a young man may hope to obtain employment in dispensing is to enter as a recruit in a particular branch of the service, "The Army Hospital Corps," where, after serving as a private, and possibly engaged in duties having no relation to pharmacy, he may on attaining the rank of sergeant be employed as a compounder of medicine. It is true that by the regulations such employment of those attaining the rank of sergeant is restricted to those sergeants who may have qualified themselves for the duties of dispenser.

Such an arrangement may, in certain instances, work well and conveniently, but it seems open to grave objections on principle, and as a system to be wholly inadequate for ensuring proper performance of the duties of dispensing. After some years' service as a private in a military corps, it is rather late, if it be not also as a rule altogether out of place, to enter upon the study of those branches of science which are essential for the pharmacist, and the acquisition of which, by study as well as practice, is supposed to require several years' undivided attention on the part of the student.

Formerly, dispensers of medicine were employed in the Army Medical Department, and on reference to the Society's Calendar for 1867-68 it will be found that they were required to have passed the examinations of the Pharmaceutical Society, and to be registered as Pharmaceutical Chemists. That system, however, has been superseded.

The subject is one well worth the attention of pharmacists, and the example afforded by France in this respect is one deserving imitation, or at least some effort in that direction. Probably at the coming meeting of the Pharmaceutical Conference someone may bring it forward with advantage.

THE ADULTERATION OF FOOD ACT.

UNDER the provisions of this Act, passed last year, the appointment of public analysts throughout the country, as our readers will be aware, becomes necessary; and in a parliamentary return just issued the number is given of the analysts who have been already appointed in each county and borough or district of the United Kingdom. The return divides the provinces from the metropolis, and considering first the information given as to these appointments in the country, we are at once able to see how few public analysts, comparatively speaking, have been as yet officially appointed. With regard to boroughs, we find that only nine possess a public analyst, and these certainly deserve mention on account of their singularity. They are Bedford, Birmingham, Bolton, Gloucester, Gravesend, Liverpool, Manchester, Sheffield, and Wolverhampton. Most of the analysts for these places have been appointed during the present year, and with the exception of Liverpool, we are not aware that any prosecutions have as yet resulted from the performance of their official duties. With regard to the analysts who have been appointed in the various counties, we do not find that such appointments have been very numerous, thus showing that the local authorities do not consider that there is any very pressing necessity for the operations of these gentlemen. We find that the following counties now possess a public analyst:—Bedford, Berks, Carnarvon, Chester, Denbigh, Derby, Essex, Gloucester, Hertford, Lincoln, Norfolk, Nottingham, Oxford, Salop, Surrey, and Warwick. It will thus be perceived that no very great activity has been manifested by the various local authorities in carrying out that provision of the Act which refers to the appointment of analysts. When, again, we begin to consider what Ireland and Scotland have done in regard to the appointment of public analysts, we find a still greater condition of apathy with respect to the provisions of the Act. In Ireland there has actually been but one analyst appointed, and that is Dr. CHARLES CAMERON of Dublin. This shows that our Irish friends consider their food and drugs do not require the careful attention of the analysts. In

Scotland, too, apparently the same confidence as to food, etc., prevails, inasmuch as, according to the official return from which we quote, there have only been two appointments made, viz., Dr. THORPE, for Glasgow, and Messrs. PATTERSON and OGILVIE for Greenock. We have not heard of any prosecutions under the Act from Scotland, excepting that the analyst for Glasgow, Dr. THORPE, has analysed some butter there, alleged it to be adulterated, and summoned the trader who sold it. Other analysts, however, who examined the same article deposed that the butter was not adulterated as the public analyst described; and thus a very considerable contrariety of chemical evidence was elicited. Much the same state of things occurred in regard to an analysis of the Liverpool analyst, Dr. BROWN; and indeed it appears that of late the provincial analysts have got themselves into rather hot water.

The official return next refers to London, and here we find that the appointment of public analysts has been very complete, as nearly all, if not all, the various parochial districts are represented by officers of this character. For the City Dr. LETHEBY was appointed public analyst in May last; while Dr. MUTER is analyst for no less than five districts, viz., St. George-the-Martyr, Southwark; St. Mary, Lambeth; St. Mary Magdalen, Bermondsey; St. Mary Newington; and Wandsworth. Dr. REDWOOD is analyst for three districts, viz., St. James and St. John, Clerkenwell, Holborn, and St. Giles. In fact, as we have said, the metropolis is most fully represented by public analysts, there being more in London, we should imagine, than there are in the whole of the provinces. Prosecutions under the Act in the metropolis, so far as our readers are concerned, have been extremely rare; and in fact the only traders selected for the operation of this law appear to be the milkmen and grocers, upon whom in many cases it has pressed very heavily.

TWO NEW DRUGS.

FROM a recent number of the *Zeitschrift des allgemeinen österreichischen Apotheker-Vereines* we learn that two plants which are natives of the Philippine Islands have attracted some attention at the Industrial Exhibition at Vienna. One of these is the *Echises scholaris*, an Apocynaceous plant, the other the *Garcinia mangostana*, one of the Guttiferæ.

The Echises is a very abundant tree in the province of Batangar in the island of Luzon, the bark of which has long been used by the natives, under the name of Dita, as a remedy against all kinds of fevers. G. GRUPPE, an apothecary in Manilla, examined the bark and he obtained from it after repeated analyses, a very hygroscopic bitter principle to which he gave the name of Ditaïn.

Professor Dr. MIGUEL ZINA, a Spaniard and chief physician of the province of Manilla, experimented with it in the hospitals under his care and found that Ditaïn is not only a perfect substitute for quinine, but also that in its use the frequently unpleasant after effects of quinine are avoided. It is administered in the same manner and doses as quinine, and it is perfectly certain in its effect. It is also remarkably efficient as a tonic. Ditaïn may be prepared in the same way as quinine. The bark yields about 2 per cent. of Ditaïn. A single tree yields a large quantity of bark without its growth being affected. In Manilla 50 kilograms of the bark cost about 10 francs, and probably Ditaïn might be produced at about half the price of quinine. It has been used successfully in Manilla.

The product of the second named plant is an extract prepared from the fruit husks, which were some years ago imported into Europe as a tanning material. The *Garcinia* occurs frequently in Madras, Cochin China and the Philippines and had previously been used in medicine as a decoction of the fruit husks, until M. GRUPPE introduced the extract which is now used in all hospitals. Numerous experiments have shown that it is a safe, rapid, and thorough remedy for dysentry and chronic diarrhœa, as well as all catarrhal affections of the bladder and urethra.

POISONOUS NUTS.

IN a letter to the *Lancet* (July 19) Dr. HARKER states that several instances of poisoning of children by means of a fruit sold by grocers, and known by the name of "Denna nuts," have come under his notice. He describes the fruit as probably a legume, containing either one or two bay-coloured beans, the case being reticulated with about eight slightly prominent ribs and of a faint straw-colour. One of these beans planted by him in a fernery has produced a plant, the leaves of which are stipulated, the stipules lance-shaped, the leaves articulated as in the pea tribe and four in number, there being no terminal leaflet. Dr. HARKER says that in the cases of poisoning by these beans the children have been sick and powerless; there has been considerable drowsiness and the pupils have been dilated, the symptoms resembling very much those which follow poisoning by laburnam seeds. He therefore suggests that the proper treatment would be to induce vomiting, if it has not already taken place, and then to give a dose of castor oil in milk. He has not yet met with a fatal case.

The plant described by Dr. HARKER as derived from the poisonous nuts is evidently *Arachis hypogœa*. The legumes of this curious plant are ripened underground; those pods which are unable to reach and bury themselves in the ground not coming to maturity. From this circumstance they are commonly called Ground-nuts.

The name of "Denna" nuts is probably derived from Yennai, the name used in India for nuts of any kind, and would seem to indicate that they came from India where they are chiefly cultivated for the sake of the oil which they yield. So far as we are aware, their poisonous property has not before been noticed. They are largely used as food in Africa and other parts of the world, but are generally boiled by the negroes before being eaten.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

July, 1873.

Present on the 9th, 18th, and 21st—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, and Umney,

Present on the 16th—Messrs. Allchin, Barnes, Bottle, Carteighe, Cracknell, Davenport, Gale, Hills, Linford, Martindale, Schweitzer, Southall, and Umney.

Present on the 17th—Messrs. Allchin, Barnes, Bottle, Carteighe, Cracknell, Davenport, Gale, Linford, Martindale, Schweitzer, Southall, and Umney.

Dr. Greenhow was present on the 18th, on behalf of the Privy Council.

MAJOR EXAMINATION.

Twenty candidates presented themselves. *Five* failed. The following *fifteen* passed, and were declared duly qualified to be registered as Pharmaceutical Chemists :—

*Fletcher, Frederick William	Totton.
*Hulme, Richard Gleave	Hammersmith.
*Roberts, William	London.
*Rimmington, George	Bradford, Yorks.
Ball, George	Ormskirk.
Mumby, Charles John Everitt	Bury St. Edmund's.
Brookes, Frederick James	Selby.
Goulden, Herbert	London.
Cottam, William Procter	Lancaster.
Baynes, James, jun.	Hull.
Hawkes, Richard	Colchester.
Jones, John	Neath.
Hart, Thomas	Manchester.
Crundall, Augustus Horton	Cirencester.
McJannet, James	North Walsham.

MINOR EXAMINATION.

One hundred and seventeen candidates presented themselves. *Fifty-one* failed. The following *sixty-six* passed, and were declared qualified to be registered as Chemists and Druggists :—

	*Carter, Arthur Joseph	London.
	*Thompson, Frank Farrow	Cambridge.
	*Gordelier, John Thomas	Sittingbourne.
	*Dobson, George	Kingswood.
	*Woolnough, Harry Arnold	Norwich.
	*Hunter, Frederick Neish	Durham.
Equal. Equal. Equal.	*Law, Alfred	Towcester.
	*Mills, Thomas William	Birmingham.
	*Collins, Thomas Robert	Leicester.
	*Thompson, Lawrence Joseph	Thirsk.
	*Botting, Charles	Wimborne.
	*Chapman, Walter	Newstead Grange.
	Amoore, Lewis Perigoe	Hastings.
	Strang, Peter	Perth.
	Stevens, Joseph	Camden Road.
	Price, James	Market Drayton.
	Spensley, Thomas Brentnall	Middlesborough.
	Hands, Henry Joseph	Chipping Campden.
Equal	Jinks, John	Tipton.
Equal.	Taylor, Herbert Edwin	Hadleigh.
Equal.	Kemp, Harry	Salford.
	Marten, Cruttenden	Liverpool.
	Turner, William Spencer	Hingham.
	Taylor, John	Carlisle.
Equal. Equal.	Bowling, John Henry	Pembroke Dock.
	Whitehouse, Thomas Arthur	London.
Equal.	Strang, David James	Perth.
	Wolstenholme, John, jun.	Bury.
	Wyles, William	Grantham.
Equal.	Elwood, William	Grimsby.
	Metherell, Kinneard	London.
	Oldfield, Frank	Hawkhurst.
Equal.	Birkett, John Robert	Morecambe.
	Osborn, William Henry	Tewkesbury.
	Peacock, Walter	Oxford.
	Ward, Charles Thomas	London.
	Willan, Robert	Ulverston.
Equal. Equal.	Eminson, Thomas	London.
	Hardy, Joseph Wrangham	Grantham.
Equal.	Stead, Thomas Albert	Heckmondwike.
	Stephen, John	Hoxton.
	Tebb, Henry	St. Ives.
	Brown, William Braithwaite	Preston.
	Sturdy, Thomas Metcalfe	Leeds.
	Whitlamsmith, Walter	Uppingham.
	Coleby, Frederick	Surbiton.
Equal. Equal.	Birchall, Thomas Barrow	Preston.
	Smith, William	Gosport.
Equal.	Norman, Joseph Slaughter	Royston.
	Taylor, Edward	Birmingham.
	Hindle, John	Gorleston.
	Whitrow, Benjamin	Winchester.
	Barling, Gilbert Harry	Manchester.
Equal.	Gadd, William Fletcher	Oxford.
	Haller, Frederick William	Hull.
	Wellington, James	Oakham.
	Sprake, David Lewis	Carmarthen.
	Hall, Ralph	Kingsland Road.
	Storey, John Charles	Hull.
	Davies, William	Llandilo.
Equal	Staning, Walter	Hull.
	White, William Charles	Barnstaple.
	Jenkyn, Thomas, jun.	Penzance.
Equal.	Hambridge, Thomas	Lower Tottenham.
	Payne, Henry	Alford.
	Woolstencroft, Benjamin	Weaverham.

The above names are arranged in order of merit.

* Passed with Honours.

The following is the result of the Preliminary examination held on the 7th instant :—

ENGLAND AND WALES.

Three hundred and thirty-one candidates presented themselves for examination, of whom *one hundred and forty-four* failed. The following *one hundred and eighty-seven* passed, and have been duly registered as Apprentices or Students :—

	Currie, Herbert William	Turnham Green.
	Dyer, Charles Frederick	High Wycombe.
	Kilvington, George	Hartlepool.
Equal.	Mill, John Brown	Holloway.
	Place, Frederick William	Knutsford.
	Reynolds, Richard James	Dewsbury.
	Harry, William	Highbury Hill.
	Martell, Richard	Portsmouth.
Equal.	Brewer, James Curtis	Gloucester.
	Jones, Thomas Glynne	Llanidloes.
	Stacey, Peter	London.
Equal.	Powell, John Alfred	Reading.
	Robertson, James Hay	Long Melford.
	Salter, George Herbert	Bath.
Equal. Equal.	Dutton, Hugh Odard	Rockferry.
	Luxmoore, Charles Mann	Bristol.
Equal.	Padley, William	Goole.
	Winfrey, Richard	Long Sutton.
	Procter, Robert	Kidderminster.
	Cole, Samuel John	Exeter.
	Bell, Frederick Leonard	Southampton.
	Little, Edward Stephen	London.
	Purdy, James Robert	Morpeth.
Equal.	Coleman, Edward James	Cardiff.
	Morris Caleb Guron	Lluynderris.
	Ritson, Fletcher	Carlisle.
	Pennington, George Edgar	Kendal.
Equal.	Drew, John	Wednesbury.
	Lunde, William John	Lancaster.
	Rendall, Theodore Stancombe	Torquay.

Equal.	Bell, Joseph	Alnwick.
	Clayton, Thomas	Malton.
	Henderson, Cristopher	Hoylake.
	Gibbs, Robert Darton	Wolverhampton.
Equal.	Cusse, Ernest	Southampton.
	Duckett, George	Preston.
	Elliott, William Alfred	Bristol.
	Thomas, Lloyd Richard	Beaumaris.
Equal	Draper, James William	Malmesbury.
	Hugill, John Howden	Edmonton.
	Logsdail, Henry	Lincoln.
Equal.	Clark, Robinson Urwin	Jarrow.
	Cuff, Robert Sweeting	Bristol.
	Davies, Daniel	Newcastle-Emlyn.
	Troup, William	Southport.
	Grover, Frank	Folkestone.
	Mansergh, William	Burton-in-Lonsdale.
	Saunders, Frederick	Manchester.
	Snow, Arthur Legge	Ross, Herefordshire.
	Savery, John Manly	Loughborough.
	Newbigin, Lesslie	Newcastle-on-Tyne.
	Gardner, Lewis Silk	Painswick.
Equal.	Bowden, Charles Edward	Hyde.
	Hogben, Howard	Huddersfield.
	Lewis, Llewellyn	Neath.
	Pitts, William Christopher	Norwich.
	Walker, George Edward	Royston.
Equal.	Dodds, Herbert Thomas	Wakefield.
	Fort, William Fairhurst	Liverpool.
Equal.	Broughton, Owen	Sleaford.
	Embley, John	Brierfield.
	Fortescue, Frank	Louth.
	Lloyd, John	Hereford.
	Savile, Harry	Hull.
	Swinbank, John	Heighington, Darlington.
Equal.	Grimshaw, Thomas	Preston.
	Stanley, Thomas	Alcester.
	Mason, Joseph Robert	Workington.
	Mortlock, William J.	Peckham.
	Panton, William Alexander	London.
	Pullin, Arthur Harry	Pontypool.
	Ratcliffe, Henry Norman	Newbury, Bucks.
	Robinson, Frederick	Dewsbury.
	Rodwell, Francis	Ripon.
	Thomson, Thomas Leonard	Birmingham.
	Wynter, Ernest Charles	Seaford.
Equal.	Galloway, James Barker	Liverpool.
	Lambell, Wm. Richard Henry	St. Austell.
	Taylor, James Henry	Pontefract.
Equal.	Cumine, Rupert Henry	Kingston-on-Thames.
	Dunn, John Henry	Hull.
	Hart, James	Sunbury.
	Hooper, David	London.
	Pridmore, Walter Snape	Hinckley.
	Smith, Morgan	Treeynon.
	Weston, Benjamin	Fenton.
	Williams, Stephen	Cardigan.
	Wilson, Erasmus	Southsea.
Equal.	Chapman, Joseph George	Binfield.
	Coleman, Alfred	Southampton.
	Foxcroft, John Peter	Skipton.
	Whitney, William John	London.
	Jones, Thomas Daniel	Seacombe.
Equal.	Coles, William Edwin	Newport Pagnell.
	Epps, James	Upper Norwood.
	George, John Irving	Tunstall.
	Halstead, Henry	Rawtenstall.
	Marratt, Thomas	Gt. Gonerby.
	Stephens, George Thomas	Hereford.
	Thomas, John Tubb	Pontypool.
	Gould, Henry	London.
Equal.	Lewis, Thomas	Newport, Mon.
	Watts, James Orr	Stafford.
	Phillips, George	Dowlais.
	Allis, William	Alford.
	Ashworth, John Robert	Ramsbottom.
	Blagg, Eli	Hanley.
	Bomford, Alfred	Oxford.
	Fletcher, Frederick John	Wolverhampton.
	Hall, William	Portsmouth.
	Hick, Allan Pearson	Wath-on-Dearne.
	Jackson, George	Hartlepool.
Equal.	Jones, David Edward	New Quay.
	Olden, Loathan	Romsey.
	Perry, Horatio Nelson	Gravesend.
	Riley, John Cowgill	York.
	Shilton, James	Sutton Coldfield.
	Stevenson, Jason	Radford, Notts.
	Taylor, Walter	Aberdare.
	Varney, Henry George	Oxford.
	Watson, Lund	York.
	Williamson, Bamford, jun.	South Shields.
Equal. Equal.	Hagon, Albert	Cardiff.
	Mitton, Richard	Skipton.
Equal.	Heaver, Arthur William	Norwich.
	Lester, Samuel	Cheltenham.
	Ridley, Herbert Horace	Walsham le Willows.
	Adamson, William Francis	Blackburn.
	Andrews, Henry Albert.	Harrogate.
	Armistead, Hugh Baldwin.	Liverpool.
	Baker, William	Leicester.
	Barson, George	York.
	Bates, George	Macclesfield.
	Beswick, Jesse.	Liverpool.
	Bird, William	York.
	Boyd, John	Durham.
	Brothwood, Harry Skarratt	Shrewsbury.
	Chaloner, William Francis	Birmingham.
	Cole, Edwin Henry.	Dorking.
	Cooper, Henry.	London.
	Dady, William.	Holt.
	Dashwood, James	Portsmouth.
	Dean, Thomas William	Linton.
	Driver, Arthur Silvester	Elmesthorpe.
	Elliston, Augustus Frederick	Lower Tottenham.
	Evans, Robert Daniel	Liverpool.
	Exley, John	Leeds.
	Fidler, Thomas William	Workington.
	Freeman, William Harrison	Leeds.
	Gilbert, Joseph Anthony	Manchester.
	Glaisyer, Edmund	Brighton.
	Greenhow, William Henry	Leeds.
Equal.	Griffith, John	Pen y Caeran.
	Hargreaves, Robert Hamer	Clitheroe.
	Hill, Arthur	Cheltenham.
	Hill, Charles Walter	Leeds.
	Holden, William Henry	Staithes.
	Jefferson, Charles	Sheffield.
	John, William	Pentre.
	Knight, William	Hinckley.
	Leach, Charles	Middleton.
	Lightfoot, William	Oldham.
	Maddison, Charles John	Swaffham.
	Mayger, William John	Northampton.
	Matthews, Arthur	Bristol.
	Mitchell, Walter	Sheffield.
	Mitchell, Joe Charles	Barnsley.
	Morris, Josiah	Belper.
	Nicholson, John	Heaton Norris.
	Norman, John Turton	Blackpool.
	Northen, Charles	Uppingham.
	Owen, John	Liverpool.
	Palmer, Frederic Henry	Lynn.
	Parry, Robert	Llugwy Pier.
	Rees, William	Pembroke Dock.
	Rich, Stanley	Swinton Bridge.
	Shaw, Arthur	Pendleton.
	Speck, Alexander	Leeds.
	Strachan, John	St. John's Wood.
	Stubbs, Thomas Shaw	Bristol.
	Thomas, Thomas Francis	London.

Todd, George.....Durham.
Tunstall, Edwin James.....Birmingham.
Wates, Fred Wain .....Blackheath.
Wilks, Cuthbert Sympson .....Lincoln.
Wilson, Ivinson.....Carlisle.
Winn, John Christopher .....Darlington.

SCOTLAND.

Thirty-three candidates presented themselves for examination; of these *sixteen* failed. The following *seventeen* passed, and have been duly registered :—

Galloway, David James .....Edinburgh.
Equal. Burley, William .....Ditto.
Equal. Hardie, John Davidson .....Fraserboro'.
Equal. Couper, Frederick Thomas .....Edinburgh.
Fingland, James ....Thornhill.
Fraser, Jonathan Innes ... .Elgin.
Equal. Wilson, James .....Buckie.
Equal. Grant, Alexander .....Cullen.
Equal. Lees, David ... .St. Andrews.
Equal. Currie, Robert Kirkwood .....Glasgow.
Equal. Dunlop, James Buchanan .....Edinburgh.
Equal. Lawson, William Cooper .....Glasgow.
Equal. Presslie, Robert Dowell .....Aberdeen.
Rae, William .....Ballater.
Wishart, William Dick .....Aberdeen.
Storie, Robert .....Edinburgh.
Cathie, Andrew .... Dunoon.

The following is a list of the Towns at which the Examinations were held, with the numbers of Candidates annexed :—

	Candidates. Examined.	Passed.	Failed.
Aberdare	2	2	
Altrincham	1		1
Andover	1		1
Bangor	4	2	2
Barnsley	2	1	1
Bath	1	1

Lochgilphead	1		1
St. Andrew's	2	1	1

The questions for examination were as follows :—

Time allowed: Three Hours.

LATIN.

Translate into English two of the following sentences :—

1. Eodem die ab exploratoribus certior factus hostes sub montem consedisse, millia passuum ab ipsius castris octo; qualis esset natura montis et qualis in circuitu ascensus, qui cognoscerent, misit. Renunciatum est, facilem esse.

2. Cæsar, primum suo, deinde omnium, è conspectu remotis equis, ut, æquato periculo, spem fugæ tolleret; cohortatus suos prœlium commisit. Milites, è loco superiore pilis missis, facilè hostium phalangem perfregerunt. Eâ disjectâ, gladiis districtis, in eos impetum fecerunt.

3. Coque per horam dimidiam, subinde agitans, et ubi liquor refrixerit, adjice aquæ destillatæ quantum satis sit ut octarios sex impleat: denique cola. In vasis bene obturatis servetur.

4. Panem in aquâ paulisper macera prope ignem; tum misce, et lini semen paulatim adjice movens ut fiat cataplasma molle. Huic admisce carbonis drachmas duas, et quod restat superficiei insperge.

5. Decline "niger" and "duo."

6. What cases do the following prepositions take—ad, ante, inter, ob, per, cum, ex, pro?

7. Parse "Deum veneramur qui nos creavit."

ARITHMETIC.

8. How many tons are there in a million ounces?

9. What are the weight and cost of a square mile of glass, each square foot of which weighs 9oz., and costs fourpence halfpenny?

10. A market woman buys herrings at 2*s.* 8*d.* the hundred of six score, and retails them at 4*s.* 6*d.* the true hundred. How many must she sell to earn half-a-sovereign?

11. Make out the following bills :—

34lbs. 14oz. beef, at . . . . . 8½*d.* per lb.
14lbs. 10oz. mutton, at . . . . . 9½*d.* „
7lbs. 6oz. lamb, at . . . . . 11½*d.* „

12. Multiply ·0025 × 4·76, and 2·5 × 4·76.

ENGLISH.

13. Parse the following :—

" And every shepherd tells his tale
Under the hawthorn in the dale."

14. Write from fifteen to twenty-five lines in the form of a letter to a friend upon *one* only of the following subjects :—

Idleness.
Ambition.
The Sun.

Proceedings of Scientific Societies.

PARIS SOCIETE DE PHARMACIE.

This Society met on Wednesday, June 4, under the presidency of M. Grassi. A specimen of opium in rolls, from Persia, was presented by M. Martin, which upon examination had not yielded any morphia, and therefore, he considered ought to be excluded from commerce. M. Martin also presented a specimen of gum kino from the Soudan, of a kind which he believed to be unknown in Europe. It was soluble in water to the extent of 80 per cent., and from its very low price, he thought it would find employment in the arts. A microscopic examination showed that it had not undergone any particular manipulation.

A letter was received from M. Gosselet, vice-president of the Society of Pharmaciens of the North of France, in reference to the recent decision of the court at Douai, to the effect that cod liver oil was an aliment, and might be sold by grocers. (See *ante*, p. 32). This affair having shortly to come before the Court of Cassation, the northern Society transmitted to the Society at Paris a number of questions which had been put to it by the Procureur-Général. After hearing the questions read and deliberating thereupon, it was unanimously agreed,—that cod liver oil is a simple drug ; that it constitutes a true medicament; that it cannot be sold in medicinal weights either by druggists or by grocers; and finally, that a distinction ought to be drawn between oil prepared for internal use and that employed by curriers, the first being obtained by the particular processes indicated in the Codex, whilst, the latter is in general, only a more or less impure fish oil.

A specimen of neutral and soluble phosphate of lime was presented to the Society, by M. Forterre, of Saint-Denis, together with a memoir upon its administration, but as the author did not disclose the method of preparation, the Society did not discuss the communication.

M. L. Soubeiran read an extract of a letter received from Mr. J. E. Howard, in which he stated that some plants of Cinchona Calisaya, which he had planted in the open air at Tottenham, near London, had grown perfectly. M. Soubeiran added, that Professor Baillon had this year made a similar experiment in Paris, and that the Cinchonas were in a flourishing state.

M. Martin presented to the Society a new refrigerator, the invention of M. Toselli. The source of cold was nitrate of ammonia, which was dissolved in water, and the machine produced a block of ice of 500 grams weight in five minutes.

M. Mayet read a note upon the preparation of the antiscorbutic syrup, by means of a liquid extract. He presented a specimen of syrup so prepared for comparison with that prepared according to the formula of the Codex.

M. Blondeau said, that this manner of operating was contrary to good pharmacy; that all the fluid extracts and concentrated alcoholates at present met with in commerce yield bad preparations, or preparations more or less differing from those of the Codex; for the fluid extracts, all contain alcohol, which they introduce into the preparations of which they are made the base, but certain syrups ought not to be alcoholic. In the case of the antiscorbutic syrup, M. Blondeau remarked that M. Mayet had only used half the proper proportion of wine, a practice that would open the door to all kinds of falsifications.

M. Marais was opposed to these preparations. He said that in most cases the extractive liquors undergo considerable alteration when they assume the consistence of a fluid extract. He did not see why a decoction should be evaporated to the consistence of an extract before putting in the sugar. Such a process had the inconvenience not only of giving an inferior product, but also of breaking with the traditions of pharmacy and of suppressing the laboratory operations which make good students and pharmacists.

M. Limousin, on the other hand, said that the fluid extracts were of great service, that they would one day replace the preparations of the Codex, and that whatever might be done their sale would increase. He added that the English and Americans are considerably in advance in this direction, and that in preparing fluid extracts with glycerine a means had been given to the pharmacist of avoiding bulk, outlay, and the trouble of preparation.

M. Mayet said that he had been induced to pay attention to this subject because pharmacists purchased bad fluid extracts and consequently obtained with them bad preparations. He was convinced that the use of fluid extracts in the extemporaneous preparation of syrups would present great advantages. It would be better to study completely these preparations to see what could be reasonably gathered from them than to reject them without examination.

M. Boudet said that a letter had been addressed to the Academy of Medicine by the Minister of Public Instruction, on behalf of the Minister of War, asking for advice as to the fusion of the military, medical, and pharmaceutical services, and whether pharmacy should be subordinate or hold the same rank as now. The Academy has named as a commission to consider the question, Messrs. Depaul, Devergie, Gubler, Bussy, Larrey, Poggiale, Gobley, Legouest, and Broca. The Society saw with regret that pharmacy was in a considerable minority upon this commission, since it comprised only three pharmacists to six medical men.

SOCIETE D'EMULATION POUR LES SCIENCES PHARMACEUTIQUES.

At the sitting of this Society, on Tuesday, June 3rd, the following paper was read on

THE SYNTHESIS OF CROTONYLENE.

BY M. PRUNIER.

Ethylacetylene is a carbide of hydrogen, formed synthetically by Berthelot, who obtained it by the direct reaction of acetylene upon ethylene at a dull red heat. The two gases combined in equal volumes with condensation to one-half—

$$\underset{\text{Acetylene.}}{C_2H_2} + \underset{\text{Ethylene.}}{C_2H_4} = \underset{\text{Ethlyacetylene.}}{C_4H_6}$$

The formation of this carbide constitutes one of the simplest and most elegant of the pyrogenous syntheses.

The question arose whether ethylacetylene were identical with either of the carbides having the same formula which had previously been obtained, especially crotonylene, a carbide which Caventou, who discovered it, obtained from bromide of butylene (itself derived from amylic alcohol) by abstracting from the bromide two equivalents of hydrobromic acid. I had also observed that crotonylene was formed during the action of a red heat upon

the petroleum carbides, and I have prepared by this means considerable quantities of its bromide ($C_4 H_6 Br_4$), which under certain conditions can be crystallized directly in the bromine flask. This tetrabromide, as is known, is a body possessing extremely characteristic properties. Moreover, the formation of crotonylene in this and in several other analogous reactions appeared to me to be due to the simultaneous presence and reciprocal reaction of ethylene and acetylene.

In order to clear up this point, I caused nearly equal volumes of acetylene and ethylene to pass into a porcelain tube heated to dull redness; the two gases combined according to the reaction before described. (Care should be taken during this experiment on the one hand to keep the temperature sensibly below red heat, and on the other to pass the previously mixed gases rather rapidly through the tube, so as not to prolong the action of the heat.) In this manner ethylacetylene is formed in sufficient quantity to be easily manifest with 8 or 10 litres of the mixed gases. The gas yielded by such a reaction was conducted into bromine flasks conveniently placed. The brominated liquors were afterward united and left for about two days in contact with a slight excess of bromine: in this manner ethylacetylene passed to the state of tetrabromide ($C_4 H_6 Br_4$).

In order to isolate it, the greater part of the bromide of ethylene was removed by distillation (up to about 130° C.), and the residue was treated by concentrated alcohol. Upon afterwards driving off the excess of alcohol, an immediate crystallization of tetrabromide of ethylacetylene was obtained. Upon treating it a second time with alcohol or ether, a voluminous nacreous body was produced, formed of needles or of extremely light plates. It melted at from 113° C. to 115° C., and could not be distilled without being decomposed. Analysis gave the following percentages:—

	Theory.	Found.
C	12·84	13·2
H	1·60	1·9
Br	85·56	85·3

The composition of this bromide, its appearance and very characteristic properties, its fusing point in particular, showed that it was identical with the tetrabromide of crotonylene described by Caventou.*

This synthetical reaction establishes the constitution of crotonylene, which is no other than that of ethylacetylene ($C_2H_2 + C_2H_4$). It gives rise also to more extended generalizations. It is known that crotonic aldehyd and the acid of the same name ($C_4H_6O_2$) have been obtained by Kekulé in condensing together two molecules of ordinary aldehyd. This mode of formation assigns to crotonic aldehyd and crotonic acid a constitution similar to that of ethylacetylene. The same occurs in the labours of Cahours upon crotonic acid† and of Frankland upon the different isomers of that acid. The following formulæ will serve to indicate these relations:—

Ethylene.	$C_2H_2(H_2)$	Ethylacetylene (crotonylene)	$C_2H_2(C_2H_4)$
Aldehyd.	$C_2H_2(H_2)O$	Crotonic aldehyd	$C_2H_2(C_2H_4)O$
Acetic acid.	$C_2H_2(H_2)O_2$	Crotonic acid	$C_2H_2(C_2H_4)O_2$

It is probable that, conformable to these formulæ, ethylacetylene could be transformed into crotonic aldehyd by the same process of direct oxidation by which Berthelot has been enabled to convert free ethylene into ordinary aldehyd. Finally in this reproduction of crotonylene by synthesis we have a fresh instance of the concordance of the results obtained by pyrogenous synthesis with those yielded by the indirect methods which proceed at a low temperature.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture II.

The Energy of Gravity, with especial reference to the Measurement of it.

The energy of gravity is one of the most silent and all-pervading of the energies of the imponderables. Although we may not be conscious of the fact, there need be no doubt that, were this energy to cease, we should be like those whom Milton describes as

> "Upwhirled aloft
> And sent transverse, ten thousand leagues awry,
> Into the devious air."

This calamity is averted by gravity putting forth that energy allotted to it by the Creator, and the work thus done enables us now to sit at ease, and gives us houses in which to dwell.

If, then, it be asked, where do we find this energy? we may say, "Look around." In this room gravity, inasmuch as we are at rest, produces but a static action; there is, however, a clock ticking, and there gravity is producing motion. The combined harmonious operations of the energies of gravity and vitality brought us together this evening. Thus it has been, ever since the creation of man; and yet there is good reason for the surmise that the energy of gravity, even if known, was little regarded in the earlier ages of the world. A history of observations on the energy of gravity, or even of traces of the recognition of this energy in these ages has yet to be written. Whether, by some of the early Greek writers, gravity was supposed to be a power innate, as a living principle—a spirit in every particle of matter; or whether this power had a residence at the centre of the earth; or whether it resided in an atmosphere surrounding each particle of matter; or whether Seneca, who lived about 38 A.D., was moved by a consideration of (to him) that mysterious principle we call gravity, to notice that the tides and the moon were somehow related, need not, this evening, concern us.

From the time of Seneca we may pass over more than fifteen hundred years, to the days of Galileo (A.D. 1600), who was perhaps the first person to notice that bodies in falling moved faster and faster. He attributed this to the effects of gravity, and considered that if he could retard speed whilst still permitting gravity to act, he might determine the law of increasing spaces in equal successive times. This he did by permitting a ball to roll down an inclined plane; friction on the plane caused the retardation, whilst gravity alone caused the motion. Thus he obtained the ratio of spaces in reference to succeeding times; but he made no attempt to measure the absolute spaces when a body fell freely.

Next to Galileo in order of time must be placed Kepler, a German astronomer, who, about 1615, in his search after certain astronomical relations, existing apparently through the mutual attraction of the planets each on the other, was led to surmises respecting the universality of the mutual influences of material bodies.

The succeeding fifty years present a blank in reference to inquiries or investigations respecting gravity. Then came Robert Hooke, who was at the same time a mathematician, an astronomer, and a mechanician. He was secretary to the Royal Society of England, and, from 1666 to 1674, seems to have frequently turned an inquiring mind to the nature of that influence which he thought he could observe to be exercised by the sun and earth upon others of the planetary system.

The great and now (1873) universally recognized law upon this subject was first laid down by observations and reasonings of Sir Isaac Newton, which, even at this day,

* Cantor Lecture, delivered February 10.

are regarded with an almost religious veneration by the advanced and intelligent men of every nation. Although it is said that Newton began in 1670 to form more clear conceptions of the law of gravitation than had been propounded by any of his predecessors, we must remember on what surmises he had to build.

Kepler, about 1615, and Robert Hooke, about 1666, had led Newton, so early as the above-named date (1670), to form these conceptions, and it is probable that he was confirmed and directed in his anticipation by the fact that Richer noticed, in 1672, that a pendulum conveyed from Paris (lat. 48 deg. 50 min. N., long. 2 deg. 20 min. E.) to Cayenne, in South America (lat. 4 deg. 56 min. N., long. 52 deg. 20 min. W.) did not vibrate in the same time. This recorded fact was as a demonstration to the mind of Newton of the deviation of the figure of the earth from perfect sphericity, and its oblateness or compression at the poles. It was not, however, until the publication of his 'Principia,' in 1687, that the law of gravitation was fully established and enunciated.

Briefly expressed, the law, as anticipated by others and propounded by Newton, is this—that the attraction of one planet upon another depends upon the masses (not upon the "weights") and distances of the two planets; not, however, is the law of increase or decrease such, that at one-half of a distance or double of any distance is the intensity of the attractive force doubled or halved. This might be a first impression. Astronomical facts refused to conform themselves to such a law. They rebelled. The parliament of planets had prescribed another code for the interrelationships of their mutual attractiveness, and although it might perhaps have been readily inferred that, as the distance between two attracting bodies was increased, the intensity of attraction would be decreased, yet the law of that decrease was the one which Sir Isaac Newton announced. It is this—that if there be two heavenly bodies, say the earth and the moon, and that these at a known distance are mutually exerting a certain attraction or drawing each to the other; then, if the distance be doubled, the influence will only be one-fourth of what it was. If the distance be trebled, then this influence will become one-ninth of what it was; if quadrupled, then one-sixteenth of what it was. Expressed in precise phraseology, the law of gravitation is that of the inverse square of the distances. Thus far satisfied the requirements of astronomers.

It is remarkable how much of the utilized information men possess has been derived from the observations of astronomers. The mechanism of the universe was known before Harvey discovered the circulation of the blood, or Watt constructed a steam-engine. The astronomers seem to have been the pioneers of every branch of human knowledge. The Old and the New Testaments open astronomically. "In the beginning God created the heaven and the earth." (Gen. i. 1.) "The wise men from the east came to Jerusalem, saying, where is He that is born King of the Jews? for we have seen His star in the east." (Matt. ii. 2.)

It must be remembered that the science of astronomy in one important respect differs from all other sciences. Astronomers are observers only—they ascertain causes by watching effects. They cannot interfere with or alter the causes in operation. They cannot make experiments. That man presumed too much upon the powers of his astronomical friend, who having invited him to bring some of his acquaintance to see an eclipse of the moon by the aid of a telescope, and arriving too late, assured those who accompanied him that the astronomer was not only a personal friend, but also a very kind-hearted man, and he did not doubt that the eclipse would be done again in order that they might see it. Yet upon these observers all experimenters erect their fabrics. The gigantic and uncontrollable phenomena, and all the laws of the universe of planets—of the ebb and flow of the tides, of meteorology, of terrestrial magnetism and its connection with the sun, are the results of observation. They could never have been known by experiment; indeed, we could not so interfere with them as to make an experiment. Remember, experiment is an interference on our parts, and a redirecting of energy into a new channel, in order that that may be observed which cannot otherwise be observed. Hence, if we wish to utilize observation it must be by the adaptation of an experiment in the presence of an observation—to contrive, in fact, a system of apparatus which may enable us to take observations and at the same time to so control the elements of an experiment as to bring them within the range of our means of observation.

Such combination of experiment and observation is to occupy much of our attention this evening, as on the records of these men—Cavendish, Atwood, Kater, Sabine, and Baily, especially Captain Henry Kater—is built our system of measures and weights; for to them we are indebted for what must constitute a court of final appeal, should the time ever come when our present standards being totally lost, it is essential to re-establish them.

The energy of gravity is peculiar, and differs from those other energies with which we are to be concerned, in that it seems inexhaustible—its power is not proportioned to the work it does. All other energies are in process of exhaustion by work when that work is measured by motion; not so gravity. Imagine a large ball, and a second small one, which gravitates towards it—the number of these small balls may be increased, and still the influence of gravity on each ball is as intense as though there was only one small ball; no exhaustion from work done affects the energy of gravity, and yet it seems not to have any power of recouping its expended energies. There is no elasticity about it—at least, none in the hands of men.

For example, we can, in food, avail ourselves of affinity, and so, through the agency of assimilation, revive the energies of an exhausting vitality. Electricity can, upon a system of relays, or upon its extraordinary property of induction, renew at a distance, not only its pristine vigour, but an energy many-fold greater than its original one. Light can have its intensity and purity restored by heat. Gravity remains in its solitariness. True, we believe that vitality, affinity, electricity, light, and heat are independent of, and beyond the influence of, gravity; yet, we know them not—we cannot bring them within the ken of our senses, except when they are associated with what owns the dull, dead, inert, and yet powerful influence of the energy of gravity. For all means yet employed have failed to develop or detect the presence of these imponderables in a *perfect vacuum*.

This fact seems to give support to the suggestion that the "potential energy of gravitation may be, in reality, the ultimate created antecedent of all motion, heat, and light at present existing in the universe."

The mode in which we estimate or measure gravity is peculiar. It is the only one of those energies with which this course of Cantor Lectures has to deal that tells its story upon a scale beam or spring balance. No concentrated rays of a tropical sun have ever caused an appreciable deviation of the most delicate balance; neither light nor heat imparted to a body *in vacuo* has ever required the fraction of a gramme to be added to the other scale-pan. But when gravity is concerned we cannot add the most minute microscopical molecule without having the equilibrium disturbed.

Gravity alone, of all the imponderables, rises up equal to the burden laid upon it. Its power seems to increase with the amount of matter involved or work to be done. The more required from it the more it does. You cannot overburden it. An avalanche of rocks or a gossamer thread are equally the playthings of gravity.

For the purpose of these Cantor Lectures, the law of gravitation which binds the planets in their courses is of little concern, unless we find that the same law binds the material elements with which we are concerned. The question whether the influence whose law Sir Isaac Newton so clearly propounded resulted from an unknown and ungovernable something, resident and centralized, as

it were, within the planets, or whether it was a property of every molecule or group of molecules, was not set at rest until Nevil Maskelyne, the Astronomer-Royal at Greenwich, went to Mount Schiehallien, in Perthshire, in 1774, to calculate the density of the earth.

The mountain of Schiehallien has very steep sides. Mr. Maskelyne suspended plumb-lines from two opposite and nearly vertical sides. Now, if those plumb-lines deviated from what one may call verticality, they would have been caused to deviate by the attraction of the mass of the mountain. Thus Maskelyne examined this—he had an instrument by means of which he could, by observations upon the stars, determine the exact direction that the plumb-line should take, and he found that the strings did not take that direction. Having done that on one vertical side of the mountain, he repeated the experiment on the other side, and found that the deviation there was opposite to that which it was on the first side.* Having determined that these strings no longer followed the vertical, he formed an estimate of how much this mountain attracted the plumb-bob at the end of the string, and so arrived at a conclusion that each particle of matter does attract every other particle. This was the first approximation to an estimate of that which forms a very important element in connection with other experiments. We may here state that in certain regulator clocks the makers put the single weight in the corner of the case, so that being removed to the greatest distance its influence upon the pendulum-bob, similar to that of Schiehallien upon the plumb-bob, may be the least possible.

This, then, established the fact that the power whose law Newton discovered was no gnome resident in some mysterious terrestrial centre, but was a property of every molecule of matter, and could not by any means or contrivance be separated from those molecules. Whether this property be within the molecule, or only in what may be called the atmosphere around the molecule, may be left to those who arrange theories.

Mr. Michael suggested to Cavendish an experiment which has ever since gone by the name of Cavendish's experiment, and from which was deduced the first pretty accurate calculation or actual measurement of the density of the earth. Cavendish, as you know, was a very wise man. It is said of him that "he was the richest wise man, and the wisest rich man, that the world ever saw." He left more than a million of money. He had also another quality which would be very desirable to cultivate in certain parts of this kingdom at the present time—he uttered fewer words than any other man who attained the same age is supposed to have done. He discovered many things, and, amongst others, he was the first to make an attempt at weighing the whole earth, and he weighed it with an accuracy which has only been confirmed in recent times.

(*To be continued.*)

* The deviation was noted by a zenith-sector, and after making the requisite corrections there was left an attraction which caused the two lines to be drawn together, so including an angle of 12 seconds due to the mountain.

Parliamentary and Law Proceedings.

Sudden Death of a Wholesale Druggist.

On Tuesday morning Mr. Carter held an inquiry at the Bull's Head Tavern, Barnes, touching the death of Mr. Benjamin Yates, aged 65, who was found dead in a first-class railway carriage at Barnes station on Saturday morning last. Deceased was a wholesale druggist, carrying on business at Southwark Street, Borough, his country residence being at Feltham. On Saturday he left Feltham by the 9·50 a.m. up train, apparently in his usual health. A Mr. Field entered the same carriage at Brentford, but noticed nothing particular about deceased till the train reached Chiswick, when another gentleman who there entered the train called his attention to deceased. The latter was leaning to one side, with his head resting on his hand. As he did not move when he was touched and spoken to, Mr. Field called for assistance at Barnes station, and Mr. Watts, the station-master, had the body taken into the waiting-room. A doctor was sent for, but on his arrival he found deceased quite dead. Some artificial teeth were found lying on the floor of the railway carriage near where deceased had sat, and it is supposed they had dropped from his mouth. Deceased's family physician, Dr. Kingsford, of Sunbury, stated that deceased, who had been under his care for 10 or 12 years, was liable to apoplectic fits, and, in his opinion, apoplexy was the cause of death. Ebenezer Gaywood, deceased's gardener, also stated that he had seen deceased fall down in the garden in a fit, and remain unconscious for some time. The jury returned as their verdict, "Found dead in a railway carriage at Barnes station."

A Chemist and Druggist Summoned for Sunday Trading.

At the Southwark police-court, Mr. Miles Doughty, chemist and druggist, of the Blackfriars Road, and several other tradesmen living in the parish of St. Saviour, were summoned, under the Lord's Day Act, for carrying on their trades and callings on Sunday morning, the 6th inst. Mr. Errington, the sanitary inspector, having proved the offences, Mr. Doughty, in defence, contended that he did not think the vestry had any authority to act as they had done. He did not keep open unnecessarily. The magistrate was of the same opinion, and thought it was for the general and public good that chemists should be open on Sundays. By their doing so they caused no obstruction, annoyance, or desecration of the day. Under those circumstances he dismissed the summons against him. *South London Press.*

Supposed Poisoning by Carbolic Acid.

An adjourned inquest, was held at Liverpool, on Saturday, July 19th, to inquire into the death of William Stringer, a bricklayer. It appeared that the deceased, who was a man of very intemperate habits, after being absent from home some days was found sitting in the yard, having got over the wall. He appeared to be in drink and was taken into the house; and some time afterwards, a doctor was sent for, but before his arrival, deceased was quite dead. A bruise was noticed on his forehead, as if from a fall. Since the inquest was opened on the 8th inst., a *post-mortem* examination of the body of the deceased had been made by Dr. O'Connor, of Everton, who stated that the stomach was empty, and exhibited signs of an irritant corrosive poison, probably carbolic acid. The injury to deceased's head was not sufficient to account for death, but from the general organic condition of the body he would not be surprised to have found the deceased dead at any time either from heart or brain disease. He believed, however, that an irritant poison, which he took to be carbolic acid, was present in the system, and that it had been the exciting cause of death. He considered the quantity of poison sufficient to account for death even in a healthy person. Dr. Brown, public analyst, had also examined the stomach and found the presence of carbolic acid sufficient to account for death. A bottle containing carbolic acid was found in the pocket of the coat which deceased wore at the time of his death, which it was stated had previously escaped notice. The coroner read an anonymous letter which he had received with reference to the case, reflecting on the character of the family of the deceased and accusing them of neglecting him both at the time of his death and previously. The inquiry, which occupied several hours, was again adjourned for a fortnight that further investigation might be made.—*Liverpool Albion.*

Prosecutions under the Adulteration Act.

Mixture of Chicory with Coffee.

At the Southwark Police Court, Mr. John Wright, grocer and tea dealer, 123, Great Suffolk Street, Borough, was on Monday summoned before Mr. Partridge by Mr. Edwards, the sanitary officer of St. George's, under the Adulteration Act, for unlawfully selling adulterated coffee. Mr. Birt, vestry clerk, prosecuted. It appeared from the evidence of Mr. Edwards that on the afternoon of the 5th he sent into defendant's shop for two ounces of chicory and a quarter of a pound of shilling coffee. He then took the packets back to the shop and told the defendant that he had purchased them for analysis. Witness afterwards placed them in the hands of Dr. Muter, the public analyst appointed by the Vestry. He now produced Dr. Muter's certificate, showing that the coffee was largely mixed with chicory. The defendant said it was well known they could not sell genuine coffee for 1*s.* a pound, and on the wrapper was printed, "This is a mixture of chicory." If he had asked for genuine coffee he would have had it. Mr. Partridge told him he was bound to tell his customers when they purchased the coffee whether it was mixed with chicory. There must be a conviction in this case, but, as he did not think that any fraud was intended, he should fine the defendant only 5*s.* and 4*s.* 6*d.* costs.

Mrs. Mary Jane Bell, grocer, 38, Tower Street, Westminster Road, was summoned under similar circumstances. Mr. Edwards purchased on the same day ¼lb. of 1*s.* coffee and 2oz. of chicory. The coffee was analysed by Dr. Muter, and found to be adulterated with chicory. Mr. Partridge fined her also 5*s.*, and 4*s.* 6*d.* costs.—*Times.*

PAPERS PRESENTED TO PARLIAMENT.

Adulteration of Food.

The following return of the number of analysts appointed under the provisions of "The Adulteration of Food Act, 1872," giving name and date of appointment in each county and borough or district of the United Kingdom has been made to the House of Commons, in compliance with an address voted April 3rd, on the motion of Lord Eustace Cecil :—

ENGLAND AND WALES (exclusive of the Metropolis.)

I.—Counties.

Bedford, Thomas Stevenson (31 Dec. 1872).
Berks, William Frederick Donkin (7 April, 1873).
Carnarvon, James Campbell Brown (9 April, 1873).
Chester, James Campbell Brown (26 Nov., 1872).
Denbigh, John Jones Bancroft (2 Jan., 1873).
Derby, Wentworth Lascelles Scott (8 April, 1873).
Essex, H. Letheby and C. M. Tidy (18 Feb., 1873).
Gloucester, John Horsley (31 Dec., 1872).
Hertford, H. Letheby and C. M. Tidy (31 Dec., 1872).
Lincoln (parts of Holland), G. May Lowe (6 Jan., 1873).
Lincoln (parts of Lindsey), G. May Lowe, 17 Oct., 1872).
Norfolk, Francis Sutton (10 April, 1873).
Nottingham, Edgar Beckit Truman (9 April, 1873).
Oxford, C. C. Pode and W. F. Donkin (7 April, 1873).
Salop, H. Johnson and T. P. Blunt (30 Dec., 1872).
Surrey, Thomas Stevenson, (28 Jan., 1873).
Warwick, Alfred Hill (8 April, 1873).

II.—Boroughs.

Bedford, Charles Edward Prior (15 Jan., 1873).
Birmingham, Alfred Hill (17 Dec., 1872).
Bolton, John Collins (15 Jan., 1873).
Gloucester, John Horsley (22 April, 1873).
Gravesend, James Henry Gramshaw (21 May, 1873).
Liverpool, James Campbell Brown (2 Oct., 1872).
Manchester, Charles Estcourt (5 Mar., 1873).
Sheffield, Alfred Henry Allen (17 June, 1873).
Wolverhampton, Edward W. Taylor Jones (1 Mar. 1873).

METROPOLIS.

City of London, Henry Letheby (23 May, 1873).

Vestries.

Paddington, William Hardwicke (4 Feb., 1873).
St. Giles, Camberwell, Albert J. Bernays (31 Jan., 1873).
St. George, Hanover Sq., W. H. Corfield (7 Nov., 1872).
St. George-the-Martyr, Southwark, John Muter (25 Jan., 1873).
St. James and St. John, Clerkenwell, Theophilus Redwood (8 May, 1873).

IRELAND.

Queen's County, Charles Cameron, M.D., M.B., M.S. Dublin (6 March, 1873).

SCOTLAND.

Glasgow, T. E. Thorpe, F.R.S.E., F.C.S. (21 Jan., 1873).
Greenock, Thomas Law Patterson and Thomas Robertson Ogilvie (7 March, 1873).

Review.

Jahresbericht uber die Fortschritte der Chemie und verwandter Theile anderer Wissenschaften. Für 1870. Giessen. 1873.

The German report of the chemical work done in 1870 is at last out. Delayed by the war, and by the death of the late editor, Professor Engelbach, we receive it now two-and-a-half years after the date of the researches which it describes. It seems almost needless to remark how much the usefulness of such a work suffers when its publication is so long delayed. The present volumes cannot possibly serve as a hand-book to the student of to-day, they are merely valuable books of reference to a by-gone period of chemistry.

The plan of the German 'Jahresbericht' is excellent. The very fact that the whole year's work is before the writers when they begin their task enables them to classify the matter thoroughly, and to describe researches in relation to others on similar subjects, by which space is saved, and the subject elucidated. But the same cause which makes the perfect arrangement of the matter possible necessitates its late publication. A 'Jahresbericht' cannot be composed until the year which it reports is completed, and the production of so bulky a work necessarily occupies much time. The comparison of this plan with the monthly reports now publishing by the Chemical Society is at once suggested. In the case of this society's journal, the yearly volume presents none of the perfect arrangement which we find in the German 'Jahresbericht,' the volume is merely the monthly numbers bound together, but we have the more

than counterbalancing advantage of reports almost contemporaneous with the original papers. The subscribers to the Chemical Society's journal are, in fact, in possession of abstracts of nearly 3000 papers, all of later date than the most recent which appears in the 'Jahresbericht' now before us. The 'Jahresbericht' is a valuable book of reference; the *Journal of the Chemical Society* is a hand-book for the student, and keeps him acquainted with the present condition of science.

The present 'Jahresbericht' is not inferior to its predecessors. The abstracts have been prepared by nine gentlemen, well known as chemists and physicists, Professor Naumann acting as editor. As far as we have been able to judge, the work of abstracting seems well done. The whole forms three bulky volumes of over 1400 pages, and is provided with two copious indices and a classified table of contents. It will be quite unnecessary for us to refer to the matter here brought together, especially as the date of the papers is so far back; one thought is, however, naturally suggested by the appearance of these bulky volumes—it is the vast dimensions which research is gradually assuming. If the scientific results harvested in a year of such dire war as that of 1870 be so numerous, what shall we expect from the future?

BOOK RECEIVED.

On Marienbad Spa and the Diseases curable by its Waters and Baths. By A. V. Jagielski, M.D., etc. London: Trübner and Co. 1873. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 17th July, 1873, of phthisis, Mr. Ernest James Tween Agnew, Pharmaceutical Chemist, of 520, New Oxford Street, London, aged 27. Mr. Agnew was a member of the Pharmaceutical Society and had several times contributed to the pages of this Journal.

Notes and Queries.

PREPARATIONS OF OLEATE OF MERCURY.

In addition to the formula of Ung. Hydrargyri Oleatis, published on p. 59 of last week's issue, the following formulæ, which occur in the Pharmacopœia of University College Hospital, recently published, may be of service to some of our readers:—

LINIMENTUM HYDRARGYRI OLEATIS.

(10 per cent.)

Precipitated Peroxide of Mercury .	1 drachm.
Oleic Acid	10 drachms.

To the oleic acid, kept agitated in a mortar, sprinkle in the peroxide gradually, and triturate the mixture frequently during twenty-four hours until the peroxide is dissolved and a viscid solution is formed.

The twenty per cent. preparation, of which the formula was given last week, is too concentrated for use without dilution. It is generally mixed with lard for use as an *ointment*. We believe that the strength of this *liniment* generally ordered by Professor Marshall is from five to ten per cent. of the oleate, and when its application causes pain, one grain of pure morphia is added to the drachm of either strength, as in the following formula:—

LINIMENTUM HYDRARGYRI OLEATIS CUM MORPHIA.

Morphia (pure alkaloid) . . .	10 grains.
Oleic Acid	5 drachms.

Dissolve and add

Liniment of Oleate of Mercury (10 per cent.)	5 drachms.

Mix.

Dispensers.—Army Hospital Corps.

Sir,—I wish to say a few words on the subject of the advertisement which appeared in the columns of this Journal of the 7th inst. with regard to the army hospital corps.

Any one reading that advertisement would naturally be led to suppose that dispensers were required, and that their remuneration *as dispensers* was to be £60 per annum, exclusive of board, lodging, and clothes.

On applying for particulars, however, one receives a paper of regulations (copy of which I enclose), from which it appears that young men are wanted to enlist in the corps as privates—nothing whatever to do with dispensing; but simply as privates—at the pay of 1*s.* 2*d.* per diem. Then, having risen to the rank of sergeant at 2*s.* 4*d.* per diem, one is eligible, if qualified, for the office of compounder; receiving for the same 1*s.* per diem extra. So that the compounders pay of £18 5*s.* per annum, and the sergeant's pay of £42 2*s.* 8*d.* per annum make up that £60 which is advertised as the pay of dispensers.

So the advertisement is either a mistake, which charity would lead us to suppose; or else it is a mean device to get young men to enlist—such a device as an enlisting sergeant at the corner of the street would hardly stoop to put in practice against any of the loafers he endeavours to entrap.

From this point of view—and it appears to me to be the correct one—a direct insult has been offered to the whole profession by the authority or authorities who sanctioned the insertion of that advertisement in such a high class Journal as this.

Brighton. Indignans.

*** The following is the substance of the regulations referred to above:—

"*Army Hospital Corps.*

"The above corps is now open for the enlistment of a limited number of eligible young men, between the ages of 18 and 28 years, who should be intelligent and of a fair education. Height 5 ft. 5 in. and upwards.

"This corps offers good advantages to such young men as may join it, both as regards pay and promotion, and comprises the following ranks:—

Private,	at 1*s.* 2*d.* per diem	(exclusive of good-conduct pay).
2nd corporal,	1*s.* 5*d.*	,,
Corporal,	1*s.* 8*d.*	,,
Sergeant,	2*s.* 4*d.*	,,
Colour-sergeant,	3*s.* 4*d.*	,,
Sergeant-major,	4*s.* 4*d.*	,,

With a further allowance of 1*s.* per diem to sergeants, who, after having qualified themselves for the duties of clerks and compounders of medicines, are employed in either of those capacities.

"In addition to the above rates of pay, each soldier in the several ranks is provided with clothing and lodging, besides a good daily ration of bread, meat, potatoes, tea, and other articles of food, free of cost, and on the termination of a service of twenty-one years to a pension, which increases in ratio according to the rank he may hold at the time of his discharge.

"As the corps is allowed an unusually large number of non-commissioned officers on its establishment, increased facility is necessarily afforded to young men for rising in the profession, which will accordingly ensure to such as merit it by conduct, zeal, and efficiency, success and speedy advancement in the service.

"N.B.—Young men desirous of joining, or requiring further information, must in the first instance apply personally at the head-quarters of the army hospital corps, No. 6, Whitehall Yard, any day (Sunday excepted) between the hours of 10 a.m. and 4 p.m., and will be required to produce testimonials, etc., to character."

SUNDAY TRADING.

Sir,—As a Registered Chemist and Druggist can the District Board of Works compel me to close my shop after 10.30 a.m., for the remainder of the day—Sunday?

MILES DOUGHTY.

26 *and* 27, *Blackfriars Road, S.E.*

I herewith give you a copy of the two documents served upon me:—

ST. SAVIOUR'S DISTRICT BOARD OF WORKS.

Board Room:
Emerson Street, Bankside, Southwark, S.E.

SUNDAY TRADING.

Sir,—The attention of the St. Saviour's District Board of Works having been called to your violation of the Act of Parliament against Sunday trading, notwithstanding their notice upon the subject (a copy of which is enclosed), they have instructed me, upon a repetition of the offence by you, to cause a *summons* to be issued against you to enforce the penalty to which you will be liable.

Trusting you will spare me this painful duty,

I remain, Sir,

Your obedient servant,

HERBERT STURMY, Clerk.

[Document No. 2.]

ST. SAVIOUR'S DISTRICT BOARD OF WORKS.

SUNDAY TRADING.

The St. Saviour's District Board of Works hereby give notice that with a view to lessen, as far as possible, the increasing evils arising from Sunday trading, they have resolved that all shops and business premises throughout their district shall (except as otherwise provided by law) be closed and business stopped before half-past ten o'clock on Sunday mornings.

And notice is also hereby given that in all cases where this resolution is not complied with the Board intend to institute proceedings for the recovery of the penalties or forfeitures which by law are directed against Sunday trading.

By order of the Board,

HERBERT STURMY, Clerk.

Board Room and Offices:
3, *Emerson Street, Bankside, S.E.*
May 7th, 1873.

[*** As will be seen from the report at p. 77, Mr. Doughty has since been summoned before a magistrate, but the summons was eventually dismissed.—ED. PH. J.]

WARNING TO THE TRADE.

Sir,—I am induced to write you requesting the favour of your laying before your readers a case of the grossest rascality it has ever been my fortune to be the subject of during an experience of nearly forty years as a chemist and druggist in my native town.

I inserted an advertisement about a month since in the *Chemist and Druggist* for a trustworthy and experienced assistant; I received a reply almost immediately from one who stated he had served an apprenticeship with Messrs. Allnut and Son, Portsea, and had been in the trade more than twenty years; was a man of very sober, quiet, and domesticated habits, and, amongst other good things, he was a non-smoker, a churchman, and so forth. He referred me to a Mr. Henry Marshall, Chemist, 30, Old Kent Road, with whom he had just concluded a two years' engagement.

I wrote this Mr. Marshall, and received the most plausible answer to my inquiries I could possibly desire, indeed, so much so that I engaged the applicant forthwith, and initiated him into my business on Saturday, the 12th inst. On the following Monday I found him so drunk behind my counter between ten and eleven in the morning that I was obliged to order him out of my shop, and on his refusal to leave I gave him in charge of a police officer for drunkenness and disorderly behaviour. I subsequently received a telegram from London that the reference to Mr. Henry Marshall was an imposture, no such a person residing at the address given; and I also found the reply to my inquiries was written by the applicant himself. The magistrates thought the case so flagrant and disgraceful that they sentenced him to a week's hard labour in the county jail.

A CHEMIST AND DRUGGIST OF
FORTY YEARS' STANDING.

P. L. B.—We must refer you to a directory. We are unable to give information respecting fees of medical men.

"*County Associate.*"—The mixture is completely incompatible; it would be impossible to prevent the alkaloid quinia being precipitated as a resinous-like substance coating the sides of the bottle.

M.D.—We should suspect that English rhubarb had been used in the place of E. I., or that the latter had been adulterated with English in the course of powdering. The English contains much more mucilaginous matter, which would account for the gelatinous appearance of the mixture. We have noticed a similar appearance before. The fact of its being recently powdered would make no difference.

"*Dubitans.*"—The expression is an incorrect one. Possibly it is a mistake for "vegetable life."

Mr. Shaw is thanked for his enclosure.

"*An Associate.*"—Candidates for the Major examination after October 1, 1874, who have passed the Minor under the present regulations, will be examined under the new regulations.

"*Only a Student.*"—Your letter is not suited for publication.

J. Rees.—The widow of a chemist and druggist can, in virtue of being an executor, administrator, or trustee of the estate, and only in those capacities, continue to carry on her husband's business without being registered, provided the business be conducted by a pharmaceutical chemist or a registered chemist and druggist as assistant. In regard to the particular case you mention, we refer you to the Registrar.

T. B., Son and Co.—We think the words "prepared only by" would render the label liable to stamp duty. But we should advise you to apply to the Inland Revenue office, where you would obtain an authoritative decision of the question.

A. J. Hughes.—We believe that no such rating exists as a "dispenser on board ship," the dispensing being done probably by the medical officer.

"*Querist.*"—(1) Bentley's 'Manual of Botany' is published by Messrs. J. and A. Churchill. (2) 1849. (3) Yes.

Homœopathic Pilules.—Mr. J. Tirrel writes in reference to an abstract from the *Practitioner* which appeared under this heading in last week's issue of the PHARM. JOURNAL, that "any reliance that otherwise might have been placed in the result obtained is destroyed by the fact that pilules cannot be medicated with the second dilution of cupri sulph.," and that "a reference to the Homœopathic Pharmacopœia will show that the third is the lowest dilution obtainable in pilules."

"*Chemicus.*"—We believe that no such examination is compulsory at present. Particulars respecting the voluntary examination might be obtained by applying to the secretary of the Royal College of Surgeons.

W. C. A. and "*Pharmacy*" are referred to the regulations respecting anonymous communications.

"*Atlantic.*"—We do not know of such a practice.

W. Orme.—Snow or pounded ice, 2 parts; common salt, 1 part. Or, sulphate of soda, 8 parts; hydrochloric acid, 5 parts.

"*Cupiens.*"—You will best obtain the information sought by applying at the College of Surgeons.

"*Upsilon.*"—We are glad to be able to inform you that cases such as those referred to by you *are* relieved from the Benevolent Fund.

H. P.—A Latin Grammar and such practical experience as can only be obtained in the shop are all that is required to fit you for passing the Modified examination. But if you prefer the assistance of a book, try Lescher's 'Introduction to the Elements of Pharmacy.'

W. B. B.—(1) *Eryngium maritimum* (Umbelliferæ). (2) *Glaucium luteum* (Papaveraceæ).

The report of the meeting of the Nottingham and Notts Association was received too late for insertion this week.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. De Vry, Mr. T. Garside, Mr. Oliver, Mr. Laird, M. P. S., A West End Chemist.

ON PAREIRA BRAVA.

BY DANIEL HANBURY.

The botanical origin of the various stems and roots known as *Pareira Brava* is extremely obscure. By most writers the drug is referred without question to *Cissampelos Pareira* Linn., a climbing plant of the order *Menispermaceæ* growing in the tropical regions of both the Old and New World.

Some years ago the difficulty of purchasing Pareira Brava of good quality in London induced me to seek a supply in the West Indies. I accordingly procured on behalf of the firm of which I was then a member, a quantity of the stems and roots of *Cissampelos Pareira* L., collected in Jamaica under the supervision of Mr. N. Wilson, director of the Bath Botanical Garden in that island. The first importation was accompanied by herbarium specimens of the plant, the examination of which removed all doubt as to its origin. I also obtained specimens of stems of *Cissampelos Pareira* similarly authenticated, from correspondents in Trinidad, Brazil and Ceylon.

From these materials it at once became evident that the long-accepted statement that Pareira Brava is derived from *Cissampelos Pareira* Linn. was erroneous.* In fact neither the stem nor the root of the plant at all resembles any of the forms of that drug I had ever met with in commerce.

What then is *true Pareira Brava?*—To answer this question we must look back to the early history of the drug.

The merit of having first given some account of Pareira Brava is usually conceded to the Dutch traveller Piso, who in his work *De Medicina Brasiliensi*, published in 1648, described a plant called by the Portuguese *Caapeba*, *Cipó de Cobras* or *Herva de Nossa Senhora*. Piso's figure is scarcely recognizable, but his description of the fruit as resembling the catkins of hop (*semen magnum coloris rosacei, e capsulis lupulo similibus prominens*) applies well enough to a *Cissampelos*, and in fact *C. glaberrima* St. Hil. is known under these Portuguese names in Southern Brazil at the present time. My friend Mr. J. Correa de Mello, of Campinas, Prov. S. Paulo, has been good enough to send me a specimen of this plant and of its root; and the latter I find to be wholly unlike any sort of Pareira Brava.

That Piso does not mention Pareira Brava was indeed remarked as long ago as 1710†; and it is only since the drug has been supposed to be derived from *Cissampelos* that authors have identified it with Piso's *Caapeba*.

Pareira Brava was certainly first brought to Europe by the Portuguese. It first attracted general attention in 1688, when Michel Amelot, Marquis de Gournay, a privy councillor of Louis XIV., and a very distinguished political personage, brought it with him from Lisbon whither he had been sent as ambassador by the French king. There can be no doubt that the drug was considered to possess extraordinary properties. Rouillé, the successor of Amelot in the Lisbon embassy, also took home with him to Paris some Pareira Brava; and in 1710 we find it claiming the notice of the French Academy,‡ who requested Etienne-François Geoffroy, Professor of Medicine and Pharmacy in the College of France, to investigate its virtues. Jean-Claude-Adrien Helvetius, a physician of great merit, who though a young man was consulted by Louis XIV. in his last days, and was afterwards attached to the court of Louis XV., tried the new drug still earlier,* and gave strong testimony in its favour.

Both Geoffroy and Helvetius were correspondents of Sir Hans Sloane, that diligent promoter of science whose immense collections gave origin to the British Museum,—and among the Sloanian MSS. I have found a letter of Helvetius† addressed in 1715 to Monsieur Duyvenvoorde, ambassador from the States General to George I., a portion of which I will here quote :—

"I am extreamly pleased s[r] that you have apply'd yor-
"self to me for my advice about the use of the *Pareira*
"*Brava* which has been recomended to you, because I can
"give you a very good account of it haveing been one of
"the first that introduced it in France. I have made
"abundance of lucky experiments about it which have
"made this medicine very well known to me, wherefore I
"assure you, you can do nothing better than to make
"tryall of it. . . The Pareira Brava is a root which
"comes to us from Brazil by the way of Lisbon, but
"which the war has rendred pretty scarce; however it is
"to be found among the good druggists and is sold [at]
"Paris for 40 livres the pound. 'Tis called in Brazill the
"Universall Medicine, and made use of there in all kinds
"of distempers. A Capuchin monk who came from
"thence told me he could not give it a greater character
"than by assuring me that in all their voyages they
"carried the gospell in one pockett and the Pareira Brava
"in another. . . ."

Helvetius recommended the finely-powdered root in five grain doses, to be taken in infusion warm like tea.

Petiver, apothecary of London, and secretary to the Royal Society, an active collector of objects of natural history of every kind, whose letters are also in the Sloanian collection, thus wrote, Dec. 11th, 1716, to Colonel Worsley, His Majesty's Envoy at Lisbon :—

". . . I am glad to hear y[e] Brasil ffleet is safely
"arrived, w[ch] I hope has brought some materialls for my
"succeeding *Collectaneas*, and amongst them nothing can
"be more welcome than specimens of y[e] leaves and fruit
"of y[e] Ipecacuanha, Pareira Brava, Balsam Capevæ and
"y[e] true Brasile and Brasiletto woods, all which will be
"very acceptable discoveries. . . ."‡

The first author to give an account in print of Pareira Brava seems to be Pomet, whose *Histoire des Drogues* was completed in 1692.§ He describes the drug as then recently seen in Paris, and he figures the specimen given him by Tournefort.

Geoffroy, in his excellent *Tractatus de Materia Medica*,‖ a work he did not live to complete, calls the drug by its Brazilian name of *Butua*, or *Pareira Brava* of the Portuguese, and describes it as a root, woody, hard, contorted, externally of dark colour, rough, with many wrinkles, some long, some running round it transversely, like that of *Thymelæa* [*Daphne Gnidium* L.], internally of a dull, yellowish hue, knit

* This fact was first pointed out in the *Pharmacopœia of India*, 1868, p. 8, *note*.

† *Hist. de l'Acad. Royale des Sciences*, année 1710, 56.

‡ Id.

* Helvetius, *Traité des Maladies les plus fréquentes et des remèdes spécifiques pour les guérir*, Paris, 1703, 98.

† Sloane MS., No. 3340, p. 291.—The letter has already been published in *Phil. Trans*, No. 346, Nov. and Dec., 1715, p. 365.

‡ Sloane MS., 3340, p. 306.

§ As proved by the letters of approbation which precede it. But it was not published until 1694.

‖ Tom. II. (1741) 21.

together, as it were, with many woody fibres, so that when cut transversely it exhibits several concentric circles, intersected by numerous rays of fibres passing from the centre to the circumference ; inodorous, somewhat bitter, with a certain degree of sweetness like liquorice, as thick as the finger, or sometimes as a child's arm. He adds that the Brazilians and Portuguese most highly extol its virtues as a diuretic, lithontriptic, vulnerary, stomachic, cordial, and alexipharmic,* and, in fact, regard it as a complete panacea.

The question now arises—Can the drug which was introduced with so much of laudation be clearly identified ?

As already stated, Pomet has figured it, and his engraving is excellent. But Sloane has left us better materials. In his collection of materia medica, now in the British Museum, there are many well-preserved specimens of the drug obtained from different persons and at different periods, *and all of one kind;* and in his voluminous manuscript catalogues and his other papers, are entries throwing light on their origin.

The first notice I have found is a letter from Lisbon, dated October 17th 1699, addressed by Joseph Geston to John Ellis,† in which the writer says :—

"By order of my brother, Wm. Geston, I send you "here inclosed six sticks of *Pareira Brava*, or *Parra* "*Brava*. The use of it, I am informed, is in powder, "one scruple, and to the strongest patient one octave "[drachm] in Rhenish wine. . . . Its vertues are for "the stone, gravell, obstruction of the urine, and for the "colick,—a very excellent remedy."

Though this letter is not addressed to Sloane, nor is he mentioned in it, yet from its occurrence among his correspondence there can be no doubt that the specimens to which it relates were intended for him.

The entries in his manuscript catalogues, which are in his own handwriting, are these :—

"652. *Pareira Brava.*—From Brasile, pretended "to be good for the stone."

"4039. *Pareira Brava.*—A root used in the stone."

"6708. The *Pareira Brava*, of a brown colour, "from Brazil, said to be the best sort.—From Monsr. "Geoffroy."

"10471. Sevll. specimens of the *Pareira Brava*, "from Lisbon, accounted a great remedy in suppres- "sion of water and the stone,—according to Monsr. "Geoffroy, the *Ambitua* or *Butua* of Zanoni.—From "Dr. Fuller, Sevenoaks."

In 1866, I applied to my friend Theodor Peckolt, druggist, of Rio de Janeiro, then residing at Cantagallo in the same province, on the subject of Pareira Brava, in consequence of which I received from him specimens of two plants, the one marked *Butua* or *Pareira Brava legitima*, the other *Butinha* or *Pareira Brava miuda* (literally *small Pareira Brava*), together with a large dried entire plant of the former. The herbarium specimens of these plants presented no characters by which I could distinguish them as two species ; and Mr. Peckolt subsequently informed me that their difference consists chiefly *in habit*, and that the first or *legitimate* Pereira Brava is found in much drier situations than the small sort or *Pereira Brava miuda.*

I have also received specimens from my friend Mr. J. Correa de Mello of Campinas, marked *Parreira Brava pequena (small Pareira Brava)* or *Abuta pequena*, and others labelled *Leaves of the plant producing Pareira Brava*, all of which seem referable to Mr. Peckolt's plant. Mr. Correa de Mello has likewise sent me the dried root, and I have also received the root as supplied by a drug house of Rio de Janeiro.

Within the last few weeks two specimens of roots bearing some leaves, marked respectively *Pareira Brava, large leaf*, and *Pareira Brava, small leaf*, have been presented to the Pharmaceutical Society as well as to myself by Mr. G. B. Francis of the firm of Hearon, Squire, and Francis. Between these two sorts I fail to recognize any difference.

The roots of Mr. Peckolt's *Pareira Brava legitima*, those sent me by Mr. Correa de Mello, and those received from Mr. Francis, completely agree with Sloane's specimens, as well as with Pomet's figure.

As to the plant, I identify it with *Chondodendron** *tomentosum* of Ruiz et Pavon, with an authentic specimen of which in the herbarium of the British Museum I have compared it. It is the *Cocculus Chondodendron* of De Candolle (Prod. I. 98), and has been figured as *Cocculus(?)platyphylla* by Auguste de St. Hilaire,† and by Eichler,‡ as *Botryopsis platyphylla* Miers. It agrees well with the plate of *Cissampelos Abutua* in Vellozo's *Flora Fluminensis*§ with which Eichler doubtfully identifies it.

Chondodendron tomentosum has been found in various parts of Brazil where it is known as *Butua* and *Abutua.* Its raceme of large oval berries, exactly like a bunch of grapes, is another evidence that it is the plant which the old Portuguese colonists called *Pareira Brava* or *Wild Vine.*|| Neither the fruit nor the foliage of *Cissampelos Pareira* have anything about them suggestive of a grape vine.

---

* Hill judiciously remarks that this is going too far in its praise, and yet omitting some of its real virtues. "It is "certainly a diuretic," says he, "of no inferior kind, and "has done great service in nephritic cases ; and in plurisies "and quinzies has been attended with more success than "almost any medicine we know of singly. In suppressions "of urine scarce anything is more efficacious or more in- "stantaneous in its effect, but it is folly to infer from this "that it will dissolve the stone. . . . In cases of ulce- "ration of the kidneys or bladder, when the urine is puru- "lent and voided with great difficulty, there is scarce any- "thing equal to this root as a remedy."—*Hist. of Mat. Med.* 1751. p. 600.

† Sloane MS., 4045, fol. 240.

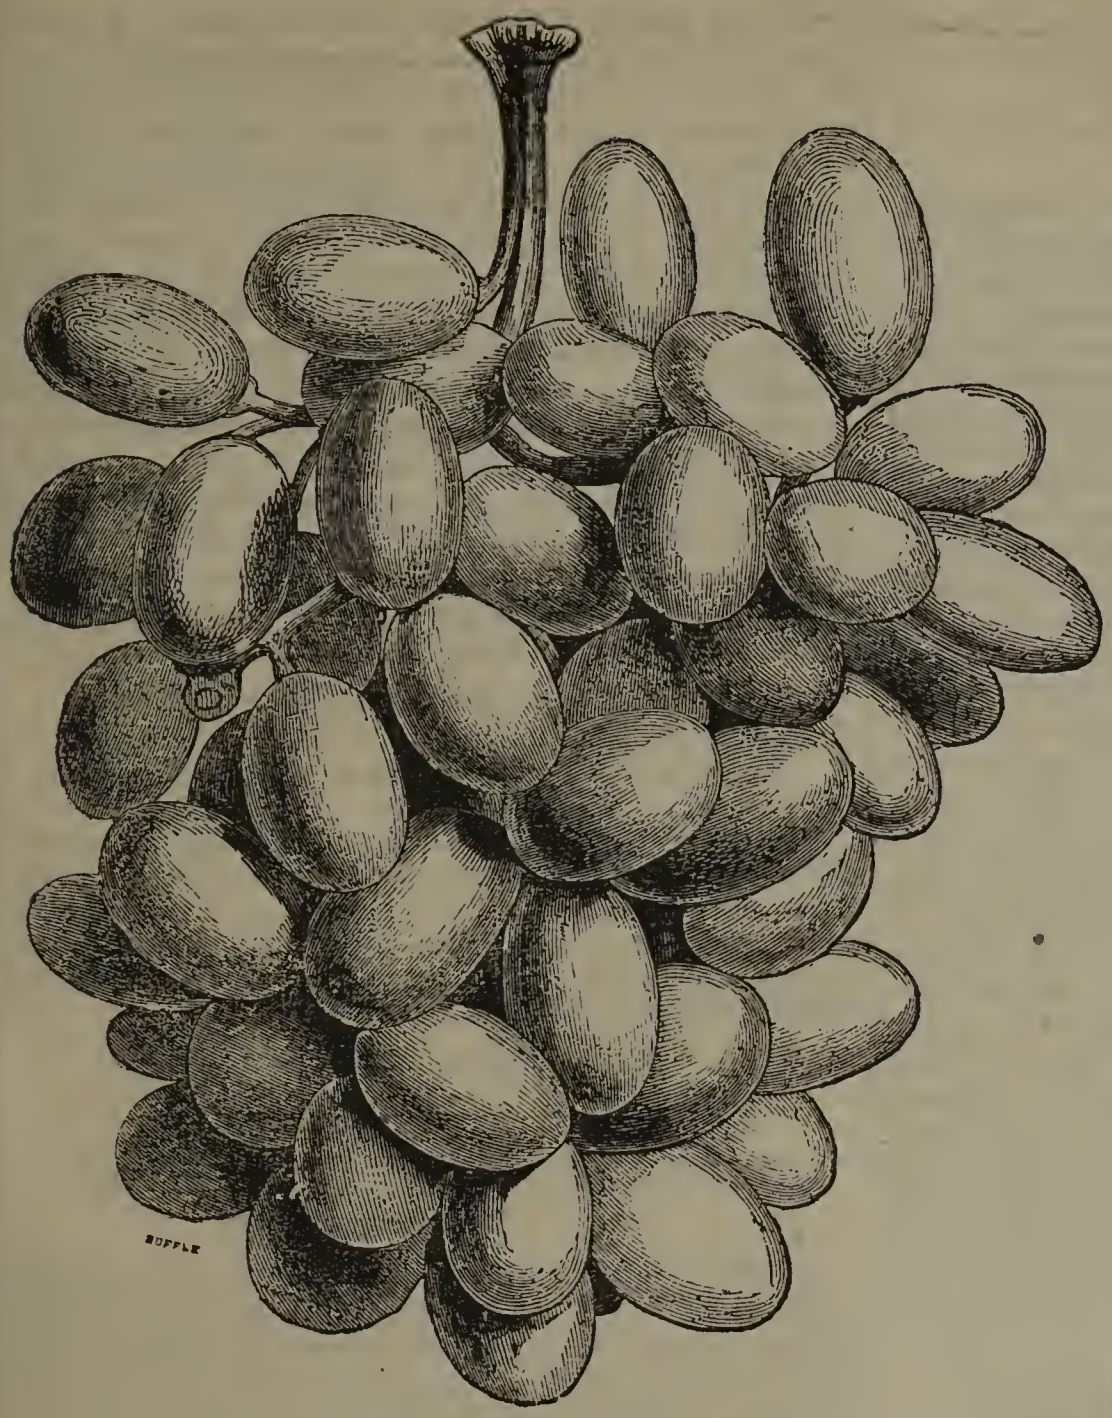
* Mr. Miers (*Contributions to Botany*, III., 307) contends for this name being written *Chondrodendron* as more in accordance with its derivation from χόνδρος. But I think it safer to retain the original spelling as accepted by all botanists.

† *Plantes Usuelles des Brasiliens*, pl. 42.

‡ Martius, *Flor. Bras.*, fasc. 38, tab. 48. Eichler makes *two* species under the name of *Botryopsis*, Miers *eight*, six of them being apparently forms of *Ch. tomentosum.* Mr. Miers's species, as named by himself, can be seen in the British Museum, and a type-specimen of the plant figured by Eichler in the Kew Herbarium.

§ Tom. X, tab. 140. Mr. Miers regards this to represent his *Abuta macrophylla*, a very different plant.

|| In Portuguese the word is written *Parreira*, and signifies a vine that grows against a wall or over an arbour. *Párra* is a vine-leaf.



BUNCH OF FRUITS OF *Chondodendron tomentosum*. R. ET P.*

(*To be continued.*)

THE PHARMACY OF THE UNITED STATES PHARMACOPŒIA.

BY WILLIAM MARTINDALE, F.C.S.,

Demonstrator of Materia Medica in University College, London.

(*Continued from page* 43.)

Pulveres.—Seven formulæ. *Pulveres effervescentes*—*syn.* soda powders—are official—thirty grains of soda and twenty-five grains of tartaric acid, in separate papers of different colours, and *pulveres effervescentes aperientes*, the well-known seidlitz powders, find a place ; these are in the proportions of those generally used, viz.—two drachms of the tartrate and forty grains of the bicarbonate in one paper, with thirty-five grains of acid in the other paper of a different colour. Hiera picra—*pulvis aloës et canellæ*—is also present. *Pulvis ipecacuanhæ compositus, pulvis jalapæ compositus* (without ginger), *pulvis rhei compositus, pulvis aromaticus* (our compound powder of cinnamon with nutmeg in addition), are all much the same as ours.

Resinæ.—Three formulæ. Those of jalap and may apple are prepared much in the same manner as the corresponding B. P. preparations ; that of scammony is prepared from the gum-resin only, the alternative process in the British Pharmacopœia—not from the root at all.

Spiritus.—Sixteen formulæ. Hoffman's anodyne, *spiritus ætheris compositus*, is official, it contains double the quantity of ethereal oil that the P. L. formula did ; a formula is given for the production of this oil also. *Spiritus ætheris nitrosi* is prepared by Dr. Redwood's process, but it is only half the strength of that of the British Pharmacopœia, and contains five per cent. of its peculiar ether. It is ordered to be preserved in well-stopped half-pint bottles, protected from the light, and that "it should not be long kept as it becomes acid by age."

Spiritus ammoniæ is ammoniated alcohol, made by passing ammonia gas into alcohol, sp. gr. 0·835, placed in a bottle which is surrounded by ice-cold water.

Spiritus ammoniæ aromaticus is prepared without distillation. The ingredients are the same as in the British Pharmacopœia preparation, with the addition of oil of lavender, but only half as much carbonate of ammonia is ordered, and even this converts such a quantity of the commercial carbonate into the normal carbonate in the preparation that by experiment I find at 50° F. some of the latter crystallizes out ; there is also much free ammonia gas present in solution. Provided pure carbonate and solution of ammonia be used—not easily procurable at present—there are great advantages in making this preparation by admixture rather than by distillation as, made by the latter process, it will always be of variable composition ; this to be the case with a preparation upon which often hangs the life of a patient is not creditable to pharmacy.

Spiritus menthæ piperitæ and *spiritus menthæ viridis*, synonymous with *essences*, are prepared by dissolving their oils in stronger alcohol and macerating with a little of the powdered herbs for twenty-four hours, to give them the green colour that some think requisite for them to have. *Spiritus limonis* is also made by dissolving the oil of lemon in stronger alcohol, and macerating with some of the freshly grated peel ; to this the synonym of *essence* of lemon is given, which, although perhaps correct, must lead to confusion, as the term essence of lemon is with us synonymous with the oil. *Spiritus lavandulæ compositus*, our compound tincture, retains its old name. *Spiritus chloroformi* is made by mixing one troy-ounce of chloroform with twelve fluidounces of diluted alcohol. *Spiritus juniperi compositus* resembles the P. L. preparation of that name. The other spirits are, like ours, solutions of volatile oil in stronger alcohol.

Succi.—Two formulæ.—Five measures of the expressed juice of the fresh leaves of conium mixed

* From a specimen preserved in alcohol, sent to me by Mr. Peckolt.

with one of alcohol, and after seven days filtered, forms the official *succus conii*. *Succus taraxaci* is prepared in the same manner from the root.

Suppositoria.—Nine formulæ. The following general formula is given :—

"Mix the medicinal portion with a small quantity of oil of theobroma, by rubbing them together, and add the mixture to the remainder of the oil of theobroma previously melted and cooled to the temperature of 95°. Then mix thoroughly without applying more heat, and immediately pour the mixture into suitable moulds, having the capacity of thirty grains each. The moulds previously made cold must be kept so by immersion in iced water. All difficulty in removing suppositories from the moulds may be obviated by having the moulds previously dusted with lycopodium. In the absence of suitable moulds suppositories may be formed by allowing the mixture, prepared as above, to cool, care being taken to keep the ingredients well mixed, and dividing it into parts, each of which shall weigh thirty grains, and may be made into a conical or other convenient form for a suppository."

Oil of theobroma is the basis, and the suppositories are made to weigh about thirty grains each. Why they are diluted with so much inert matter is not very evident ; with us fifteen grains is often thought to be too much, as it is found that this quantity is apt to soil the patient's linen. *Suppositoria acidi tannici* have five grains of tannin in each ; *suppositoria morphiæ* have half-a-grain of the sulphate of morphia in each ; *suppositoria opii* have one grain of the extract of opium in each, with water, q. s. ; *suppositoria plumbi* have three grains of the acetate of lead in each ; *suppositoria plumbi et opii* have three grains of the acetate and half-a-grain of extract of opium in each, with water, q. s. ; *suppositoria belladonnæ* have half a grain of alcoholic extract of belladonna leaves in each, with water, q. s.; *suppositoria aloës* have five grains of purified aloes in each ; *suppositoria assafœtidæ*—a fluidounce of tincture of assafœtidæ is evaporated to a thick syrup, and mixed with oil of theobroma to make twelve suppositories ; *suppositoria acidi carbolici* have one grain of carbolic acid in each, with water, q. s., to liquefy it—the acid would mix better with the oil of theobroma *without* the addition of water.

Syrupi.—Twenty-three formulæ. *Syrupus* consists of thirty-six troyounces of sugar, and nineteen fluidounces of water, it is, therefore, slightly weaker than ours. *Syr. ipecacuanhæ, syr. rhei* and *syr. rubi* are made by mixing the fluid extracts of these drugs with simple syrup. That of krameria may also be prepared in the same way, or an alternative process is given by percolating the powdered root with water, concentrating by evaporation and adding sugar. *Syrupus zingiberis* is made from the fluid extract by mixing this with carbonate of magnesia and sugar, then with water, dissolving and filtering, adding more sugar, and lastly straining while hot. *Syrupus tolutanus* is prepared in a similar way from the tincture of tolu.

Syrupus acidi citrici is flavoured with oil of lemon.

Syrupus alii (syrup of garlic).—Diluted acetic acid is macerated four days with the bruised garlic, the liquor pressed out, filtered, the sugar added, and converted into a syrup without the aid of heat.

Syrupus amygdalæ.—A strong emulsion is made with a portion of the sugar, water, and one part of bitter and three of sweet almonds blanched, and the remainder of the sugar is dissolved in the emulsion by the aid of heat. The utility of this preparation is doubtful, as it will not keep a week, and there is an emulsion official. *Syrupus corticis aurantii* is made from an alcoholic tincture prepared by percolation : the tincture is evaporated to a small bulk, mixed with carbonate of magnesia and sugar, and treated in the same way as syrup of ginger ; in making this and some other syrups I think the game is not worth the candle. In making *Syrupus lactucarii* and *Syrupus rosæ Gallicæ*, tinctures of the lactucarium and rose petals (dried) are made by percolation with diluted alcohol, and these are concentrated and mixed with sugar or syrup. *Syrupus ferri iodidi* is half as strong again as ours ; it is directed to be kept in two-ounce well-stopped vials. *Syrupus limonis* is prepared with sugar and equal parts of lemon juice and water, *sine* the peel. *Syrupus Aurantii Florum* is made with sugar and orange-flower water without dilution. Syrup of Wild Cherry is frequently prescribed in England. The following is the formula for it :—

"*Syrupus Pruni Virginianæ.*

Take of Wild Cherry in coarse powder, five troyounces ;
Sugar, in coarse powder, twenty-eight troy-ounces ;
Water, a sufficient quantity.

Moisten the Wild Cherry thoroughly with water, and allow it to stand for twenty-four hours in a close vessel ; then pack it firmly in a glass percolator, and gradually pour water upon it until a pint of filtered liquid is obtained To this, transferred to a bottle, add the sugar, and agitate occasionally until it is dissolved."

(*To be continued.*)

ETHEREAL TINCTURE OF IODOFORM.*

BY MM. ODIN AND LEYMARIE.

At the request of Dr. Gubler, who uses an ethereal solution of iodoform as a topical application, the authors sought to ascertain the most favourable conditions for its preparation, and to determine the relative proportions in which the iodoform is soluble.

(1.) A solution prepared in a flask of white glass after a little time became discoloured ; the canary yellow passed to an amber, and then brown colour. This change was the result of the liberation of a portion of the iodine, which coloured starch paper blue.

(2.) When iodoform previously pulverized was used, the solution, exposed to diffused light, altered much more quickly than the first.

(3.) When two ethereal solutions were made simultaneously, the one with crystallized iodoform, the other with powdered iodoform, and using red glass bottles, the first preserved its yellow tint, the second assumed a brown colour after a few days.

Solubility.—Experiments were made with pure ether of 65° Baumé (sp. gr. ·724), and also with ethers of 62° and 56°, the temperature being 13° C. Eight grams of tincture obtained with these ethers contained iodoform in solution respectively to the following extent :—

Ether of	65°	Baumé	1·61 grams.
„	62°	„	1·26 „
„	56°	„	1·13 „

The iodine being equal in the first case to 25·195 per cent. of the ether ; in the second to 18·694 per cent., and in the third to 16·044 per cent., or in round numbers, at 65° B., one-fourth ; at 62° B., one-fifth, and at 56° B., one-sixth,

The conclusions drawn by the authors from the foregoing experiments are—

* *Répertoire de Pharmacie*, June 25, p. 350.

(1.) To employ iodoform in the crystalline state.
(2.) To make the solution in a *red* glass flask by simple agitation.
(3.) To use the following proportions :—

Crystallized Iodoform	1 gram.
Ether (60° Baumé)	4 grams.

A METHOD OF DETERMINING THE SPECIFIC GRAVITY OF LIQUIDS WITH EASE AND GREAT EXACTNESS.*

BY HERMANN SPRENGEL, PH. D.

The *Laboratory* for 1867 (p. 191) contains a paper on Specific Gravity, by Matthiesen and Hockin, in which the use of a small pipette is recommended in place of the specific-gravity bottle, when only a few centigrams of liquid are at the operator's disposal. I also had independently, for a number of years, availed myself under all circumstances of pipette-shaped vessels in preference to the usual specific-gravity bottle. But our instruments, and our way of using them, differ sufficiently to justify me in giving a short description of my method.

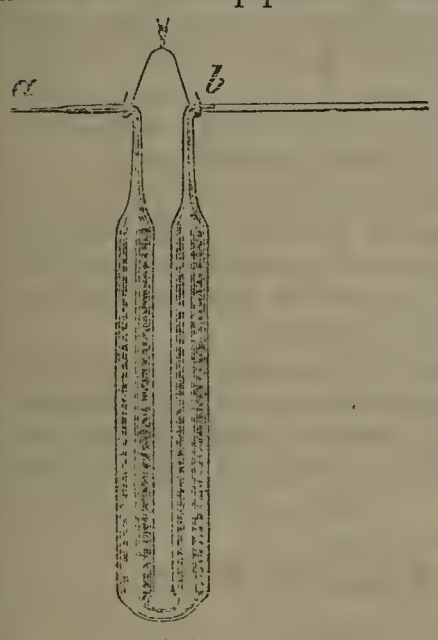


Fig. 1.

The form of my instrument, as shown in Figure 1. is that of an elongated U-tube, the open ends of which terminate in two capillary tubes, which are bent at right angles in opposite directions. The size and weight of this instrument should be adapted to the size and capability of the balance, in which it is to be weighed. As our usual balances indicate $\frac{1}{10}$ milligram when loaded with 50 grams, the U-tube, when charged with the liquid, should not be heavier (1000 grains = 64,799 grams). The instrument which served for my determinations, mentioned below, had a length of 17·7 cm. (7 inches), and was made of a glass tube, the outer diameter of which was 11 mm. ($\frac{7}{16}$ of an inch). It hardly need be mentioned that the U-shape is adopted for the sake of presenting a large surface, and so rendering the instrument sensitive to changes of temperature. The point, however, which I wish to notice more particularly (for reasons explained below) is the different calibre of the two capillary tubes. The shorter one is a good deal narrower (at least towards the end) than the longer one, the inner diameter of which is about $\frac{1}{2}$ mm. The horizontal part of this wider tube is marked *near* the bend with a delicate line (*b*). This line and the extremity of the opposite capillary tube (*a*) are the marks which limit the volume of the liquid to be weighed.

The filling of the instrument is easily effected by suction, provided that the little bulb apparatus (as represented in Figure 2) has previously been attached to the *narrow* capillary tube by means of a perforated stopper, *i.e.* a bit of an india-rubber tube, tightly fitting the conical tubulus of the bulb. On dipping the *wider* and longer capillary tube into a liquid, suction applied to the open end of the india-rubber tube will produce a partial vacuum in the aparatus, causing the liquid to enter the U-tube. As this partial vacuum maintains itself for some time (on account of the bulb, which acts as an air-chamber), it is not necessary to continue the suction, if the end of the india-rubber tube be timely closed by compression between the fingers. When bulb and U-tube have about equal capacity, it is hardly necessary during the filling to repeat the exhaustion more than once. Without such a bulb, the filling of the U-tube through these fine capillary tubes is found somewhat tiresome. The emptying of the U-tube is effected by reversing the action and so compressing the air.

After the U-tube has been filled it is detached from the bulb, placed in water of the standard temperature almost up to the bends in the capillary tubes, left there until it has assumed this temperature, and, after a careful adjustment of the volume, it is taken out, dried, and weighed.

Particular care must be taken to ensure the correctness of the standard temperature, for (as I shall show below) a mistake of 0·1° causes the weight of 10 c.c. of water to be estimated either too high or too low by 0·14 milligram, giving rise to an error in the 5th decimal, or making 100000 parts 100001·4 parts. Those determinations have been made in Dupré's apparatus, which, when furnished with a sensitive thermometer, allows the fluctuations of temperature to be fixed within the limits of 0·01°. If many determinations had to be made I should avail myself of Scheibler's (*Zeitschrift für analytische Chemie*, vol. vii, p. 88, 1868) electro-magnetic regulator for maintaining a constant temperature.

A peculiar feature of my instrument is the ease and precision with which the measurement of the liquid can be adjusted at the moment it has taken the standard temperature ; for it will be found that the liquid expands and contracts only in the wider capillary tube, viz., in the direction of the least resistance. The narrow capillary tube remains always completely filled. Supposing the liquid reaches beyond the mark *b*, it may be reduced through capillary force by touching the point *a* with a little roll of filter-paper. Supposing, however, that in so doing too much liquid is abstracted, capillary force will redress the fault, if point *a* be touched with a drop of the liquid under examination ; for this gentle force acts instantly through the whole mass of the liquid, causing it to move forward again to or beyond the mark.

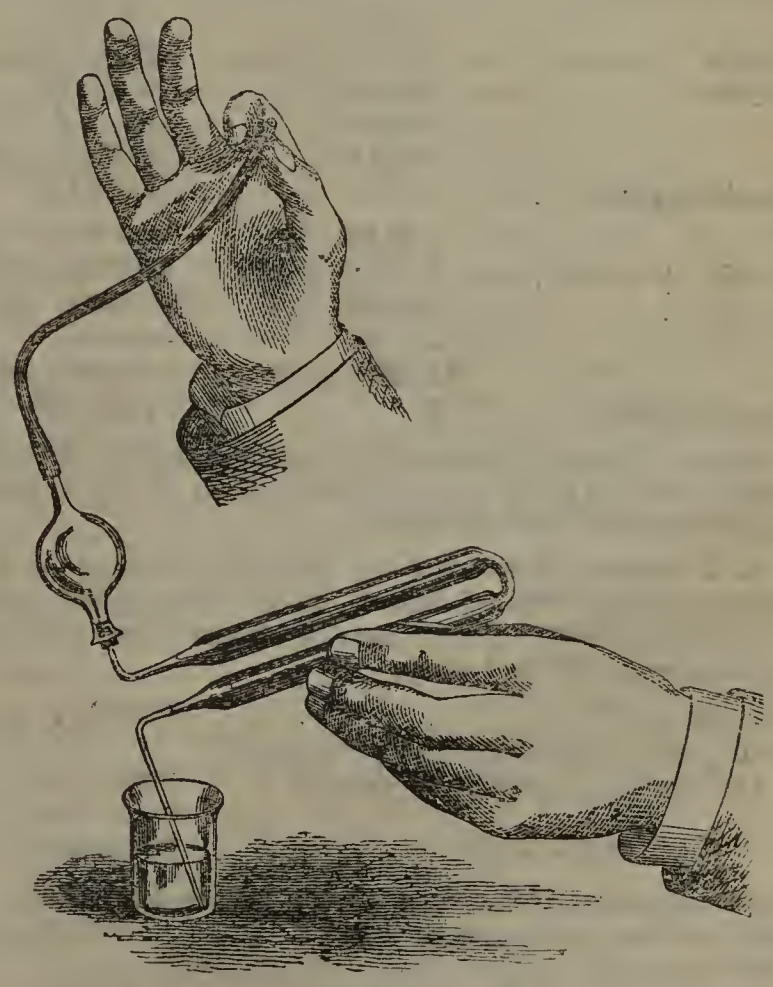

Fig. 2.

As the instrument itself possesses the properties of a delicate thermometer, the time when it has reached the standard temperature of the bath may be learned from the stability of the thread of liquid inside the wider capillary tube. The length of this thread remains constant after the lapse of about *five minutes*.

In wiping the instrument (after its removal from the

* Paper read before the Chemical Society; reprinted from *Journ. Chem. Soc.* [2], xi. 577.

bath) care should be taken not to touch point *a*, as capillarity might extract some of the liquid; otherwise the handling of the instrument requires no especial precaution.

The capillary tubes need not be closed for the purpose of arresting evaporation, at least that of water. I have learned from the mean of several determinations that the error arising from this source amounts in one hour to $\frac{1}{20}$ milligram.

In cases where the temperature of the balance-room is high and the expansion-coefficient of the liquid to be examined is considerable, it may be found necessary to put a small cap (bead-shaped and open at both ends) over the extremity of the *wider* capillary tube, for the purpose of retaining the liquid, which during the time of weighing might otherwise be lost, owing to its expansion. Raising the standard temperature of the bath is another way of meeting this inconvenience. When a cap is used, the wider capillary tube need not be longer than the narrow one.*

The nicety attainable by this method is very satisfactory. As a proof of this I beg to draw attention to the following two examples :—

1. Six weighings in succession were made of the same sample of distilled water, measured three times at 16°, three times at 15°. The instrument was filled and emptied three times, while Dupré's bath was raised and lowered to the desired temperature six times in succession. The weighings were noted down after the instrument had hung inside the balance-case for ten minutes. No counterpoise was used in the shape of another similar U-tube. The results were these :—

	At 16°.		At 15°.
U-tube + water . =	41·9648 gram.		41·9675 gram.
U-tube . . . . =	23·3332 „		23·3332 „
	18·6316 gram.	:	18·6343 „
Specific gravity. .	1	:	1·000145
	At 16°.		At 15°.
U-tube + water . =	41·9648 gram.		41·96735 gram.
U-tube . . . . =	23·3332 „		23·33320 „
	18·6316	:	18·63425 gram.
Specific gravity .	1	:	1·000143
	At 16°.		At 15°.
U-tube + water . =	41·9648 gram.		41·9674 gram.
U-tube . . . . =	23·3332 „		23·3332 „
	18·6316 gram.	:	18·6342 gram.
Specific gravity .	1	:	1·000140

NOTE.—This table shows that the instrument is obviously applicable also to the exact determination of the apparent expansion-coefficient of liquids.

2. A sample of water taken from the Houses of Parliament on the 29th of March, 1873, as supplied by the Government Water Works near Trafalgar Square from an artesian well 380 feet deep,

showed at 15°	1·000794 sp. gr.
while, after being boiled for $\frac{3}{4}$ hour under the usual precautions, it showed . .	1·000711 „
Difference	0·000083

On evaporating 100 grams of the water (unboiled), the solid residue was found to weigh . . . . 0·0835 gram,
while the solid residue from 100 grams of water (boiled and filtered) weighed . . . 0·0775 „
Difference . . . . . 0·0060 gram.

This water, although it contains a considerable amount of mineral matter, was chosen on account of its softness, for, by Clarke's test, its degree of hardness (unboiled) was . . . . . 5·3
(boiled) . . . . . 0·75
Difference . . . . . 4·55

These data suffice to prove that the well known precipitation of carbonate of lime through boiling (in this case 4·55 grains per gallon) was the main cause of lowering the specific gravity of the water after boiling. As we have learned from example No. 1 that reliance may be placed on the correctness of the 5th decimal, the quantity of matter (with reference to the above difference 0·000083, which became insoluble might have been eight times less before its absence ceased to be indicated by such specific gravity determinations. Now the 8th part of 0·006 gram is 0·00075 gram, and represents the difference which refers to the solid residue from 100 grams of water. In other words, if we dissolve in 10,000,000 parts 75 parts, or in 1 litre of water 7·5 milligrams, or in 1 gallon about $\frac{1}{2}$ grain of mineral matter (such as carbonate of lime), its presence in the water can thus be ascertained quantitatively.

If the varying constituents dissolved in natural waters influenced the specific gravity of water to a like degree, the above method would give the readiest means for determining the amount of matter in solution, but an approximation only can thus be obtained.

When, however, a solution contains only one unknown constituent, the relative proportion between this constituent and its solvent can, by means of this simple and quick analytical operation, be ascertained with all the accuracy needed.

* The instrument may be obtained from E. Cetti and Co., 11, Brooke Street, Holborn, London.

ANALYSIS OF THE BRAZIL NUT.*

(*Bertholletia excelsa.*)

BY B. CORENWINDER.

The *Bertholletia excelsa*, which belongs to Schomburgk's section Lecythideæ of the natural order Myrtaceæ, was first described by Humboldt in his work, 'Des Plantes Équinoxiales.' This gigantic and majestic tree presents in its fruit,—a kind of rounded pericarp of thick wood which contains triangular seeds,—a most remarkable example of the power of organic force. It grows abundantly on the banks of the Orinoco, and in Brazil, attaining a height of 33 metres (108 feet) and even more. Its trunk is straight, cylindrical, and about 9 decimetres in diameter; the leaves as well as the branches are alternate. The fruit is a spherical nut about the size of a child's head, divided internally into four cells each containing several seeds. These number from six to eight in each division and are monospermous, obtusely triangular in shape, tuberculate and of a cinnamon colour. The pericarp, which is hard and woody, contains an oily kernel, which when fresh has an exquisite flavour but quickly turns rancid. The fruit has hitherto presented little of interest in an economic point of view, but the author was led to analyse it during some researches upon oleaginous seeds.

The study of the reproductive organs of vegetable life is full of charms for the chemist who has a love for nature. Just as the milk of mammals,—composed of casein, sugar, butter, albumen and phosphates,—is the type of animal alimentary matter, so in fruits, in seeds, nature has condensed the immediate principles which by germination undergo modifications rendering them soluble. They constitute then a vegetable milk which contains oil, sugar, nitrogenous substances and the phosphorus necessary to stimulate and maintain the life of the plant. These principles are found in all seeds, but in varying proportions; though doubtless there reigns a harmony and concordance between these proportions and the medium in which the young plant is born and developed.

* *Journ. Pharm. Chim.* [4], xviii., 14; from the *Mémoires de la Société des Sciences de Lille.*

The elements which constitute the seed have probably special destinations. M. Corenwinder thinks that the oil supplies, by its combustion, the initial heat necessary for the excitation of life and supports his hypothesis by the fact that in maize grains, amongst others, the oil is contained in cells which immediately surround the embryo. When favourable circumstances, such as humidity and warmth, provoke the first symptoms of germination, the tissues swell, the fatty matter burns slowly, absorbing oxygen and disengaging carbonic acid; and the vegetable fœtus, excited by a gentle heat, commences to grow. In a later phase of the phenomenon the starch of the perisperm is transformed into sugar; the nitrogenous materials and phosphates present are dissolved in the weak acid which is developed by chemical action and the milk of the young plant is constituted.

The experiments of the author were made with nuts in a fresh state, to which he attributes the following composition as representing the kernels in the normal state :—

Water.	8·00
Oil.	65·60
Nitrogenous matters.	15·31
Non-nitrogenous organic matters . . .	7·39
Phosphoric acid. . . 1·35 / Lime, potash, silica, etc. 2·35	3·70
	100·00

These figures compared with the following composition attributed to the ground nut (*Arachis hypogœa*) by the author show that in the seeds of the *Bertholletia excelsa* there is a larger proportion of oil, but the nitrogenous matter is less abundant.

Analysis of Ground Nut.

Water.	6·76
Oil.	51·75
Nitrogenous matter	21·80
Non-nitrogenous organic matter containing starch	17·66
Phosphoric acid. . . . . 0·64 / Potash, chlorine, magnesia, etc. 1·39 .	2·03
	100·00

The proportions of phosphoric acid found in the perfectly white ash of these two nuts were as follows :—

Brazil nut	36·54 per cent.
Ground nut	31·53 „

In Brazil and Guiana an excellent edible oil is extracted from the fresh Brazil nut; it is possible however that the facility with which these nuts turn rancid has helped to deter European manufacturers from attempting to utilize them for such a purpose. But even if it were not possible to procure supplies of the nuts sufficiently fresh for the purpose in Europe, the author considers an oil might be obtained from this source suitable for the manufacture of soaps and other industrial purposes; while the oil-cake might be advantageously used as manure or perhaps even as a food for cattle.

EXPORT OF SALTPETRE FROM PERU.

A law relating to the taxation of exports has been published in Peru, which, in respect to saltpetre, contains the following articles :—1. In the exportation of saltpetre 50 per cent. will be charged on the difference between the cost price and the market value, which is to be decided by a commission appointed for the purpose.—2. In the exportation of the raw material (*caliché*) a duty of 25 cents. will be recovered on every 100 lbs.—3. The Government is to adopt any means that may suit to collect this duty. The law, however, with regard to article 1, providing for the charge of 50 per cent. on the profits, has been altered by establishing the production of the saltpetre as a Government monopoly, the State paying two soles and 40 cents (or about 12*s.*) per quintal (100 lbs.) to the producers, and reserving to itself the privilege of fixing a market price to purchasers of the article. The Peruvian government is evidently aware now that the whole realizable amount of guano cannot be calculated at over 3,000,000 of tons, nitrate of soda must become more valuable in the English markets. A proposition has also been made to have the nitrate sold at the markets of Iquique and Lima. Such a monopoly, however, it is stated by good authorities, is not likely to stand before the increasing export of the like material from the republic of Bolivia; and a hope is also entertained of new discoveries in the extensive desert of Atacama, which joins Chili to Bolivia and Peru. The reports of the exports of saltpetre from Iquique show a marked increase during the past two years; the largest quantity of the articles appears to be taken by England. The increase in the trade is considerable. According to a comparative statement of the exports of saltpetre from Iquique for the first six months in the years 1870, 1871, and 1872, we get the following results :—to England, 1870, 299,663 quintals; 1871, 382,698 quintals; 1872, 260,385 quintals; to France, 1870, 168,172 quintals; 1871, 24,443 quintals; 1872, 29,000 quintals. The total exports during these periods were as follows :—1870, 1,415,916 quintals; 1871, 1,542,882 quintals; and 1872, 2,221,540 quintals. The immense increase in the first six months of last year will thus be perceived.

RECENT EXPERIMENTS ON OLD AND NEW ALKALOIDS OF OPIUM.

BY A. GUBLER.

(*Concluded from p.* 28.)

The beautiful researches of M. Cl. Bernard on the alkaloids of opium have opened new ways to clinicians and experimenters. As is known, he has been induced to range the active principles of opium in three series, according to their soporific, convulsive, or toxical action. But what is most interesting, as regards applications in medicine, is that *narceine*, formerly neglected, has now come to be regarded as a valuable means of procuring deep and calm sleep, free from the disturbance generally attendant on opiaceous narcotism.

But if the hypnotic action of narceine be indubitable, it is yet evident that this alkaloid does not show in man the power it has with several lower animal species.

The observations of MM. Behier, Bouchardat, and others, leave no doubt upon this point, and I have come to value the hypnotic power of narceine at a fourth, or a fifth only, of that of morphine.

This inferiority is the more regrettable in practice, since narceine, less abundant in opium, is necessarily much dearer than morphine. Hence the employment of it has not become general. M. Liné has noted a more considerable diminution of diuresis from narceine than from morphine, and this has been verified in England by Dr. Harley, who has besides found the tubuli of the kidneys charged with crystals of narceine, to which circumstance may probably be attributed the symptom mentioned, while excessive doses of narceine may produce an irritation of the urinary glands, or, in other words, catarrhal nephritis.

While this alkaloid stupefies the encephalon, it at the same time influences the sensory nerves, and from this double action results a notable degree of analgesia. Dr. Petrini has especially insisted on this property, and he also attributes to narceine anti-emetic properties superior to those of hydrochlorate of morphine.

One experimenter only, M. Bouchut, refuses to this alkaloid all therapeutical value. He declares that, administered to children in the relatively large dose of ten centigrammes, and even (an incredible thing) seventy-five centigrammes, it continues absolutely inert. A result so paradoxical cannot be explained simply by the administration of the medicine in pilular form, as M. Rabuteau thinks it must be supposed that the chemical substance was of bad quality, or that the young subjects experimented on did not have it really ingested.

The hypnotic virtues of *codeine* have been justly called in question by Schroff, who observed in the rapidly efficacious doses of 10 centigrammes merely the power of provoking nausea, with marked retardation of the pulse. Using a dose of 6 centigrammes with children, M. Bouchut obtained no hypnotic effect, and a dose of 30 centigrammes did not produce more than a slight depression, moisture, and pupillary contraction. These results, partly confirmed by M. Rabuteau, did not surprise me, as I had long since been struck with the weakness of codeine, and perceived it had a slight narcotic or hypnotic and anodyne action more transient than that of other alkaloids (morphine, narceine), and with which one ought not to be contented, except in the less serious cases, or in treating subjects of excessive impressibility for opiaceous preparations.

Narcotine, to which M. Cl. Bernard assigns only convulsive properties, has not shown any soothing or hypnotic virtue, in the recent experiments made by MM. Bouchut and Rabuteau.

According to the same experimenters, *meconine* or *opianine*, in the large dose of 20, and even up to 50, centigrammes, was inert or very nearly so. But here some reserve is necessary, in view of the observations of Dr. Harley, who attributes to this alkaloid, though in small measure, the soothing and soporific qualities of morphine. The opportunity for meconine, therefore, as for codeine, would be with susceptible subjects, and especially with young children, if it were not subject to the inconvenience of being ill-absorbed by the stomach, and requiring hypodermic injection.

A good deal has lately been said about *papaverine*, ranked by M. Cl. Bernard among the convulsive alkaloids above thebaine and codeine. The German observers, Leidersdorff and Breslauer, supported by Baxt and Stark, have opposed the eminent French physiologist, holding that papaverine is purely sedative and produces sleep, with pupillary contraction, retardation of the pulse, and depression of strength. They point out, also, in its action, a slowness of manifestation (after four to seven hours) and a duration (reaching to 24 or even 48 hours) which would make it an agent preferable to opium and to morphine in a large number of circumstances. They, therefore, recommend this alkaloid as a palliative of insomnia, and of over excitement in mania and other forms of insanity.

One of their fellow-countrymen, K. B. Hoffmann, has sought to dissipate these illusions which first experiments have originated. Experimenting on himself, he took, during three consecutive days, 12, 24, and 36 centigrammes successively, of hydrochlorate of papaverine, without procuring either muscular relaxation, or hypnotism, or any effect whatever on the respiration, the pulse, the temperature, or the urinary secretion. On the other hand, he suffered from frontal headache, epigastric uneasiness, and a troublesome hiccough.

These results agree, at least the negative portion, with those of M. Bouchut, who administered 1 gramme of papaverine to a child 14 years old, without remarking any functional modification, or phenomenon imputable to this alkaloid. Indeed, M. Rabuteau thinks papaverine favours the anæsthetic action of chloroform; which would imply, on his part, the ascertainment of a certain degree of stupefying action, but the opinion being based on only one experiment wrought on a dog, does not afford much valid support to the view expressed by Leidendorff and the partisans of papaverine.

Thebaine or *paramorphine* has lately been studied in two theses, one by Dr. Couloma, at Montpellier, the other by Dr. Mihran, a student of the Paris School. It has also, previously, engaged the attention of several physiologists, (Harley, Vulpian, Müller, Falck, etc.) the results being, on the whole, confirmatory of those of Magendie and of M. Cl. Bernard, and demonstrating the tetanising action of this alkaloid, which Falck does not hesitate to place by the side of brucine.

In its toxical action we may distinguish three phases: 1. a period prodromic, or of excitation; 2. a period convulsive, tetanic; 3. a period of collapse or paralysis.

Like the alkaloids of *Strychnos*, thebaine seems to excite the medullary centre, and, when it happens to produce tetaniform convulsions, it appears to give rise at the same time to all the symptoms characterizing the convulsive paroxysms of pathological or artificial tetanus. At least I observed elevation of temperature, and increase of secretions; but it is impossible for me to affirm that the sudoral secretion is augmented, as it is in tetanic paroxysms, for the experiments were generally made on frogs and dogs, which do not perspire. But the mechanism of death by arrest of the respiratory movements, and asphyxia (Harley), as also the lesions found on autopsy, are essential features in the similitude I seek to establish. Dr. Harley points out the absence of crepitation, and the fœtal state of the lungs. M. Rabuteau, in his turn, has found the lungs, the coats of the brain, and the liver, hyperæmic, and often charged with ecchymoses, exactly as in the case of tetanus or of strychnism.

This similarity of action between thebaine and strychnine or brucine being admitted, I can scarcely suppose that the alkaloid of opium is far removed from its powerful congeners in effect on the sensory nervous system, and that, in place of exciting the sensory nerves, like the other convulsive poisons, it soothes and dulls them. Nevertheless, M. Arzerouny asserts the anæsthetic power of thebaine, and that he has proved it with several patients having painful affections. I might be content with opposing to his assertions the contradictory observations of M. Rabuteau or M. Bouchut. I prefer to remark that the facts stated by our young Armenian brother (and which refer to only six cases observed) have not the probatory value he claims for them. [Dr. Gubler briefly criticises each case in succession.]

In fine, thebaine appears, according to the most ample information, which has been furnished by the works of Magendie, and of M. Cl. Bernard, to be a convulsive agent and nothing more.

As for *opianine*, to which its discoverer (Kugler) attributes narcotic properties as energetic as those of morphine, I simply notice a recent statement of M. Rabuteau, who, on the faith of the foreign author, and without previous experiment, was content to say that the action of opianine is comparable with that of morphine.

I designedly pass over the observations made on opianic and meconic acids, as I am occupied exclusively with alkaloids of opium; but this review would be incomplete if I omitted the important researches of Dr. Harley on the pretended absolute antidotism of opium to belladonna, and reciprocally; an antidotism which, for my own part, I have never accepted in the terms in which it has been formulated.

After experiments as numerous as varied, and perfectly conducted, the learned English physiologist states the following conclusions:—

The antagonism does not appear from the cases cited. On the contrary, they show that belladonna is without influence in accelerating recovery after thebaic intoxication. The principal effects of opium, somnolence, stupor, narcotism, and coma, are often prolonged when the poisonous solanea is made to act concurrently. Belladonna is powerless against the chief danger of opium, the depression of the respiratory function.

In fine, the results of the combined action of opium and belladonna are the same for therapeutical as for toxical doses. Still, while belladonna cannot in any way be considered an antidote to opium, or *vice versâ*, it is fitted, on the other hand, to render some service, joined with other remedies, and administered in small quantity, by aiding in dissipation of the phenomena of thebaic poisoning.

These observations, in my opinion, faithfully sum up the facts which have been well observed, and I adhere to them almost without reserve.

NOTES ON PEPSIN.*

BY EDWARD H. HOSKIN, M.D.

Much has been said about physicians' prescriptions being inaccurately compounded, and much fault found with the incompetency of apothecaries and their assistants —frequently, no doubt, without injustice to either party. As much fault may be found with some of the preparations, because of their impurities, and often of the positive inertness of what should be the active principle on which the efficacy of the drug depends. Amongst these preparations, pepsin is particularly alluded to.

The market is flooded with pepsin, of German, French, English and American manufacture, its elixirs, wines and troches—elixirs *per se*, and in alleged combination with bismuth, iron, strychnia, etc.—in fact, so elegantly, and apparently therapeutically combined, as to please the eye, taste and judgment of the physician, and by its promised combination, to appear to him as the very thing he wants in his daily practice. All is not gold that glitters, nor is all pepsin that is called so, nor do all its preparations contain the promised principle.

Curiosity at first induced me to examine a sample of of French make, and getting a negative result, I still more carefully tried three other samples of the same make, and found all inert; I then tried another make, and with the same result, and then various samples of American preparations, but not one could I find that was in any way a solvent of coagulated albumen. I next tried some elixirs, and not one of these would produce the required result; then some of the wines, and with the same lack of success.

After these experiments, I came to the conclusion that pepsin, as sold in the shops, was a fraud, that physicians were defrauded of their success, and the patient of his health and his means, through the worthlessness of the drug supplied.

But on looking over a review of the new Pharmacopœia, in the Journal of March 13th, I noticed the mention of the pepsin made by Scheffer, of Louisville, and being anxious, if possible, to find a reliable article, I wrote to him for a sample, and received by mail two descriptions —"saccharated pepsin," and "concentrated pepsin." I at once experimented with them, and obtained most excellent results. With one grain of the concentrated article, I obtained the solution of one hundred grains of coagulated albumen, and with five grains of the saccharated, sixty grains of albumen—in each case using one ounce of water and six drops of muriatic acid. With one grain, also, of the former, I procured the solution of 137 grains of raw, lean beef.

These results are, I think, eminently satisfactory, and prove, at least, that there is one reliable article to be had —of home manufacture, also, instead of heavily dutied foreign goods, and which so frequently are considered the only reliable preparations.

I have been sceptical as to the therapeutic value of the so-called pepsin wines and elixirs, and my experiments have proved that, at all events, the pepsin used in their manufacture is not of any use, for there is no solvent action exerted whatever on coagulated albumen by any of them I have yet tried.

This may be the proper place to describe the method I adopt for detecting the presence of what I will call active pepsin. It is known that the presence of albumen in diabetic urine is an obstacle to the detection of the sugar, and that a fine mauve or purple colour is produced on the addition of either Trommer's or Fehling's test solution. It occurred to me that this reaction would just come in for my purpose. Take coagulated albumen, and put into the pepsin wine or elixir; submit to one hundred degrees Fahr. in a water-bath, and if there is any of the active peptic principle present, solution of so much of the coagulum will ensue, and the albumen reduced to an allotropic condition, which, when added to the test solution, would produce the purple colour.

On trying the experiment, no such thing occurred; but, on making a simple solution of pepsin in water, adding acid and albumen, and digesting for half an hour, I procured a solution which, on addition of the cupreous test, at once yielded the splendid colour; repeated trials have yielded the same results. Flesh, or cheese, may be used in place of albumen, as all that is required is to obtain a peptone, and the reaction will show it; hence proving that pepsin must have been present in order to its production.

I have repeatedly dissolved a perfectly good pepsin in sherry wine, added hydrochloric acid and albumen, and submitted to a water-bath and then tested for peptone; but in no case have I been able to detect it. From this fact, I conclude that pepsin wines are useless, as far as the drug is concerned, and that the presence of the alcohol, or the small proportion of tannin, or both, distroys its catalytic action. Tannin, in solution, does the same thing. So, also, do most metallic salts; and here I would quote from Dr. T. King Chambers 'On the Indigestions,' page 94: —"But for the time named, I advise its being given alone, and the action not interfered with in general by other medicines. *Many* will really *prevent* its chemical *effect*, and all will confuse one's judgment of the advantage gained."

But, if to a peptone already formed, either wine, alcohol, tannin, or a metallic salt is added, the addition of the test will at once exhibit its reaction, though tannin, if in large quantity, somewhat masks it. From this, it appears that the failure of the test to indicate pepsin in wine or dilute alcohol, or in the presence of tannin, or a metallic salt, does not result from the action being masked, but from the fact of the pepsin (under the conditions) being inert.

If, then, these elegant pseudo-pharmaceutical preparations will not accomplish the conversion of a protein substance into a peptone in the test tube, there is, I think, small likelihood of their doing so in the disabled stomach. It is true the other ingredients may be of service, but often it is the pepsin that the physician is prescribing the compound for, and frequently the one thing the patient most requires; so that, if the above conclusions are true, then, indeed, are physicians labouring in the dark, and their patients done out of their health and their money.

Since writing the above, I have tried samples of Dr. Hawley's preparations, and find that his wine and glycerole of pepsin are good articles, but the wine does not appear to be a pure sherry, and the proportion of alcohol so small as not to interfere with the functions of the principle. They both will dissolve albumen, but not so actively as Scheffer's.

I give these few facts for what they are worth, and hope at least they may be of some service to the profession, especially to those who have not the time for making the investigations they otherwise would do, and to those who may have been disappointed in not obtaining results they may have been led reasonably to expect.

* *Boston Medical and Surgical Journal*, May 22nd, 1873.

THE PRODUCTION AND USE OF TURF AS FUEL IN THE NETHERLANDS.

The production and use of peat or turf as fuel in the Netherlands forms the subject-matter of a very interesting report by Mr. Newnham, her Majesty's Consul at Amsterdam, and another by Mr. Fontein, British Vice-Consul at Harlingen. These have been included in a volume of consular reports recently presented to Parliament, to which we are indebted for the following abstract.

Peat or turf—now generally considered to be a vegetable matter, formed by the decomposition of plants amidst an abundance of moisture, and varying in colour from light-brown to blue-black, according to its more or less perfect state of decomposition and the depth of the layers—is extensively used for fuel throughout the Netherlands. With the exception of a moderate supply of wood, it is, in fact, the only kind of fuel that country produces, so that even in remote times the attention of the industrious inhabitants was directed to the expediency of cutting up and clearing the immense tracts of peat-bog or waste-land in the northern provinces, particularly in

Friesland, Groningen, and Drenthe, with the two-fold object of applying the combustible matter on the surface, to a depth of from two to twenty-five feet, for fuel, and of bringing the soil below it into a state of cultivation.

Peat, however, being a light and bulky kind of fuel, is not adapted for exportation, as it cannot be conveyed to considerable distances without too great an expense, so that its consumption is confined to the country where it is produced. This is the principal reason why the reclaiming of vast waste-lands in many districts is not carried out on a more extensive scale, for if too large a quantity of peat were to be produced at one time the market value would be reduced to such a low figure that the proprietor or contractor, instead of making a profit, would have to sustain a considerable loss. It is true that the soil below is usually found to be well adapted for conversion into arable land, but it takes a number of years, and requires a considerable outlay in wages, to arrive at this desideratum.

As yet peat has been chiefly employed for domestic purposes, in the manufacture of bread, bricks, tiles, etc., and, in general, wherever the use of a more compact kind of fuel is not a requisite. But of late years efforts have been made to render it more generally useful by compressing it until its specific gravity is nearly equal to that of coal. The well-known peculiarity in the character of the Dutch people in general, that of strongly adhering to old habits and customs has, however, hitherto proved a stumbling-block to the manufacture of this new article, so that the compressing of peat has not been prosecuted on an extensive scale, notwithstanding that its advantages in every point of view are sufficiently obvious.

The ordinary way of reclaiming the high peat-bogs in Holland, and of preparing the layers of peat for fuel, is by an efficient system of drainage. This takes a period lasting from ten years, during which nothing further can be done except occasionally deepening the drains a few inches whenever the marshy state of the soil permits it. As soon as the bog has sufficiently settled down and is fit to be operated upon, the crust or surface is pared off with the spade to a depth of from two to four feet, so as to remove the coarse, undecomposed vegetable matter, which, though unfit for fuel, is yet carefully put by for future use in bringing the undersoil into a state of cultivation. The peat is then cut out in pieces, like bricks, by means of a long, narrow spade, which are set up in rows to dry. The process of drying being invariably done in the open air, it depends entirely on the state of the weather ; and it not unfrequently happens, after a wet summer, that consumers who have not laid up a stock of turf dried in the previous year are obliged to make use of the new stock in a damp state.

This is the simplest and most usual method of saving and drying turf. The new plan, however, of compressing the peat and considerably reducing its bulk, is said to offer many advantages. The whole depth of combustible vegetable matter, whether partially or entirely decomposed, is reduced to a pulp and mixed together, consequently one part thereof is not more valuable than the other ; whereas, when turf is procured in the ordinary way by cutting out layer after layer, the upper part, being less perfectly decomposed and therefore of an inferior quality, has to be disposed of at a price that does not even pay the cost of labour, so that the proprietor or contractor does not obtain any profit or interest for his outlay until two or three years later, when the lower and more valuable layers are brought to market. Compressed peat is also said to be an excellent substitute for coal. Being far more compact than ordinary turf, it can be conveyed and warehoused at a considerably cheaper rate, so that when once its advantages are fully appreciated, it cannot fail to come into use for many purposes for which ordinary turf, through its bulk, is totally unfit. As the process of drying does not depend on the weather, compressed peat can be produced with far more certainty and expedition than ordinary turf.

A few years ago an attempt was made in Holland to introduce peat-charcoal or carbonized turf made from compressed peat, but although it was proved by chemical research that this article was equal, and, in some respects, superior to wood charcoal, the consumption was so small that the scheme was abandoned.

Compressed peat or turf is formed by machinery. The raw material dug out of the beds is ground, mixed, compressed, and formed into blocks. The object of grinding or cutting up the raw material is to destroy the roots and fibres of plants contained therein, as these absorb a great quantity of moisture, and are the cause of much delay in drying ordinary turf. These presses used are of various sizes, sometimes a pair coupled together, are driven by donkey-engines of from six to twelve horse power, and combine the process of grinding, mixing, compressing, and forming the raw material into blocks. The price varies from £100 to £350, according to size ; with the largest from 50,000 to 60,000 blocks or turves of about 12 inches in length by 3½ inches breadth and depth, can be manufactured in a day of twelve hours, with the assistance of eight men and four boys. The weight of such a press would be about seven tons.

Peat is also extracted from low beds, or those situated below the ordinary water level, but covered with a crust of clayey soil, forming, in most cases, excellent arable land, and annually yielding abundant crops. In olden times only barren land was used for this purpose, but at a later period proprietors of land, tempted by the profits produced by the peat trade, were induced to destroy fertile plains and fields for the purpose of extracting the peat hidden beneath the upper soil. The result was that in many parts of the Netherlands rich fields were converted into lakes, until the government at last interfered, and set a limit to these proceedings. At the present time no one is allowed to extract peat from land until he has obtained permission from the authorities, and this permission is not granted unless the parties interested bind themselves to excavate the turf and drain the bottom of the peat-bed within a fixed term.

The system generally adopted is as follows :—During the winter the upper crust, usually about two or three feet deep, is carefully removed and deposited in another part of the field, until the peat has been extracted and the water drained off, when, as with the high peat-beds, it will form the basis of fresh cultivation. As soon as the upper surface is removed water appears, and the bed of peat underneath is left bare until the following spring, when workmen in long water-proof boots get into the water with spades and extract the peat.

As the surface of the water completely conceals the peat-bed, these men feel their way, and cut the earth with their spades, seize the divided sod, and throw it into a barge. The barge having been filled is brought to land, and the peat discharged into a wooden trough, where the shapeless and compact sods are crushed by a workman with his feet, and simultaneously freed from large roots, stones, and other impurities. After the peat has been kneaded like dough in the wooden trough, it is thrown on the ground and left for a short time to dry. When sufficiently dry it is trodden down by other workmen, with little planks fastened to their feet, and soon presents a smooth surface. After this process the peat is again left to dry, and then divided into oblong squares by means of a kind of rake. After a time the divided pieces are taken up with spades and placed in rows and heaps until completely dry, which usually takes about three months, and then brought to market. When the low peat-bed is worked out nothing remains but water, which, after having been surrounded by an embankment, is pumped out by windmills, and the ground underneath, with the help of the upper crust of the peat-bed which was previously removed, converted into arable land.

Mr. Consul Newnham says that he has been informed by Irish landed proprietors that the peat or turf of their country is far inferior to that of the Netherlands.

The Pharmaceutical Journal.

SATURDAY, AUGUST 2, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BRITISH ASSOCIATION AND PHARMACEUTICAL CONFERENCE.

WITHIN six weeks from the present time, the meetings of these bodies will have commenced at the town of Bradford, one of the centres of our worsted manufacture, itself presenting in that respect many features of interest for the visitor, and surrounded on all sides with some of the most remarkable examples of industrial and commercial enterprise. In the town there are the enormous factories and palatial warehouses, in which goods are stored. In the neighbourhood, within easy distance, are the extensive works and town of Saltaire, as well as the celebrated iron-works of Low Moor and Bowling.

In connection with the local Mechanic's Institute, there will be an Art Treasures and Industrial Exhibition, which will remain open during the continuance of the meetings.

The natural attractions of the locality are also considerable for the lover of fine scenery; there is the charming valley of the Wharfe, with its varied features of river and of wood, with the old abbey of Bolton to add the zest of antiquarian and traditional interest. Abundant entertainment will also be found for the botanist in the Scar or Mountain Limestone district of Craven; and for the geologist in the great fault of the limestone at Malham Cove and the caves of Ingleton.

A reception room, a meeting room, and news room will be open for Members of the Conference at the Institute, on Monday, Tuesday, and Wednesday, the 15th, 16th, and 17th of September.

As yet no details are published respecting the excursions to be made by members of the British Association, but it is expected that an excursion to Bolton Abbey will be arranged for the Pharmaceutical Conference, on Friday, the 19th September, and the local committee will organize a Conference dinner at the Victoria Hotel, for Tuesday evening, the 16th. Early application should be made to the Local Secretary for tickets by those desiring to be present.

The general business of the Conference will be commenced at 10 a.m. on Tuesday, the 16th of September, in the lecture hall of the Church of England Literary Institution, under the presidency of Mr. BRADY, by the delivery of the usual introductory address, and then the reading and discussion of papers will be continued until the afternoon of the following day. Members intending to be present are requested to communicate with the local secretary of the Conference, Dr. R. PARKINSON, 8, Sun Bridge, Bradford, or with the local vice-president, Mr. F. M. RIMMINGTON, Ivegate, Bradford, who will give all information concerning hotel accommodation, railway routes, etc.

The British Association will meet on Wednesday, the 17th September, and information as to lodging accommodation may be obtained from the local secretaries, the Rev. J. R. CAMPBELL, D.D., RICHARD GODDARD, Esq., and PEILE THOMPSON, Esq. Owing to the illness of the President-elect, Dr. JAMES PRESCOTT JOULE, he will be unable to perform the duties of President, and Professor WILLIAMSON, of University College, has been selected to fill his place.

EXAMINATIONS MADE EASY.

AN ingenious young gentleman, whose future profession is that of medicine, has developed a new industry which in these days of "struggle for existence" deserves the widest publicity. In the Liverpool papers there recently figured an advertisement to the following effect:—"£1 may be earned in a day by any gentleman possessing a good knowledge of mathematics.—Apply immediately to ALPHA, Upper Hope Place." Appearances, to say the truth, are rather against this invitation, savouring as it does of the obtrusive generosity of the Cheap Jack with his "gold snuff box filled with the best snuff, and all for a penny." Curiosity, however, may have induced certain people to respond to "ALPHA," and accordingly a shower of answers arrived at the newspaper office—one of them from a Cambridge B.A. in temporary impecuniosity being preferred by the advertiser. To him, therefore, "ALPHA" immediately addressed himself in the following terms:—

"—, Upper Hope Place, Liverpool.

"Dear Sir,—I want to find a gentleman with a thorough knowledge of the first two books of Euclid and Algebra up to simple equations, and if you are quite master of these I shall be glad to further (*sic*) you with information, but it will be *strictly confidential*, and what I say to you must not be revealed. And if you are anxious to earn one pound, it will necessitate on your part a journey out of town, but I shall pay your expenses. A line by return will oblige, yours, etc.,

"ALPHA."

The "£1 in a day" which the Cambridge man perhaps rashly concluded to be £1 every day, or £300 a-year, dwindles down to £1 altogether; but even that sum seems to have been a consideration, for he replied at once to "ALPHA" wanting further particulars. That gentleman's response came to hand by return of post, and runs on this wise:—

"—, Upper Hope Place, Liverpool.

"Dear Sir,—Yours just to hand. And now you have assured me that I may place the utmost confidence in you I will explain matters more fully, and hope you will do what I want of you. Well, about eighteen months ago I

went to Glasgow for an examination in general education, and succeeded in everything but mathematics; and as I intend entering at St. Thomas's Hospital, London, this July, it will be necessary for me to get the mathematics passed before entering, and *I* cannot possibly get away to go myself, or I should do so. And unless I get it passed this month it will throw me back nearly a year, so I want you to go to Glasgow about the middle of July, *and pass the mathematics in my name* (*!*). I shall pay your fare both ways and give you one pound for the journey! You will be only one whole day away. So just say whether you will go, and I will call some evening this week to see you, unless you can come over here. Of course I wish *you to personate me, and no one will be any the wiser!* Now please keep this a profound secret, and oblige, yours most truly, ALPHA.

"P.S.—You can leave Lime Street Station on July 18th, get to Glasgow on Saturday morning—the examination is on Saturday—and return from Glasgow on Saturday night. What is your age? Let me have a line on Tuesday afternoon. What is the nearer ferry to your house—Tranmere or Woodside?"

But the Cambridge man, though impecunious, was honest; so his reply to this last communication of "ALPHA'S" took the form of a note to the editor of one of the Liverpool papers, enclosing the entire correspondence. His silence, however, increased the astonished "ALPHA'S" importunity, and the two following missives reached him in close succession:—

"—, Upper Hope Place.

"Dear Sir,—I should be glad of a reply to my last note at your earliest convenience.—Yours, etc.,

"ALPHA."

"—, Upper Hope Place,
4th July, 1873.

"Dear Sir,—I should be glad to know AT ONCE whether you will undertake that little affair, and, if so, I will run over and see you about it to arrange matters. By letting me have a line this evening or to-morrow morning, you will oblige.—Yours truly, etc.,

"ALPHA."

Deception is never armed at all points; so "ALPHA," though concealing his name, gives his address which has, we believe, set the police on his traces, with what result we shall soon learn.

This fraud, proposed with such signal coolness, does not always, we fear, incur such prompt exposure. Instances must be numerous in which examining boards have unconsciously been assisting at a 'Comedy of Errors' and passed the wrong DROMIO for the right one. The "industry" of which "ALPHA" must be an accomplished *chevalier* is surely an extensive one. On no other hypothesis can we explain the business-like *sangfroid* with which he states the fee, and that a small one, for "value received." If one pound will secure the imprimatur of a body like Glasgow University for proficiency in mathematics alone, the same fee we suppose would enable the donor to pass in each of the other subjects, and so embark on the professional part of medical study as destitute of the "education of a gentleman" as an army or navy surgeon in the days of RODERICK RANDOM. Much as may be said, therefore, in support of the view that preliminary examinations should not be conducted by professional examiners but that degrees in art and certificates of having passed such local examination boards as those of Oxford and Cambridge should suffice, the risk of being imposed upon by such *chevaliers d'industrie* as "ALPHA" must be guarded against before that view can be universadopted in practice. Other professions besides the medical might be victimized by "ALPHA" and his accomplices, whose examiners would find themselves in the predicament of the Athanasian heresiarch—"confounding the person," while "ALPHA." "divided the substance."

THE BRITISH MEDICAL ASSOCIATION.

FOR the second time during its forty years of existence the British Medical Association is to hold its annual meeting in the metropolis, and during the coming week London will be visited by many medical gentlemen, who will avail themselves of the opportunity thus afforded them of seeing old friends and making new ones among their professional brethren. As is well known, the objects of this Association are very analogous to those sought by the Pharmaceutical Society and the Pharmaceutical Conference, and are connected with the elevation of the profession to which its members belong; whilst in its custom of varying the locality where it holds its annual meetings it has an additional similarity to the Conference. We are glad to observe in the report of an address recently delivered by Dr. QUAIN before the Metropolitan Counties' Branch that the increase in the number of members during the last six years has been very great, and that, while eight years ago the Association only numbered 2000 members, they now fall little short of 5500, a result justly attributed, by Dr. QUAIN, in great measure to the influence exercised by the ably conducted journal of the Association.

The meeting will be commenced on Tuesday morning, by a service at St. Paul's Cathedral. At three p.m. the members will meet at King's College, to hear the address of the President-elect, Sir WILLIAM FERGUSSON, Bart., F.R.S., to receive the report and to transact other business. In the evening the LORD MAYOR will hold a reception of the Association at the Mansion House. The meetings of the various sections will be held on Wednesday, Thursday, and Friday, at King's College. On Wednesday there will also be a reception by the President and Council of the Royal College of Surgeons; on Thursday, the Association Dinner; on Friday, a soirée at University College; whilst Saturday will be devoted to the carrying out of various excursions that have been planned.

ON Saturday last the twelfth annual dinner in connection with the firm of BURGOYNE, BURBIDGES, and Co., took place at the Downs Hotel, Epsom. There were present twenty-six visitors and eighty-two *employés*. Several valuable prizes were competed for by the visitors and *employés*, and the proceedings throughout the day were marked by the most unqualified enjoyment.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The fifth annual meeting was held at the Society's rooms, Exchange Buildings, on Friday evening, June 20th. Mr. Atherton, President, in the chair. The Secretary's report was read, congratulating the Society on the termination of a successful session. Dr. Souter had delivered a course of lectures and practical lessons on "The Chemistry and Botany of the Pharmacopœia." Contrary to usual custom, the Council, with the consent of the lecturer, arranged for their delivery in the morning instead of evening. This had been followed by good results in attendance, but not, apparently, by equal success in attaining knowledge, as only five students presented themselves for examination out of an attendance of nineteen.

Another new feature in the last session has been the "Conversazione," to which many rare and valuable articles were kindly lent by friends of the Society. A number of microscopic objects of interest to chemists were exhibited and explained by members and friends who were kind enough to bring their instruments.

The number of members has slightly increased; but it is a matter of regret that the associates are so few; also that the attendance of members at the monthly meetings has been so small. This failure has had the effect of limiting the number of papers. It is but a poor compliment to be asked to read a paper to empty benches.

As an experiment, the retiring president has promised to obtain papers and lectures from various gentlemen on interesting subjects for every meeting during the next session, and the Council earnestly hope that members and associates will make an effort to attend them.

The Council takes this opportunity of acknowledging with gratitude the very timely aid to the Museum expenses afforded by a grant from the Pharmaceutical Society of £15.

The statement of accounts, showing a balance to treasurer of £3 4*s.* 7*d.*, was examined and audited by Mr. FitzHugh and Mr. Williams. The officers for the year were then elected :—President, Mr. R. FitzHugh; Vice-President, Mr. W. H. Parker, re-elected; Treasurer, Mr. J. Rayner, re-elected; Council, Messrs. Abbey, Atherton, Jackson, Lewis, Mayfield, Smith, White, and Wilford; Secretary, Mr. W. P. Williams.

After a vote of thanks to the Chairman, the meeting broke up.

Proceedings of Scientific Societies.

ACADEMIE DE MEDECINE.

NITRATE OF POTASH IN PLANTS.

At the sitting of the Academy of Medicine, on Tuesday, July 8, M. Chatin read a communication upon the very general presence of nitrate of potash in plants. Long since recognized in some plants (*Parietaria*, *Urtica*, *Borago*, *Isatis*, *Chenopodium vulvaria*) it has been indicated recently in the *Amaranthus blitum*, by M. Boutin, who made it the subject of a communication to the Academy of Sciences. M. Boutin found 11 per cent. of nitre, which he supposes to be produced at the expense of the nitrogen in the air. Further investigation of the subject by the author has led him to the following conclusions :—

(1) The small number of plants in which the presence of nitre has hitherto been noticed belong to the species of decumbent plants called "ruderals."

(2) All ruderal plants are strongly nitriferous, like the substratum upon which they grow by preference.

(3) Species of rupestral plants, those especially of porous, calcareous rocks, are nitriferous, like those of the walls.

(4) Species of the meadows (meadow-sweet) and of the woods (belladonna) contain nitrates no less than those of the rocks and walls.

(5) Many plants of the fields (fumitory, knot-grass, etc.) are rich in nitrates.

(6) Among cereals, wheat, barley, oats and rye scarcely contain nitre; the contrary is the case with buckwheat, and especially maize.

(7) Species of certain natural families (*Chenopodiaceæ*, *Solanaceæ*, *Amarantaceæ*, *Papaveraceæ*, and *Fumariaceæ*), have a greater tendency than those of other families to form nitrate of potash.

(8) It may be said, under some reserve, that the dicotyledons are more nitriferous than the monocotyledons; that the mosses are true nitrifers; and that algæ, fungi, and lichens contain only traces of nitrates.

(9) Exhausting cultivated plants (*Gramineæ*), are in general much less nitrated than fallow crop plants (lucerne grass, clover and papilionaceous plants in general).

(10) It is in the herbaceous parts, sometimes in the roots, that the nitrates accumulate.

(11) That the proportion of nitre diminishes towards the time of fructification.

The author stated that by Boussingault's process (sulphate of indigo) he had found in some plants as much as from 5 to 7 per cent. of nitre. In others the quantity was smaller, and in some almost infinitesimal.

THE POSITION OF MILITARY PHARMACISTS.

M. Broca read the report of the commission appointed to consider the letter of the Minister of War, touching the respective positions of the medical men and pharmacists in the service. It commenced by stating that the three pharmacists who had been appointed on the commission (MM. Bussy, Poggiale, and Gobley) had thought fit to retire after the first sitting, and had not voted on the conclusions of the report. The report recommended that the whole health service of the army should have an autonomic constitution, under the responsibility of a chief chosen from its members, who should be under administrative control. As to whether the person to be chosen to superintend the service should be a medical man, a pharmacist, or an administrative officer, it stated there was no doubt the direction should be given to a medical man as the most necessary member of the health service, and also the most competent and most popular with the army. The subordination of the pharmaceutical to the medical element would be the natural consequence of this system, but it was urged that this would not cause any lowering of the position of the pharmacien militaire, the fact being that instead of being subordinate to a subintendant, pharmacy would be subordinate to the chief of the health

service in the same manner as the medical and administrative portions of the service. The opposition to this change on the part of the military pharmacists, was described as the result of long habit rather than of the common interest, and their willingness to continue the present system was ascribed to their not having, like the medical men, daily occasion of seeing its inconveniences.

QUEKETT MICROSCOPICAL CLUB.

The eighth annual general meeting was held on Friday evening, July 25, at University College, Gower Street, Dr. Braithwaite, F.L.S., F.R.M.S., President, in the chair. The report of the committee for the past year was read and testified to the continued prosperity of the club, which now numbers 570 members. The President delivered the annual address, in the course of which he noticed the progress of microscopical investigation in botany and zoology during the past year. The ballot then took place for the election of officers. Dr. Braithwaite was re-elected President. Dr. Matthews, Messrs. B. T. Lowne, T. W. Burr, and C. F. White, Vice-Presidents, and Messrs. Bywater, Crisp, Hailes, Hind, Waller, and T. C. White were elected to fill the six vacancies on the committee. Mr. J. E. Ingpen succeeded Mr. T. C. White who retires from the office of Hon. Secretary (owing to increase of his professional duties) after four years of unremitting and valuable service. The proceedings terminated with the usual conversazione. The next meeting will be held on Friday, August 8.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture II.

The Energy of Gravity, with especial reference to the Measurement of it.

(*Continued from page 77.*)

The apparatus that Cavendish used was double the size of this which you see before you, but it was similar in construction. He had two balls of lead, similar to these large ones, suspended from a very light bar, that bar being trussed, as it is called, by a kind of triangle of wires, and the whole being attached to a hook in a pulley, round which he passed a cord, by means of which the balls of lead can be moved to any position you please. In order to exclude every external influence, the apparatus was enclosed in a room of its own, and to observe the phenomena that took place within that closed room lamps were applied at small orifices, and telescopes were placed at others. In addition to this apparatus with the two balls of lead, which weighed about three cwt. each (as far as my memory serves), he had another apparatus placed below the other, as you see here. From a centre immediately under the pulley to which a frame carrying the leaden balls is attached, was suspended by an exceedingly fine wire a light rod with two little balls less than bullets, and these balls held a certain position, and could not move from it beyond certain limits. Being placed in the aforesaid enclosed room, where there were no draughts or variations of temperature, or anything external to affect them, after they had been left for some time—say, for 24 hours—they became stationary, and would not move unless some external force were applied to them. At the end of the light bar carrying these small balls was an ivory scale and a pointer, and upon this was directed the light of a lamp from outside the room, whilst a knob was also placed outside, by turning which the motion of the large leaden balls could be controlled. At another orifice was placed a telescope, by means of which the motion of the pointer could be observed. After the little balls had become quite stationary, by the cord he very gently swung the larger balls to a position close to the small ones, and after a certain lapse of time, varying from a quarter-of-an-hour to an hour, he observed the space through which the small balls were moved from the position they had occupied. It may be well to state that a thorough examination had been previously made as to whether any influence could be due to magnetism.

This experiment had to be repeated very frequently, because of the minuteness of the range of these balls and the magnification of it. The application of the results was to be so important. He therefore made three experiments on each occasion, and observed the position that the balls took. He also observed another matter which is of great consequence, the number of oscillations made by the small balls before they come to rest. These balls oscillate like a pendulum, and by the number of times they swing before coming to rest certain calculations of great importance to the inquiry may be made. These calculations completed, the conclusion he arrived at was that the earth was 5·4 (say 5½ times) heavier than water.

Now it is only right that you should be told how from these balls the density of the earth can be deduced. The mass or quantity of matter in these balls is known; their attraction upon the little balls is known from observation. The mass therefore of any other ball being known, we can tell the attraction that it would have upon these balls. It is quite clear that if this large ball had double the mass it would have double the attraction at the same distance; if treble the mass, treble the attraction, and so on. Again, if the mass of the little ball was known and the attraction of the great one known, and the mass of the great one known, then if the mass of another ball is known, we shall get the attraction of the other ball. It should also be attempted to make clear how from these two balls we can weigh the earth, and probably it will keep your interest alive in the matter if informed that, in 1835 (Cavendish's experiments being made at the close of the last century, about 1798), Mr. Baily, the founder of the Astronomical Society, repeated them. Mr. Baily had been a stockbroker in London; he retired from business, and purchased a house in Tavistock Place, the one, I believe, in which Mr. Digby Wyatt now lives. He there made many experiments, and some most extraordinary calculations, and did a large amount of astronomical work. Amongst other things he undertook to weigh the earth, and he weighed it as Cavendish did, namely, by an apparatus constructed on the same principle as the one before you. He swathed the box or chamber, in which the balls were, with flannel, and put a gilded cover over all. He also lined the inside with tin-foil and connected it by a copper wire with the earth. These precautions were intended to neutralize, as far as practicable, changes in atmospheric temperature and terrestrial electricity. How important he considered it, you may judge from this that he made more than 2500 experiments with balls of this character; he sat watching them for 1200 hours, and that number of experiments extended over some years. The repetition was planned in 1835, commenced in 1837, and concluded in 1842. The result of these 1200 hours of watching, exclusive of the calculations which followed, led to the conclusion that Cavendish was right within a fraction of 2-10ths., that is to say, Cavendish concluded that the density of the earth was 5·4 times that of water; Baily concluded that it might be 5·6 times that of water.

It may be permitted to repeat the reasoning in order if possible to make clearer the principle on which it proceeds. From the weights we know the masses of the large ball and of the small one. We know that the small balls in relation to the large ones were free from the influence of gravity; we also know by observation how much the one attracts the other. Double the ball, and you get double the attraction, and so on. Now, we know the size of the earth, and by placing this little ball on a spring balance, we know how much the earth will attract it. Therefore, the weight of the little ball being known, and the size of

* Cantor Lecture, delivered February 10.

the earth being known, there is nothing left except the attraction to find, and, as we have the attraction from these two balls, we can, by a simple arithmetical operation, determine that the earth is 5·6 heavier than water.

This seems the best opportunity to mention that the present Astronomer-Royal (Prof. Airy) investigated by very different means and on very different principles this question of how much heavier than a globe of water the earth is. Qualifying the conclusions from his experiments as himself suggests, consequent upon certain geological considerations, it may be asserted that Cavendish's result is very nearly correct.

Time passed by: Cavendish's experiment was made, as I told you, about 1798, and Baily repeated it about 1835. We must now go back, as a matter of history, to Cavendish's time, and the next step we arrive at in determining the energy of gravity was the experiment that was made by Atwood, who was born in 1746. He was a fellow of Trinity College, Cambridge, and was the first to entertain the idea of devising some plan of measuring the force of gravity. Let me endeavour to make this matter clear. Cavendish determined the density of the earth, but he did nothing whatever as to determining the force of gravity. Force, as stated in the first lecture, can only be measured by motion. We can easily obtain motion from the action of gravity, but we must observe that motion in order to measure force. If a weight be let fall it falls far too quickly to permit of an estimate of the rate at which it falls. That rate is due to gravity. Atwood thought, as Galileo had previously done, that by causing the fall to be delayed he might be able to draw a conclusion as to the exact force of gravity, and the plan he adopted was this. You are aware that the intervals between the ticks of a pendulum vary according to its length. Here is a pendulum, and you see the rate at which it is going; if, now, the pendulum weight be lowered, so as to lengthen the rod, you may observe that the pendulum ticks more slowly—in fact, it is now beating seconds. You were told in the first lecture, that we must have a certain unit of measurement, and the *second* is the unit of measurement usually taken for time. If we want smaller measurements, for it is easy to divide the second into a hundred parts, they are taken by another contrivance. A very simple and sufficient one is a clepsydra, or water-clock, arranged specially for this purpose.

What Atwood thought of doing in order to measure the force of gravity, having, you remember, no previous measurements to guide him (for Galileo did not touch the problem that Atwood proposed to solve), was to take two weights evenly balanced over pulleys such as these, the apparatus being most delicately made. You see that these two small weights are exactly balanced, one being at each end of a cord which passes over pulleys at the top of the apparatus, so that the weight in descending passes down in front of a graduated scale. These weights, then, are exactly balanced. Here are three very small weights, fractional parts of the ones which are suspended. If one of these small weights falls by itself, it would fall so rapidly that its rate of falling could not be observed; but if, whilst it is falling, it is caused to bring this mass of matter with it, the rate of falling will be retarded, whilst the law of the rate remains the same, *i.e.*, the law which governs the rate of falling will be similar, although the mass moved is increased. If now there be placed upon one of these balanced weights two of these little fractional weights, there is a something that will cause the connected mass to move, and this platform at the bottom will be struck about four seconds after the motion commences. The usual plan is to let the motion be commenced by electricity, which at the same time sets the pendulum in motion. You can count the strokes of the pendulum from the commencement to the end of the motion. You can see this mass of matter has been moved through eighteen spaces in four seconds. If the measure be altered, you will readily understand that these fractional weights would carry it through a different space in the same time; if other weights be put on, they would carry it through other spaces. The experiment as made before the apparatus was brought here shows that the force of gravity is such as to cause a body to fall through about 32 feet in one second, the meaning being that if this small weight had not been required to bring the other weights along with it, then it would have fallen from rest through 32 feet in the first second. That was the first attempt of estimating by measurement the force of gravity.

But Atwood's apparatus, though exceedingly good as matter of illustration, falls very far short indeed of that which Captain Kater adopted; and all that we have, and all that we know, of the form of the earth, and the true kinetic measure of gravity, spring from Kater's experiments, and not from either Cavendish's, Baily's or Atwood's. Kater felt that if instead of weights; falling as they have fallen in the experiments of Atwood, he could observe the effect of gravity upon the weight falling without associating it with other weights; if it could be kept distinct, and if in any way he could cause gravity to repeat the operation slowly and deliberately without any interference whatever, we might get at the conclusion much more rapidly than Atwood could by his arrangement, because the friction of the wheels, the weight of the cord, and other incidental matters affect the problem. What Kater did was to design a pendulum, of which this is a copy. It was from a pendulum like this that not only was the force of gravity determined in all parts of England, but also the form of the earth itself has been decided and estimated. Our standards of weights and measures all come from a pendulum like this. If, in fact, the standards were all lost, it would be from such a pendulum they must be restored. Let me anticipate the conclusion by stating that when the standards were lost in the burning of the Houses of Parliament they were restored by seeking for copies, because the great number of corrections and the great difficulty of counting this pendulum and freeing it from interfering causes are very serious obstacles. Few are aware of the enormous difficulty there is in placing a pendulum so as to be free from external influences, and counting the oscillations of it.

Whilst upon weights and measures, your attention may be directed to a small piece of wood here, which is a model of the standard one pound weight of Great Britain. It is one which a committee of learned men obtained, and this in my hand is a copy. The real standard is made of platinum. It is a cylinder 1·35 inches high and 1·15 inches in diameter. Observe there is a groove turned in it, and there is an ivory fork by which it is to be lifted—these standards are not to be touched. There are only five of them made, and if ever the one pound weight is lost in England it is to be recovered, not by repeating Kater's experiments, but by copying one or other of these five standards. The five are kept—one at the Exchequer Chambers, at Westminster, one at the Royal Mint, one with the Royal Society, one at the Royal Observatory, Greenwich, and one is immersed in the sill of the recess on the east side of the lower waiting-hall of the New Palace at Westminster.

To return, then to Kater's experiments. He had first to determine a pendulum which should vibrate seconds in the latitude of London. He did it in the house of Mr. Brown, in Portland Place, which house has an astronomical bearing from Portland Chapel of 74 deg. 38 min. 50 sec. west from north, the distance being 283 feet, and therefore the house is about half way up Portland Place on the left-hand side. In that house the pendulum was first adjusted. Nothing seems easier than to deal with a simple vibrating ball on a string. It is not, however, so easy as it seems. It can not be made to swing in the same plane as this one now appears to do. If left free to choose its plane of vibra-

tion it is seldom contented. It will not have a dozen swings in the same plane, it must, therefore, somehow or other, be made rigid, and so prevented from such vagaries. Here is a small vessel of lead, hanging by a bundle of untwisted fibres from a hook, and you might think nothing could be easier than to let it swing backwards and forwards on the same path, but it will not swing for two minutes in the same path; hence, pendulums are all compelled to act in restrained paths, and generally supported on knife edges. French clocks have two strings of silk to the pendulum. These are fastened to two hooks at the top, and the pendulum rod being hung from the junction of the two silken cords, it is constrained to describe a path in a plane at right angles to that in which are the silk threads.

To return to the leaden vessel. It is now filled with fine white sand, and at the bottom there is an opening, out of which the sand can trickle whilst the vessel swings freely. The figure caused by the sand falling on a board beneath will show the path that the vibrating body describes. It shall now be let go in what appears to be a straight line. If you watch that path you will see it is a very curious one. The sand at once indicates that the ends of the line are travelling round, also that the line itself is becoming wide in the middle. In fact, a straight line is seldom formed by the falling sand from such pendulums. Even if a circular path be commenced you will find it cannot be retained. It reminds one very much of one of the secular astronomical changes, that is, our year of 365 days and a fraction results from this gradual advance of the perihelion path of the orbit of the earth; observe it tends first to a straight line, then through an ellipse to a circle, and then a return action commences, and it will repeat this process from the straight line opening out again, and so pass on through various phases until it comes to rest. Hence, a pendulum constructed of a simple form is of no value, and yet it is in its simple form we require it. It was needful to assume for the purpose of the calculation that we can make a pendulum do that which this swinging vessel of sand is not doing.

Captain Kater was the first to deal with the case of converting the compound pendulum into a simple one. A pendulum is said to be a simple one when it consists of a heavy particle at the end of a very light thread. Such is almost an imaginary pendulum. All pendulums that we see are compound ones. Now, by pursuing the plan adopted by Captain Kater, he was able to obtain from the compound pendulum what would be the length of an equivalent simple pendulum. His pendulum has two pairs of knife-edges, a pair at the upper end, on which it swings, and a pair at the lower end. He placed one pair of these knife-edges on a smooth, hard surface, so that the pendulum might vibrate without anything causing it to continue its vibrations except the force of gravity. Now, if you look to this diagram you will see the motions of a compound pendulum. If it were short it would move thus, and if it were longer it would move more slowly. The black dots in the diagram represents the lower ends of pendulums of different lengths. Assume that the black dots are the ends of separate pendulums, one behind the other, from the same support, they will then occupy those places after the same interval of time from rest; if, however, these pendulums are united, then the one is kept by the action of the other; now they are really united in a compound pendulum. There is, however, some point or other at which, if all these masses were concentrated, the velocity at that point would be the velocity of the mass, therefore such a pendulum would vibrate in the same time, and it would be called a simple pendulum. Kater found that this collected point, which is called the centre of oscillation, and this at which the pendulum is suspended, are interchangeable, in fact, he found that if the pendulum was accurately adjusted by means of these moveable weights, he could suspend it upon a pair of the knife-edges, and he could get a certain number of vibrations in a minute or a second. Then, if he turned it upside down, assuming the pendulum to be right, and caused it to swing as before, upon the other pair of knife edges, it would make the same number of vibrations. Those two points he marked, and the distance between them is the length of an equivalent simple pendulum. With such a compound pendulum as now described, and of which the one before you is a copy, counting the number of vibrations it makes, you can always deduce the length of a simple pendulum that would make the same number of vibrations.

What Kater did, then, was this—he had a clock kept going, strictly to truth, that is, to true astronomical time. The clock was furnished with a gridiron pendulum of the construction shown in the diagram, and so carefully arranged as not to be altered in length in consequence of change of temperature. On the bob of the pendulum, in front, was a white speck, as on the pendulum bob of this clock. He placed the compound gravity pendulum, which has been described, in front of the clock, the clock pendulum beating 86,400 strokes per mean solar day. The rate of the clock was determined by astronomical observations, and therefore, on any part of the earth's surface, it would be possible to so arrange the solar pendulum that the clock should always record 86,400 beats in a mean solar day.

Now let us turn to this two-ended pendulum of Capt. Kater. It is of an invariable length, and acted upon directly by the force of gravity; there are no weights or clockwork in connection with it. When it is up on one side, it is the power of gravity that causes it to fall, and it is gravity which keeps it going. If, for example, a powerful magnet be placed under that pendulum, then it will come to rest sooner than it would otherwise do, because it is pulled down with greater force. If, therefore, gravity changes in its pull on this pendulum, it will tell on the rate of its vibrations. The rate of vibration of the equivalent simple pendulum is known, because it has been calculated from this compound one; hence, if this compound pendulum be placed in front of the clock keeping astronomical time, and if the vibrations of the pendulum be counted whilst the vibrations of the clock pendulum are being recorded, it might be ascertained whether the force of gravity varied in different places.

The means by which Kater compared these vibrations are very simple. You see the white speck, previously referred to, on the bob of this gridiron pendulum. He took a telescope and placed it at some distance on a level with that white speck. Between the white speck and the telescope, and near to the gridiron pendulum, swung the gravity pendulum, which moved slower than the other, being made a little longer. Keeping his eye upon the telescope, and directed upon a narrow piece at the end of the gravity pendulum, which was the same width as the white circular speck upon the bob of the clock pendulum, he could tell when the two coincided. As one pendulum swung slower than the other, it was quite clear that a coincidence must take place, and he noted the time of the coincidence. That was the beginning of counting vibrations, and he then waited until they separated and until the coincidence again took place a second time, which gave the number of the vibrations in a given time as recorded by the clock. Experiments like these were repeated very frequently and carefully, until at length the average was obtained as to the number of vibrations that this gravity pendulum made, compared with the vibration that the one on this mean solar clock made. Within the tube of this telescope there are crossings of very fine wires—so fine as to be hardly visible to unaided vision; the threads of a spider's web were formerly used for this purpose. A spider is taken in the fingers, then, if shaken he would run his web out to save himself, and this web was placed in the focus of the eye-piece, and the threads were so that the crossing of them was in the axial line of the telescope. It was by looking along that axial line that the time was observed when the coincidence of these two pendulum marks took place. The accuracy with

which that was done is more easily to be imagined than realized.

Assuming that this has been accomplished, let us look for a moment to other elements which would disturb the result. In the first place, the pendulum vibrated in air; and you were told, in the first lecture, that a body weighed in air and weighed in any other medium is not balanced by the same weight. Hence the effect of the air upon the pendulum has to be considered. Then the pendulum is vibrating in a changing atmosphere, sometimes warm, sometimes cold, and a change of the temperature causes an expansion or contraction, hence the effect of that expansion was to be considered. And, simple as it seems, to estimate whether a pendulum is longer or shorter is really very difficult. Indeed, great was Captain Kater's perplexity about it.

He measured the length of his pendulum thus: he formed a box similar to the one on the table, and laid his pendulum in it, and applied a microscope over one of each pair of opposite knife edges, placing behind them a piece of white paper, so that the edge might be seen. He then applied the microscope. Again he put beneath them a piece of black paper, and he found that the measurement with the white paper was never the same as the measurement with the black paper. After describing how with microscopes he attempted to measure between knife-edge and knife-edge, by placing them when white on a black ground, and when black on a white ground, he adds:—"In one case, the knife-edges seemed to start forward to each other." This difficulty is summed up thus:—"On the cause of this extraordinary fact I can hazard no conjecture, and it remains an interesting subject for future investigation."

We now know that this resulted from a phenomenon called "irradiation." Hence he was bound, even in looking through those microscopes to strike an average of the apparent errors.

Another error that occurred, which he also found great difficulty in remedying, and indeed never did remedy, so that in fact the experiments he made are liable to some infinitesimal corrections still, was this:—If a pendulum vibrates, as this one was doing just now, the air clings to it, and is carried along with it, from what is called the "viscosity" of the air. That viscosity is such, that if you were to put a short piece of gold leaf projecting edgeways upon the face of the pendulum bob, you would find that the gold leaf moved with the action of the pendulum, and was carried along with it, so that it turned neither to one side nor the other. If, however, the gold leaf projected beyond a certain distance, then you would find it bend with the air. Therefore the atmosphere in immediate contact with the bob was dragged along with the pendulum, and that particular element Captain Kater was not aware of. Government, some years ago, in order to set this question at rest, had large vacuum chambers erected, and pendulums set vibrating in them, to ascertain how great an error was caused by the viscosity of the air.

Captain Kater having determined the length of this pendulum in the latitude of London in 1818, it was thought of great consequence to ascertain how far the force of gravity varied in different latitudes.

A memorial was presented to the government in 1818, in order to ascertain by means of a pendulum how gravity varied throughout the British Isles, and Kater was commissioned to take steps for the purpose. Government placed at his disposal certain members of the Royal Corps of Engineers, with whom he set out to the north of Scotland, and made experiments at various places. He went up to Unst, in the Shetland Isles, then he came down to Portsey, then to Leith, then down to Clifton in Yorkshire, then to Ashbury, then to London, and then to the Isle of Wight, and in each of those places he made certain experiments based upon the principles now too briefly described. This lecture would extend far beyond the allotted time if it entered into details with reference to local arrangements and special calculations. It may suffice to refer to the table on the wall for particulars of the results. The following is a copy of the table:—

Name of place.	Latitude of place.			Vibrations in a mean solar day.	Length of a pendulum to vibrate seconds.
	deg.	min.	sec.		
Unst	60	45	28·2	86·096·90	39·17146
Portsoy	57	40	58·65	86·086·05	39·16159
Leith Fort ..	55	58	40·8	86·079·40	39·15554
Clifton	53	27	43·12	86·068.90	39·14600
Ashbury hill..	52	12	55·32	86·065·05	39·14250
London	51	31	8·4	86·061·52	39·13829
Shanklin, or rather Dunmore	50	37	23·94	86·058·07	39·13614

From this table it will be seen that the length of a pendulum vibrating second in the places respectively entered is that given in the last column.

These lengths are sufficient to enable a mathematician to calculate the force by which the pendulum is caused to swing. Now, as the only force causing this swing is that of gravity, such a calculation determines the force of gravity at that place in relation to its powers to produce motion. Hence is deduced those 39 inches, which in ordinary expression is thus broadly stated to be the length for pendulums vibrating seconds in the latitude of London. Captain Kater deduced that 39·13829 inches was the length of the pendulum vibrating seconds in Mr. Brown's house in London. This length requires to be reduced to sea-level. Now, the rooms of the Royal Society, at Somerset House, are 81 feet above low water, and by the aid of a mountain barometer, made by Ramsden, Kater found the room in Portland Street to be two feet below those of the Royal Society, and as the length of pendulum above the floor was four feet, the elevation of pendulum above sea-level is 83 feet.* Now, gravity varies inversely as the square of the distance of the place from the centre of the earth, therefore, the length of pendulum must be increased in this proportion; and taking the radius of the earth for the latitude of Portland Place to be 3954·583 miles, we have 39·1386 inches for pendulum vibrating seconds at the level of the sea in the latitude of London.

The greatest difference between the mean and that of any of the sets of experiments is only ·00028 of an inch, or $\frac{1}{139959}$ of length of pendulum. The length 39·1386, as thus determined, is that required to perform one vibration in $\frac{1}{86400}$ of a mean *solar* day, under the circumstances described, and at the level of the sea.

Finding how much could be obtained from this, with regard to the British Isles, Government commissioned Captain Sabine to go to different places on the east coast of Africa, the Island of Ascension, Bahia, Trinidad, Jamaica, New York, Greenland, and Hammersfest, in Norway, and repeat Captain Kater's experiments. These experiments are repeated, and then, by an arithmetical process, which need not be referred to in detail, it was very easy, having given the number of vibrations of this invariable pendulum (for the distance between these knife edges did not vary) performed in a solar day, to calculate the power that was pulling it; and from that calculated power could be obtained the mass of the earth beneath the place where it was being pulled, making, of course, all the allowances for corrections and other circumstances. That calculated power gives the thirty-two feet which we are all acquainted with as the measurement of gravity. The meaning of which is, that gravity will generate in a 1lb. weight, in one second, a velocity of thirty-two times greater than that which it is agreed shall be called the unit or absolute measure of force. Put con-

* There is reason to conclude that these measurements require to be corrected.—A. R.

versely—the absolute unit of force is equal to the weight of $\frac{16\text{ oz.}}{32{\cdot}2} = \frac{1}{2}$ oz. nearly.

Captain Foster afterwards repeated these experiments, and made others, and from them has been obtained the figure of the earth, and calculations of all kinds used in scientific investigations throughout the globe depend upon them. Captain Foster was unfortunately drowned in the river whilst observing some of his experiments, but Mr. Baily undertook to tabulate his results, and completed the calculations on the data which had been obtained by Captain Foster's observations. The calculations Mr. Baily made for this purpose occupy many closely-printed quarto pages of figures. The result was solely to ascertain the length of the pendulum, and so deduce the figure of the earth. Great beyond all ordinary estimate is the amount of care, patience, perseverance, and anxiety that attends experiments of this kind.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

The Juries Bill.

On Monday, July 28, the Attorney-General announced the intention of the Government to withdraw this Bill, and the order was accordingly discharged.

The "Chlorodyne" Dispute.—Browne v. Freeman.

(*Before the Lords Justices of Appeal.*—July 23, 1873.)

This was an appeal against a decision of the Lord Chancellor exercising his original jurisdiction in hearing the causes set down before the Master of the Rolls. The bill in this suit was filed by Dr. Collis Browne for an injunction to restrain the defendant, a chemist in the Kennington Road, from advertising, or in any other way representing, that by the decision of Vice-Chancellor Wood, he was entitled to the sole right to use the word "original" as a prefix to cholorodyne. It was the third suit between the parties. The plaintiff began to supply the public with chlorodyne in 1855, having invented it, as he stated, in 1846, and used it with success in his practice in the East. The first bill was filed in May, 1862, to restrain the defendant from using the name of chlorodyne as descriptive of a medicine prepared by plaintiff; but on the defendant putting in an answer, claiming to have discovered his preparation in 1844, and denying that he had ever advertised it except as Freeman's chlorodyne, the plaintiff dismissed his bill. The second bill was filed in December, 1862, to restrain the defendant from advertising his own preparation as "the original chlorodyne, manufactured by the inventor, Richard Freeman." In 1864, Vice-Chancellor Wood dismissed this bill, on the ground that, as far as the name of chlorodyne went, the plaintiff had, by acquiescence in the use of it by other persons, lost the right to treat it as his own trade mark, and that the defendant had not actually represented that his chlorodyne was of the manufacture of the plaintiff; but, as his Honour disapproved the course pursued by the defendant, he dismissed the bill, without costs. There was no appeal from this decision. In January, 1872, the present or third suit was brought in consequence of some advertisements issued by the defendant, one of which was as follows :—

"The original chlorodyne and only genuine invented by Richard Freeman, pharmacist, entitled by the decision of Vice-Chancellor Sir W. Page Wood, January 11, 1864, to the sole right to use the word 'original' as a prefix to 'chlorodyne,' which decision was confirmed July 12, 1864." The plaintiff also complained of the defendant's representing that the genuine chlorodyne is only sold under the protection of Government authority, with a stamp bearing the words "Freeman's Original Chlorodyne," and that without such stamp no chlorodyne is genuine; and that several testimonials to the efficacy of chlorodyne as a remedy for various disorders which were really given in favour of the plaintiff had been appropriated by the defendant and printed on the wrappers of his bottles. The Lord Chancellor thought the matter was virtually concluded by the former suit, and that the defendant's misrepresentation of the effect of Vice-Chancellor Wood's decree gave the plaintiff no right to any relief. His Lordship also thought that no case had been made out as to the testimonials, and the bill was dismissed, with costs. The plaintiff then presented a petition of rehearing.

Sir R. Baggallay, Q.C., and Mr. B. B. Rogers were for the plaintiff; Mr. Southgate, Q.C., and Mr. Stirling were for the defendant.

Lord Justice James said he thought the suit was an entire experiment, it had been instituted without any authority. Probably it might have answered the object of the plaintiff as another advertisement of the superiority of his chlorodyne over any other. It had been long ago settled in this court that the word "chlorodyne" had become the mere name of an article, which it was open to anyone to use. Freeman was as much entitled to say that his was "the original" chlorodyne as was Browne. Freeman always placed his own name upon what was sold by him. It was simply the case of two rivals in trade selling their own manufactures under the same descriptive name. It appeared to their Lordships (though the defendant had not been heard) that the defendant had misrepresented the effect of Vice-Chancellor Wood's judgment. But still this afforded no ground for the interference of the Court; there was no representation that Freeman's manufacture was the same thing as Browne's. If it amounted to anything, it was a slander on the plaintiff; but it was not a violation of any trade mark or of any right of property which this Court would interfere to protect. His Lordship thought the decision of the Lord Chancellor was quite right.

Lord Justice Mellish was of the same opinion. He thought the decision of the Lord Chancellor was quite right upon the ground on which he had put it. The advertisements complained of had been first published during the pendency of the former suit, when an application might have been made to the Court by the plaintiff, and the defendant having continued them ever since, it was now much too late for the plaintiff to complain. At the same time his Lordship (the Lord Justice) did not see how the plaintiff could be entitled to any remedy. There could be no right of action at law, for all the advertisements plainly stated that what the defendant sold was manufactured by himself. If an action was maintainable at all, it would be on the ground that there was a slander of title or of the plaintiff as a professional man. But the difficulty was that the advertisements did not allude to the plaintiff at all—the utmost they did was to make a false statement. Puffing advertisements often did this, and they might no doubt prejudice a fair dealer who did not care to go to the expense of issuing such things. But this was no ground for the interference of the Court. In this case both the parties were advertisers, and had done the best they could for themselves in that way. The petition of rehearing must be dismissed, with costs.

Conviction of an Assistant for Theft.

At the Woodbridge Petty Sessions, on July 23rd, Joseels Boulton, late assistant to Mr. B. D. Gall, pharmaceutical chemist, of Woodbridge, Suffolk, appeared on remand charged with embezzling 3*s.* 6*d.* The prosecutor stated that having a suspicion that he was being robbed he communicated with the police, and through their agency purchases were made from the prisoner, serving in Mr. Gall's shop, to the extent of 7*s.* 6*d.*, which were paid for with marked money. This should have been put in the till which was kept locked by the prosecutor; but upon ope ng the till only 4*s.* of marked money was found. Upon being spoken to prisoner produced the missing 3*s.* 6*d.* from under some paper in a drawer. The prosecutor asked to be allowed to withdraw the case as since the first hearing the offence had been acknowledged by the prison r and he did not wish him punished further.

This however the magistrates refused to allow, and the prisoner having pleaded guilty was sentenced in deference to Mr. Gall's appeal for leniency, to two months' imprisonment with hard labour.—*From the Woodbridge Reporter.*

Adulteration of Mustard.

At the Epsom Petty Sessions, on Monday, July 21, Mr. William Moore, grocer, of Headley (Surrey) appeared in answer to a summons charging him with selling mustard as pure and unadulterated, which, upon examination, was found to be adulterated with flour and turmeric. Mr. Sherrard, Solicitor, appeared for the defendant. John Page, an inspector appointed under the Adulteration of Food Act, said that on the afternoon of the 3rd inst. he called at Mr. Moore's shop, and purchased two ounces of mustard, for which he paid 2*d.* He told Mrs. Moore, the wife of the defendant, that he wanted it for the purpose of having it analysed. She said, "We sell the mustard the same as we get it, and if it is adulterated we cannot help it." On the following day witness took the same mustard which he had purchased at the defendant's to Dr. Stevenson, of Guy's Hospital, to be tested. On the afternoon of Saturday, the 12th inst., he received a certificate from Dr. Stevenson, showing that the mustard was adulterated by the admixture of flour and termeric. In answer to Mr. Sherrard the witness said Dr. Stevenson did not tell him what was in the mustard, but sent him his certificate. Witness told Mrs. Moore that he intended to take the mustard to Dr. Stevenson on the following day to have it analysed, but made no appointment with her to attend. Witness did not think that he had ever tasted pure mustard. He was not aware that pure mustard was uneatable. Mr. Sherrard, on behalf of the defendant, contended that the prosecution would fall to the ground, owing to the inspector not having complied with the requirements of the Act, and given the defendant notice of the day on which the analysis was to take place. He did not asked for pure mustard, and everyone knew that pure mustard could not be eaten. Mr. Sherrard then called Mr. W. J. Bellville, of the firm of Keen, Robinson, and Bellville, the manufactures of the mustard, who deposed that upon all their tins was the following notice:—"This is an admixture in which no injurious ingredient has been used." There was a large quantity of genuine mustard sold, but it was at a very much higher price than the other. They used the best wheaten flour, which made the mustard white, and turmeric was used to colour it. The only fault in the mustard would be that persons could eat more of it, but then they paid a much lower price for it than they would for the genuine article. The magistrates said they were of opinion that the charge was proved. They considered that sufficient notice was given to the defendant, and therefore would inflict a fine ot 3*s.* and costs. The money was paid.—*Grocer.*

Sudden Death of a Chemist and Druggist.

An inquest has been held at Bournemouth to inquire respecting the death of Mr. John Mason, chemist and druggist, of that town. Evidence was given by the housekeeper of deceased that between five and six in the morning she heard a strange noise in the deceased's bedroom, but she had heard a similar noise before, and deceased upon being spoken to respecting it said it was only the nightmare. In the morning as deceased did not come down the door of his room was opened and he was found lying in bed dead.

Mr. Nunn, surgeon, deposed that he was sent for a little before eight, and when he arrived Mr. John Mason appeared to have been dead about two hours. There was nothing in the appearance of the body to show the cause of death. A *post-mortem* examination was therefore ordered and at the adjourned inquest Mr. Nunn stated that the heart was so diseased as to cause death by syncope and that he had no doubt that was the cause of death. A verdict in accordance with this evidence was accordingly returned.

Poisoning by Ammonia Solution.

An inquest has been held at Pendleton on the body of George Gaythorp, aged 24 years, a billiard marker, who died from the effects of a quantity of ammonia solution which he drank inadvertently on the afternoon of Friday, the 11th of July. Deceased, after eating a good dinner, went to bed and slept some time. On awaking he got up and drank from a cup on a table a quantity of ammonia solution which his wife had got to clean his coat. He immediately vomited and became seriously ill. Medical attendance was called, but deceased became worse and died. It seems that he had had some nettle-beer for his dinner, and that a quantity had been left in a cup on the table, close beside the cup containing the ammonia. Before his death, deceased twice affirmed that he had taken the ammonia by mistake, and his relatives and friends had no reason to doubt his statement. The jury returned a verdict that the deceased came to his death by misadventure.—*Manchester Courier.*

Supposed Death from Morphia.

An inquest has been held at Newton Abbot touching the death of an infant three weeks old. It appeared that a girl had been sent to Mr. Ponsford for some medicine for the child, who was troubled with the wind. Medicine was sent, with written and verbal instructions that a teaspoonful should be given. The nurse could not read, and the messenger either delivered a wrong message or the nurse misunderstood. Two teaspoonfuls—or a double dose—were given, and the child died.

There being some doubt as to the cause of death, the inquest was adjourned to allow an analysis of the medicine to be made. At the adjourned inquest it was stated that the medicine had been analysed by Dr. Stevenson, of Guy's Hospital, who reported that it consisted of a solution of a preparation of morphia in dill water, together with sugar or syrup. The quantity of morphia present was so small that it was found to be impossible to separate enough to weigh. He made experiments, however, which satisfied him that the medicine contained not less than one-fifteenth of a grain of a salt of morphia per ten drachms of the medicine. If two doses of the medicine had been taken, one seventy-fifth part of a grain of a salt of morphia would have been swallowed.

Dr. Gaye said it would be impossible to say whether 1-75 part of a grain would cause death. Children had been known to take more without death ensuing, and others have died from taking a less quantity. It would depend on the health of the infant. The discolouration was owing to impeded circulation. Generally speaking, he did not believe the dose given would cause death. If the dose was given to the child according to the label—half-a-teaspoonful—the quantity of morphia (150th part of a grain) would not kill. Convulsions would not be a sign of death by morphia. As described at the former inquiry, the appearance of the child gave symptoms of poisoning by morphia in the last stage. There was a case on record of a child dying by taking a hundred and twentieth part of a grain.

The jury retured a verdict of death from "Natural Causes."

Obituary.

Notice has been received of the death of the following:—

On the 23rd July, 1873, Mr. Alfred Rook Squire, Pharmaceutical Chemist, of the firm of Barron, Squire, and Co., Bush Lane. Aged 27.

On the 5th May, 1873, Mr. William John Wright, Chemist and Druggist, of Hastings.

On the 22nd July, 1873, Mr. John Vincent Nunn, Chemist and Druggist, of Bury St. Edmund's.

Correspondence.

The Society's Examinations.

Sir,—Being on a visit to London, and having a little business to transact with the secretary of our Society, I called at Bloomsbury Square for that purpose. It so happened that candidates were undergoing the Minor examination, and, by virtue of the office I hold as local secretary at Wolverhampton, I was invited to enter the room where the examinations were going on, in order that I might judge for myself of the system that was adopted. I was much pleased with everything that I saw, and as it is now seventeen years since I underwent the ordeal for both Major and Minor, I noted several important improvements.

They have a most excellent collection of prescriptions neatly arranged in books, and these prescriptions do not seem to be selected on account of their difficult nature, but are a fair representation of what would be met with in the ordinary run of a dispensing business.

There is also a much better collection of Materia Medica specimens; these I find are not accessible to students as formerly, so that they do not run any risk of being handled and crushed, as the old collection used to be.

The dispensing counter is quite new since I was there, and offers to the candidate a most excellent means of showing a practical knowledge in the preparation of mixtures, emulsions, powders, pills, etc., even to the wrapping up and finishing off of each article.

I was shown the result, in two cases, in the preparation of an emulsion from the same prescription, and with drugs out of the same bottles, one was beautifully mixed, and as much like milk as possible; the other almost looked dirty and badly mixed. There can be no doubt about the utility of this department, as well as of the fairness with which it is conducted.

In the botanical department I saw a collection of fresh medicinal plants, gathered that morning, also a collection of dried specimens, and on inquiry I found the latter were for those candidates who never had any facility for studying from fresh plants. This I thought was quite right, for I know something of the great difficulty that exists in some parts of obtaining some of the fresh specimens of plants of regular use.

Although there were many candidates to be examined, I was much struck with the patient and quiet manner in which everything was conducted, and however nervous a candidate may be before he enters the room, it certainly ought to disappear when he experiences the nice familiar way that each examiner accomplishes his task, as no one but the examiner and his candidate can hear what is said, in fact, it more represents two gentlemen engaged in a quiet drawing-room conversation, and I can imagine the pain it must cause when a badly-prepared candidate presents himself—but this should be avoided as much as possible.

But it is very evident that many go up too soon—they try to do in about two months what ought to have occupied a period of two or three years. Let the apprentices of the present day get a good ground-work of chemistry and botany by attending classes and lectures for that purpose, and then when they come to prepare for their examination they will find their work comparatively easy, and the examination easier still; but it is to only such as these that the remark will apply.

Those of our local secretaries who have not yet seen how the examinations are managed, I should advise by all means to take the first opportunity of doing so.

W. Y. Brevitt.

The Sale of Patent Medicines.

Sir,—I should like, with your permission, to bring before the council of the Pharmaceutical Society and of the trade generally the following facts. An enterprising draper in a leading West End thoroughfare displays in one of his shop windows all the most ordinary patent medicines ticketed 10¾*d.* the 1*s.* 1½*d.* article, and 2*s.* 3½*d.* the 2*s.* 9*d.* Seidlitz powders 7½*d.* the box of twelve; citrate of magnesia, 6¾*d.* the 1*s.* bottle; bottles holding apparently 3 oz. of tincture of myrrh, 7¾*d.*; of syrup of Tolu, 5¾*d.*; while drugs, such as camphor, borax, precipitated chalk, etc., are retailed inside at 10 per cent. above the wholesale price list. Such a mode of doing business appears to me to be far more injurious to us than a co-operative store. All our lady customers visit drapers' shops, and if they are there offered Steedman's powders at 10¾*d.* and Rowland's macassar at 1*s.* 11½*d.*, before many months are over the occupation of a chemist will be confined to the dispensing of prescriptions and the sale of poisons, and the annual returns of the so-called first class family and dispensing business diminished by about one half.

Now, Sir, if the whole trade were to combine under the leadership of the council of the Pharmaceutical Society surely something might be done to check the progress of this gigantic evil. A West-End Chemist.

The Sale of Fly Papers and the Pharmacy Act.

Sir,—Some time ago you had a series of letters from correspondents on the sale of "vermin killers" as affected by the Pharmacy Act. There is one phase of the question not then mentioned I should like to see cleared up., viz., the sale of "fly papers." How are they affected by the said Act? May we sell any quantity of paper saturated with strychnine or arsenic as heretofore to customers of all sorts and sizes? Or ought they to be registered same as vermin killers? "Papier moure" and others of the fly papers are as much preparations of strychnine and arsenic as Hunter's or Butler's vermin killers are preparations of these poisons and would be as effectual for criminal purposes as either of the latter. That being so, what about the registration? Are we to go through all the forms of registration for the sale of a single paper which is oftenest wanted, or are we to increase the danger by forcing the public to take half-a-dozen or more in order to remunerate us for our extra trouble, or are we to sell as use and wont and defy the Act, its pains and penalties.

Dundee, 23rd July, 1873. William Laird.

M.P.S.—The Tinct. Ferri Perchloridi, B.P., is an unsatisfactory preparation, the spirit being looked upon in some quarters as unnecessary, useless, and deleterious, for unless the liquid contain an excess of acid, the ferric chloride is decomposed, and an insoluble oxychloride of iron is formed; while, on the other hand, if the tincture be acid, there is after some time a formation of ether. The subject was discussed at the last meeting of the British Pharmaceutical Conference (Pharm. Journ. iii. 234), when Mr. Schacht stated his opinion that the change taking place in this tincture was due to deficiency of chlorine, and he found all difficulty could be avoided by the following plan:—Instead of adding the whole quantity of nitric acid and then heating until exhalation of red fumes, he first heated the acid protochloride and then added the nitric acid gradually, and only until the red fumes were given off. It has been suggested to do away with the tincture altogether and use the liquor; but it must not be forgotten that the tincture in which the formation of ether has taken place is sometimes specially prescribed both in this country and America, whilst sometimes the water in the liquor, as instanced by Mr. Haselden, would be incompatible with the other ingredients in a mixture.

W. Wilkinson.—Received with thanks.

Messrs. Edmonds, Davies, and Co.—The advertisement has been handed to the publisher.

If "*Omicron*" sends his name and address, he will be supplied with the information asked for.

H. Arnold Woolnough.—The new regulations respecting the Jacob Bell Memorial Scholarships state that after the competition in 1873, "Candidates must be Registered Students or Apprentices of the Society under twenty-one years of age, and have passed not less, or been engaged for not less, than three years in the pharmacy of a Registered Pharmaceutical Chemist or Chemist and Druggist." You are recommended to communicate with the secretary.

Mr. B. P. Guest.—The report we give at p. 98 we think will be sufficient.

T. Garside.—Yes; the licence is the same.

Communications, Letters, etc., have been received from Dr. Royle, Mr. J. Walker, Mr. Jackson, Mr. Harper.

ARTIFICIAL ICE.

The utility of ice for a great variety of purposes is now sufficiently well known not to require especial elucidation, and few of our readers are unaware of the enormous extent to which the ice trade has developed during the last few years. For domestic purposes however the use of ice is much less general in this country than it is in America, where it is regarded almost as much a daily necessity of life as tea, coffee, milk, or bread, and in some cities of the Western Continent is supplied to the residents with the same regularity as those commodities.

The fact that the natural production of ice takes place only in places or at the season when there is no particular need for it as a cooling agent necessarily involves either its storage in such a manner as to resist thawing until such time as it is wanted, or its transport from those cold latitudes where it is permanent. Both plans are costly, and they have also the further disadvantage of not being easily adapted to the varying relations of supply and demand. Hence it may happen that ice sometimes commands a price three times as much as it can be bought for at other times.

These circumstances are naturally suggestive of the production of ice by artificial means which could be set in operation at will whenever required. One of the earliest attempts to attain this end was described in the PHARMACEUTICAL JOURNAL for 1856-57, vol. xvi., 477, also vol. xviii., 30. That plan, in common with most others which have been tried, was based upon the fact that when a volatilizable liquid is converted into vapour there is always absorption of heat, or in other words heat is employed to maintain the state of vapour and thereby becomes latent. In vaporizing liquids for various industrial purposes the heat thus requisite in the formation of vapour is supplied by the combustion of fuel, as in evaporation or distillation, but if the formation of vapour be managed in such a way that the requisite heat be taken from that determining the temperature of the liquid vaporized, there will then of course be a reduction of its temperature such as is felt when a few drops of ether are allowed to evaporate in the hand.

By evaporating with sufficient rapidity a liquid requiring a considerable amount of latent heat for the formation of vapour, such a reduction of temperature may be produced as to freeze water surrounding the vessel in which the vaporization takes place, the sensible heat of the water being transferred to the evaporating liquid and rendered latent in the formation of vapour. This is the whole theory of ice making, but practically there are some difficulties to be overcome. In the first place it is necessary to have a liquid which combines with high latent heat of vaporization such a degree of vapour tension that it will evaporate rapidly enough within the range of temperature at which the operation of ice-making has to be conducted.

Taking for instance ordinary alcohol, which has a latent heat of vaporization about one-third that of water, the tension of its vapour at 32° F. is only one-tenth what it is at its boiling point, and the facility with which it is vaporized at those temperatures differs in the same degree. In the case of ether the difference is not so great, the vapour tension at 32° F. being one-fifth what it is at its boiling point; consequently ether is a much more efficient material for ice making than alcohol, although its latent heat of vaporization is not quite half that of alcohol.

But even with ether the rate of evaporation at the low temperature necessary for ice making is too slow under ordinary conditions, and in order to maintain a sufficiently rapid vaporization it is necessary to employ an exhaust funnel, working in such a way that the ether vaporizes as if into a vacuum, and every stroke of the pump removes a quantity of vapour corresponding to its capacity. In the reverse stroke of the pump the vapour is forced into a condenser, where it is liquefied and introduced into the refrigerator for use again.

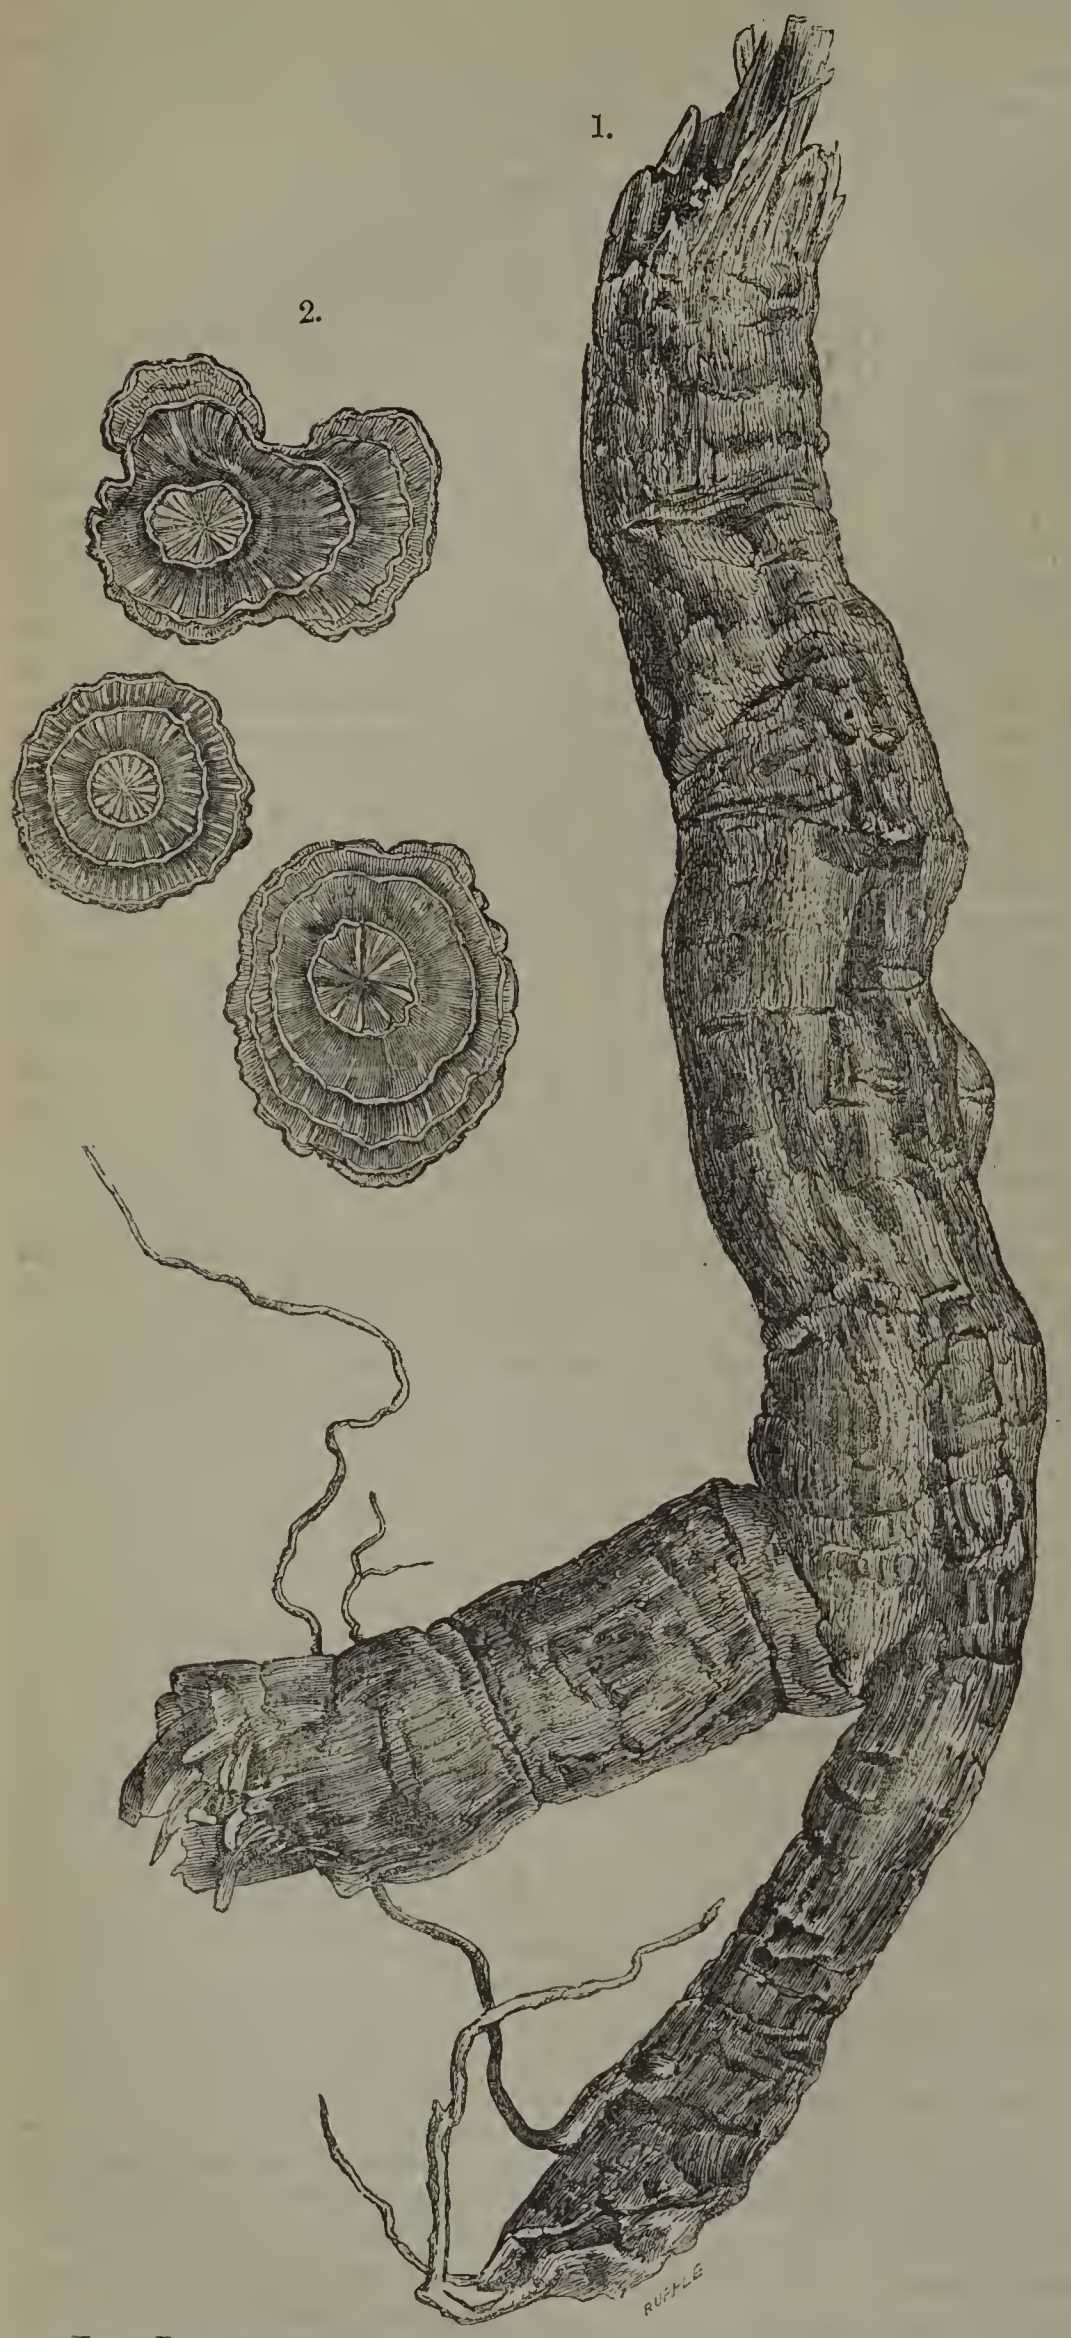
Hitherto ether is the material that has been most successfully used in the artificial production of ice; but there is another material which possesses characters such as to indicate the probability that it may prove far more efficient than ether. This is liquid ammonia—not solution of ammonia but the dry gas liquefied. In the case of this material the difficulty attending vaporization at a low temperature almost disappears, for its boiling point under normal pressure is −29° F. and the tension of its vapour between 50° and −4° F. is about eighteen times as great as that of ether vapour. At the same time the latent heat of vaporization of liquid ammonia approaches very near to that of water. Ammonia is therefore a material eminently suited for the production of ice artificially, and it has for some years past been employed for that purpose by Carré in the following manner:—a concentrated solution of ammonia in water is heated in a vertical boiler under a pressure of 100 to 135 lbs. on the square inch. The ammonia gas thus produced, mixed with about one-third its weight of steam, passes off through an ascending coil of tube attached to the upper end of the boiler into a tubular condenser, where it is cooled and liquefied under the same pressure, collecting in a receiver, from which it passes at a regulated rate into the vessel which is used for cooling. This vessel—the refrigerator—somewhat resembles a steam boiler with vertical tubes; its upper end is connected by means of a pipe with a vessel termed the absorber, into which the vaporized ammonia is from time to time discharged and brought in contact with a jet of water, by which it is absorbed, forming a solution that is continuously pumped away to supply the boiler, where ammonia gas is produced. By an ingenious arrangement the hot liquor, exhausted of ammonia in the boiler, is made to flow through a system of pipes, outside of which flows, in the opposite direction, the fresh solution of ammonia from the absorber, and thus an exchange of temperature takes place, the solution of ammonia being heated while the water is cooled sufficiently to be used for absorbing ammonia gas in the absorber. The operation of this apparatus is therefore continuous, as in the case of the ether machine. The main defect of this apparatus is, that not more than $\frac{1}{2}\frac{1}{4}$ of the ammonia is really usefully employed in cooling. For example, the liquefied ammonia produced contains about 25 per cent. of water, and since water at a temperature of 22° to 40° F. is capable of retaining in solution its own weight of ammonia, it follows that only two thirds of the ammonia in the liquid supplied to the refrigerator can be available for cooling, and that the residual solution must be from time to time run back again to the boiler. Again, since the liquor in the boiler is not entirely deprived of ammonia, but still retains 25 per cent.; it will, after cooling, only absorb 5 per cent. more ammonia, and it will be necessary to supply six times as much of this liquor to the absorber as would be needed of pure water.

(To be continued.)

ON PAREIRA BRAVA.

BY DANIEL HANBURY.

(*Concluded from page* 83.)



True PAREIRA BRAVA—ROOT OF *Chondodendron tomentosum.**

* 1. From a sample purchased in London in 1862. 2. Sections of roots received from Mr. J. Correa de Mello.

The root of *Chondodendron* cannot be confounded with the stem, which is woody and fibrous and of a different structure. Geoffroy's description of the former which I have translated at page 81 is correct so far as it goes. I may add that the numerous specimens I have seen present but little variation. All are portions of a tortuous, branching root, wrinkled longitudinally and having transverse fissures, constrictions, or ridges. The root is externally of a blackish-brown, and light yellowish-brown within. In Mr. Francis's drug there are young roots having the remnants of green aerial stems rising from their upper part. In Mr. Peckolt's specimen the aerial stems are fully preserved, as thick as the finger and many feet in length. The root seems to be gorged with juices so that under the penknife it cuts more like a very hard fat or wax than as a fibrous wood. In transverse section it does not display zones of the same regular and beautiful definition that one sees in ordinary Pareira Brava. In the root of Chondodendron there is a large well-marked central column composed of wedges diverging from a common axis, around which are arranged a few concentric rings intersected by wedge-shaped rays which are often irregular, scattered, and indistinct. The axis is not often eccentric.

In *Cissampelos Pareira* the root and stem are nearly alike in structure, and in transverse section show no concentric rings. Those received from Jamaica, which were the largest that could be collected, were rarely so much as an inch in diameter, and in many localities it is difficult to obtain the stem or root thicker than a goose quill.

TRANSVERSE SECTION OF STEM OF *Cissampelos Pareira L. From a Jamaica specimen.*

The Pareira Brava of English commerce is mostly of larger size than the root of *Chondodendron*, and is a much more woody substance. Its internal structure, which is familiar to most druggists, is very remarkable, consisting of a series of layers which are often developed exclusively in one direction. Nothing is known of the botanical origin of this drug, beyond the fact that the structure of the wood is that of the order *Menispermaceæ*.

Of late years even this sort has become rare, and its place has been taken

by a drug completely devoid of medicinal power. This latter consists of cylindrical woody truncheons which have an internal structure not very diverse from that represented below, though generally less eccentric, with always a distinct central pith. The wood is tasteless, and often seems to have been in-

ROOT (?) COMMONLY KNOWN AS *Pareira Brava*, AND ERRONEOUSLY REGARDED AS DERIVED FROM *Cissampelos Pareira* L.

jured by damp. It should be rigidly excluded from pharmaceutical use.

Several other sorts of Pareira Brava are known—at least in South America. One, of which there is a parcel now in the London market, is remarkable for its large size, and for being internally of a fine yellow. As it is also very bitter, it probably contains berberine.

Another sort is derived from *Abuta rufescens* Aublet, a well-marked plant growing in Guiana and North Brazil. Specimens of a thick woody root, marked *Abutua grande* or *Parreira Brava grande*, and attributed to this species have been sent to me by Mr. Correa de Mello; they exhibit numerous concentric layers traversed by very distinct, darik medullary rays, the inter-radial spaces being whte, and rich in starch. It is apparently a well-marked sort, and one I have not seen in commerce.*

In conclusion I strongly advocate returning to the use of the root of *Chondodendron*, which is the drug on which the reputation of Pareira Brava was originally founded.

In Brazil this root is regarded as the legitimate sort, and is still held in the highest esteem.

Though it has not been clearly recognized by European writers, is not altogether unknown. Guibourt† seems to nave been acquainted with it and even correctly surmised its botanical origin. It is the root figured by Göbel and Kunze,‡ and there is an old specimen of it in the Pharmaceutical Society's Museum marked *Pareira Brava*. I myself met with it in the market in 1862. Lastly Dr. Squibb has pointed out§ that some small lots of Pareira Brava imported into New York in 1871 consisted in large part of a drug entirely different from any previously seen, and that he at first supposed it an adulteration; but that subsequent examination had shown him that the drug in question agreed well with the older descriptions of Pareira Brava, and especially with Pomet's figure, so that he was convinced it was true *Pareira Root*. From Dr. Squibb's description I feel sure that the drug before him was the same as that to which I have called attention in the present paper.

There can be no doubt that it would become plentiful if the demand should arise, and that it would advantageously replace the worthless kind now found in the drug trade.

THE PHARMACY OF THE UNITED STATES' PHARMACOPŒIA.

BY WILLIAM MARTINDALE, F.C.S.,

Demonstrator of Materia Medica in University College, London.

(*Concluded from page* 84.)

Syrupus rhei aromaticus is made by adding to simple syrup a tincture prepared from rhubarb, cloves, cinnamon, and nutmeg, by percolation with diluted alcohol. *Syrupus sarsaparillæ compositus* is intended to represent the famous French *Sirop de Cuisinier*. It is made by macerating and percolating sarsaparilla, guaiacum wood, pale rose petals, senna, and liquorice-root, all in moderately fine powder, with diluted alcohol, evaporating, mixing with water, and in that dissolving the sugar, lastly, the oils of sassafras, anise, and gaultheria are mixed thoroughly with the syrup so produced. *Syrupus scillæ* is much the same as ours. *Syrupus scillæ compositus* is intended to represent an old popular

---

* When Aublet was in Guiana, 1762-64, the stems of *Abuta rufescens* were shipped to France as *Pareira Brava blanc*. He says there is a variety of the same with the woody parts reddish, which is known in Cayenne as *Pareira Brava rouge*. He also describes and figures a plant he calls *Abuta amara* or *Pareira Brava jaune*, which has the wood yellowish and very bitter.

This last is, I think, identical with the yellow wood of which, as I have said, there is a quantity now on sale as "*Pareira Brava*."—See *Hist. des Plantes de la Guiane Françoise*, i. (1775), 618-21, tab. 250-51.

† *Hist. des Drog.*, ed. 4, iii. (1850) 671.

‡ *Pharm. Waarenkunde*, ii. (1830-34) tab. 13. fig. 1, b-c.

§ *American Journal of Pharmacy*, March 1, 1872, 107.

nostrum in America, known as Coxe's Hive Syrup. It has the following composition :—

Syrupus Scillæ Compositus.

Take of Squill, in moderately fine powder,
Seneka, in moderately fine powder, each, four troyounces ;
Tartrate of Antimony and Potassium, forty-eight grains ;
Sugar, in coarse powder, forty-two troyounces ;
Diluted Alcohol,
Water, each a sufficient quantity.

Mix the squill and seneka, and having moistened the mixture with half-a-pint of diluted alcohol, allow it to stand for four days. Then transfer it to a conical percolator, and pour diluted alcohol upon it until a pint of tincture has passed. Boil this for a few minutes, evaporate it by means of a water-bath to half-a-pint, add fourteen fluidounces of boiling water, and filter. Dissolve the sugar in the filtered liquid, and having heated the solution to the boiling point, strain it while hot. Then dissolve the tartrate of antimony and potassium in the solution while still hot, and add enough boiling water, through the strainer, to make it measure three pints. Lastly, mix the whole thoroughly together.

There is also a *Syrupus acaciæ*.

Tincturæ.—Fifty-seven formulæ. The following note precedes the formulæ :—

"When tinctures are prepared by percolation, great care should be taken to observe the directions given at page 3 ; so that the substances treated may be, as far as possible, exhausted of their soluble principles, and a perfectly clear liquid obtained. When prepared by maceration, they require to be frequently shaken during the process, which should be conducted in glass bottles, well stopped."

The general strength of simple tinctures is such that eight fluidounces of tincture represent one troyounce of drug. The following are exceptions :—

Name of Drug.	Troyounces.	Produce of Tincture, fluidounces.
Aconitum	12	32
Arnica	6	32
Benzoinum	6	32
Cannabis (Ext. Indian)	¾	16
Cantharis	1	32
Capsicum	1	32
Castoreum	2	32
Cinchona (yellow)	6	32
Cinnamon	3	32
Guaiacum	6	32
,, (ammoniated)	6	32
Humulus	5	32
Iodium*	1	16
,, (compound)*		
Iodum, Potassium Iodidum	½, 1	16
Jalapa	6	32
Kino	¾	32
Krameria	6	32
Myrrha	3	32
Nux vomica	8	32
Opium (in powder)	2½	32
,, (,, deodorized)	2	20
,, (,, acetated)	2½	32
Quassia	2	32
Rheum		
Rheum, Cardamomum	3, ½	32
Balsamum Tolutanum	3	32
Veratrum viride	16	32
Zingiber	8	32

* Tincture of iodine is the same as the old P.E. preparation, and the compound nearly the same as P.L.

All except the following are made by percolation : —*Tr. aloës, Tr. assafœtidæ, Tr. benzoini, Tr. benzoini composita, Tr. cannabis, Tr. castorei, Tr. ferri chloridi, Tr. guaiaci ammoniata, Tr. iodinii, Tr. iodinii composita, Tr. opii acetata, Tr. opii camphorata, Tr. opii deodorata, Tr. rhei et sennæ, Tr. tolutana, Tr. valerianæ ammoniata.*

Alcohol, sp. gr. 0·835, is the solvent used for making the following tinctures :—

Tinctura.	Tinctura.	Tinctura.
Aconiti	Castorei	Nucis vomicæ
Aloës et myrrhæ	Guaiaci	Tolutana
Assafœtidæ	Iodinii	Veratri viridis
Benzoini	Iodinii composita	Zingiberis
,, composita	Lupulinæ	
Cannabis	Myrrhæ	

Diluted alcohol, sp. gr. 0·941, is used for the next list :—

Tinctura.	Tinctura.	Tinctura.
Aurantii	Cubebæ	Opii camphorata
Belladonnæ	Digitalis	Quassiæ
Calumbæ	Gallæ	Rhei
Cantharidis	Gentianæ composita	Rhei et sennæ
Capsici	Hellebori	Scillæ
Cardamomi	Humuli	Serpentariæ
,, composita	Hyoscyami	Stramonii (seeds)
Catechu	Krameriæ	Valerianæ
Colchici (seeds)	Lobeliæ	
Conii (leaves)	Opii	

Tr. arnicæ (flowers), *Tr. cinchonæ* (yellow bark), *Tr. cinchonæ composita* (with red bark, bitter orange peel, and serpentary root only—no saffron or cochineal), and *Tr. sanguinariæ*, are percolated with a mixture of three volumes of alcohol (sp. gr. 0·835) and one of water ; in the case of *Tr. arnicæ* diluted alcohol is used in displacement.

In making *Tr. cinnamomi, Tr. jalapæ*, and *Tr. kino*, two volumes of alcohol and one of water are used, and for *Tr. aloës* three of water and one of alcohol ; this also contains liquorice (commercial extract). *Tr. ferri chloridi* is about the same as our *Tr. ferri perchloridi. Tr. guaiaci ammoniata*, and *Tr. valerianæ ammoniata* are prepared with *spiritus ammoniæ aromaticus.*

Tr. opii contains one grain of powdered opium in about thirteen minims. In making it, the opium is first macerated three days in water, then the same quantity of alcohol is added and the maceration continued three days longer ; it is afterwards transferred into a percolator, and, when the liquid ceases to pass, diluted alcohol is poured upon it until the required quantity of tincture has been obtained. *Tr. opii deodorata*—a watery fluid extract of opium—is treated by agitation with ether, the ether decanted off and the liquor evaporated till all traces of ether have disappeared, it is then diluted with water, and alcohol—the latter forms one-fourth its volume ; it is of the same strength as the ordinary tincture. *Tr. opii acetata* is one in ten (six of distilled vinegar and four of alcohol) made by maceration. The *elixir proprietatis* of Paracelsus—*Tr. aloës et myrrhæ*—contains no saffron as the old P.L. formula did. *Tr. rhei et sennæ* is composed of rhubarb, senna, coriander, fennel, liquorice (commercial extract), raisins and diluted alcohol. Macerate seven days.

Trochisci.—Thirteen formulæ. These are, chalk (four grains), cubeb* (half a minim of oleoresin), subcarbonate of iron (five grains), liquorice and opium

* These resemble Brown's bronchial troches.

(extract of opium $\frac{1}{20}$ grain), ipecacuanha ($\frac{1}{4}$ grain)' morphia and ipecacuanha (sulphate of morphia $\frac{1}{40}$ grain and ipecacuanha $\frac{1}{12}$ grain), chlorate of potash (five grains), santonin ($\frac{1}{2}$ grain), bicarbonate of soda (three grains), and there are also troches of ginger made with the tincture and syrup of ginger.

Unguenta.—Twenty-nine formulæ. Fifteen have lard alone as a basis, viz. : *ung. acidi tannici, ung. antimonii, ung. belladonnæ (c. ext.), ung. benzoini (c. tinct.), ung. creasoti, ung. gallæ, ung. hydrargyri nitratis, ung. iodinii, ung. iodinii compositum, ung. potassii iodidi, ung. stramonii (c. ext.), ung. sulphuris, ung. sulphuris iodidi, ung. tabaci (c. aq. ext.), ung. veratri.*

Seven ointments have simple *unguentum*—eight parts of lard and two parts of yellow wax—as a basis, viz. : *ung. acidi carbolici, ung. hydrargyri ammoniati, ung. hydrargyri iodidi rubri, ung. hydrargyri oxidi flavi, ung. hydrargyri oxidi rubri, ung. plumbi carbonatis* and *ung. plumbi iodidi. Ung. picis liquidæ* is the same as P.L.—equal parts tar and suet. Cold cream is official under the name of ointment of rose water, and bearing this authority I insert the formula for it :

Unguentum Aquæ Rosæ.

Take of Expressed Oil of Almond three troyounces and a half ;
Spermaceti a troyounce ;
White Wax one hundred and twenty grains ;
Rose Water two fluidounces.

Melt together, by means of a water bath, the Oil, Spermaceti, and Wax ; then gradually add the Rose Water, and stir the mixture constantly while cooling.

Ung. benzoini is prepared by adding the tincture of benzoin to melted lard and applying heat to drive off the spirit ; it is used as a basis for *ung. zinci oxidi. Ung. cantharidis* is *ceratum cantharidis* (our emplastrum) diluted with *ceratum resinæ*—this formula reminds one of two blacks making one white. *Ung. hydrargyri* is twenty-four ounces of mercury with the same quantity of basis—equal parts of suet and lard. *Ung. mezerei* is prepared by adding the fluid extract of mezereon to melted wax and lard and heating to drive off the spirit. On making *ung. hydrargyri nitratis* the solution of nitrate of mercury is directed to be added to the melted lard (*sine* olive oil) at a temperature of 200° F. and stirred, etc., to form an ointment.

Vina.—Nine formulæ. The basis of all the *vina* is sherry—in *vin. rhei* a little diluted alcohol is ordered —three are prepared by percolation—*vin. colchici radicis, vin. opii* (c. pulvere opii, cinnamomo et caryophyllo), and vin. rhei (c. canellâ). *Vin. ipecacuanhæ* and *vin. ergotæ* are made by mixing the fluid extracts of ipecacuanha and of ergot with sherry. *Vin. ipecacuanhæ* will be above double the strength of ours. The following are made by maceration—*vin. aloës (c. cardamomo et zingibere), vin. antimonii,* (as B.P.,) *vin. colchici seminis* and *vin. tabaci.*

Casting a final glance at the work, which possesses much interest pharmaceutically, one cannot but admire its simplicity of arrangement, and the desire to obtain definiteness and uniformity. It is essentially a book of instructions for the pharmacist to prepare his medicines by ; it is not a "cram" book —the student must make his own table of the strengths of preparations and the medical practitioner his of doses, and each will thus become more conversant with it. Free use has been made of the processes in the British Pharmacopœia without any acknowledgment—and I think the compilers have assumed the existence of more skill—and percolators —than will be found in the majority of drug stores in the United States. The result will be that certain makers will acquire a reputation for a few preparations, their make will be nearly always indicated on prescriptions and on a large scale these manufacturers will ignore the pharmacopœia processes entirely as not being adapted for their purposes.

How does the work reflect American pharmacy generally ? I fear not as completely as it might do. Where are the elixirs of bark, the syrups of the phosphates and the eclectic preparations ? But perhaps

"'Tis wisely done ;
What would offend the eye, in a good picture,
The painter discreetly casts into shade."

IS THERE A THIRD ALKALOID IN HYDRASTIS CANADENSIS ?*

BY A. K. HALE.

Whilst preparing hydrastia from an aqueous percolate of *Hydrastis canadensis*, from which the berberine had previously been removed as hydrochlorate, the author noticed the product obtained by adding solution of ammonia as long as a precipitate was thrown down, filtering, dissolving the precipitate in and crystallizing from alcohol, was coloured by and intimately mixed with a yellow powder. To a fresh quantity of percolate, therefore, he added only sufficient ammonia to render it neutral, and the precipitate thus obtained, upon crystallizing from alcohol, formed well defined prismatic crystals of hydrastine, free from yellow matter. Ammonia was then added to the percolate until it was strongly alkaline, which caused the separation of a fresh precipitate, darker than berberine, and neutral in alcoholic solution. Compared with berberine it was less soluble in cold nitric acid, but both formed a red solution when the acid was heated. In water at 60° and cold liquor potassæ it was the least soluble of the two, but both dissolved in hot water. In hot sulphuric acid, berberine formed a yellow, the new substance a reddish-brown solution. Dissolved in hot hydrochloric acid, berberine crystallized abundantly in bright yellow needles while the acid was still warm ; the new body sparingly in darker and larger needles only when the solution was nearly or quite cold. Dissolved in warm water berberine gave with iodohydrargyrate of potassium an abundant yellow precipitate ; the other body gave one less abundant, very light yellow, and almost straw coloured. In order to ascertain whether the new product was a modification of berberine by the action of ammonia, some of that alkaloid was submitted to the influence of ammonia during several days without any change being noticed.

NOTE ON THE REPUTED VALUE OF POLYGONUM AVICULARE, L. FOR STONE.

BY JOHN R. JACKSON, A.L.S.

Members of the order Polygonaceæ are far from being rare, either to the British, Continental, or American botanist ; least of all, perhaps, is the knot-grass (*Polygonum aviculare*), which generally flourishes best where its presence is not wanted, and defies eradication. With such quantities of this weed at our very doors, it seems somewhat ludicrous to import it from ever so short a distance, let alone from Russia, but such is the case that amongst the numerous contributions of vegetable products, "good, bad, and indifferent," which are constantly being received at Kew, a bundle of knot-grass recently arrived from Berdiansk, with a wonderful account of its extraordinary power of curing stone and gravel diseases. Our correspondent says his attention was attracted to it by a case which fell under his own observation—that of a

* Abstracted from a paper in the *American Journal of Pharmacy* for June, p. 247.

man who suffered so excessively, that he was told by the doctors he must undergo an operation ; in the meantime, a quantity of the *Polygonum* was given him by a person who happened to hear of the case, the sufferer drank two tumblers full of the decoction, and, in about fifteen minutes, he felt an intense pain in the bladder and surrounding regions, as if the parts were being torn to pieces, this was immediately succeeded by an irresistible desire to pass water, which was done with great pain, but nothing could check the force of the bladder in ejecting the water, which brought away with it a great quantity of gravel and bits of stone, some of the pieces passed were very large, but the instant they came out they opened into flakes and broke up into thin plates. The man is stated to have quite recovered, and the person who gave him the *Polygonum* is said to have been distributing it in all such cases that have come under his notice for the last thirty years, and always with success.

The following is given as a suitable way of taking the medicine :—Take a good, liberal handful and boil gently in six tumblers of water, till it is reduced to about four tumblers. The dose is one or two tumblers to be taken in the morning on an empty stomach. In bad cases it is given several times throughout the day, but diet must be strictly kept. As a purifier of the blood, one tumbler of a weaker decoction is recommended to be taken every morning.

The discovery of such an apparently valuable medicinal agent by anyone not sufficiently acquainted with plants to recognize it must have been a source of much gratification. Emetic, carthartic, and diuretic properties have been ascribed to many of the Polygoneæ, and even to *P. aviculare* itself. At one time it was stated that the plant was an excellent febrifuge, and it was used in Algeria, and other parts of Africa, as a substitute for quinine. In 1845, a French doctor reported upon it as being an excellent remedy for chronic diarrhœa, the means of applying it being in form of a strong decoction.

At the present time the only really valuable medicinal product of the *Polygoneæ* is rhubarb.

GLYCERITE OF GINGER.*

BY J. B. MOORE.

There is, perhaps, no aromatic more popular or more highly prized for its therapeutic properties than ginger. And as a domestic remedy, in the form of the officinal "tincture," under the well known title of "Essence of Ginger," there is scarcely a preparation of our Pharmacopœia more extensively or more universally used. The "Tincture of Ginger" is, for many purposes, a most excellent and trustworthy preparation of the drug, yet in many cases of children and delicate persons, its strongly alcoholic character disqualifies it for use, and this especially in diseases of the stomach and bowels when irritation or an inflammatory condition exists. The "Syrup of Ginger," as made by the U. S. P., is too weak to possess much medicinal value, and even in its use as a flavour it is of but trifling importance. So there would seem to exist a necessity for a preparation of ginger intermediate in strength between the tincture and syrup, and at the same time free from alcohol. The "Glycerite of Ginger," a preparation whose formula I here present, is admirably adapted to supply this want. It is about triple the strength of the officinal syrup of ginger (U. S. P.), contains no alcohol, and mixes in all proportion with water and syrup without precipitation or turbidity.

The following is the formula and process for its preparation :—

℞	Ext. Zingiber. fluid	f℥i.
	Magnes. Carbon.	℥x.
	Glycerin.	f℥xvj.
	Aquæ	q. s.

Mix the glycerin with an equal measure of water

* From the *Pharmacist*, vol. v., p. 172.

Triturate the fluid extract of ginger thoroughly with the magnesium carbonate. Then add, very gradually, one pint of the mixture of glycerine and water, rubbing well after each addition of liquid, and strain the mixture through strong, close muslin with strong expression. Rub the residue in like manner with the remaining part of menstruum. Then transfer the mixture to a half gallon bottle containing the expressed liquid first obtained and shake the whole vigorously together. Lastly, filter through paper, passing sufficient water through the filter to make the filtered liquid measure 32 fluid ounces.

To insure a good preparation, such as the formula and process will afford, if properly manipulated, it is necessary that some care and judgment be exercised in its manufacture. In the first place the fluid extract of ginger, if purchased, should be of known reliable quality, or else it should be prepared by the pharmacist himself. Secondly, the fluid extract and magnesium carbonate must be thoroughly triturated together before the menstruum is added, which adding must at first be very gradual, with much rubbing after each small addition. The straining and expression directed after the incorporation of the first pint of menstruum, being a little troublesome, may be omitted, and the whole of the menstruum supplied in successive portions at once, and the whole afterwards well shaken in a bottle. But the manipulation directed in the process insures the most reliable product, and I would advise that it be carried out.

The "Glyceritc of Ginger," prepared as above directed, contains the activity of 15 grains of ginger to the fluid ounce, and is about the colour of sherry wine, and possesses the characteristic flavour and pungency of the ginger very strongly marked. Both of which, however, are somewhat marked and blunted by the glycerine.

It will prove an excellent corrigent addition to the various tonic, diarrhœa and stomachic mixtures. It can be associated in prescription with almost all kinds of mixtures. For pain in the stomach, accompanied by sickness, acidity or flatulence, and for many other purposes which may suggest themselves to the physician, the following formula furnishes an excellent combination, and is not an unpalatable mixture :

℞	Sodæ Bicarb.	℥j.
	Liq. Morph. Sulph.	℥ss.
	Tr. Cardamom. Comp	f℥ij.
	Sp. Ammon. Aromat	f℥ij.
	Sacch. Albi	℥iij.
	Glycerit. Zingiber	f℥ij.
	Aquæ Menth. Pip. q. s. ut ft.	f℥iv.

For an adult, one tablespoonful as required. The physician may, of course, vary the ingredients and their proportions to suit his own views. In cases of diarrhœa and other lax conditions of the bowels, Tr. Krameriæ, Tr. Catechu, Tr. Kino or other astringent remedies may be added, and the desired quantity of Tr. Opii or Tr. Opii Camph. substituted for the Liq. Morph., as these preparations are generally preferable to morphina in astringent mixtures. In cases of diarrhœa, etc., accompanied by tenesmus, a little castor oil, say from one to two fluid drachms, will be found a valuable addition to the above. The castor oil can be formed into a smoother mixture with the other ingredients, by the addition, also, of about two drachms of powdered gum arabic. By omitting the solution of morphine from the formula as it stands, and adding one fluid ounce of Comp. Tinct. Gentian., it will form a most elegant and efficient remedy in certain forms of dyspepsia and other disordered conditions of the stomach. As an astringent addition to the above preparation, I would recommend the tincture of Krameria as perferable to either the Tinct. of Catechu or Kino. It being, as far as my experience and observation has gone, not only equally efficient, therapeutically, with either of the latter preparations, but at the same time more agreeable to the taste and forms a more elegant mixture with this and other similar combinations.

The Pharmaceutical Journal.

SATURDAY, AUGUST 9, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SCHOOL OF PHARMACY.

NEXT October the opening of the thirty-second session of this School will take place under conditions essentially different from those which have previously obtained. As will be seen from the Report of the Council proceedings (page 111), the whole course of instruction has been very considerably modified, and a prospectus is to be issued by the Society to all members of the trade, setting forth what is proposed, and giving a syllabus of the several lectures, demonstrations, etc., as well as the regulations affecting prizes, scholarships, etc., and attendance in the reading-room and museum.

What we desire to call especial attention to here are the introductory remarks, serving as a preface to this prospectus which will soon be in the hands of our readers. Starting with the axiom that the object of the Society in promoting a School of Pharmacy was to provide sound instruction in the principles on which the practice of pharmacy should be based, it is stated that the Council of the Society will still retain a controlling influence over the arrangements of the School, and that they are determined to maintain its high character.

It may therefore be assumed that the intentions thus expressed are to be accepted as a guarantee against any such depreciation of the standard of instruction as has been apprehended as likely to result from the modified curriculum which the Council has thought it desirable to authorize.

In the communication from the Privy Council Office (p. 109), it will be seen that a suggestion is offered in respect to an interval of three years between the Preliminary and Minor Examinations being made compulsory. This suggestion, occurring as it does simultaneously with the issue of the prospectus above referred to, adds additional force to the opinion therein expressed by the Council, that it is of the utmost importance for all youths to pass the Preliminary Examination prior to apprenticeship or pupilage, and that during this period they should by study, no less than by the acquisition of such practical knowledge as the shop or dispensary may afford, prepare themselves for taking full advantage of the instruction provided by the School of Pharmacy.

We earnestly recommend these suggestions to the attention of both apprentices and those in whose charge they are placed, for we feel sure that due regard to them cannot fail to be of advantage to both, as well as conducive to the general interests of the drug trade and the advancement of pharmacy.

THE BRITISH MEDICAL ASSOCIATION.

THE Annual Meeting of the British Medical Association has come off, in some respects with greater *éclat* than the most distinguished of its predecessors. It was peculiarly happy in its President, whose general popularity infused a genial influence over the Sections, and whose address, shrewd with the sense and racy with the humour characteristic of his countrymen, struck an effective key-note between the theoretical and the practical. The social features of the gathering were also successful—the banquet in Lincoln's Inn Hall being graced by the presence of the PREMIER, fresh from the cares of office and full of the animation of holiday. The papers were of more than average merit, and the discussions they evoked were marked by the temper and toleration proper to science. Two of the leading deliverances, however, were characterized by an intelligence, power, and finish, which dwarfed the others by contrast. We refer to the address of Dr. E. A. PARKES, of the Netley School of Medicine, and to the speech of the President of the Conference of Medical Officers of Health, Mr. ERNEST HART.

Dr. PARKES gave a comprehensive and luminous survey of the progress of medicine during the last forty years, touching less, however, on its therapeutic development than on its advances in diagnosis and pathology. The recognition of kidney-degeneration by BRIGHT, and the device of auscultation by LAENNEC were the first great triumphs of the epoch, but destined to be equalled if not surpassed by the discoveries of later years. The splendid induction of VIRCHOW, whose presence at the meeting was one of its most attractive features, has, in its demonstration of embolism, that is, of the effect of minute capillary blockage, proved most pregnant in results. It has separated one form of apoplexy from other apoplectic forms; but it has also accounted for the production of morbid growths by the transference of cells, and their arrest in other parts. The cognate doctrine of thrombosis, that is, the spontaneous clotting and interception of the circulation, is another of the same pathologist's invaluable contributions to medicine. The knowledge of entozoic diseases, such as trichiniasis for instance, which has often been mistaken for specific fevers, has yet further enlarged the physician's power; while the recognition of the implantation of those minute bacteroid bodies, still called plants, opens up a vast field for the diagnosis and treatment of many hitherto unknown or misinterpreted maladies. And so the lecturer proceeded in his enumeration of the triumphs of pathological research till he came to a natural halt at the threshold of preventive, "the child of curative, medicine."

The practical deduction from the address of Dr. PARKES was necessarily this: that "those who are conducting the vast plans which the Legislature has devised for improving the national health, may remember that the profession which has so far searched out the causes of individual and national ill-health must be entrusted both with the execution of the plans and the continued search into a subject which is still in its infancy." The Association was thus well prepared for the vindication of its claims on the Local Government Board, which was next day delivered by Mr. ERNEST HART. Speaking as Chairman of the Parliamentary Bills Committee, that gentleman traced the progress, if such it could be called, effected in Public Health administration since 1872. Now, what does such administration imply? First, the necessity of medical officers whose local position gives them special knowledge of unhealthy localities; in other words, the Poor Law medical officers. But, essential as these functionaries are to any such organization, they cannot be the only element—their area of action being too small, and their means inadequate. Union areas and the Union medical officers must be grouped together under a consolidated board with the assistance of a consultative medical health officer, possessing as complete a familiarity as possible with hygienic science. Public health being matter of imperial concern, it is necessary to bring these two elements of local administration into relation with the Central Board. Inspectors must be employed to this end who shall consult with the local authorities and their officers, and ultimately report to the department of the Local Government Board which decides. Such was the obvious groundwork open to Mr. STANSFELD in his Public Health Bill, and no pains were spared to lay before him its constituent facts. But with what result? His own health officers were never consulted by him. The wide and accurate knowledge they alone possessed he ignored. The Local Government Board designedly sought to aggrandize itself at the expense of the very bill it had itself framed. The inspectors, through whom it was to be brought into relation with the district authorities, it selected from every class but the medical—from men who, whatever their intelligence in other respects, had neither knowledge, reading, instruction, nor experience in public hygiene. To them it intrusted the task of organizing a health administration throughout the country, with what result it would be alternately ludicrous and distressing to relate. Their diverse and conflicting action is perhaps the least of their misdoings.

Mr. HART carried along with him the great bulk of his numerous audience, and a motion was introduced and adopted expressive of its adhesion to his policy, and of its desire to see medical officers replacing the present lay inspectors in administering the provisions of the Public Health Act. *In suâ arte cuique credendum*—a wise saying, but one which the Local Government Board has yet to appreciate. The British Medical Association has done good service to the community in many ways; but not the least is its impressive appeal to the better judgment of the Legislature, in the imperial question of sanitary administration, just made by its spokesman, Mr. ERNEST HART.

THE WORKING OF THE ADULTERATION ACT.

Now that there is so much said and written about the position of scientific men, and one of our leading scientific journals has raised almost an outcry about the endowment of research, it is unfortunate that there should have been a succession of miscarriages on the part of several individuals holding positions in the scientific community, and that this should have happened in what might fairly be regarded as the ordinary exercise of their business. We refer to the cases under the Adulteration Act, in which the analysts' reports have either been withdrawn by themselves, or have failed to bear the test of criticism. One such case is reported in this week's Journal, where it is evident that there must have been either great want of care in taking the samples or else serious error in the analytical operations to which they were subjected for the purposes of the Act. Thus, we find Dr. THORPE reporting, in the first instance, that butter contained 19·5 per cent. of curds and farinaceous matter, and 19·4 per cent. of water; while, on the other hand, Dr. WALLACE reports only 1·1 and 1·5 per cent. of curdy matter. Then, on the reference of this question to other chemists, we have reports that the amounts of curd are 1·01 and 0·97 per cent. from one chemist, and 0·91 and 0·94 per cent. from another; while the amounts of water are given as ranging from 4·73 to 8·52.

In the now celebrated Liverpool case, also referring to butter, there is the same unsatisfactory state of things and similar discrepancies between the testimony of chemical witnesses. Whatever foundation there may be for the statement of Dr. CAMPBELL BROWN respecting the detection of foreign animal or vegetable fats when mixed, as adulterants, with butter, this much is certain, that there is no published, or, as we believe accessible, account of the evidence on which Dr. BROWN'S statements are based. Moreover when Dr. BROWN'S chemistry is, by his own showing, manifestly so little creditable to the degree he holds, it is not surprising that there should be reluctance to accept his statement unsupported.

We might refer to other cases in which there have been similar unsatisfactory results, but as they probably have not yet been finally disposed of, we will merely express our regret that any apparent justification should thus have been furnished for the notion that chemists' opinions and evidence might be obtained one way or other, according to circumstances.

WE are requested to state that in consequence of the alterations now being made, the Library will be closed during August and September.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

August 6th, 1873.

MR. THOMAS HYDE HILLS, PRESIDENT.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT.

Present—Messrs. Atherton, Baynes, Betty, Greenish, Hampson, Mackay, Owen, Radley, Robbins, Sandford, Savage, Schacht, Shaw, Stoddart, Urwick, and Williams.

The minutes of the previous meeting were read and confirmed.

British Pharmaceutical Conference.

The President said the members of Council were doubtless aware that in consequence of the meeting of the British Association for 1874 being arranged to take place at Belfast, a question had arisen whether, in the present unsettled state of the position of Pharmacists in Ireland, it was advisable for the Pharmaceutical Conference to follow its usual course, and hold its meeting in the same place as the British Association. As the possibility of the meeting being held in London had been suggested, he would move—

"That in the event of the members of the British Pharmaceutical Conference deciding to hold their meeting next year in London, the Council authorize the President of the Pharmaceutical Society to write to the President of the Conference, offering the use of the Society's rooms for the purposes of the meeting, and the Council further desire to add that they will be happy to afford every facility for promoting the success of the meeting."

The Vice-President seconded the motion, which was carried unanimously.

Mr. Williams said that in the event of the meeting being held in London, it would be desirable to fix a day not so close as usual to the meeting of the British Association, and no doubt this would be done, as some members of the Conference, being also members of the Association, would otherwise be prevented from attending both.

The Privy Council and the Board of Examiners.

The Secretary read the correspondence which had taken place with the Medical Officer of the Privy Council, with reference to the appointment of Mr. Haselden as an examiner. Mr. Simon stated in reply to a letter sent by the Secretary, pressing the desirability of sanctioning the appointment, that the Privy Council must adhere to the decision already arrived at, not to approve the appointment of any gentleman as examiner who within twelve months had been a member of the Council. He also stated that the Privy Council were not aware at the time they sanctioned the appointment of Mr. Edwards that he had been so lately a member of the Council.

The New Bye-Laws.

The Secretary also read a letter from the Medical Officer of the Privy Council, acknowledging the receipt of the amended Bye-Laws, and suggesting that they should be further amended, inasmuch as clause 6, sec. 10, appeared intended to render the last year's President and Vice-President eligible for the Board of Examiners, which the Lords of the Privy Council could not accept. He therefore recommended the omission of the words: "other than the President or Vice-President," after which amendment the Privy Council would be prepared to approve the present alterations. At the same time, he begged leave to suggest, for consideration, a further alteration in clause 16, to the effect that the Preliminary examination should, in all cases, be passed three years prior to coming up for the Minor examination.

The President remarked that if these alterations were made the Bye-Laws would have to be passed at three Council meetings, and submitted to a general meeting.

Mr. Mackay said that the latter suggestion, however valuable it might be at some future time, would at present often work very great hardships.

Mr. Sandford thought the Privy Council would not object to substitute a period of six months instead of twelve during which late members of Council were disqualified, and if that were acceded to the Council might be content to give up the exception in favour of the President and Vice-President. The other suggestion was a very valuable one, but it could not be entertained at present without going through a repetition of the formalities necessary for new laws.

Mr. Mackay suggested that those members of the Council who previously saw Mr. Simon on this subject be requested again to wait on him and settle the wording of the new bye-law.

This was agreed to, and the President reminded the members that at the next meeting it would be necessary to elect an Examiner in place of Mr. Haselden.

An Associate who had neglected to pay his subscription within the proper time was ordered to be restored to his original status on payment of his subscription and a nominal fine.

The following being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society :—

Ball, George.
Baynes, James, jun.
Brookes, Frederick James.
Cottam, William Procter.
Crundall, Augustus Horton.
Fletcher, Frederick William.
Goulden, Herbert.
Hart, Thomas.
Hawkes, Richard.
Hulme, Richard Gleave.
Jones, John.
McJannet, James.
Mumby, Charles John Everitt.
Rimmington, George.
Roberts, William.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Baynes, James, jun. .....Hull.
Butten, Joseph ....Penzance.
Crundall, Augustus Horton.....Kensington.
Dowty, Robert .....London.
Gibbs, James.....Tenby.
Gilmour, David.....Edinburgh.
Goulden, Herbert .....Canterbury.
Hart, Thomas ....Manchester.
Hawkes, Richard .....Ely.

Chemists and Druggists.

Butler, Thomas Edward, jun....Somerset East, Cape of Good Hope.
Butterfield, Richard Brigham ...Shipley.
Lloyd, John Walters .....Swansea.

ASSOCIATES.

The following having passed their respective examinations, and being in business, were elected "Associates in Business" of the Society :—

Minor.

Spong, Douglas Morton .....Biggleswade.

Modified.

Coker, Owen Cole.....Plymouth.
Cregeen, James Henry.....Bayswater.

The following having passed their respective examinations, were elected "Associates" of the Society :—

Minor.

Baikie, Peter..... .....Belfast.
Birchall, Thomas Barrow.....Preston.
Birkett, John Robert.....Morecambe.
Bowling, John Henry ....Pembroke Dock.

Carter, Arthur Joseph..... ...London.
Coleby, Frederick .....Surbiton.
Elwood, William, jun. .....Grimsby.
Gadd, William Fletcher .....Oxford.
Gordelier, John Thomas .....Sittingbourne.
Gould, William Robert .....Southsea.
Hall, Ralph .....Kingsland Road.
Haller, Frederick William .....Hull.
Hambridge, Thomas.....Lower Tottenham.
Hindle, John.....Gorleston.
Hunter, Frederick Neish .....Durham.
Jinks, John.....Tipton.
Kemp, Harry.....Salford.
Law, Alfred .....Towcester.
Marten, Cruttenden .....Liverpool.
Metherell, Kinneard.....London.
Norman, Joseph Slaughter .....Royston.
Osborn, William Henry .....Tewkesbury.
Peacock, Walter .....Oxford.
Pendrigh, John Cuthbertson ...Sanquhar.
Pitts, Thomas Cruso.....Norwich.
Robertson, John .....Inverness.
Sharp, Robert Henry .....Portobello.
Smith, William.....Gosport.
Sprake, David Lewis .....Carmarthen.
Staning, Walter .....Hull.
Stead, Thomas Albert .....Heckmondwike.
Storey, John Charles .....Hull.
Strang, Peter.....Perth.
Tebb, Henry .....St. Ives.
Thompson, Lawrence Joseph ...Thirsk.
Ward, Charles Thomas .....London.
White, William Charles ....Barnstaple.
Willis, Blankley William.....Kidderminster.
Wolstenholme, John, jun.....Bury.
Wyles, William.....Grantham.

Modified.

Andrew, Ablett Ashworth ...Clitheroe.
Brodie, Robert .....Glasgow.
Holttum, Richard .....Maidstone.
Stones, William.....Manchester.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination were elected "Apprentices or Students" of the Society :—

Barlow, Joseph Alexander ... ..Rochdale.
Beswick, Jesse ..... Liverpool.
Brewer, James Curtis .....Hereford.
Cardwell, Ernest .....Lytham.
Coleman, Alfred .....Southampton.
Cooper, Henry .....London.
Elliston, Augustus Frederick ...London.
Epps, James .....Upper Norwood.
Evans, Robert Daniel .....Liverpool.
Exley, John, jun. .....Leeds.
Fletcher, Frederick John.....Wolverhampton.
George, John Irving.....Tunstall.
Grant, Alexander .....Cullen.
Henderson, Christopher .....Hoylake.
Holden, William Henry ... .Staithes.
Lloyd, John .....Hereford.
Mayger, William John.....Northampton.
Olden, Loathan .....Romsey.
Perry, Horatio Nelson .....Gravesend.
Phillips, George.....Dowlais.
Pridmore, Walter Snape .....Hinckley.
Purdy, James Robert .....Morpeth.
Ridgley, Thomas .....Newport, I. W.
Shilton, James .....Sutton Coldfield.
Stacey, Peter.....London.
Stephens, George Thomas ..... Hereford.
Swinbank, John.....Ferryhill.
Thomas, John Tubbs .....Newark.
Thomson, John .....Edinburgh.
Walker, George Edward .....Royston.
Winn, John Christopher .....Hurworth.

GIFT OF A PRIZE FUND BY THE PRESIDENT.

The PRESIDENT said he had much pleasure in presenting to the Society another Russian bond for £100, the interest of which was to be applied to giving a prize of books to each candidate who passed the Minor examination first in honours at the ordinary examinations in Edinburgh. The conditions would be the same as had been announced on a former occasion, viz., that such books should be given as would be of assistance to the student in preparing for his Major examination. This gift as he had before stated was simply to make up the amount which he had hoped would have been received for the sale of the engraving of Mr. Jacob Bell's portrait. The result of the publication had not been so successful as he had anticipated, and he therefore had much pleasure in making up the amount.

Mr. MACKAY begged to propose that the most cordial thanks of the Council, and in particular of the North British Branch, be offered to the President for his munificent donation.

The VICE-PRESIDENT seconded the motion, adding the thanks of "the rising generation" to those of the Council and the North British Branch, and the motion was then passed by acclamation.

The SECRETARY said it was only right to add that the President had handed him £2 10*s*., the amount of dividend last received on the bond.

FINANCE.

The report of the Finance Committee was received and adopted, and sundry payments were ordered to be made.

BENEVOLENT FUND.

The report of this Committee was read. It included a letter from Mr. Balkwill, of Plymouth, giving particulars of the satisfactory manner in which he had been able to apply a grant of £10 recently made for the benefit of the wife and family of a member at Torquay afflicted by mental alienation.

Upon the recommendation of the Committee a grant of £10 was made in each of the following cases :—

The widow of a member of the Society formerly residing at Yoxall.
A member of the Society residing at Halifax.
A registered chemist and druggist residing at Kibworth.

The report and recommendations of the Committee were received and adopted.

PARLIAMENTARY.

The report of this Committee was read. It appeared that the Registrar had written to six persons who had been reported to be infringing the Pharmacy Act, and had received replies from two only, one of whom had taken steps to be registered, and the other assured him that the offence would not be continued. He had been directed to write again to the remaining four before further proceedings were taken. The report was adopted.

HOUSE.

The report of this Committee consisted mainly of the estimates which had been obtained for repairing and painting the premises, including replacing the windows on the ground and first floors with plate glass, and the opening of the three sham windows in the library, and consequent alteration in the shelving. There were considerable variations in the estimates, and the Committee recommended that the tender of Messrs. Patman and Fotheringham be accepted.

Mr. MACKAY suggested that a little more consideration should be given to the matter before £100 and upwards was expended on the alterations in the Library, the simple effect of which would be, as he understood, to give more light.

Mr. BETTY supported the recommendation. He thought it would be very bad taste when making such important alterations and improvements in the premises to spoil the whole thing for the sake of a little extra expense. There was hardly enough accommodation in the library at present, either for readers or books, and by the proposed

alteration, and the adoption of the modern system of bays or recesses, this would be secured. He would put it to the Council how they would like to see a notice to this effect affixed to the last plate glass window in Great Russell Street—

"Beyond this, penury refused to go,
They glazed the rest but here they stuck stucco"?

He would only add that he had on a former occasion himself gone to the expense of obtaining an architect's opinion on this subject, when he received a report recommending the scheme now brought forward, and which had received the strongest approval of the Society's architect.

Mr. SAVAGE doubted the advisability of the alterations, as he did not think there would be any gain of accommodation, seeing the blank space would be destroyed.

Mr. MACKAY said it was not his intention to move an amendment on the subject; he simply wished to draw attention to what seemed a large item of expenditure for an insufficient object. He had never noticed any deficiency of light in the library.

Mr. WILLIAMS said this subject had been discussed on several previous occasions, and he thought it was now the almost unanimous opinion that the windows should be opened.

Mr. SANDFORD had been throughout opposed to this alteration, and did not see any necessity, even as a matter of taste, for it. Neither did he think any more light was required. It must also be remembered that the bays would necessarily be so narrow that any one reading at the tables therein would have to move if the librarian required a book from the shelves. He did not really think the Society was justified in expending so much money for such a purpose.

Mr. SCHACHT said the whole question turned upon whether the library would be substantially improved. He had hitherto taken this for granted, but from what was said by Mr. Sandford, he somewhat doubted, and should like to hear particulars of the measurements.

Mr. SAVAGE said he believed the opening would be about 5ft. 6in. in width.

Several members of the Council having inspected the library, Mr. Savage moved an amendment that the alteration of the library be not carried out, but on being put only four members voted for it, and the resolution was then put and carried.

REPORTING PROCEEDINGS AT THE PHARMACEUTICAL CONFERENCE.

The SECRETARY having reported the steps which had been taken in former years with reference to this matter,

The PRESIDENT said he considered it very important that the proceedings should be fully reported in the Journal, and suggested that the Council should vote a sum not exceeding ten guineas for the purpose, the report to be published in the Journal.

Mr. SAVAGE seconded the proposition.

Mr. HAMPSON said he presumed it would be left in the hands of the Editor to make arrangements for the report.

Mr. GREENISH did not understand why the expense should be so great as ten guineas.

Mr. HAMPSON thought a copy of the proceedings must be taken for the Conference, which the Society might have the benefit of.

Mr. SCHACHT said he was quite sure the Conference, who had no money to spare, would not be prepared to vote ten guineas for the purpose of a report, and probably they would have to fall back on the amateur labours of some of the more enthusiastic members, with such local assistance as could be obtained.

After some further conversation, the resolution was put and carried.

LIBRARY, MUSEUM, AND LABORATORY.

The report of this Committee was read, recording the proceedings which had taken place at several meetings with reference to the future arrangements for the Society's educational department. The professors had attended the meetings, and a prospectus or syllabus of the school had been prepared. This had undergone considerable discussion in the Committee, and it was now submitted for the consideration of the Council. It was prefaced by a letter signed officially by the Secretary and Registrar.

The PRESIDENT said this was a very important subject, and as all members of the Council had a copy of the prospectus, he should be glad to hear any remarks upon it, especially by those who had not attended the Committee.

Mr. WILLIAMS said it might save time to first state the position in which matters stood. As would be gathered from the report of the Committee, the acceptance of the document now produced was not at all unanimous on the part of the Committee. In fact a great deal of discussion had taken place, whether it should be published at all, and only as a kind of compromise was it agreed that it should be recommended to the Council to be published with the authority of the Society, but for this year only, the publication not to be taken as a precedent. He thought, therefore, it would be well for the Council in the first place to decide whether they would publish such a prospectus at all in the name of the Society, especially as the Committee were not unanimous upon the matter. Of course, the wish of all the parties was that they should retain the power of promoting a scheme of education for the purpose of advancing the science of pharmacy in its higher and better sense, not merely a system of instruction which would probably produce the best commercial results; because it was obvious that what might pay the professors best would be simply to pass as many young men as possible through the school in such a way as to pass the examinations of the Society. The Council, however, would, he thought, agree that that was not at all desirable, the end to be aimed at being rather a high standard of education than success in passing students through their examinations. He did not for one moment suggest that the professors did not agree in that view of the object of the school, but the question was whether sufficient guarantees had been taken to insure the supremacy of that idea. It rather appeared to him that the publication under the authority of the Council of such a syllabus as the one laid before them would tend to attract young men to the school with the idea of passing their examinations rather than for the purpose of obtaining real scientific knowledge. That was why it was opposed by some members of the Committee who did not consider such a course consistent with the honour and position of the Society. As now presented, however, the prospectus was much improved to what it was when it first came before the Committee, and he did not see the objections to it now that he did at first. Appended to it, however, there was a list of names of all those who had gained prizes in connection with the school. He did not think it at all desirable to publish such a list, seeing that it would induce other parties to publish similar lists in rivalry, and thus a complexion would be given to the matter which was not at all desirable. There were one or two other points which would have to be discussed, namely, whether the library and reading-room should be open to all students attending the classes whether connected with the Society or not; but he thought the first thing to be decided was whether any prospectus at all should be published.

Mr. MACKAY agreed with Mr. Williams, and said there appeared to him to be three main points to be taken into consideration; first, whether such a syllabus should be published at all with the authority of the Council; secondly, whether or not the list of prize students should accompany it; and, thirdly, whether all students should be admitted to library and museum. Now, on the first point, considering that the Council had already decided on a change of a very sweeping character with regard to the School of Pharmacy, a change now about to be inaugurated, and one which would last certainly a year, he thought it would be only fair to themselves, to the Society, and to the professors, to issue some such pros

pectus at the commencement of this new experiment, though he apprehended the Council would still retain the power of changing the *modus operandi* of the lectures hereafter if it seemed desirable. The prospectus would put not only those connected with the Society, but all chemists and druggists, in a position to understand what the Council had done. It was not their province to speculate as to what might be the ultimate result of the change. The reducing a ten months' session to five, might have the effect that many young men who had not come up for the longer period would find it comparatively easy to spend five months in London, and in that way get some good and solid addition to their pharmaceutical knowledge; therefore, while he was not prepared to say what might be done in future years, he would move—

"That a circular containing a general description of the school of pharmacy be issued to pharmaceutical chemists and chemists and druggists generally throughout the country, by authority of the Council, and at the expense of the Society, prior to the opening of the ensuing session."

Mr. SAVAGE seconded the resolution.

Mr. SCHACHT said the resolution as proposed did not imply that there was to be any statement prefixed to the prospectus similar to that now accompanying it, stating the Society's views upon the matter.

Mr. HAMPSON said the resolution was general, and it would be quite competent to the Council to make verbal alterations afterwards.

After some further conversation, Mr. Betty moved that the circular as printed be taken into consideration. This was seconded by Mr. Urwick and agreed to.

The VICE-PRESIDENT said one or two verbal alterations in the opening letter had suggested themselves to him.

Mr. SCHACHT said the letter did not make any reference to the scheme which followed it; there was no sequence in it.

Mr. BETTY said that arose from their having to adopt a letter drawn up by other persons. It was really written by the professors, who thought it would be advisable to have something of that sort to introduce the syllabus. The Committee had curtailed it to some extent, and they must not be supposed to criticise it too keenly. If, however, any verbal alterations could be suggested to improve it, there could be no possible objection to accepting them. He originally objected to publish it at all, but that having been carried, they must do the best they could with it.

Mr. SHAW said the issue of the prospectus did not necessarily include the accompanying letter.

Mr. WILLIAMS said he would move that the letter be not published, inasmuch as it really committed the Council to a course of instruction which might possibly not turn out exactly what they desired.

Mr. ATHERTON having seconded the motion,

Mr. MACKAY suggested that they had better first decide on the broad principle whether any letter or not should accompany the syllabus.

Mr. WILLIAMS suggested that this was a matter which really ought to be discussed in Committee, and that the reporter should be requested to withdraw.

Mr. SCHACHT said he should object to that.

Mr. BETTY said there was no objection to another letter being drawn up.

Mr. SANDFORD said they were now about to pass over a school which had existed for thirty years to the professors, endowing their chairs, and calling them the professors of the Society. If they wished to keep up the high character of the school, it would appear to be a very ungenerous act to launch it forth without one single word of recommendation. He thought there should be some authoritative introduction of the school by the Council.

Mr. MACKAY said he was prepared to move that a letter accompany the syllabus.

Mr. SCHACHT said it was important that the letter proposed to be sent should be before them.

The VICE-PRESIDENT proposed that the letter already printed, with one or two slight verbal alterations, be issued.

Mr. ROBBINS supported the proposition.

Mr. SCHACHT said they were about introducing a most important change, and he could not see that this letter was at all a proper introduction to the matter. He considered that the object of the founders of the Society was to establish such a system of instruction as should form a standard in pharmacy, and it was because he believed that standard was about to be lowered that he regretted the change. This change however was now an accomplished fact, and he did not intend to say any more about it; but it was necessary to state plainly what the change was, so that all might clearly understand it. Here he thought the letter was deficient, as no allusion was made to the great changes which were now being introduced. He would therefore move as an amendment:—

"That the letter to accompany the Syllabus of the School of Pharmacy be referred back for reconsideration to the Library, Museum, and Laboratory Committee."

After some further discussion the amendment, which was seconded by Mr. Savage, was negatived, but in order to meet if possible the views of those who were dissatisfied with the wording of the letter, the Vice-President and Mr. Betty were requested to withdraw into another room and see if they could suggest any amendment. On their return, the letter as amended was approved, and a resolution passed authorizing its circulation together with the prospectus. [This document is not inserted here, as it would occupy much space, and it will be in the hands of all the members shortly.]

Mr. URWICK desired to raise a question relative to the prize regulations, namely, whether all students should be eligible to compete for the prizes, although not connected with the Society as associates or students. They might have young men attending the classes who were devoting their whole time to the study of scientific botany or chemistry, and it hardly seemed fair that they should be allowed to compete with others who might be engaged in business.

Mr. SANDFORD remarked that it was very difficult to draw the line so as to place all competitors on perfectly equal terms. Some two years ago an extra medal was awarded to a student not connected with the Society, because it was not clearly defined who were eligible.

Mr. MACKAY said they ought not to lessen the attractions of the School of Pharmacy by excluding any one from the prize competition. At the same time he should like to see a special prize offered to first year's students only, because it was quite possible that young men who had studied or attended courses of lectures in the country might come up year after year and carry off the bronze medal from those who could only attend the classes of their own professors. He would suggest that those who had previously attended lectures, either at this or any other school, should be ineligible for the bronze sessional prizes.

Mr. WILLIAMS thought they had no right to handicap the students in that way. They simply offered such and such prizes to the most able students, and they could not disqualify those who had attained their knowledge in a particular way.

Mr. RADLEY remarked that many of the country schools were not so efficient as the one in Bloomsbury Square, and it would be unfair therefore to disqualify young men who had attended them.

Mr. BAYNES added that such a regulation would act very prejudicially on the provincial schools.

Mr. GREENISH proposed, and Mr. RADLEY seconded the proposition—

"That a bronze medal be given to the second prizeman of the ten months' or Sessional Course in Chemistry and Pharmacy, and Botany, and Materia Medica."

The motion was negatived.

A long discussion next ensued with regard to the proposed regulation stating that the library, museum, and reading-room of the Society would be open to all students in the School of Pharmacy.

Mr. WILLIAMS objected to the clause. The fees were now the same for all students attending the lectures, and it would be only right that those who wished to avail themselves of the advantages of the Society should pay a small fee of 10*s.* 6*d.* per annum. If it were not so, the Society would lose £500 a-year.

Mr. MACKAY doubted the last statement. He should like to know how the Society would lose that sum by admitting all the students to the library and museum.

Mr. BETTY said he could prove it. This was an important question, and he hoped it would be thoroughly discussed. When the Society had been so liberal to the school, endowing the professors' chairs, granting the free use of the laboratory and lecture room, and so on, it was very hard that it should be also called upon to perform this crucial experiment, to prove whether or no it would sacrifice £500 a year. It simply resolved itself into this, if some inducement were not held out to young men to join the Society, more particularly at the commencement of their career, the position of the Society must be endangered, seeing that simple registration now gave a man the right to carry on business? The financial position of the Society was the keystone of its success, and they must be cautious in meddling with it. For the session 1872-3 there were 113 students, of whom only 25 were not connected with the Society, and at least one-third of them afterwards joined, leaving only 17 outside students; was it then worth while to run such a risk for the sake of 17 students, or to attempt to loosen any bond which still attached young men to the Society? If students unconnected with the Society were absolutely denied admission to the library and museum, they would be only doing what was done in every medical school in London, but he did not propose any such restriction as that. He simply objected to giving such men the *right* to the advantages of the Society, but should be quite willing to afford them every facility, as a matter of courtesy, on application to the Secretary. What was given away lavishly was always lightly valued, but the young man who entered the museum by the courtesy of the Society would think a great deal of the honour or privilege accorded him. Again, a person who paid four guineas for perpetual admission to the lectures would, according to this regulation, be entitled to walk in and out of the library or museum whenever he pleased for the term of his natural life, but he doubted the power of a Council sitting only from year to year to grant such a privilege for absolutely no consideration. The Committee were unanimous in their opinion that this recommendation, which came from the professors, should not be agreed to, and he hoped the Council would support the Committee.

Mr. MACKAY still failed to see how the Society would lose £500 a-year. The whole thing was now changed, and whereas hitherto students had joined for the sake of attending the lectures at half-fees, the simple right to use the library and museum was now relied upon to bring an immense number into the ranks of the Society. However, if it were understood and published that admission would be granted as a matter of courtesy on application to the Secretary, he had no objection. He believed young men would join the Society from a feeling that it was an honour and privilege to be allowed to do so, and the PHARMACEUTICAL JOURNAL also was an inducement. He did not think, therefore, anything would be lost by liberality in this matter.

Mr. ROBBINS said it was never intended to exclude young men altogether. The matter had been fully discussed in Committee, and the only question was whether or not the privilege should be granted without any condition. They might find in a few years many persons coming to avail themselves of the lectures and laboratory instruction who had no connection with the Society or the trade whatever, and then the members might very naturally complain of the school being supported at their expense.

Mr. BAYNES said they had already settled the principle that they would make no difference between the students who were and who were not connected with the Society.

Mr. HAMPSON was sorry to oppose Mr. Betty in this matter, but he was convinced that the safest policy was that of liberality in this matter. He could not think that the Society would lose anything in the long run by it, or, if so, it would be a very small sum. On the other hand, it would save a great deal of trouble to have no distinctions between the different students.

Mr. GREENISH had advocated a liberal policy in Committee and must still continue to do so.

After some further conversation it was unanimously decided to pass the regulation in the following form :—

"The Library, Reading-room, and Museum of the Pharmaceutical Society of Great Britain are open to all students connected with the Society. Other students may obtain orders for admission thereto by application to the Secretary."

The proposition to append to the syllabus the list of prizemen was then negatived without a division, and resolutions were passed stating the conditions on which the professors were to have the use of the apparatus, etc., belonging to the Society.

It was then resolved—

"That the prospectus of the School of Pharmacy, as now amended, be issued, and a copy sent to each registered chemist and druggist. Such issue, however, is not in any way to be considered as a precedent."

GENERAL PURPOSES.

The Report of the General Purposes Committee on the Reports of the Board of Examiners and of the Professors on the competition for the Jacob Bell Scholarships and Sessional Prizes was received, and the following awards made :—

JACOB BELL MEMORIAL SCHOLARSHIPS.

The Board reported that *one* candidate presented himself for the Senior Scholarship, and *eight* for the Junior.

On the recommendation of the Board it was resolved—

" That the Senior Scholarship be awarded to

Sydney Plowman,

and the Junior Scholarship to

Edmund John Henry Thring,

with free laboratory instruction and materials for the Session 1873-74, in the School of Pharmacy, and free admission for the same period to the lectures on Chemistry and Pharmacy, Botany and Materia Medica, and Systematic and Practical Botany."

SESSIONAL PRIZES.*

The Board reported, that during the past Session *sixty-three* candidates had passed the Minor Examination, and *nineteen* the Major Examination in Honours, of whom *fourteen* competed for the prize of Books, and *five* for the Pereira Medal.

On the recommendation of the Committee it was resolved—" That the

Pereira Medal

be awarded to

Sydney Plowman,

and that the

Prize of Books

be awarded to

Walter Tearle.

On the Reports of the Professors on the results of the competition for the Prizes offered by the Council, the Committee recommended, and it was

Resolved—" That the following awards be made."

---

* The Sessional Prizes and Certificates will be distributed at the Evening Meeting on the 1st October next. Successful candidates will be expected to attend. An address to the students will be delivered by Mr. G. W. Sandford, of London. Ladies are invited to be present.

Chemistry and Pharmacy.

Silver Council Medal .....Sydney Plowman.
Certificates of Merit ... { Edward Lawrance Cleaver. / Frederick Bascombe.

Botany and Materia Medica.

Silver Council Medal .....Sydney Plowman.
Bronze Council Medal ...Edward Lawrance Cleaver.
Certificate of Honour .....Frederick Bascombe.
Certificates of Merit..... { Arthur Pearson Luff. / Henry George Greenish. / Arthur Compton.

Practical Chemistry.

Silver Council Medal .....Sydney Plowman.
Bronze Council Medal ...Frederick Bascombe.
Certificates of Honour... { Charles Alexander Blake. / Frederick Wm. Fletcher. / Thomas Edward Greenish.
Certificates of Merit ... { George Rimmington. / Alexander Wood.

Botanical Prize.

Upon the Report of the Professor of Botany, and the recommendation of the Committee, the following awards were made—

Silver Medal .....John Henry Bibbings.
Certificate of Honour ... ..Conrad William Wright.

Mr. SCHACHT drew attention to the remarkable fact that so small a number of the individuals attending the classes presented themselves for examination. The Secretary had kindly furnished him with the returns, showing that in the chemistry and pharmacy classes the number of students had been, last year, 82, and only 5 examined; the previous year 75, and 15 examined; the year before 76, and 11 examined. In Botany and Materia Medica, last year 107, and 9 examined; the year before 113, and 16 examined; the year before that 102, and 13 examined. This was certainly not very creditable, and it was very desirable it should be altered if possible. In Bristol they would consider it a great reflection on the management of the school if such a result occurred; but there, although the classes were not numerous they were enthusiastic, and 18 or 19 out of 20 or 21 attending the chemistry class went in for examination. The botany class was small, but with one exception all the students were examined and passed with more or less honour. Possibly the reason of so few going in for the examination might be that knowing the superiority of Mr. Plowman, and being able to pick out the second-prize men with tolerable accuracy, the students felt it useless to compete and were thus discouraged from presenting themselves. To meet that difficulty it might be worthy of consideration whether the plan adopted at Bristol should not be followed, of giving a small prize, a book, or something of that kind, to every man who passed in the first class. He suggested that the whole arrangements with regard to prizes should at some future time be considered by a committee with a view to increase the number of competitors.

Mr. GREENISH said that this subject had for some time occupied his attention, and it was within his knowledge that many of the younger pupils attending Professor Bentley's lectures were quite disheartened with regard to the prizes, remarking that it would be useless for them to compete with students who, having passed their Minor and Major examinations, had proved that they already possessed competent botanical knowledge for these two ordeals. He would confine the Bronze Medal for the five months' course essentially to first year's young men, and if a student had attended a course of lectures previously, either in the Metropolis or elsewhere, attendance in that course shall render him ineligible to compete, on the same principle that it would operate against a student who had attended one course at Bloomsbury Square. The subject was too important to be settled off-hand, and he hoped it would be remitted to a committee for consideration. Their object should be to encourage young men to present themselves in the classes as early as possible, but under the present arrangements the inducement was rather to wait until they were a year or two older, when they would have a better chance of gaining the prizes. He hoped the Council would also consider the question of calling in independent professors in the various subjects to examine the students, of course putting into their hands the syllabus of the lectures upon which they would found their examination. And would urge on the Council, that every sessional prize given by the Pharmaceutical Society, whether it be for Chemistry and Pharmacy, Botany, or Practical Chemistry in the Laboratory, should be the result of a report from special examiners on the different subjects.

Mr. STODDART thought the last suggestion a very good one, and desired to add to what had been said by Mr. Schacht, that young men in the country were in the habit of noticing the small number of Bloomsbury Square students who took prizes, and drawing unfavourable comparisons.

Mr. GREENISH said that at the last competition for the Botanical Prize, there were eight candidates, of whom two being Bell scholars, three had passed their Major examination. In Professor Redwood's class there were five competitors, of whom three had passed the Major.

Mr. BAYNES said that in Leeds a very fair proportion of students went in for examination, but they were divided into two classes, and those who had been upwards of three years in the business were not allowed to compete with juniors.

Mr. MACKAY said it was scarcely fair to a young man that he should have to compete with one who had attended three or four courses of lectures previously. The prize regulations now provided that those who had done so should be ineligible.

Mr. SHAW said that only referred to the five months' sessional prizes, and did not refer to classes or lectures elsewhere. It was a very good proviso so far as it went, but a young man might attend lectures in Liverpool and then come up to London and very probably carry off the prizes. This seemed unfair, but he did not see how it could be avoided.

The SECRETARY said the Board of Examiners had arranged, subject to the approval of the Board in Scotland, that in future the names of successful candidates in the

Erratum.—On p. 14, col. ii., line 13 from the top, *omit the asterisk* preceding "Galloway, George Ross, Inverness."

Preliminary examination should be published in two divisions, the first consisting of those who had obtained a certain proportion of marks, and the second of those who did not come up to that standard, though they were entitled to pass. This it was hoped would prove a stimulus to young men to exert themselves. He had written to the Board in Scotland on the subject, and they cordially agreed n the suggestion.

The Board also reported that they found it impracticable to conduct the examinations for the Pereira Medal and the Prize of Books satisfactorily in the country, and they therefore suggested that in future candidates should be required to attend either in London or Edinburgh.

Mr. SANDFORD said they could not discuss that question at so late an hour, but he should be prepared to propose a motion on the subject at the October meeting of the Council, based on the suggestions of the Board of Examiners.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

ON THE ENERGIES OF THE IMPONDERABLES, WITH ESPECIAL REFERENCE TO THE MEASUREMENT AND UTILIZATION OF THEM.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture III.

On the Energy of Vitality, with especial reference to the Measurement and Utilization of it.

The "Energy of Vitality" is a manifestation by motion of the unknown and unseen power which is associated with life—indeed that which may (perhaps) be said to constitute life itself. This vital power (some may call it force) is presented to our notice in two forms, the animal and the vegetable; hence the two sciences of zoology and botany.

In seeds, in eggs, in frozen toads, in suspended animation, in hybernating animals, are examples of the potential energy of vitality. The power is there, but it awaits those surroundings which may convert this potential or dormant energy into kinetic or active energy. So long as a body lives, it possesses kinetic energy; it has power to move. Such a power is not possessed by any dead body, although from external sources it may be introduced into one.

The energy of vitality is converted into the energy of affinity in the assimilation of food, into that of electricity in muscles and muscular action, into that of light as in glow-worms and certain fishes, and into that of heat as in warmth of the body. One peculiarity of this vital power is the ability to seize on that which is material, and to adapt or select therefrom whatever may be suited for its special purpose. The earliest or most elementary of the animal forms in which this vital power of adaptation displays itself is called a protoplasmic germ. This germ, or, as it may be described, this microscopical cell, if placed in congenial surroundings, manifests an energy of growth or reproduction which adapts these surroundings in a way and under an influencing power quite unknown to us. The power of gravity enclasps all matter, the power of vitality exercises a selectiveness from matter; gravity influences all matter but changes the shape of none; vitality changes the form of all it influences. For example: the process of fermentation is one in which a minute molecule possessed of a vital power can communicate a similar power to another molecule, this again to another, in each case appropriating or attaching the molecule to itself for a while, and so producing a rapidity of what we call growth, which seems almost as a process of crystallization when the water of solution is being evaporated.

Between the development of a crystal, however, and of life, there is this marked difference. A crystal grows by appropriating *like* molecules, and deals with them according to laws unknown to us; a body having vitality not only appropriates various molecules, but re-combines, re-forms, and rejects. This the crystal cannot do. The growth of a crystal is a phenomenon in physics—the growth of an animal is a phenomenon in chemistry. In both cases the powers of reproduction or enlargement are mysterious. Although under the influence of vitality many forms of matter are produced, yet the crystalline one never appears; as soon, however, as the excretory process is completed, or the vital power is withdrawn, then commences work of a crystalline character.

How vitality is transferred, or what it is, or in what contained, how nourished, or how destroyed, we know not. With the energy of vitality, as manifested in the processes of reproduction and growth, we are not this evening required to deal. Within that frame thus mysteriously developed, there are combinations of mechanical and chemical apparatus fulfilling conditions with which we are deeply concerned. This apparatus, however, does not from year to year retain the same power. Owing to the vital action, the apparatus with which we are to deal, whilst in incessant fluctuating change, yet attains a climax, then slowly subsides, then follows that phenomenon, even more mysterious (if possible) than any other of the vital ones, viz., their sudden cessation, which we call death. Neither in its earliest development nor in its mysterious cessation are those phenomena presented which are consequent upon energies we can either measure or utilize. Whence that comes which imparts vital energy, and whither it goes, are problems rather for human faith than human understanding. When an engineer has to estimate the power of a steam-engine, he does not ask of its early formation and past biography, nor does he speculate upon its future uselessness; he regards it as he finds it. So with animal vitality. We have to regard the animal as an engine, and in lieu of steam we have vitality. The engine is constructed so as to be utilized by the power of vitality, as that other engine is by the power of heat. Animals are much more economical engines than any man has made. The Creator's work is still far in advance of the work of the creature. Count Rumford showed that the amount of work done by a horse is much greater than could be obtained by employing its food as fuel for a steam-engine.

Note, also, what an economical conserving of energy there is in hybernating animals, which store up in summer that which they expend in winter in maintaining animal heat. To those who intend to offer the results of their ingenuity in the economizing of fuel for the gold medals and fifty pound prizes offered by this Society, in December next, may be commended for especial study this property of hybernating animals. Your lecturer has no authority to make the statement, but he can with some confidence assure them that, if successful in teaching us to economize fuel as they do, they will win not only the prizes of the Society, but also the thanks of the nation.

An animal body is, indeed, a wonderful self-acting and self-regulating machine. It is a structure composed of moveable parts, yet firm, and at the same time locomotive. Its hinges are well fitted with self-acting lubricators; its furnace supplies itself with fuel, and can regulate the supply to the demand; its telegraphic communications are extensive, rapid, and need no superintendence; in its laboratory are performed experiments in the very highest departments of organic chemistry.

There are two forms of vital energy which have so much of a kinetic character that we may utilize them. Indeed, one form is self-utilized; vitality seems to have engaged its exclusive services, and whether the animal be waking or sleeping, vitality claims all those services from

* Cantor Lecture, delivered February 17.

the machinery of the body which are rendered in the circulation of the blood, the digestion of the food, the operation of breathing, the propelling action of the heart. These all are motions resulting from some impressed laws, which have hitherto been hidden from our powers of research. That they continue, and that we are unconscious of them; that we cannot stop them, and even if we could by any means measure them, that we could not transfer them to any other purpose is clear without demonstration.

Therefore, since for scientific physiology the study of this form of vital energy is of paramount importance, it very naturally and properly would rank as one of the chief subjects for medical students. Indeed, the minds of physicians are necessarily often guided by circumstances to meditate upon its operation, and they are called upon to accelerate its action here and to retard it elsewhere. Hence the observant anatomist becomes, if not a kinetic, at least a static mechanician; the thoughtful physician reflects and harmonizes the external evidences of these internal energies, and combining the events which fall under his notice, he deduces conclusions which link the laws of vital energies in their operations with those of the other imponderable influences which pervade all the universe.

Under such circumstances as these Dr. Mayer of Heilbron, in Germany, was led to conclusions in respect to the relations between heat and work which the further investigations of others by very different processes—processes in which the energy of vitality does not enter—have established as correct.

There is another form of vital energy similar to this over which we have control, and which we employ as we please within the limits which the vital power and the construction of the apparatus through which it acts permit. This is that to which we usually give the name of "muscular energy."

The qualifying words, "within the limits," are essential, for the limit is in each case a hard and fast line, and we cannot overstep it. This limit is perhaps more admirably arranged in the animal frame than in any construction of man's devising. Although there are hundreds of muscles, yet their names, shapes, and businesses are very varied. Throughout all these changes one remarkable principle applies: every muscle is exactly adapted to the work it is likely to be called upon to perform.

There is a principle in mathematical science called the "Principle of least action." It may be explained thus—Given an object to be accomplished, then "the principle of least action" should teach how, with the smallest quantity of material and with the least expenditure of power, that object would be done. The more the muscular system is examined under this guidance, the more we are lost in wonder how exactly every portion of the body is suited for its specific work, and for the amount of work it is likely to be called upon to discharge, and more curious still, how (in special cases) the muscle may develop in order to meet certain requirements, as, for example, the muscles in the arms of a smith, as well as other muscles. And, further, how perfectly these muscles are varied in form and construction so as to meet the requirements of their respective occupations, and, if called upon by prospective emergencies, to be ready for more than ordinary exertion. Certain muscles are so prepared for extraordinary exertion, and then relapse into their normal state, thus strictly carrying out the "principle of least action."

As an illustration of this principle of least action, look at that most extraordinary muscle of all in the animal economy—the heart. Although certain features of its action should come under notice at a later portion of the evening, yet it bears upon the present subject, in that it is a bundle of small muscular fibres. There are probably more than a million of them, complex in their arrangements and perplexingly curious in their relative and combined actions, and yet this, regarded as one muscle, weighs on an average, in man, only 9·39 ozs. Its screw-like construction is such that at each action it propels forward the whole of its contents, leaving no filled-in corners. It has power to propel these contents to the vessels in the extremities of the body. Were not this muscle "up to the mark," these extremities would die for want of nourishment; if "beyond the mark," then some of the vessels along which the blood is driven might be burst in consequence of a liquid pressure greater than that they were calculated to sustain.

The balances required are perfect, and this little muscle of 9·39 ozs. sends life to all parts of the body—by day and by night—from birth to death. Now, the work it is continually performing is as though it lifted its own weight through nearly twenty thousand feet in an hour. The height of St. Paul's Cathedral, from the ground to the top of the cross, is 404 feet, therefore the heart could place itself on the top of St. Paul's Cathedral nearly fifty times in one hour. Let a man consider how often in an hour he could ascend, even on the assumption that he was never tired, and then he may obtain an idea how much more work his heart is doing than he can do. Put otherwise, the heart, regarded as we regard a locomotive, can raise itself through a vertical height of nearly four miles in one hour. The most powerful locomotives, built specially for the ascent of gradients, can only raise their own weight through about half-a-mile, or one-eighth of that which the heart can do. The directors of an Alpine railway (that from Trieste to Vienna) offered a prize for the locomotive which could lift its own weight through the greatest height in one hour. It was allotted to the locomotive (Bavaria), which lifted its own weight in one hour through 2,700 feet, or about half-a-mile. The experiment was simply made by means of inclines on railway lines; the subject this evening does not warrant a larger reference to this matter.

By no contrivance can we make a machine which shall bear such proportions between size and work as the heart does. Here is a little machine, weighing say ten ounces, put in action and worked by vitality, as a steam-engine is worked by heat; and this little engine, which we could easily put in our pockets, can lift itself twenty thousand feet high in an hour. There must indeed have been a master-mind that designed and executed the manufacture of the animal machinery, and so perfectly carried out the "principle of least action."

By careful anatomical and mathematical investigations similar to those which are to be alluded to near the close of this lecture, the daily work of the heart can be shown to be one hundred-and-twenty-four foot tons. This is nearly one-third of the daily labouring force of the whole body.

This muscle of the heart is not only capable of exerting this wonderful power through the action of the vital force, but it seems not to need any rest, and yet it does not wear out, for the muscles in the heart of an old man are apparently as sound and healthy and fit for continuous work as those in the heart of a youth. How through life they have been so maintained, how as other muscles in the frame lose somewhat of energetic power, yet these fail not, is one of the many perplexities to science. That muscular power is, as we may say, restored by rest and food, any one who cares to think upon what he experiences and witnesses will readily admit; indeed, further, the nature of the work and the character of the food must be suited each to the other. Now the muscles of the heart never rest. The variation in their energy is within very narrow limits, so narrow that we may say that any series of observations however long continued and whenever taken—as a series—would always average the same result. Hence the inference that in the animal economy these muscles possess the power (peculiar probably to themselves) of at one and the same time parting with energy and restoring it. This ever-balanced and ever-exerted energy, this actual external utilization of energy, coupled with a perfectly self-recuperative operation, is what the searcher for perpetual motion, like

the asymptote to the hyperbola, is ever approaching but never attaining.

If men can find out how these particular muscles are exempted from the laws of muscle, with which laws these Cantor Lectures are mainly concerned, they will have advanced further in solving the problem of perpetual motion, which some enthusiast in every generation pursues with commendable but hitherto unsuccessful zeal.

(*To be continued.*)

Parliamentary and Law Proceedings.

The Glasgow Butter Case.

At the fortnightly meeting of the Glasgow Police Board on the 14th July, the minutes of the Health Committee were read, in which a report of the Sanitary Inspector was referred to stating that, as directed at the meeting held on 26th May last, he had forwarded to Drs. Anderson and Macadam one half of each of the samples of butter produced in the case against Daniel Gibson, and submitting the following reports by these gentlemen on their analyses, and also a memorandum by Professor Thorpe :—

"Report on the analysis of two samples of salt butter—marked No. 19, 8th April, 1873, and No. 26, 9th April, 1873—sent by Kenneth M'Leod, Esq., Sanitary Inspector.

"I have carefully analysed two samples of butter contained in two small tin boxes, the lids of which were pierced with small holes, and find their composition to be as follows :—

	No. 19.	No. 26.
Water	6·72	6·10
Curdy matter	1·01	0·97
Salt	11·57	15·06
Fats	80·70	75·87
	100·00	100·00*

Both these samples are undoubtedly of very inferior quality. Their smell is rancid, their taste unpleasant, and their appearance to the eye very far from satisfactory. They are entirely free from starchy matter, such as mashed potatoes or any similar vegetable substance. The quantity of water which they contain is not very considerable, and probably not in excess of what is to be found in average samples of salt butter. It is to be observed, however, that these samples have now been kept for about two months, and if during the whole of that time they have been preserved in the boxes in which I received them, there can be little doubt that the percentage of water must now be considerably less than it originally was. The proportion of salt in both samples is decidedly much in excess of that found in average samples of good salt butter. I believe the ordinary practice is to mix one ounce of salt to each pound of butter, which quantity amounts to 5·88 per cent. of the mixtures. The salt, however, is too generally used merely by guess, so that considerable variations may be expected in the percentage found in different samples of genuine butter, and I notice that Dr. Hassall, who has examined a large number of genuine butters, gives 8·24 as the largest quantity found. There is no doubt that the use of an excessive quantity of salt is as much an adulteration as that of a deleterious or absolutely poisonous substance, but as there is no authoritative declaration of the proper quantity of salt which a genuine butter should contain, it is impossible to tell where its legitimate use ends and adulteration commences ; or at least, it must be a matter of individual opinion. As an individual, I think the quantity present in both samples is clearly above the legitimate quantity, which should not, in my opinion, exceed 7 or 8 per cent., and I should, therefore, describe both these samples as adulterated, though, of course, not to a large extent.

"Thomas Anderson, M.D.

"University of Glasgow,
"21st June, 1873."

"Analytical Laboratory, Surgeons' Hall,
"Edinburgh, 14th June, 1873.

"I hereby certify that I have carefully analysed two samples of butter forwarded to me by the local authority of Glasgow, through Mr. Kenneth M. Macleod, on the 4th instant. These samples were each wrapped up in paper and enclosed in tin canisters, which were covered with paper and sealed. They were respectively labelled "19 (8th April, 1873)," and "26 (9th April, 1873)." The analysis of each sample separately gave the following results :—

	"19 (8th April, 1873)."	"26 (9th April, 1873)."
"Butter	79·56	75·17
Curd of milk	0·91	0·94
Chloride of sodium (common salt)	11·01	19·16
Water	8·52	4·73
	100·00	100·00

"These results prove that the samples of butter under examination are of genuine quality as 'salt' butter, and contain less water and not more common salt than which are found in the average samples of genuine salt butter. No potatoes, starch, or other adulterant were present.

"Stevenson Macadam, Ph.D., F.R.S.E., F.C.S.,
"Lecturer in Chemistry.

"*Note.*—The amount of curd present in butter varies much according to the care taken in the preparation of the butter. It is simply the casein or cheese matter of the milk which has not been thoroughly separated from butter, and in the bad butter the quantity approaches but does not exceed one per cent. As the samples under examination contain respectively 0·91 and 0·94 per cent., the amount of curd may be regarded as the nominal quantity. The proportion of common salt added to butter for its preservation from rancidity, ranges from 5 to 25 per cent. in salt butters. There is no fixed proportion. The respective quantities of 11 and 19 per cent. found in the butters '19' and '26' are, therefore, not excessive. The amount of moisture in the samples is below the average proportion in salt butter, which I have determined to be 10 per cent. The smallness of the percentage, especially in No. 26, is probably due to absorption by the paper in which the butter was wrapped up, and possibly to exposure to the air. The absence of farinaceous matters, such as potatoes, raw or boiled, and starch in the samples "19" and "26" was placed beyond doubt by microscopic, as well as by chemical tests. When potatoes are present the cells are recognized under the microscope, whilst the starch is detected by the iodine tests; and where the potato starch is alone present, the chemical test at once identifies it. I have never failed to indicate the presence of the adulterants, where only 2 per cent. of the potatoes or starch were added to butter.

"S. M."

"Andersonian University, Glasgow,
"July 7, 1873.

"To the Hon. the Lord Provost and Members of the
"Police Board.

"Gentlemen,—Mr. Macleod, the Sanitary Inspector,

* The figures here given are quoted from the *Glasgow Herald*, but there appears to be some error, as their total amount is only 98·00.

has forwarded to me, through Mr. Paterson, copies of the reports of Professor Anderson and of Dr. Stevenson Macadam on the nature of the butter which was analysed in my laboratary in connection with the recent prosecutions under the Adulteration of Food, etc., Act. Considerable discrepancies are likely enough to occur in the numerical results of the analysis of butter from the heterogeneous nature of the matter analysed and from the impossibility of properly sampling and mixing it. Thus no constituent of butter is more easily and more accurately determined than the salt, and yet the amount of this substance in the same butter, as determined by Drs. Anderson, Macadam, and Wallace, is as follows :—Salt—Professor Anderson, 15·067 ; Dr. Macadam, 19·167 ; Dr. Wallace, 13·57. The portion of the sample of the same butter analysed by me contained only a trace of water (not more than one per cent.) It contained, however, a considerable quantity of a white substance which was distributed very irregularly throughout the mass. (See report of case in *Herald* of April 23.) I purposely selected the portion of the sample left by the inspector in which this matter seemed present in largest quantity, as I wished to ascertain its nature after the separation of the fatty matter. In my report to the Sanitary Inspector I described it as made up of curdy and starchy matter. It was impossible to estimate the relative quantity of the two substances by any exact quantitative process. Some misconception has arisen as to what I actually said respecting the nature of the white substance. I distinctly stated when under examination that I was unable to satisfy myself of the exact nature, and, further, that I could not swear whether it consisted of potatoes. (See report of evidence in *Herald* of April 23.) No mention was made of potatoes in my report to the Sanitary Inspector. I was asked (I believe by the bench) to state the manner in which curdy or starchy matter could have been introduced. I quoted the evidence of the Mayor of Cork (Sir John Gordon) given before the Parliamentary Committee on Adulteration, as to the addition of curds; and I mentioned, among other methods by which starch could be introduced into butter, that the addition of potatoes boiled until they acquired a pulpy or gelatinous consistency was a form of adulteration extensively practised on butter—the manner of effecting the admixture has been described to me by butter merchants of this city. I quite concur with the remarks of Professor Anderson respecting the use of excessive quantities of salt, although I do not go quite so far as Professor Calvert, who, in evidence given before the Parliamentary Committee above referred to, stated that butter ought not to contain more than $2\frac{1}{2}$ per cent. of salt. A large quantity of salt is frequently added to butter which is already unsuited for food, with the futile object of arresting its decomposition or of disguising its badness. Dr. Macadam is of opinion that butter may contain 25 per cent. of salt and yet be considered of good quality. I have examined many samples of butter, some of them of very doubtful character, but I never met with one to which the maker had thought fit to add salt to the extent of one-fourth of the weight ; nor among the analyses of butter which had been published have I been able to find an example in which the amount of salt was stated at more than 14 per cent.—I have the honour to be, gentlemen, your obedient servant,

"T. E. THORPE."

Mr. Ure moved the adoption of the minutes. The members would notice that the minutes were burdened with very long reports upon the analyses of the butter on which the case recently before the Police Court was founded. They would observe that the two first-named chemists pretty much agreed upon the analyses, and disagreed with Professor Thorpe, but that gentleman gave a memorandum of explanation why he should come to an opposite conclusion.

Mr. Osborne thought as a member of the Board, of the Health Committee, and of the trade, it was unfortunate that the case had fallen through in the way it had done. He was of opinion that it would have been much better had Dr. Thorpe's report been unwritten, or, as he wished, unread. Dr. Thorpe had there mentioned that some members of the butter trade in Glasgow had told him that some adulteration went on in the city ; the members of the butter trade did not know that, and were very desirous to discover it. He thought that the Board and the Health Committee must have felt very great sorrow at the break-down of the first case that had followed upon the report of their analyst. Many people believed that butter was largely adulterated, but he did not share in the belief. It was a great mistake for any member of the community to suppose that all cheap butter was adulterated. There was no doubt that in the case in question, as the price indicated, the butter was inferior. To say that it was over salted, and therefore adulterated, was a mistake on the part of Dr. Anderson. Great difference of opinion existed as to what constituted oversalted butter. The action had been unfortunate, both as regarded the Health Committee, the analyst, and the individual who was the victim ; and it was, perhaps, most unfortunate for the poor man who was the victim of the prosecution. It was unfortunate for the Board that having appointed an analyst in whom they should have the utmost faith, he should have gone so carelessly about his work. He thought Dr. Thorpe must have gone carelessly about it, because the Board could not have appointed a man who was so incompetent as to give such an absurd analysis of an article. The reports of the two medical gentlemen, which had been read, were confirmed by Dr. Hassall, of London and another medical man in the city. The matter was very unfortunate for the victim of the prosecution—Gibson, who was a man in a humble trade, but who, he believed, was an honest man, who was dealing honestly, no doubt in inferior qualities, but by no means spurious butter. He sold butter deteriorated a little from age, but he was doing an honest trade. The butter was honest butter, made honestly by the manufacturers, though it had a little too much salt in it, and bought honestly, and being sold honestly by the retailer. In less than a fortnight after the trial of Gibson's case, he was obliged to close his shop, his customers having left him, and he lost very much indeed. Now, Gibson was a ratepayer—entitled to the protection of the Board, and it was hard that he should have suffered so much as he had done at the hands of the Board. The action had also been very unfortunate for Dr. Thorpe. To say that he should continue their analyst now, and think of raising other actions, would be a very great mistake indeed. He trusted Dr. Thorpe would have the good sense himself to retire, for he had no hesitation in saying that, if any other similar case was brought by Mr. Lang before the Police Court the public would have no faith in Dr. Thorpe.—*From the Glasgow Herald.*

PROSECUTION UNDER THE ADULTERATION ACT.

At Marylebone Police-court on Saturday last, Mr. Christopher Kirby, grocer, of 212, High Street, Camden Town, was charged on an adjourned summons before Mr. D'Eyncourt, under the 3rd section of the Adulteration of Food Act, with selling cocoa adulterated with cane-sugar, arrowroot, and sago. Mr. Cooper, solicitor, prosecuted on behalf of the Vestry of St. Pancras ; Mr. St. John Wontner, solicitor, defended.

Mr. Bartlett, analyst, gave evidence as to the properties of cocoa. He stated that the admixture of sugar, farina, etc., in the cocoa did not add to its solubility, and certainly not to its wholesomeness. The cocoa nib in its pure state would be an equally useful article for public consumption. The nib could be roasted and ground pure by the manufacturer, and sold in that state, and it would take no longer to prepare for drinking than any of the so-called soluble cocoas. He believed that a large quantity of the nib was purchased by the public—in fact, it would be cheaper for the poor man to buy pure cocoa, and if he de-

sired to do so, add the amount of starch and sugar he considered necessary. Dr. Stevenson deposed to the correctness of his certificate as the result of his analysis of these samples. Sugar was much in excess. These ingredients were not necessary for the solubility of the article. Doubtless they made it cheaper. He gave about three shillings a pound for his cocoa, which he considered would be cheaper as a beverage for a poor man to buy than the cocoas at 8*d.* or 1*s.* a pound. It would go further, and was richer in nutritive value.

Mr. J. Holm, a partner in the firm of Dunn and Hewett, the manufacturers of the cocoa in question, said that cocoa was not really soluble in anything, however it might be prepared, and, in point of fact, there was no such thing as soluble cocoa. In the cook's sense, it was soluble when mixed in a certain way with sugar and arrowroot, these substances having been previously prepared, and it then formed an emulsion. The pure cocoa, nib was very inflexible if taken in large quantities. This was the reason why people did not care to buy it. Cocoa powder, commonly called soluble cocoa, had been sold to the public for fifty or sixty years. He considered the most wholesome and digestible form of cocoa to be that mixed with sugar and arrowroot, though he declined to say in what proportion, as this would be entering into a question of recipes, which they could not give up to other cocoa manufacturers. In the month of May, in the present year, his firm sold 43 tons of soluble cocoa, and 10 tons of chocolate to one ton of pure cocoa nib, without any admixture, and merely deprived of the husk. They made these preparations of cocoa, not for the purpose of increasing weight or bulk, but for the purpose of manufacturing an article which would be generally accessible to all classes of the community.

Mr. Kennet M. Morris, a seed-merchant in the Borough, who had formerly been traveller in the service of Messrs. Dunn and Hewett, said that soluble cocoa had been known in the trade for many years.

Mr. D'Eyncourt said that it was clear that the object of the cocoa being mixed with the sugar and sago was not a fraudulent one, unless it were carried to excess. What would have to be shown was that there had been an adulteration beyond all good use for general purposes, and that the retailer knew it. The preparation had been sold for many years, and there was no fraud at all in selling that which had been recognized in the trade for fifty years as cocoa. He felt it would be impossible to convict in this case, therefore the summons would be dismissed.

Review.

"Medical Notes and Queries."

With this title a weekly journal, price one penny, has been started under the auspices of "a large staff of eminent medical authorities," as they call themselves in the "Introduction." These "authorities profess to supply a desideratum "long felt in every family circle" — "a medium for the interchange of experience and thought that must prove of priceless value to the professional man."

The publication has now reached its sixth number, and after a perusal of its contents we must express our unqualified disapproval, both of its design and its execution.

The professional man has already access to three or four weekly journals for "the interchange of experience and thought." He is, as a rule, connected with societies (such as the branch societies of the British Medical Association) before which he can propound any inquiry or ventilate any theory he may think fit. So far from being in want of a medium of communication with his fellows, he suffers from a plethora of such, and if proof were required of his contentment with the same, it would be his "conspicuous absence" from the columns of *Medical Notes and Queries.*

Indeed, the bulk of the periodical is compiled, not always intelligently or judiciously, and certainly not neatly, from its older contemporaries, lay as well as professional. In general, its "leading matter" is in point of freshness well-nigh a week behind that of the *British Medical Journal* or the *Lancet*, and in point of style and tone inferior to them in all respects. Excerpts from newspapers, comic and serious, fill up the columns not reserved for "correspondence and replies;" and from the noble impartiality of the borrowing fully bear out "our motto," badly given (p. 44) from Terence, "*nil humani alienum puto.*" But the really mischievous part of the publication lies in its correspondence. Patients, real or imaginary, unfold their ailments to the editor, and that ingenuous philanthropist forthwith provides a prescription, or, with the careful injunction to "avoid all quacks as you would Satan," asks for "fresh particulars." It is a curious coincidence that a large proportion of the patients are like "Madoc" (p. 60) who is advised to "be a man," and assured that he "will soon get rid of this foolish weakness" if he follows "our advice," while the most conspicuous of the advertisements are those of medical electricity and 'Nervous Diseases and their Treatment,' accompanied by the names and addresses of the advertisers. One of these gentlemen has, according to the *British Medical Journal*, "attained an unhappy notoriety as a medical adviser." Another is the writer of a book on 'Revitalization,' of which the table of contents is highly suggestive of those bills which are sometimes found unerased in places of public convenience. The remainder of the correspondence and of editorial advice is of the most promiscuous kind, and must tax severely the resources of the "eminent medical authorities" who sit in conclave over all the "ills that flesh is heir to." We should like to know the results of so much "advice gratis." May we expect the periodical at the close of its first volume to announce the names of its correspondents as "specimens out of fifty thousand cures?"

Surely all this ill becomes a profession claiming the scientific and social status of the medical! The conductors of *Medical Notes and Queries* are careful to conceal their names, unless indeed these are to be gathered from its advertising columns. If the periodical maintains the vitality so freely promised to its readers in the advertisements, the General Medical Council, must be compelled to institute inquiries as to its responsible conductors. In neither of the sister callings of the Church or the Bar have we seen anything parallel to this publication, which proceeds from a profession claiming to be the equal and the auxiliary of both.

BOOKS RECEIVED.

A Manual of Practical Hygiene intended especially for Medical Officers of the Army and for Civil Medical Officers of Health. By Edmund A. Parkes, M.D., F.R.S. Fourth Edition. London: J. and A. Churchill. 1873. From the Publishers.

Pharmacopœia of the Hospital for Diseases of the Throat:—based on the British Pharmacopœia, 1867. Edited by Morell Mackenzie, M.D. Lond. Second Edition. London: J. and A. Churchill. 1873. From the Publishers.

Advice to Sanitary Authorities and to Individuals on the Threatened Approach of Asiatic Cholera. By John M. Fox. London: Simpkin, Marshall and Co. 1873.

Obituary.

We regret to announce the death, on the 3rd July, at Brighton, of Mr. Charles Davy, Pharmaceutical Chemist, aged 76, for many years a member of the firm of Davy, Yates, and Routledge, and one of the original founders of the Pharmaceutical Society.

Examinations Made Easy.

My attention has been called to one of the editorial articles which appeared in your Journal of Saturday, regarding an attempted personation at the preliminary examination of the University of Glasgow. Of course this might happen before any board, but, that it was *not* Glasgow University which was to be imposed upon in this particular instance, the following letter from Professor Young, Dean of the Medical Faculty, which appeared in the *North British Daily Mail* of July 23rd will at once prove:—

"Sir,—The curious history, quoted by you on Friday last from the Liverpool *Porcupine*, appeals to the authorities of Glasgow University. The Registrar of this University has pointed out to me that the appeal is unnecessary, since the date of the examination at which the personation was to be attempted was the 19th July—a date at which no examination in preliminary knowledge is held here. Moreover, the University requires *three* books of Euclid: the Board before which "Alpha" has to appear requires only *two*.

"I am, etc.,

"John Young, M.D.,

"Clerk of the Medical Faculty.

"Registrar's Office, University of Glasgow, 22nd July."

The examination must have been that of the Faculty of Physicians and Surgeons which is simply a *licensing* and not an *educating* body, and has nothing more to do with Glasgow University than the Royal College of Surgeons of England has with London University.

I believe the Secretary of the Faculty has placed the whole matter in the hands of the police.

H. M.

The Sale of Fly Papers.

Sir,—As one of those "correspondents that wrote to you some time ago" on the sale of "Vermin Killers," I will trouble you with my opinion on the subject of "Fly Papers," mooted in your Journal by Mr. Laird of Dundee.

I think it right to observe that our Council did not include "Vermin Killers" in Part I. of poisons to be registered, till one or two murders, some attempted murders, and several suicides had occurred through the great facility with which such articles could be obtained from oilmen, grocers, and chemists, without any inquiry or registry. The public, through their coroners and the coroners' juries, called for more care in the supplying of vermin killers, because human life was sacrificed through the ready facilities for procuring the fatal dose, and not, *per se*, because such packets contained strychnia or arsenic. From these premises I deduce that there is no illegality or at any rate no penalty attached to the sale of fly papers so long as love-sick swains abstain from making a decoction of "papier moure" and swallowing it to settle their love, or spiteful servants-of-all-work do not chop them up to mix with their mistress's tea or coffee when they have been scolded for stopping out too late on bank-holiday, or failing in some of their manifold household duties.

James Slipper.

London, August, 1873.

The Sale of Carbolic Acid.

Sir,—I do not entirely agree with the remarks of a "Country Chemist" respecting the sale of poisons. He appears to consider that he has done all that is required when he has complied with the regulations of the Pharmacy Act. I conceive that something more is due from a careful chemist than just abiding by the strict letter of the law. Is it nothing to avoid the odium which attaches to a chemist even if he be guiltless and unblameable in the eye of the law, when death or severe injury results from some article he has vended? I contend that every precaution ought to be taken, whether specified in the Act or not, to avoid preventible mischief. After an experience of thirty years, during which I have invariably followed the plan of labelling *all* poisons very distinctly, besides giving verbal instructions, and even going the length of refusing to sell to some whom I did not know, or whom I judged to be very careless, I can say to-day that I have never yet had a serious accident with poisons of any kind. True, I have lost custom in many cases, where little huckster shops have got the benefit, but I have nothing to regret. As an instance, I may mention that, though emerald green and similar things are sold indiscriminately, I make a point of cautioning the purchaser. Strictly, I suppose, emerald green would come under the Act, as an arsenite of copper, but I have not heard of any one taking any notice of the fact.

I would, not merely as a matter of policy, with the view to establish the reputation of a careful man of business, but also on the higher ground of possibly saving a life, recommend to my brother chemists a stricter code in the selling of ordinary poisons than usually prevails. Know the persons to whom you sell, impress them with the consequences of carelessness or misusage, and do not consider that you have done all that ought to be done when you have merely kept within the confines of the Act; and the death-rate by accidental and even wilful poisoning will as a consequence assuredly be much lessened. There are people stupid enough to perform any silly trick no matter how careful you may be, and it was certainly a stupid trick to take the carbolic acid, as mentioned in the report. But supposing a red label with the word "poison" had been on the bottle, does any one suppose the man would have been fool enough to have taken it then? Certainly not, and thus lives may be thrown away, and still *nobody be to blame*.

Joseph Walker.

Pudsey, near Leeds, July 23, 1873.

"*The Dishonest Dipsomaniac.*"—We are informed that notwithstanding the condition upon which Mr. D'Eyncourt recently discharged the above individual he rang up one of the assistants at a West-end pharmacist's, on Sunday morning last, at 5 a.m., and asked for a supply of chloroform. Fortunately, he was recognized, and was got rid of by a threat to give him in charge.

"*Solution.*"—If you refer to the Pharmacopœia you will see that several simple solutions are described, and it is to the strength of these solutions, doubtless, that the words have reference.

"*Spes.*"—The equations are correct.

"*Mr. Slater.*"—We are obliged to you for forwarding the newspapers. We do not, however, think that there is much that is objectionable in the paragraphs in question.

R. C.—We have received a communication from *R. C.* complaining of the practice of enclosing within the package of a patent medicine circulars offering the supply of other articles by retail through the post. We agree with *R. C.* that it seems hard to be thus made the medium of advertising a competitor without one's consent being asked. We would remind our correspondent, however, that this is but another aspect of the question whether it is the business of the druggist to inquire what are the contents of such packages. We have also received a letter on this subject from a firm who make patent medicines. They admit that they adopt the practice above referred to, but excuse themselves on the ground that the price charged for the articles they advertise in the circular is the ordinary retail price. We cannot, however, view this explanation as fully satisfactory in regard to the gravamen of the complaint urged by *R. C.*, which is that, by the use of such circulars as he describes, the proprietors of patent medicines, to some extent, seek to deprive the vendors of their preparations of their legitimate business, in so far as they offer to supply their commodities through the post. Fortunately, the evil now complained of is one that allows of the application of a very obvious remedy, and one to which patent medicine manufacturers are as susceptible as most people.

"*Syrupus.*"—It would depend upon the conditions of the engagement, and whether they would allow of the young man attending the laboratory during the prescribed hours.

"*Nemo*" and *R. C. P.* are referred to the regulation respecting anonymous contributions.

Communications, Letters, etc., have been received from Dr. De Vry, Mr. J. N. Place, Mr. T. E. Gibb, "Sine Granâ Salis," "A Deceived One."

ANALYSIS OF SOME CINCHONA BARKS GROWN IN JAMAICA.

BY DR. J. E. DE VRIJ.

A few years ago I read in this Journal* an interesting paper on "The Introduction of Cinchona to the Island of Jamaica," and was, therefore, much pleased when recently the Crown agents for the Colonies sent to me, at the request of the Government of Jamaica, six samples of Cinchona bark, grown in that colony, in order that a quantitative analysis might be obtained of them. I quite agree with Dr. Hooker† "that the results obtained in one country cannot be correctly regarded as a gauge for the productiveness of the same species in another country," and take, therefore, much interest in the analysis of bark grown in different localities. As the Crown agents have not only no objection to the publication of the results contained in my report to them, but assured me that they would be pleased by it, I proceed now to the publication in this Journal.

The barks sent to me were derived from the following species :—

1. *C. Pahudiana.* 2. *C. officinalis.* 3. *C. succirubra* (from the locality called "Cold Spring"). 4. *C. succirubra* (from another locality). 5. *C. Calisaya, and* 6. *C. micrantha.*

1. C. Pahudiana.

a. 20 grammes of dry bark yielded 0·745 gramme of mixed alkaloid . . . . .
b. 20 grammes of dry bark yielded 0·749 gramme of mixed alkaloids . . . . .
} average 3·735 per cent.

Molecular rotation of the mixed alkaloids $[\alpha]\, j =$ 72°·1↖. Calculated from the facts $\frac{V}{p} = \frac{19{\cdot}8}{1{\cdot}494}$; $l =$ 100 ; $a° = 5°{\cdot}5$ ↖.‡

Alkaloids soluble in ether, 2·156 per cent. $[\alpha]\, j = 52°{\cdot}5$↖ Calculated from the facts $\frac{V}{p} = \frac{20}{2{\cdot}096}$; $l = 100$; $a° =$ 5°·50↖.

Alkaloids insoluble in ether, 1·579 per cent. $[\alpha]\, j$, not determined through an accident.

The 2·156 alkaloids soluble in ether yielded 1·707 herapathite = 0·601 per cent. crystallizable quinine, and 1·192 amorphous alkaloid, containing a new crystallizable lævogyre alkaloid. The 1·579 alkaloids insoluble in ether yielded 0·904 bitartrate of cinchonidine,§ = 0·608 cinchonidine, and 0·971 of a mixture of two alkaloids. This mixture consisted of a *new* lævogyre crystallizable alkaloid, very soluble in alcohol, and ordinary cinchonine.*

40 grammes of dry bark yielded 0·057 gramme of quinovic acid = 0·142 per cent.

Conclusion.

This bark contains 3·735 per cent. of mixed alkaloids consisting of :—

Crystallizable quinine	0·964	soluble in ether, 2·156
Amorphous alkaloid containing a new crystalline alkaloid	1·192	
Cinchonidine. . .	0·608	insoluble in ether, 1·579
Cinchonine and a new alkaloid . .	0·971	
		3·735

2. C. officinalis.

a. 20 grammes of dry bark yielded 0·166 of mixed alkaloids . . . . . .
b. 20 grammes of dry bark yielded 0·167 of mixed alkaloids . . . . . .
} Average, 0·832 per cent.

Molecular rotation of the mixed alkaloids $[\alpha]\, j =$ 179·°6↖. Calculated from the facts $\frac{V}{p} = \frac{19}{0{\cdot}67}$; $l = 300$; $a° = 19°$↖

The total amount of alkaloids at my disposal was too small to allow a separation by ether. From 0·832 gramme of the mixed alkaloids I obtained 0·814 herapathite = 0·46 crystallizable quinine. Although the amount of quinine could be ascertained without the least doubt, the small quantity of disposable alkaloids did not allow me to investigate the real nature of the other existing alkaloids, and it was only possible to ascertain the absence of amorphous alkaloid.

40 grammes of dry bark yielded 0·135 of quinovic acid = 0·337 per cent.

Conclusion.

This bark contains 0·832 per cent. of mixed alkaloids, consisting of :

0·46 crystallizable quinine and 0·372 other alkaloids.

3. C. succirubra (*Cold Spring*).

a. 20 grammes of dry bark yielded 2·17 grammes of mixed alkaloids . . .
b. 20 grammes of dry bark yielded 2·165 grammes of mixed alkaloids . . .
} Average, 10·837 per cent.

Molecular rotation of the mixed alkaloids $[\alpha]\, j =$ 0°↖

This is the first instance observed by me that the

---

* Second Series, Vol. X., No. 111 (September, 1868), p. 166.

† Ibid, p. 167.

‡ Third Series, Vol. II., No. 1 (July, 1871). Since the publication of this paper I never analyse barks without using the polariscope, and, notwithstanding the still existing imperfections of this process, it affords to me not only a great aid in my analysis, but also controls its results. So, for instance, I discovered a new alkaloid, which without the application of the polariscope would have escaped me and increased the amount of cinchonine. Since Professor A. C. Oudemans discovered the influence of the menstruum, in which the active substance is dissolved, on its rotary power it is necessary to mention that in these determinations I always use a weak acid containing five per cent. of pure sulphuric acid.

§ Since the publication of my paper "On the Separation and Quantitative Determination of the Different Cinchona Alkaloids," in this Journal, Vol. ii., p. 642 (1872), I have made the following modification of my process. To the solution of the part insoluble in ether I add a solution of iodide of sodium, and, after separating the hydriodate of quinidine,—if that alkaloid be present—a solution of bitartrate of sodium is added to the filtered liquid, which precipitates the bitartrate of cinchonidine.

* After collecting the bitartrate of cinchonidine upon a filter, I precipitated the alkaloid from the filtered liquid by caustic soda, in order to collect the cinchonine. In testing, however, the supposed cinchonine by the polariscope I found it to possess only a very slight dextrogyre rotation, viz. $[\alpha]\, j = 14°$ ↗ which fact led me to the conclusion that it must be a mixture of two alkaloids, which supposition was confirmed by treating the precipitate with a little cold alcohol which dissolved a lævogyre alkaloid, whilst the undissolved part proved to possess the strong dextrogyre rotation of cinchonine, with which alkaloid is proved to be identical.

different rotations of the alkaloids exactly neutralized each other.

Alkaloids soluble in ether, 3·728 $[\alpha]\,j = 123°{\cdot}1\curvearrowleft$ Calculated from the facts $\frac{V}{p} = \frac{18}{0{\cdot}7306}$; $l = 300$; $a° = 15°\curvearrowleft$

Alkaloids insoluble in ether, 7·109 $[\alpha]\,j = 51°{\cdot}7\curvearrowright$. Calculated from the facts $\frac{V}{p} = \frac{14}{0{\cdot}632}$; $l = 300$; $a° = 7°\curvearrowright$.

The 3·728 alkaloids soluble in ether yielded 3·466 of herapathite = 1·958 crystallizable quinine and 1·77 amorphous alkaloid. This amorphous alkaloid presented the peculiar property, hitherto unobserved by me, that it proved to possess a lævogyre rotation, its molecular rotation being—

$[\alpha]j = 48°{\cdot}3\curvearrowleft$.* Calculated from the facts $\frac{V}{p} = \frac{6{\cdot}7}{0{\cdot}277}$; $l = 200$; $a° = 4°\curvearrowleft$.

The 7·109 alkaloids insoluble in ether yielded 2·564 bitartrate of cinchonidine† = 1·724 cinchonidine and 5·385 cinchonine, containing a very small quantity of an alkaloid which, in regard of its compound with hydriodic acid, has some analogy with quinidine, but is not identical with it.

40 grammes of dry bark yielded 0·103 gramme of quinovic acid = 0·257 per cent.

Conclusion.

This bark contains 10·837 per cent. of mixed alkaloids, consisting of—

Crystallizable quinine 1·958 Amorphous alkaloid . 1·770	soluble in ether .	3·728
Cinchonidine . . . 1·724 Cinchonine containing a trace of a new alkaloid . . . . 5·385	insoluble in ether	7·109
		10·837

4. C. SUCCIRUBRA.

a. 20 grammes of dry bark yielded 1·18 of mixed alkaloids . . . . . }
b. 20 grammes of dry bark yielded 1·154 of mixed alkaloids . . . . . } Average, 5·835 per cent.

Molecular rotation of the mixed alkaloids $[\alpha]\,j = 67°{\cdot}3\curvearrowleft$. Calculated from the facts $\frac{V}{p} = \frac{13{\cdot}5}{0{\cdot}802}$; $l = 100$; $a° = 4°\curvearrowleft$.

Alkaloids soluble in ether, 2·28 : $[\alpha]\,j = 6°{\cdot}3\curvearrowright$. Calculated from the facts $\frac{V}{p} = \frac{20}{1{\cdot}0524}$; $l = 300$; $a° = 1°\curvearrowright$.

Alkaloids insoluble in ether, 3·555 : $[\alpha]\,j = 88°{\cdot}3\curvearrowleft$. Calculated from the facts $\frac{V}{p} = \frac{14{\cdot}8}{0{\cdot}335}$; $l = 300$; $a° = 6\curvearrowleft$.

This fact that the alkaloids soluble in ether obtained from this bark are dextrogyre, whilst the alkaloids insoluble in ether are lævogyre is quite anomalous and deserves particular attention, as it proves how great the mistake is made by many chemists who consider the part soluble in ether to be quinine. The 2·28 alkaloids soluble in ether yielded 0·82 of herapathite = 0·463 crystallizable quinine, and 1·817 of a mixture of two alkaloids, the prevailing one being a new crystallizable alkaloid, whilst the second one was an amorphous alkaloid.

The 3·555 alkaloids insoluble in ether yielded 1·973 bitartrate of cinchonidine = 1·33 cinchonidine, and 2·225 of a mixture of two alkaloids, the prevailing one being a new crystallizable alkaloid, very soluble in alcohol and lævogyre, whilst the second was ordinary cinchonine.

The bitartrate of cinchonidine obtained from this bark crystallized in the same shape as that obtained from the former bark (No. 3).

4 grammes of dry bark forwarded 0·16 gramme of quinovic acid = 0·4 per cent.

Conclusion.

This bark contains 5·835 per cent. of mixed alkaloids consisting of—

Crystallizable quinine . 0·463 New crystallizable alkaloid and amorphous alkaloid . . . . 1·817	soluble in ether, 2·280	
Cinchonidine . . . 1·330 New crystallizable alkaloid and cinchonine . 2·225	insoluble in ether, 3·555	
		5·835

5. C. CALISAYA.

a. 20 grammes of dry bark yielded 0·551 of mixed alkaloids . . . . . }
b. 20 grammes of dry bark yielded 0·549 of mixed alkaloids . . . . . } Average 2·75 per cent.

Molecular rotation of the mixed alkaloids $[\alpha]\,j = 91°\curvearrowleft$. Calculated from the facts $\frac{V}{p} = \frac{15{\cdot}4}{1{\cdot}10}$; $l = 100°$; $a° = 6°{\cdot}5\curvearrowleft$.

Alkaloids soluble in ether 1·68 : $[\alpha]\,j = 128°{\cdot}2\curvearrowleft$. Calculated from the facts $\frac{V}{p} = \frac{20}{1{\cdot}6372}$; $l = 100$; $a° = 10°{\cdot}5\curvearrowleft$.

Alkaloids insoluble in ether 1·07 : $[\alpha]\,j$ not observed.

The 1·68 alkaloids soluble in ether yielded 2·24 of herapathite = 1·265 crystallizable quinine, and 0·415 amorphous alkaloid. The 1·07 alkaloids insoluble in ether yielded 0·26 of bitartrate of cinchonidine = 0·175 cinchonidine and 0·895 of a mixture of two alkaloids, the prevailing one being a new crystallizable lævogyre alkaloid, very soluble in alcohol and analogous to that obtained from the bark No. 4, whilst the second was ordinary cinchonine.

40 grammes of dry bark yielded 0·184 gramme of quinovic acid = 0·46 per cent.

---

* In my former analysis of barks I generally found the amorphous alkaloid to possess a slight dextrogyre rotation, and inclined therefore to the supposition that perhaps it might be identical with Pasteur's quinicine, but a comparison with quinicine, which had been kindly given to me by Pasteur himself, proved that it was different from it. It appears now, by the observation of a lævogyre amorphous alkaloid, that I was right in using only the general definition, "amorphous alkaloid," and leaving to the future the further investigation of its real nature.

† As this bitartrate crystallized in quite another shape than I was accustomed to, I stated in my official report that the cinchonidine of this bark might be a modification of the ordinary cinchonidine. Since that time, however, further investigations convinced me that it was not a modification but quite identical with ordinary pure cinchonidine, which was also confirmed by my friend, Professor A. C. Oudemans, who at my request kindly investigated with the greatest accuracy its rotatory power. After dissolving the alkaloid, separated by me from the apparent abnormal bitartrate, in alcohol of 93 per cent., he found the molecular rotation *in that menstruum* to be $[\alpha] = j\ 116°{\cdot}7\curvearrowleft$.

Conclusion.

This bark contains 2·75 per cent. of mixed alkaloids consisting of—

Crystallizable quinine.	1·265	soluble in ether, 1·68
Amorphous alkaloid .	0·415	
Cinchonidine . . .	0·175	insoluble in ether, 1·07
New crystallizable alkaloid and cinchonine .	0·895	
	2·75	

6. C. MICRANTHA.

a. 20 grammes of dry bark yielded 0·662 of mixed alkaloids . . . . .
b. 20 grammes of dry bark yielded 0·690 of mixed alkaloids . . . . . } Average 3·402 per cent.

Molecular rotation of the mixed alkaloids $[a]\ j = 28°·3$ ↖.

Calculated from the facts $\frac{V}{p} = \frac{14·5}{0·512}$; $l = 100$; $a° = 1°$ ↖.

Alkaloids soluble in ether 2·202 $[a]j = 25°·7$ ↖. Calculated from the facts $\frac{V}{p} = \frac{20}{1,942}$; $l = 100$; $a° = 2°·5$ ↖

Alkaloids insoluble in ether 1·2 $[a]j$ not observed.

The chemical investigation of the mixed alkaloids proved very unsatisfactory. As the whole amount of powdered bark at my disposal did not exceed 100 grammes I had only 3·4 grammes of mixed alkaloids. These would however have been sufficient for my chemical investigation if they had not proved to be very anomalous. They were very dark-coloured and contained a dark brown resinous matter which adhered very tenaciously to them so that a relatively great loss was sustained before they could be obtained sufficiently pure for further investigation.

The alkaloids soluble in ether yielded only 0·284 of iodosulphate which had much analogy with quinine-herapathite, but its appearance was however somewhat anomalous. I investigated this presumed herapathite accurately and the result was that I could not accept it as quinine-herapathite. But even if the 0·284 gramme of iodosulphate was, against my conviction, really quinine-herapathite, the amount of quinine in the 2·202 grammes of alkaloids soluble in ether would only be 0·16. From the mother-liquor of this presumed herapathite I obtained 1·105 of amorphous alkaloid, which had *no* action on the plane of polarization, and 0·938 of a brown resinous matter insoluble in diluted acids.

The alkaloids insoluble in ether yielded no bitartrate of cinchonidine, but, besides distinct traces of quinidine, a mixture of two alkaloids, the prevailing one being analogous to that obtained from the barks mentioned *sub* 4 and 5, whilst the second was ordinary cinchonine. Although I did not obtain any bitartrate of cinchonidine from the alkaloids insoluble in ether, I presume that this alkaloid was present in a very small quantity, which had been dissolved in ether by the aid of the relatively large amount of amorphous alkaloid, and to this supposed presence of cinchonidine I ascribe the formation of the mentioned iodosulphate, as this compound of cinchonidine has really much analogy with the quinine-herapathite.

Conclusion.

This bark contains 3·402 per cent. of mixed alkaloids consisting of :—

Crystallizable quinine (very dubious)	0·16	soluble in ether, 2·202
Amorphous alkaloids .	1·104	
Brown resinous matter .	0·938	
New crystallizable alkaloid and cinchonine, with distinct traces of quinidine	1·200	insoluble in ether, 1·200
	3·402	

As the commercial value of cinchona barks for quinine manufacturers depends chiefly on their amount of crystallizable quinine, I give the following tabular review of its quantity in 100 parts of the different barks subjected to my investigation.

	Pure Quinine.		Crystallized Sulphate.
C. succirubra (Cold Spring)	1·958	=	2·50
C. Calisaya	1·265	=	1·612
C. Pahudiana	0·964	=	1·229
C. officinalis	0·46	=	0·586
C. succirubra	0·463	=	0·59
C. micrantha	??		

As the introduction of Cinchona cultivation in Jamaica dates only from 1867, I consider the results of my analysis of the bark obtained in that colony from *C. succirubra*, *C. Calisaya*, and *C. Pahudiana*, very satisfactory. Comparing the results of my analysis of the bark of *C. officinalis* with those obtained by me from barks of the same species grown in Ceylon and the Neilgherries, I have not much confidence in the success of the cultivation of that species in Jamaica. It is, however, possible that the low percentage of quinine in the bark is caused either by its being still too young or being grown at a not sufficient elevation above the sea, as it is proved that this species requires at Ootacamund, where it gives excellent results, an elevation of about 8000 feet. As to the *C. micrantha*, I have not the least expectation that it ever will produce a bark fit for quinine manufacturing.

THE MATERIA MEDICA OF THE UNITED STATES' PHARMACOPŒIA.

BY E. M. HOLMES,

Curator of the Museum of the Pharmaceutical Society.

(Continued from Vol. III., page 1031.*)*

Having briefly reviewed the changes which have taken place in the U. S. P. since its last issue, it now remains to compare it with our own pharmacopœia, and to direct attention to any points worthy of notice which may present themselves.

The features of the materia medica of the U. S. P. which differ from those of the B. P. deserve a few passing remarks before entering into the difference in details.

The descriptions of and tests for the inorganic substances are, as a rule, much shorter than those of the B. P. and seem to have been written with a view to their being thoroughly practical. The forms of crystals are rarely described, and when they are, scientific terms are avoided. There are few perhaps, who, unless they have made crystallography a special study, could determine the crystalline form of a substance by mere inspection, without the aid of a goniometer, although they might perhaps recognize

the crystals from familiarity with their general appearance ; so that a description of the exact crystalline form is hardly necessary. The descriptions of the organic substances are much too short ; no descriptions or tests being given where they are really needed ; in many cases there is little more than an enumeration of the parts to be used, the quality of the article being left entirely to the honour of the pharmaceutist, who it is to be hoped never uses any but drugs of the best quality. As there is a public inspector of drugs in America there is perhaps not so much chance as there is in England for inferior drugs to find their way into the market, and this may perhaps account for the absence in so many cases of adequate descriptions and tests.

The class of remedies which more properly belong to the province of the nurse or cook is comparatively a large one, thus *avenæ farina*, *canna*, *icthyocolla*, and *maranta*, *sago* and *tapioca* find a place in it. Articles of this class were omitted from the last B.P., and with good reason, for although frequently ordered by medical men for their patients, they are rarely prepared by the dispenser or pharmaceutist, and unless the whole of the dietary commonly ordered by physicians be included in the materia medica they are better left out altogether. If they are admitted, Liebig's extract of meat, Ridge's and Neave's food, mutton broth and calves' foot jelly have an equal claim to a place in the pharmacopœia, as they are certainly more frequently ordered than sago or tapioca.

There are a few more flavouring agents than there are in the B. P. Anything that tends to make medicine more palatable and at the same time does not diminish its efficacy must be regarded as an useful addition. The articles of this class in the B. P. offer but a limited choice to the physician who may be anxious to disguise the taste of castor or cod-liver oils, etc.

The number of articles in the U. S. P. exceeds that of the B. P. by 143. There are 402 in the former and 259 in the latter. This difference might naturally be expected in the materia medica of a country so much larger than Great Britain. It is not however really so important as it appears to be, for there are no less than 67 articles in the U. S. P. which have been dismissed from the pharmacopœias of this country during the last 150 years. It is rather singular that forty-two of these are to be found in the primary list. Among these may be noticed *allium*, *chimaphila*, *helleborus niger*, *marrubium*, *rosmarinus*, *ruta*, *salvia* and *cataria ;* and in the secondary list *achillea*, *tanacetum*, *rubia* and *delphinium consolida*. It is evident that these old-fashioned remedies are held in higher esteem in the United States than they are in this country. This is the more remarkable since America is by no means conservative in its tendencies. Twelve of the articles of materia medica in the U. S. P. have processes given for their preparation in the B. P. ; these are *acidum citricum*, *acidum muriaticum*, *acidum tartaricum*, *adeps*, *alcohol dilutum*, *aqua ammoniæ fortior*, *magnesii carbonas*, *plumbi acetas*, *potassii chloras*, *potassii permanganas*, *zinci sulphas*, and *zinci valerianas*.

There are 117 articles altogether which have never appeared in the pharmacopœias of this country, seventy of which are obtained from plants indigenous in America. The remainder of the 117 includes among other articles several now introduced into the U. S. P., and a few derived from plants which are indigenous in this country, but which, so far as I can discover, have never been used in medicine here, although species closely allied to them are familiar herbs in England. The plants alluded to include *geum rivale*, *rumex crispus*, *ranunculus bulbosus*, and *matricaria chamomilla*. The remaining articles of the materia medica, 206 in number, are *common to both pharmacopœias*. This fact may interest those who are anxious for the formation of an universal pharmacopœia. If this desirable work is to become a fact in the future, one of the first steps towards its accomplishment must be to ascertain the number of articles of materia medica and of preparations which are common to all pharmacopœias.

The following summary will show at a glance the comparisons made above :

	U.S.P.		B.P.
Formerly official in B. P. . .	67		
In preparations in B. P. . . .	12	Do. in U. S. P. . .	18
Indigenous in U. S. and not in B. P.	70	Do. in B. and not in U. S. P. . .	8
Not indigenous in U. S. and not in B. P. . . .	47	Do. in B. . . . Do. in B. P. . .	27
Common to U. S. P. and B. P. . .	206	Do.	206
	402		259

Most of the indigenous plants which are official in the B. P. are used also in the United States, the following being the only exceptions : *cochlearia armoracia*, *lactuca virosa*, *quercus pedunculata*, *rhamnus catharticus*, *papaver rhœados*, *rosa canina*, *sambucus nigra*, and *ulmus campestris*. Some of these however are represented by American plants in the U.S.P., thus—*quercus alba* takes the place of *Q. pedunculata ; sambucus canadensis* that of *sambucus nigra*, while *lactuca virosa* is represented by *lactucarium*.

The seventeen articles of materia medica of the B. P. for which processes are given in the U. S. P. are acidum benzoicum, ammonii bromidum, aqua aurantii florum, creta preparata, ol. anisi, carui, caryophylli, copaibæ, cubebæ, juniperi, lavandulæ, menthæ piperitæ menthæ viridis, pimentæ, rosmarini, rutæ, sabinæ, and potassii carbonas.

The twenty-seven articles of the B. P. which do not occur in the U. S. P. are the following :—

Acidum aceticum glaciale.
Anethi fructus.
Arnicæ radix.*
Belæ fructus.
Cadmii iodidum.
Catechu pallidum.*
Ecbalii fructus.*
Elemi.
Farina tritici.
Hemidesmus.
Hirudo.
Lac.
Laurocerasi fol.
Mica panis.
Mori succus.
Oleum anethi.
anthemidis.
coriandri.
myristicæ expressum
sinapis essentiale.
Sapo mollis.
Sassafras radix.*
Scammonii radix.
Senna, Tinnevelly.†
Sumbul.
Thus.
Vinum aurantii.

With the exception of acidum aceticum glaciale, cadmii iodidum, oleum sinapis essentiale and scammonii radix, vinum aurantii, and the few which are

* Represented by similar substances in the U. S. P.
† Included under senna in the U. S. P.

represented by other articles of a similar nature in the U. S. P., the remainder might without any great loss be banished from the B. P. altogether, as they are mostly but little used in this country.

Of the 206 articles which are common to both pharmacopœias, those tests and characters of inorganic substances only will be mentioned which are not found in the P. B., as the tests given in the two works are, for the most part, very similar; those of the U. S. P. being, as a rule, rather less full than those of the B. P. Omissions in the U. S. P. of tests or descriptions of organic substances—descriptions of which occur in the B. P.—will only be noticed in such cases as they appear to be of importance; the comparisons now made being principally intended for the purpose of bringing forward any points of interest to the British pharmaceutist.

Before commencing this comparison, it will be well, perhaps, to notice the difference which occurs in the two pharmacopœias in the nomenclature of several of the articles :—

U. S. P.	B. P.
Citrus vulgaris.	Citrus bigaradia.
Galipea officinalis.	Galipea Cusparia.
Angustura bark	Cusparia bark.
Myrospermum peruiferum	Myroxylon perciræ.
——— toluiferum.	——— toluifera.
Barosma crenata.	Barosma betulina.
Calx chlorinata.	Calx chlorata.
Jateorrhiza palmata, Miers.	Jateorrhiza Miersii.
Agathotes chirayta, Don.	Ophelia chirata.
Chiretta.	Chirata.
Momordica elaterium.	
Ecbalium agreste, Richard	Ecbalium officinarum, Richard.
Gambogia.	Cambogia.
Glycerina, glycerin.	Glycerinum, glycerine.
Myristica fragrans.	Myristica officinalis.
Flaxseed meal.	Linseed meal.
Melaleuca cajuputi.	Melaleuca minor.
Oleum amygdalæ expressum.	Oleum amygdalæ.
Phasianus gallus.	Gallus bankiva, var. domestica.
Simaruba excelsa.	Picrœna excelsa.
Rheum palmatum, etc.	Rheum, undetermined species.
Cassia acutifolia.	Cassia lanceolata, D. C.
Scilla maritima.	Urginea scilla.
Veratrum sabadilla.	Asagræa officinalis.
Artemisia Cina.	Artemisia, undetermined species.
Koosso.	Kousso.

With regard to cusparia or angustura bark, it is said by Royle to be the produce of two species, cusparia bark being produced by *G. cusparia* and angustura by *G. officinalis*. Other authorities, however, state that the two plants are but varieties of the same species.

It will be observed that rhubarb is attributed to *rheum palmatum* in the U. S. P. Its true source (*R. officinalis*) was not known at the time the work was published, and, for a similar reason, santonica is attributed to an undetermined species of artemisia in the P. B. It is rather unfortunate that the two pharmacopœias do not agree as to the gender of glycerine—one making it a feminine, and the other a neuter noun. Students will be puzzled as to the correct termination of the word in reading prescriptions. No difficulty, will be felt, however, as to the correct pronunciation of this and other words, seeing that all the names are accented in the index. This was formerly the case in pharmacopœias in this country, only that the materia medica list was accented instead of the index. It is much to be regretted that this was discontinued. At the present time, many names are pronounced according to the fancy of the speaker without any definite rule, sometimes according to the derivation of the word, sometimes Anglicised, and often contrary to any known rule whatever. In the absence of a pronouncing dictionary of scientific names and terms this attempt at uniformity of pronunciation is well worthy of imitation.

In comparing the articles in the two pharmacopœias, it will be more convenient to consider them under the sections above given; hence the 206 common to both will be first noticed, then those which do not occur in the P. B., and are not indigenous in America, and, finally, those which do not occur in the P. B., and are indigenous in America :—

Acidum accticum.—This is slightly stronger than that of the P. B. (about 2 per cent.), the sp. gr. being 1·047, while that of the P. B. is 1·044. The only test not given in the P. B. is, that after neutralization with bicarbonate of potassium the liquid should be free from an acrid taste.

Carbolic acid.—Essential oils are mentioned as solvents for this, and the additional tests are that its solution coagulates collodion, and combines with alkalies, from which combination any weak acid, even carbonic, displaces it.

Acidum muriaticum.—This, as well as the nitric and sulphuric acids, are of the same strength as in the B. P. The gold leaf test for free chlorine is given under muriatic acid, in addition to those in the P. B.

Aconiti folia and *radix* have no direction appended as to the best time to gather them. This is an important omission, for it is well known that both the root and the leaves vary according to the time at which they are gathered; thus the root contains twice as much aconitine after as it does before flowering, so that the tincture made with roots gathered at different periods is liable to considerable variation in strength—a matter of no small importance in the case of so powerful a remedy as aconite.

Alcohol.—The sp. gr. is given as 0·835, thus being a little stronger than that of the P. B., 0·838. Alcohol dilutum is directed to be made by mixing the above with an equal measure of distilled water. The sp. gr. of the mixture is 0·941, and is consequently rather weaker than the proof-spirit of the P. B. This slight difference cannot diminish the solvent properties of the spirit to any material extent, while the convenience of mixing equal quantities is very great, so much so indeed as to lead in this country to the very frequent use of spirit mixed in these proportions. Possibly the excess of profit thus yielded may in some measure influence those who adopt this practice, but I am charitable enough to believe that if these proportions were ordered in the P. B., the strength of the rectified spirit being stronger, a larger proportion of water than ordered would not then be used.

Alcohol Amylicum.—Additional tests are—it does not take fire by contact with flame, and does not leave a permanent greasy stain when dropped upon paper.

Ammonii carbonas.—Additional test—its odour should be free from empyreuma.

Aqua ammoniæ fortior.—This is not quite so strong as that of the P. B., its sp. gr. being 0·900 (P. B., 0·891).

This is one of those articles which might readily and reasonably be made of equal strength in both pharmacopœias.

Belladonnæ folia and radix.—No directions are given as to the best time to gather the leaves, but the roots are directed to be gathered from plants more than two years old, a direction not to be found in the P. B.

Calx chlorinata.—The following is given as a test of its strength. When forty grains, triturated with an ounce of distilled water, are well shaken with a solution of seventy-eight grains of crystallized protosulphate of iron and ten drops of sulphuric acid in two fluid ounces of distilled water, a liquid is formed which does not yield a blue precipitate with ferricyanide of potassium. It is also very properly described as a dry powder, it being often sold in a damp and much deteriorated state.

Capsicum.—This is described as the fruit of the *C. annuum*, *C. fastigiatum*, and of other species of capsicum.

Cardamomum.—This is simply described as the fruit, so that it would appear that the husk, which forms a considerable proportion of the weight, is to be used as well as the seed.

Catechu.—That prepared from the wood of the *Acacia catechu*, and known in commerce as Bombay or black catechu, is directed to be used. It contains $2\frac{1}{2}$ per cent. more tannin than the *Terra japonica* (pale catechu) official in the B. P.

Cerii oxalas.—The following tests are given:—"Insoluble in water, alcohol, and ether, soluble in sulphuric acid; the solution, mixed with chloride of ammonium,* yields a precipitate with caustic potash, insoluble in excess of the precipitant. Exposed to heat, the salt is decomposed, and leaves a black powder which, in contact with the air, burns to yellow peroxide of cerium." The blackish powder here mentioned is only formed if the oxalate is heated in a *closed* vessel.

Cinchona rubra.—It should contain not less than 2 per cent. of alkaloids which yield crystallizable salts. The B. P. is content with 1·5 per cent. The latter is too small a percentage, as good red bark is stated to yield 2·5 per cent. of quinine and nearly $1\frac{1}{2}$ per cent. of cinchonine.†

Cinnamomum.—The use of cassia is authorized by giving both *C. zeylanicum* and *C. aromaticum* as sources of cinnamon. This must cause some little annoyance in dispensing, if cassia has been used at one establishment and cinnamon at another, the odour and taste, although similar, being quite distinct.

Colchicum.—The best time for gathering this corm is not mentioned, although it varies greatly in strength at different seasons of the year, nor are any characters given by which to judge of its quality.

Creosotum.—Its sp. gr. is given as 1·046. That of the B. P. is 1·071. Additional test—"It does not coagulate collodion when mixed with it, and does *not* impart a blue colour to a slip of pinewood, dipped first into an alkaline solution of creosote, and then, after, drying, into muriatic acid." It is stated in the B. P. that both creosote and carbolic acid produce the greenish-blue colour.

Digitalis folia.—These are directed to be obtained from plants of the second year's growth. Like most other biennial plants their activity is greater then than during the first year.

Elaterium.—No test for ascertaining its strength is given. This is an important omission, good elaterium being such an extremely active drug.

Glycerine.—Additional tests—"Not soluble in ether. When mixed with twice its bulk of cold sulphuric acid it does not produce a brown colour. When diluted with water it does not afford a precipitate with hydrosulphate of ammonia, ferrocyanide of potassium, nitrate of barium, oxalate of ammonium, or nitrate of silver. It combines with potassa and baryta, and also with sulphuric acid." In the P. B. there is no test given for ascertaining its freedom from impurity.

Guaiaci lignum.—The dark portion, or heart-wood, is ordered instead of the whole of the wood, as in the B. P.

Hydrargyrum.—Additional tests—A globule made to roll over white paper leaves no trace. It is dissolved without residue in nitric acid. Sulphuric acid agitated with it and afterwards evaporated leaves no residue.

Hyoscyami folia.—No distinction is made in the value of the leaves of the annual or biennial plant.

Kino is described as the inspissated juice of *Pterocarpus marsupium* and of other plants. Thus the kino from *butea frondosa*, *coccoloba uvifera*, and *eucalypta resinifera* may all be considered as official articles.

Krameria.—It may be here noticed that a large quantity of *krameria ixina* or savanilla rhatany is met with in commerce in this country, and appears to possess greater astringency than the official species.

Oleum cinnamomi.—This does not include the oil of cassia, as might be supposed from the two barks being official under one name.

Oleum limonis.—No test is given for the purity of this or other essential oils, either in the P. B. or U. S. P. This is to be regretted, as many essential oils are very subject to adulteration.

Oleum morrhuæ is described as the fixed oil obtained from the liver of *gadus morrhua* and of *other species* of *gadus*. This is more correct than that given in the P. B., for a large portion of the oil met with in commerce is not derived from the codfish alone. Some specimens of this oil are probably much more efficacious than others, for the writer has found that some specimens cannot be emulsified by shaking with liquor potassæ, while others readily form a permanent emulsion with it. Specimens of the former kind are hardly likely to be readily absorbed into the system of a patient with weak digestion.

Oleum olivæ.—It is a pity that no test is given either in this pharmacopœia or our own to test the quality of an article so frequently adulterated, and so variable in quality.

Pareira is simply described as the root of *cissampelos pareira*. If there is one article of materia medica more than another which requires a definite description, it is pareira brava. The roots and stems of several different plants are now and then met with in the drug market which have a kind of family resemblance, but which are evidently the produce of different plants. It has already been shown by Hanbury that the root and stem met with in commerce is not that of *cissampelos pareira*,* and that the greater proportion of the pareira brava met with in commerce is not a root at all, but the stem of a plant at present undetermined. The root formerly imported, and described by Pereira, has lately appeared in commerce again, and has been determined to be the produce of *chondodendron tomentosum*, another menispermaceous plant. The true root yields about 25 per cent. of extract, while the false root or woody-stem yields only about 5 per cent., which, however, has by no means the sensible properties of the former.

Potassii bitartras.—Additional tests: freely soluble in a hot solution of potassa, anything that remains undissolved being impurity.

---

* Chloride of ammonium would detect lead or silver, and the formation of the double sulphate of cerium and potash as an insoluble precipitate is a characteristic test for cerium.

† Royle, Mat. Med., p. 513.

---

* See ante, p. 81 *et seq.*

Potassii permanganas.—According to the U. S. P., forty grains of crystallized sulphate of iron, acidulated with two fluid drachms of diluted sulphuric acid, are sufficient to completely decolorize a solution of five grains of permanganate of potash; but forty-four grains of the *granulated* sulphate are required to effect the same result, according to the P. B.

Sarsaparilla.—The description given permits the use of any of the commercial varieties, as sarsaparilla is stated to be the root of *smilax officinalis*, and of *other species* of *smilax*.

Scammonium.—According to the U. S. P., ether dissolves at least 75 per cent. of it; while, according to the P. B. it should dissolve from 80 to 90 per cent. of it. Additional test: the residue of the evaporation of the ethereal solution, dissolved in a hot solution of caustic potash, is not precipitated by dilute sulphuric acid.

Senna is simply described as the leaflets of *cassia acutifolia*, Delile, *cassia abovata*, D. C., and *cassia elongata*, Lemaire—thus allowing the use either of pure Alexandrian senna, E. Indian, or Tinnevelly.

Serpentaria is described as being the root of several species of *aristolochia*, of which two are mentioned by name—*A. serpentaria* and *A. reticulata*.

Spiritus vini gallici.—It is described as containing from 48 to 56 per cent. by volume of absolute alcohol, being free from odour, and not less than four years old.

Syrupus fuscus.—This is better known to English pharmaceutists as theriaca.

Veratrum viride.—No characters are given by which to distinguish it from veratrum album, which is also official, and which it closely resembles in appearance.

Secondary List.

Brayera is described as the flowers and *unripe fruit* of *brayera anthelmintica*.

THE MOLECULAR CHANGES THAT ACCOMPANY THE MAGNETIZATION OF IRON.

BY W. F. BARRETT, F.C.S.

The following abstract of a lecture delivered at the London Institution, on the 23rd April, is taken from the *Journal of the London Institution* for July :—

The lecturer first briefly referred to the various theories of magnetism that have been suggested from the time of Thales to the present day, pointing out how magnetism is now generally regarded as a mode of electricity in motion. Putting aside all hypotheses, the object of the present discourse was to gather some of the scattered observations that have been made of late years on the molecular changes that are associated with the magnetization of iron. It was hoped that by bringing into juxtaposition the labours of eminent men in this direction, some conception might be formed of the architecture of a magnet;—at any rate, a clearer view would thus be gained of the broad distinctions between the molecular structure of iron before and after magnetization.

The various means of converting iron into a magnet were shown. In every case it was evident that the profound change which had passed over the iron was quickly, but not instantaneously imparted—*time*, as Faraday long ago pointed out, being an essential element in the phenomenon. No evidence of the nature of the change from unmagnetized to magnetized iron could be gleaned from a scrutiny of the iron; its appearance, temperature, weight, and density remained unaltered. Iron filings scattered round the iron revealed the direction of the force as it spread from the magnetized iron. Its direction *within* the magnetized iron was shown by constructing a hollow magnet along the axis of which the filings were seen to be arranged in parallel striæ. In these experiments the filings were scattered on dry glass plates and strips which had been previously gummed. After the filings had arranged themselves, breathing on these plates fixed the filings sufficiently to enable the plates to be used as a magic lantern slide, and thus the lines of force were shown on the screen. It was seen that the direction of the lines was from pole to pole within the magnet. Using still finer particles of iron—the magnetic oxide of iron in a state of chemical division, suspended as a cloud in water—the famous experiment of Mr. Grove's was exhibited: an experiment of special interest in this place, from its association with the London Institution. The cloud of iron and water was enclosed within a powerful helix, and the lime-light sent through its axis; the faint image on the screen became conspicuously brighter on magnetizing the helix. Here the setting of the iron dust axially permitted freer transmission of light than when it was scattered in every direction. Before magnetization it was a mere turbid liquid; after magnetization an end-to-end arrangement of the particles had occurred, and a definite structure was thus impressed. In like manner, though one might not be able to see through the confused mass of a mob, one could see along the lines of a regiment of soldiers.

This marshalling of the molecules which signalizes the magnetization of iron makes clear why concussion equally aids the act of magnetizing, and also lessens the power of a magnet. In the one case it mechanically assists the molecular movement, in the other it helps to destroy it when acquired. This is easy to comprehend. For example: tapping will help the formation of the magnetic curves, but, once formed, continued tapping will tend to destroy them. The high cohesive power of steel resists the molecular change due to magnetization, and retains it when impressed. Destruction of that cohesive power, by heat, renders steel as easily magnetized by induction as soft iron, whilst sudden quenching of the hot steel permanently fixes this otherwise transitory condition, So also, when the cohesion of steel is destroyed by reducing it to dust, mere agitation will overthrow the magnetized state. A long test-tube, filled with fine steel filings, was drawn over one pole of a magnet, and shown to be powerfully magnetized, behaving like an unbroken bar magnet. The test-tube was then shaken, and the magnetized state had disappeared. The filings now attracted both ends of a magnetic needle.

Variations in the quality of iron or steel affect its aptitude for magnetization. A cube of fibrous iron suspended between the poles of a magnet sets its fibre axially; as we might infer, magnetization is easier in this direction than any other, and so the cube turns its fibres from pole to pole. Magnetized in a given direction, and then demagnetized, a bar of steel is easier and more powerfully magnetized in its first direction than in any other. The fact, long ago pointed out by M. Marianini, has recently been again observed by M. Jamin.

The lecturer, hoping to reveal an altered structure in iron or steel by magnetization, submitted bars of hard and soft iron to the action of weak nitric acid. Each specimen of iron was cut in two lengths: one was magnetized during the experiment; the other not. No definite results were gained; the nitric acid, even after prolonging the action for weeks, seemed to act equally upon both bars. But the experiment is worth repetition with higher magnetic force.

The evidence that a molecular change accompanies magnetization is still further established by the remarkable discovery of Mr. Page. This American philosopher made public the fact that a *sound* was emitted by iron on magnetization, and again on demagnetization. Heightened by the resonance of a sounding-box, this magnetic click was palpably heard by the audience; several fine iron wires stretched within a helix and rapidly magnetized and demagnetized yielded the loudest tones. Too great a strain on the iron wires lessens the intensity of the sound, nor is any strain at all necessary. A poker inserted into a helix was heard to emit a sound, which vanished when the poker was withdrawn. Two massive bars of pure nickel

and pure cobalt, lent by Messrs. Johnson and Matthey' were also shown by the lecturer to yield a distinct sound, the cobalt giving a more decidedly metallic clink than iron. This was believed to be the first time the effect with these metals had been observed.

The famous discovery of Dr. Joule's, that iron *lengthens* on magnetization, was next experimentally shown, as affording some evidence of the nature of the molecular change that occurred on magnetization. The apparatus for exhibiting Joule's discovery was skilfully made for the lecturer by Mr. Yeates, of Dublin, and was a modification of an arrangement first employed by Dr. Tyndall. By a system of levers moving a mirror, on which a ray of light was thrown, the lengthening of the bar was made evident to the audience; a considerable movement of the reflected ray being apparent every time the iron was magnetized. It was noticeable that the return on demagnetization was comparatively small and slow, even the softest iron retaining for a long period some magnetism. The normal disposition of the particles of iron is slowly resumed after the sudden strain put on them by magnetization.

The apparatus here described is also adapted to show the effect of magnetization on the dimensions of nickel and cobalt, a subject at present under examination.

No absolute increase in bulk occurs in iron when magnetized; the method by which Dr. Joule established this being shown. An electro-magnetic bar was enclosed in a tube of water, furnished with a capillary ending: no alteration in the level of the water was perceived on magnetization. Hence iron contracts transversely as much as it expends longitudinally on magnetization.

This transverse contraction gives magnetized iron a greater density in that direction. This affects the conduction of heat and electricity. A sheet of iron covered with wax was heated through a hole in its centre by a hot rod; the wax melted in a circle. The iron was magnetized; the wax now melted in an ellipse, the major axis of which was at right angles to the magnetic axis. This fact, observed Dr. Maggi, had its precise analogue in the conduction of electricity in magnetized iron and nickel, as shown by Sir W. Thomson.

Other facts were briefly referred to in further support of the particular nature of the change caused by magnetization. M. Guillemin has shown that a strip of iron bent by a weight is partly straightened by the act of magnetization. M. Wiedemann has shown that an iron wire, hung in the centre of a helix and twisted, is more or less untwisted when a current traverses the helix and thus magnetizes the iron. Twisting a magnet lessens its magnetic force; but stretching a magnet slightly adds to its power, as has been proved by M. Matteucci. A powerful apparatus, designed by Mr. Gore, was shown, whereby the effect of strain on hard iron, slightly magnetized, was made evident. Straining the iron in the direction of its length was seen to augment its magnetic force; when the strain was removed the magnetic state of the iron reverted to its original condition. These changes were made obvious by the creation of an electric current in a long helix of wire surrounding the experimental wire, the presence and direction of the current being declared by the reflection of a ray of light from the mirror of a new form of Thomson's galvanometer.

The action of heat in destroying the magnetism of steel, and even the magnetic condition of iron, nickel, and cobalt, was then shown: nickel first losing its magnetic state, hen iron, and lastly cobalt, at a very high temperature. Associated with this, a remarkable experiment of Mr. Gore's was exhibited. An iron wire, heated, to whiteness, was so arranged that on its contraction an index was moved, visible to the whole audience. It was seen that at a particular moment of cooling, when the iron was at a red heat, the contraction was instantly reversed into a sudden and momentary expansion of the iron. The critical temperature at which this extraordinary molecular change in the iron occurred appeared to be that at which iron returns to its magnetic condition. An investigation of this important point, and also of the deportment of nickel and cobalt under like circumstances, has yet to be made.

From this body of experimental evidence, there can be no doubt a molecular change of a definite nature accompanies the magnetization of iron. M. De la Rive was the first to recognize this important fact.* Magnetized iron would seem to differ from ordinary iron by a state of longitudinal strain impressed on its molecules. Assuming that the molecules of iron have one dimension longer than another, the polar force given to each molecule appears to act in the direction of that longest dimension. The crystalline structure of iron, as well as its other physical properties, should therefore be matched by similar properties in nickel and cobalt. A strict inquiry into this point was made by the lecturer, and the extraordinary similarity of these three metals was undeniably evident. The accompanying table exhibits a comparison of some of these properties, wherein it will be noticed that both in physical and chemical characteristics these metals are allied. Over and above the well-known similar features of the iron group, there is seen to be a peculiar and subtle analogy running through the metals named.

Substance.	Density water=1.	Atomic weight H.=1.	Specific heat: water=1.	Atomic heat.	Dilatation by heat.	Lengthening by strain.	Conductivity for Heat: silver=1.	Conductivity for Sound; air=1.	Tenacity and melting point.
Iron ...	7·8	56·0	0·113	6·37	·0926	·0387	·168	15·0	v'ry high
Nickel...	8·3	58·5	0·109	6·38	·0899	·0394	·131	14·9	ditto
Cobalt...	8·5	58·5	0·107	6·26	·0981	·0436	·172	14·2	ditto

The lecturer concluded by remarking, his function in this discourse had been only that of a guide, not that of an explorer. If he had not altogether failed in the task he had ventured upon, he hoped that—on reviewing the ground they had traversed that evening—some line of light would be found, aiding the imagination towards a better conception of the inner structure of that wonderful thing called a magnet. We may justly hope that the researches of the next half-century will largely add to our present little stock of knowledge in this direction. But, after all, the utmost scientific inquiry can do is to transfer the phenomena of nature from what has been well termed "the region of disorderly mystery, which is ignorance, into the realm of orderly mystery, which is science."

GERMAN COMMISSION ON CHOLERA.

An Imperial Cholera Commission, including the most important scientific authorities on the subject in Northern and Southern Germany, has just been opened in Berlin. The Commission is charged to draw up a plan for inquiring into the nature of the disease, to be followed by all the Government physicians in the various countries. Another and equally important duty of the Commission consists in collecting, digesting, and criticising all the scientific material which can be provided bearing upon the mitigation of this frightful plague. Cases in Berlin as yet are very few, but mostly end fatally.

* And it was further developed by Dr. Tyndall in a lecture at the Royal Institution; a full report of which is published in Dr. Tyndall's work 'On Diamagnetism and Magnecrystallic Action,' p. 239.

The Pharmaceutical Journal.

SATURDAY, AUGUST 16, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

A DOSE OF DIGITALIS.

AN habitual drunkard incurs an attack of *delirium tremens* and a surgeon in the absence of his usual medical adviser is called in. The surgeon diagnoses the case as one of acute alcoholism and prescribes a grain of opium in pill. Finding his patient no better he prescribes half-an-ounce of digitalis and one and a-half ounce of distilled water, intending to repeat it in four hours' time if it failed of effect. The druggist to whom the prescription is sent declines to make it up—a fact which the surgeon ascertained only on his return, when he found the patient worse. The surgeon then gives a dose of morphia out of his own medicine chest; but it proves of no avail and the patient dies. At the coroner's inquest evidence is adduced to throw the blame of the patient's death on the druggist, and the jury in bringing in a verdict of "died from natural causes accelerated by excessive drinking" are of opinion that the chemist should have dispensed the prescription.

Such is the outline of a case which came before the Coroner at Ramsgate on Thursday the 7th inst.; and is more fully reported at page 135. We agree with the jury in their verdict, except so far as Mr. FISHER is concerned, and are of opinion that he was quite justified in refusing to dispense the medicine. He knew perfectly well that half-an-ounce of digitalis was an excessively dangerous dose; and that none of the authorities of the profession recognized its administration in such proportion. True, a Mr. JONES of Jersey, had treated certain cases of *delirium tremens* with such doses of digitalis, and the patients had recovered. But Mr. JONES' experience is not yet endorsed by the profession, and is still in the tentative stage of acceptance. Mr. FISHER exercised a wise discretion in declining to make up such a prescription, relying on the authority of the recognized standards, rather than the *ipse dixit* of a general practitioner. But for such an intelligent reluctance to make up fancy prescriptions as Mr. FISHER manifested, cases of poisoning would be innumerable—cases in which the raw assistant surgeon exceeded the proper dose, or the rash practitioner acting on a speculative or ill-established theory prescribed a poisonous drug in unrecognized proportions. We feel sure the public will side with Mr. FISHER, and congratulate itself that there are pharmacists who have the courage to adhere to the professional standards, and to decline to deviate from them, under any pretext whatever.

GERMAN TRADE WITH ENGLAND IN CHEMICALS, ETC.

AN interesting report has been published from Dantzig with reference to this subject, and an epitome of the most salient points contained in the report will be of interest to the readers of this Journal. The German manufacturers are good customers of England for soda and a variety of chemical products, and also of oils required by them in their numerous industries, all these articles being extensively imported into that country from the United Kingdom. The chemical products exported to Germany from the United Kingdom were valued at an average of £128,790 annually between the years 1867 and 1870, and at £271,938 in 1871. Our export of alkali to Germany consisted of 485,544 cwts. in 1870, and increased to 682,627 cwts. in the following year. So great and rapid appears to be the development of every branch of Germany industry that even the enlargement of the various chemical works (which is being carried out in numerous German towns) does not appear to adequately meet the increasing demand for these goods. It must be remembered, too, that chemical preparations of various kinds are extensively produced in Germany, and some of them enjoy even at the present time a remnant of protection in the form of a duty on the importation of certain foreign articles belonging to this class. There is, however, a pretty general desire amongst the manufacturers of Germany who employ these products that the trade should be completely relieved from the few taxes which have still been continued on foreign productions of this character. As German manufacturers have been extending their markets for the goods they produce in every quarter of the globe, they are obliged to look more and more to the means most conducive to cheapen the production of their goods, especially those which they have to send for sale to foreign markets. However unimportant, comparatively speaking, the remaining duties imposed in Germany on chemical products may be, as these goods enter largely for the use of German manufacturers, a desire to see the duties entirely abolished from the German tariff seems a very natural one, which cannot be too speedily and effectually carried into effect.

Statistics of this branch of trade show that the uses of fat, unctuous substances of every description, vegetable and mineral oils, tallow, etc., have of late years taken a vast development, and the expansion of the trade in this direction is very noteworthy. Thus, in 1860, olive oil was imported into the Zollverein for home consumption to the amount of 23,580 centals, while in 1871 the amount had increased to 54,163 centals, thus showing an important

augmentation in the consumption of olive oil. Paraffine and stearine, were imported in 1860 to the amount of 129 centals, and in 1871 to the amount of 7602 centals; turpentine oil in 1860, 63,612 centals, 1871, 105,552 centals; resin, 1860, 568,972 centals, 1871, 722,068 centals. A large increase is thus shown in the imports of all these articles; and it is still more remarkable that, whilst in 1860 there was no petroleum used at all in the Zollverein, in 1871 the imports reached the large total of 4,067,603 centals. It will thus be perceived that the growth of this article into use has been most rapid and considerable.

The duties still in force, since 1st October, 1870, on these goods are as follows, per German or Zoll. centals, equal to 110¼ pounds English :—on linseed oil, and fish train oil, and on other unenumerated oils—with the exception of cocoa and palm oil—and also on paraffine, spermaceti, or stearine oils, at the rate of 1*s.* 6*d.* (half-a-thaler) per cental. Cocoa, palm oil, all dregs or residue of oil, and also olive oil, the latter for manufacturing use only, and if properly rendered totally unfit for every other purpose, are now admitted free of all duty, with the two following exceptions: fish blubber pays at the rate of one mark or 1*s.* per cental, and olive oil (pure), whether in casks or bottles, at the rate of 2*s.* 6*d.* The produce of the duties thus levied on chemicals, including alkali, and on drugs, realized together the following sums, viz., in 1869, 380,621 thalers, or £57,093; in 1870, 384,775 thalers, or £57,716; in 1871, 387,789 thalers, or £58,168. In addition to these sums, about £14,000 annually is realized on other fat substances. On soda alkali the amount of duty realized was as follows :—in 1869, £22,573; in 1870, £26,306; and in 1871, £19,421. Judging from these figures, it seems evident that these duties might be repealed completely without making much appreciable difference to the revenue, and with very considerable advantage to those branches of industry most directly interested in the matter.

The value of the exports from the United Kingdom, direct by sea, to Germany of oil (seed), and foreign oils, is thus stated :—value of British oil, annual average between 1867 and 1870, £257,340: value of foreign oils, £255,212; total estimated value in 1871, British oil, £406,051; foreign oils, £288,865. It will be seen from these figures that the exports of these products from the United Kingdom to Germany have largely increased of late years; and doubtless there is abundant opportunity for still further enhancement in the future.

Generally speaking, the chemical trade of Germany with England appears to be in a very healthy and active condition, constantly on the increase, and capable of very considerable development. Assuredly, when everything in the shape of import duties is removed from the German tariff in respect to this class of goods, and all indications of the ill effects of "protectionist" ideas are abolished, this branch of the trade will make more advance than it has done in the past, and will become more valuable as a distinct branch of the commerce of the country, than it is at the present time. It is to be hoped, therefore, that an enlightened conception of the benefits of wise free trade policy will prevail in respect to this matter.

IMPORTANT CASE UNDER THE ADULTERATION ACT.

The St. Pancras Vestry, acting under the provisions of the recently passed Adulteration Act, have during the past few weeks issued summonses against tradesmen in that district for selling articles alleged to be adulterated, cocoa being generally the article selected as that upon which the charge should be based. One of the most important of these prosecutions was disposed of in the Marylebone Police Court on Saturday, Aug. 2nd. It was a summons against Mr. C. Kirby, a local grocer, for selling two samples of cocoa—one at 8*d.* and the other at 1*s.* a pound—which were certified by the analyst for the parish to be adulterated by admixtures of cane sugar, arrowroot, and sago. The importance of the case may be perceived from the fact that it was adjourned twice, in consequence of want of time to hear it. The manufacturers of the cocoa—Messrs. Dunn and Hewett and Messrs. Taylor Brothers—repudiated the charge of adulteration altogether. The contention of the defence was that this was no adulteration, and in fact that this very article had been recognized for a great many years as a pure and genuine article of commerce. Its sale was legalized by Act of Parliament in the reign of George IV., and as an article of sale it was generally recognized and known. More than two-thirds of the cocoa imported into this country in its pure state being manufactured into soluble cocoa.—Mr. D'Eyncourt, the magistrate, pointed out that he did not see anything in the third section of the Act which made the retail vendor guilty of fraud supposing he knew nothing of the fraud. They must first of all show that the fraud was committed by somebody, and then they must show that the retail vendor knew that the article was so mixed with fraudulent intent. He considered it appeared pretty clearly from the evidence that cocoa was never sold pure, that it was not desired that it should be sold pure, and if so sold would not be purchased. He also held that it was evident the mixture had been recognized for many years in trade; and that to say under these circumstances a retailer was guilty of selling an adulterated article in selling this mixture as cocoa was to convict a man of fraud when probably he was guilty of no fraud at all.

25,000 lbs. of opium was entered for home consumption at Melbourne, in 1871. The 25,000 Chinese in the colony must be large consumers at the rate of nearly one pound per head, for the consumption for medicinal purposes cannot be very large. A duty of 10*s.* per pound is levied on the opium.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The annual meeting was held at the Bristol Museum and Library, on Friday, the 1st inst., Mr. Charles Townsend, President, in the chair.

A copy of the following report had previously been sent to each member and associate :—

REPORT OF COUNCIL FOR YEAR ENDING JULY 31ST, 1873.

The Council of the Bristol Pharmaceutical Association have much pleasure in submitting to the members the report of another year's proceedings.

Circumstances have not yet enabled them to establish a Museum and Library. The difficulty of obtaining rooms convenient and suitable for the purpose has still to be overcome, but they hope that so important a project will continue to be kept in view, and that its accomplishment will not be long delayed.

The monthly evening meetings have been attended with considerable success, both as regards the numbers that have gathered to listen and the quality of the instruction afforded. The Council record their high appreciation of the kindness manifested by those gentlemen who have been good enough to render their voluntary services, and acknowledge their obligations to Mr. Coomber, Mr. Thomas Wills, Dr. Tilden, Dr. Armstrong and Mr. Carteighe, who during the year have so ably assisted them to carry out this portion of their scheme.

The discussion of subjects more distinctly pharmaceutical upon the evening devoted to that purpose was well sustained. The attendance was good, and interesting matters were introduced by Mr. Giles, Mr. Schacht, Mr. Stoddart and Mr. Little. Mr. Little was at that time a pupil of the Association, and his paper, entitled "Examination of some Samples of Ferrum Redactum," was deemed worthy of transcription into the scientific journals. The Council refer to this fact in the hope that it may encourage other junior members of the Association to similar efforts.

The courses of lecture upon Chemistry and Botany, delivered as heretofore by Mr. Coomber and Mr. Leipner, were in all respects equal to those of previous sessions; and the Council rejoice to be able to point to the success which continues to attend this department of the Association's work.

For the course on Organic Chemistry six students of the Association entered, and five of these presented themselves for the Government examination at the end of the session. The following passed :—

Mr. Jas. Goulter.....Elementary Grade.....1st Class.
Mr. Thos. Stubbs ... „ „ ..... „ „
Mr. A. H. Higgs ... „ „ .....2nd „

For the course on Inorganic Chemistry sixteen entered, and twelve presented themselves for examination. The following passed :—

Mr. C. J. Miles.....Advanced Grade.....1st Class.
Mr. Jas. Goulter ... „ „ .....2nd „
Mr. R. H. Nuttall . „ „ ..... „ „
Mr. A. H. Baldwin Elementary Grade ..... 1st „
Mr. Thos. Hall..... „ „ ..... „ „
Mr. A. H. Higgs... „ „ ..... „ „
Mr. A. Towerzy ... „ „ ..... „ „
Mr. J. H. Baker ... „ „ .....2nd „
Mr. H. J. Bliss ... „ „ ..... „ „
Mr. J. Morris ..... „ „ ..... „ „
Mr. C. E. Tritton „ „ ..... „ „

The foregoing results relate to the ordinary examinations in Chemistry. But Dr. Frankland, the examiner, following the plan he introduced last session, appended *special* questions for the purpose of testing the knowledge of the candidates in Laboratory practice. The following passed :—

Organic Chemistry.

Mr. Jas. Goulter.....Elementary Grade.....1st Class.

Inorganic Chemistry.

Mr. C. J. Miles.....Advanced Grade.....1st Class.
Mr. Jas. Goulter ... „ „ .....2nd „
Mr. R. H. Nuttall „ „ ..... „ „
Mr. A. H. Baldwin Elementary Grade ..... 1st „
Mr. Thos. Hall..... „ „ ..... „ „
Mr. A. H. Higgs ... „ „ ..... „ „
Mr. A. Towerzy ... „ „ ..... „ „
Mr. J. Morris ..... „ „ .....2nd „

For the Lectures on Botany (Vegetable Anatomy and Physiology, and Systematic and Economic Botany) five students of the Association entered, and three of these presented themselves for examination. The following passed :—

Vegetable Anatomy and Physiology.

Mr. A. H. Higgs ... Elementary Grade ... 2nd Class.
Mr. F. G. Taylor ... „ „ ..... „ „

Systematic and Economic Botany.

Mr. A. H. Higgs ... Elementary Grade ... 2nd Class.
Mr. F. G. Taylor ... „ „ ..... „ „

The Association is again indebted to Mr. Stoddart, the generous friend and supporter of every scheme having for its object the promotion of scientific pharmacy, for a course of lessons on Materia Medica, designed by him to assist students preparing for the examinations of the Pharmaceutical Society. The fees received for this course, amounting to the sum of seven guineas, have been added to the Museum and Library Fund. The Council desire, on behalf of the Association, to express in the warmest terms their sense of Mr. Stoddart's great kindness in this matter.

In conclusion the Council again confidently commend the objects of the Association to the consideration of their fellow-members, and earnestly invite a continuance of their support and co-operation. Whilst it is possible that the expectations of some have not been fully realized, the Council trust it will be conceded that they have directed the limited materials at their disposal to good purpose, and upon a plan that will admit of development to greater completeness. They trust, therefore, that no differences of opinion upon minor points will be allowed to imperil the efficiency of an Association which has unquestionably done good, and which is (as they believe) earning for itself a name in the pharmaceutical world.

The Treasurer's Report, duly audited, is as follows :—

THE TREASURER IN ACCOUNT WITH THE BRISTOL PHARMACEUTICAL ASSOCIATION, 1872 AND 1873.

Dr.	£	s.	d.
To Balance from last year	13	12	·

	To Balance from last year	17	17	0
May 15	,, Cash from 7 Students who attended Mr. Stoddart's Lectures	7	7	0
		£25	4	0

The President in moving the adoption of the report and accounts, said that their Association had now been in existence for four years, a time sufficiently long to test its strength, and to form an opinion as to whether it had really taken root and become firmly established, and he thought they might fairly consider that it had done so; the number of members had not fallen off, and they had as many students as they could reasonably expect. He was happy to feel that the position of those engaged in the study of pharmacy in the city was better and higher than when the Society was established; and he believed that many who at first gave attention to the requisite studies only from a sense of the absolute necessity for doing so were now seeking knowledge for its own sake. The proportion of the students who went up for the South Kensington Examinations was very gratifying, and the proportion of those who passed, as would be seen from the report, equally so. Bristol had also taken a fair position in the recent Preliminary examination, but still, three out of eight failed. It struck him as somewhat remarkable, in looking over the published list, that the failures had been most numerous in several of the largest centres, where the facilities for study are presumably the greatest. Thus in Birmingham eight out of eleven failed, in Manchester eleven out of seventeen failed, and in Liverpool four out of eleven failed. Many of the smaller towns had done much better than this. With reference to the monthly meetings held during the past session, they had been highly successful; the lectures had been exceedingly good and interesting, and they had been attended not only by members and students of the Society, but by many of the leading members of the medical profession, and by other well-known scientific gentlemen. He (the President) trusted that they would be able to do even better in the future than they had done in the past, and gain a high position for the Bristol School of Pharmacy. They had all to thank their good and constant friend Mr. Stoddart, for his valuable help, and for the fund which formed the basis of the museum and library fund. The financial statement was upon the whole satisfactory, the expenses of the year had been somewhat larger than usual, but the receipts had not fallen off. His term of office was now nearly at an end, and he wished before retiring to express to the members of the association his very hearty thanks for the cordial manner in which they had invariably supported him. He had done his best, and he hoped that his successor, who would, he was sure, receive the same generous consideration, would be able to preside over the affairs of the society with as much pleasure and satisfaction as he had done.

Mr. Keevill seconded the motion. The President, he said, had alluded to all the topics which seemed to call for any comment. He was sure they must all feel gratified at the prosperity which had thus far marked the career of their association. No doubt that prosperity was in some measure due to their good fortune in possessing the services of gentlemen of considerable reputation and influence, not only on account of their high scientific attainments, but also because of the leading part they had always taken in promoting the progress of pharmacy. The associates seemed to be fully sensible of the opportunities for improvement held out to them. In looking over the report he had been struck by the large percentage of candidates who had succeeded in passing the examinations. He was also much pleased, as probably they all were, to hear of the distinction achieved by their late pupil, Mr. Little. The Treasurer's statement, he noticed, still showed a balance in hand. Altogether, then, they had every reason to feel satisfied, and he trusted that in the hands of the new Council the prestige and usefulness of the association would be fully maintained.

After some general observations by Mr. Giles and Mr. Schacht, in the course of which the latter alluded to the new regulations recently initiated by the Council of the Pharmaceutical Society.

Mr. Stoddart moved a vote of thanks to the retiring President. No one, he said, had served, or possibly could serve, the office better than Mr. Townsend had done. In selecting him the Council had indeed made a most fortunate choice, and the success of their proceedings had been materially enhanced by the judicious and courteous way in which he had presided over them. The motion was carried by acclamation.

An examination of the voting papers then took place, and the President announced the election of the following gentlemen on the Council for the ensuing year:—Messrs. Boorne, Boucher, Cuff, Giles, Isaac, Martin, Pitman, Schacht, Stoddart, Stroud, Taplin, and Townsend.

The re-appointment of Mr. Collings as auditor concluded the proceedings.

At a meeting of the Council, held on Friday, the 8th inst., the following officers were elected:—President, Mr. Schacht; Vice-President and Treasurer, Mr. Boorne; Honorary Secretary, Mr. Pitman. The arrangements for the coming session were discussed, and a sub-committee consisting of the President, Vice-President, and Honorary Secretary, appointed to confer with the Professors of Chemistry and Botany, and to draw up a scheme for the approval of the Council.

CHEMISTS AND DRUGGISTS' SOCIETY OF IRELAND.

A meeting of the above Society was held on Monday evening, August 4th, at 44, Molesworth Street. Mr. P. T. Bermingham, T.C., in the chair.

The following gentlemen were admitted to membership: Mr. J. Laird, Limerick, Mr. H. Bell, Waterford. After considerable discussion connected with the prices of various articles connected with the trade, and the vending of poisons by grocers, etc., it was agreed to publish a price list similar to the one issued by the Glasgow Chemists' Association.

Several amendments to the rules of an unimportant character were agreed to. The number of the committee was reduced from nine to six, three to form a quorum.

The election by ballot of officers for the next twelve months was then proceeded with, with the following results:

President, E. M. Hodgson, Esq.; Vice-President, Wm. Allen, Esq.; Hon. Treasurer, J. Goodwin, Esq.; Hon. Secretary, Wm. Hayes, Esq. Committee, P. T. Bermingham, Esq., T.C., W. L. Erson, Esq., J.P., G. H. Grindley, Esq., J. A. Ray, Esq., R. Simpson, Esq., W. F. Wells, Esq.

It was agreed to appoint a gentleman as assistant-secretary and librarian, and applicants were requested to communicate with the hon. secretary.

It is intended to establish a library and reading rooms, and to make arrangements for the delivery of lectures and formation of classes during the winter months.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

ON THE ENERGIES OF THE IMPONDERABLES, WITH ESPECIAL REFERENCE TO THE MEASUREMENT AND UTILIZATION OF THEM.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture III.

On the Energy of Vitality, with especial reference to the Measurement and Utilization of it.

(*Continued from page* 117.)

The energy of vitality, as utilized and controllable by ourselves, is manifested chiefly through the agency of muscles. The physiologist regards these muscles, with their attached

* Cantor Lecture, delivered February 17.

tendons and nerves, as to the functions and offices they discharge in the economy of the individual; we are to regard them as to the external use to which they may be applied and the work to be obtained from them. How much we copy from nature may be concluded when we refer to the earliest attempt at locomotion from machinery. It was by basing the form and structure upon the muscles of animals. To thus imitate muscular action has hitherto baffled the ingenuity of man. If any one has not satisfied himself of the nature of this action let him put the hand on the muscles of the arm when it is in repose; they are soft and yielding. Let him now make an exertion with the arm, such as raising a weight; the muscles become tense and hard. The weight raised is extraordinary compared with the weight of muscle employed, for it may be from sixteen to seventeen thousand times its own weight.

The physiologist considers the striated and unstriated variety of muscle, the nucleated cells, the vitality in each cell, the electrical relations of various tissues. With none of these need we be concerned.

Engineers regard muscles as machines for doing work, and as it is needful to know the structure of a machine before we can say how it can be made to work, so now the structure of muscle, as a machine, must be considered.

When a muscle is examined after vitality has ceased, it is found to consist of a great number of separate parts, or strings. If this piece of string were a muscle, there would be a bundle of strings or fibres together, just the same as if I had doubled the string several times, and encasing them there is a covering or sheath, much the same as an india-rubber tube, which covering encloses a number of muscular fibres or strings. That covering has none of the contractile elements of the muscle in it; it is merely an elastic covering enclosing that which has the contractile powers. Then, side by side with this bundle of fibres or strings, in its case, is another one, also covered in the same way, and another, and another. These are kept in their place by the tubing or covering spoken of, and a combination of these is called a muscle, which consists then of these fibres, which again are separated into fibrillæ. With such a peculiar arrangement of contractile strings it is clearly a problem for the mathematician and the mechanic to obtain a solution to the question of how much work can vital energy do when operating through the means of such apparatus as is thus supplied. The muscles are so varied in form, combination, and number, that but little progress has hitherto been made to deduce results and bring them into measurement.

Now, no substance is known that can act the part of a muscle. A muscle left free is in the state of an india-rubber band when slightly stretched. It is called into action by contracting, exactly the converse to that of india-rubber, which is brought into action by being stretched. A number of these fibres are put together, and form a group like a number of india-rubber bands. Sometimes the groups act in a straight direction, sometimes they take a sloping form. If they take a straight form, and if we know the number of fibres and the power of endurance of one, it is easy to calculate the power of the whole; but if the muscle acts diagonally, then it brings in the parallelogram of forces, and we need the mathematician to deduce the amount of energy which can be utilized by this form. Sometimes the fibres are twisted like a screw, sometimes they spring from one point and spread out like a fan, and all these screws and fans the mathematician must get hold of and calculate; this is now being done.

Having endeavoured very briefly to explain the mode in which animal vitality can be utilized through the agency of muscle, it may, perhaps, be well to state that between that part of the system where the will is localized and the muscle, there are telegraphic ramifications of nerves. These nervous processes enter within the muscle, and by some means unknown to us, influence the muscle to exert its mechanical powers—convey, in fact, the will to that agent which is expected to do its bidding through the power introduced by vitality.

With this nerve power we are not concerned; the nerve, as a material substance, is intermediate between the will and the muscle; it has nothing to do with the amount of work done; its business is chiefly to connect the mental and the material processes of life. Of that which is the will, of that which travels along the nerve, in consequence of the will, we know nothing. Call it electricity; that is not any advance, for we know nothing of what electricity is. The first region in which the vital power gives a measurable evidence is when the muscle begins to act. Prior to that all is speculation, and furnishes a very pleasant hunting ground for physiological enthusiasts.

Whether muscle is a means or apparatus for the transformation of force, or whether it is the material out of whose chemical changes or electrical states force and consequent energy result, are beyond our present knowledge. A plant transforms light into energy, so may muscle transform what, for want of a better name, may be called vitality into energy, and yet not be itself consumed or destroyed. Although, for obvious reasons that energy which is localized in animals is called the energy of vitality, yet it must not be inferred that such energy or source of energy is self-existent. The animal extracts it in those wonder-working laboratories—the stomach and the lungs. By some unknown process it is deposited in the muscle as potential energy, and awaits the decision of the will as to when and how it shall become kinetic. Although ignorant of the analytic chemistry of vitality, yet we are not ignorant of the materials with which it experimentalizes. With this knowledge we must rest; we cannot repeat the experiments vitality makes. Given, every material and contrivance within reach, neither the physicist nor chemist, separately or jointly, can accomplish the phenomena with which the changes of these ingredients are concerned when they are associated with the vital principle.

To form an estimate of the number of the fibres in any muscle is an investigation requiring more of care and caution than of difficulty. Determining from a series of averages the magnitude of one—*i.e.*, the area of cross-section of one muscular fibre, and knowing the area of the section of muscle, the number is merely the quotient of the division.

The muscles are exceedingly small and delicate, and the way in which their size is calculated is by cutting a piece of cardboard exactly to the section of the muscle. Then another piece is cut out of the same cardboard to, say, a square form, and they are weighed against each other until the square card is exactly the weight of the irregular piece. Thus, when the weights are equal the areas are equal, and by calculating the area of the square piece, you are able to arrive at the area of the section of the irregular muscle. By the aid of a powerful microscope we can ascertain the size of a section of one of these fibrillæ—and it is found to be in men $\frac{1}{350}$ of an inch in diameter, so that in an inch there would be 350 of them, in women it is about $\frac{1}{450}$—*i.e.*, in one inch there would be 450 of them. It may here be mentioned that these elementary fibres are not circular but polygonal, owing to their mutual pressure, and at the angles of the polygons are the vessels which supply blood. Hence, it obviously follows that where these fibrillæ are very small, the supply of the blood, which is the food of the muscle, can get at them more readily than when they are very large. Where they are large, they have greater strength, that is, can lift heavier weights, but where they are small they will have greater endurance, because more freely and easily supplied with blood. Hence, as they are smaller in women than in men, the muscles of women have more power of endurance, but not the same strength as those of men. If a man wishes to test this, he has only to nurse

a child, and then compare the length of time he could do so without fatigue, with the length of time for which a mother can nurse it, and he will soon find the difference, and give a verdict adverse to himself.

There are two muscles in the arm with which we are especially concerned in estimating the measurement of such vital energies as we may utilize; indeed, it may suffice to consider that the muscles in the arms and legs are the only ones to which the subject of this evening's lecture directs attention, and we may illustrate the question of the great number of muscular fibres by calculating in the mode described their presence in the two most important muscles in the arm—viz., the one called "biceps," the other called "brachialis anticus." In the biceps there were found to be 449,000 elementary fibres; in the brachialis there were found to be 349,000; total, in these two muscles of the arm, 798,000 fibres.

Now, to examine these muscles—their fibres and their fibrillæ, to watch their action, and to speculate upon the causes of this action, is a department of science full of interest, and from which much that is valuable may be brought. The object of this lecture does not require that any such investigation should be made, and the competency of the lecturer is not equal to the task. Dr. Haughton, of Trinity College, Dublin, has for many years sought for means and opportunities, and availed himself of them, even at the risk of his own life, for determining accurate measurements of muscular force. This first mention of the name of one who for twelve or fourteen years has given that attention to this subject which enthusiasm alone could induce, must not be passed without this addition. In reply to a letter, towards the close of 1872, Dr. Haughton most kindly sent me 400 pages of the proof-sheets of a work on 'Animal Mechanics,' which has not yet been published.* This work is my authority for the figures relating to experiments in respect to muscular strength and endurance. With the results his careful and numerous opportunities have afforded him we are clearly concerned. How carefully these have been collected may be judged from the following. He writes: "This much I can guarantee, all the dissections, weighings, and observations have been made by my own hands, with every precaution of which I could think to ensure accuracy. My observations have also been made without preconceived hypothesis to guide them; and many of my most interesting results have been forced upon my notice by the facts placed before my eyes in the dissecting-room and laboratory."

First, as to the expression "co-efficient of muscular force." On the wall is a table of "co-efficient of muscular force."

In the arm . . .	94·7 lbs.	per square inch.
„ leg . . .	110·4 lbs.	„ „
„ abdomen . .	107·0 lbs.	„ „
Average . . .	104.0	

The term "co-efficient" is a word of common occurrence in scientific investigation, and is plainly attainable from "co-efficiency." When we speak of co-efficiency we mean "that two or more things combine to produce an effect." It is the figure by which a unit measurement is multiplied in order to produce a result. To find the co-efficient of muscular force is to find some quantity which may be so combined with a measured area of muscle as that we can have a result on which to rely in reference to the question proposed. Adopting the view which the lectures on energy and gravity propounded, it may suffice for the present to say that the table on the wall tells us that, knowing the number of square inches contained in the cross-section of any muscle, then multiplying these by the figures there stated, we obtain the weight which the particular muscle can, on sudden emergencies or for a very short space of time, sustain. It is the limit of endurance—it is the measure of load which is just sufficient to cause the muscle to break—if a small weight more be added then the muscular fibres will be broken. It is the very extreme tension to which muscular fibre may be subjected without actual rupture. It is obtained by treating muscle as engineers treat wrought-iron rods when they seek to ascertain what load they can carry by tension. This explains that the table does not give a co-efficient of work the muscle can do; such a co-efficient depends upon the energy that vitality (or vital force, if the term be preferred) can infuse into the muscle; but, however great that vital power may be, the work done by the muscle must be less than that obtained in the table to which these remarks apply. A few words in illustration may not be misplaced.

We find from experiments, which would occupy far more than an hour to narrate, that in order really to tear one square inch of muscle across it would require 94·7 lbs. in the arm, and in the leg 110·4 lbs. It is somewhat remarkable that in the arm, which does not carry the body, you have 94 as the strength of the muscle. When you come to those connected with the leg, which have to carry the body as well as do work, the fibres are very much stronger. Taking the average of the whole body, the co-efficient of one square inch of muscle in the human frame is 104. Therefore, if we know the size of any particular muscle and multiply it by 104, we get in lbs. weight the limit of strain it will endure before fracture.

Now the next question is, how much will it raise? In this view of the case motion enters. Supposing a fibre was in the form of a string, a very long one, and by contracting it will raise 2lbs. weight through 10ft. If, now, that fibre were doubled and only half the length, it would raise 4lbs., but it would only lift it through half the space, because its power of contraction would be diminished by the doubling. Now, the products of the weight raised, and the distance through which it is raised, are the same in both cases. If it raises 2lbs. through 20ft. 40 would be the measure of that muscular exertion; and if it raised 20lbs. through two feet, 40 would still be the measure; but the distances are different. After illustrating experimentally these statements, the lecturer remarked that if an ounce of muscle be distributed with large sectional area, then its contraction will be little, but the weight raised may be great.

Muscle has also another peculiarity different from anything with which we can deal. If a bundle of it be taken, as you are aware, it acts by contraction; but while it contracts it does not change its bulk. It does not swell out as we understand the word—it merely contracts. Thus if you had a long muscle acting in a vessel of water, and it contracted ever so powerfully, it would not in the slightest degree affect the level of the water in the vessel.

Now we come to the mode in which the mechanical action of these combined muscular fibres is to be brought to a question of simple calculation. As far back as 1798 Dr. Wollaston occasionally observed a peculiar sound in his ears, for which he could not account. He pondered over this sound until about 1808, when a faint dawn began to enlighten the gloom. In 1809 he made clear to his friends what he was about, and in 1810 the results were published in the Philosophical Transactions. What he then did is the basis of all our present knowledge of this subject of muscular power.

Dr. Wollaston began to surmise that the sound in his ears arose from muscular contractions. He stated that he

* Since the delivery of this lecture the work has been published, under the title of 'The Principle of Animal Mechanics,' by the Rev. Samuel Haughton, F.R.S., Fellow of Trinity College, Dublin. London: Longmans, Green and Co. Dr. Haughton states in the preface that "the work is offered to the public with the view of showing the mutual advantages obtainable by anatomists and geometers from a combination of the sciences they cultivate. Anatomists will gain by the increased precision which numerical statements must give to their observations, and geometers will find in anatomy a new field of problems opened out to their investigations."

was led to infer the existence of intermittent contractions, from a sensation perceptible upon inserting the extremity of a finger in the ear. A sound is then perceived which resembles most nearly that of carriages at a great distance passing rapidly over the pavement. The sound is not dependent upon the degree of pressure upon the tympanum, for when the ear is stopped with great force without the presence of muscular action no such sound is produced. For instance, if the head press with its whole weight upon the ball of the thumb no noise is perceived unless the extremity of the thumb be at the same time pressed against the head, or some other muscle be brought into play. To judge of the frequency of this contractile action, he contrived to imitate the sound, and to render the sound itself and the imitation audible by the same ear. It was accomplished thus. While the ear rested on the ball of the thumb the elbow was supported by a board lying horizontally, in which were cut notches about $\frac{1}{8}$ inch asunder, similar to those in this board. By rubbing a pencil along these notches with a regular motion he imitated pretty correctly the tremor produced, and by counting the marks and noting the time, he found repeated observations agree with each other as nearly as could be expected. He also varied the experiment. One variety was this—the ear was stopped by a cushion pressed upon by the end of a notched stick that rested on his foot and conveyed the vibrations from the muscles of the leg to the ear along with the tremor produced by friction upon the notches; and still the results were nearly the same, viz., that the muscular vibrations resembled the sound of carriages at a distance. He induced many friends to repeat the experiments, and by going through the form of the experiment anyone may, when convenient, satisfy himself. The humming sound will, of course, be perceptible only to the ears of the experimenter.

Parliamentary and Law Proceedings.

Unjust Censure of a Druggist.

On Thursday last an inquest was held at the Elms Hotel, Ramsgate, before J. C. Martin, Esq., coroner, and a jury, touching the death of Mr. J. H. Davidson, an ironmonger, etc., in that town, whose death took place under the circumstances adduced in the subjoined evidence. The jury having viewed the body, the first witness called was

Henry Turner, who said: I live in Alexandra-road, St. Lawrence, and am a porter. I knew the deceased, John Hector Davidson, and was his servant. I was employed at his place of business in King-street, Ramsgate. I saw deceased alive yesterday morning about half-past seven; he was then at the shop, and appeared to be rather excited and nervous; his eyes, I observed, were rather bright. I again saw him at half-past ten, when he appeared to be about the same. I was with deceased again about half-past ten last night: he was then in his bed; he appeared rather excited, but not from the effects of drink. A little milk and soda was given deceased. He died about half-past one or two this morning. He was not at all violent, but made noises, and bawled out once or twice. I have known deceased ever since he has been in Ramsgate, about seven years. He occasionally got intoxicated, but was never violent or excited on such occasions. Yesterday some medicine had been given deceased by Dr. Leake.

The foreman: You know, I presume, that deceased was addicted to freeness in drinking, and took rather more than was good for him?—Witness: Lately he has.

Foreman: Did deceased make any complaint as if in pain?—Witness: Not at all; but he made allusion to shadows of some persons being in the room, but was very quiet with it.

Jonas Richard Leake said: I am a surgeon on the retired list of Her Majesty's Army, a L.R.C.S.E., M.R.C.S.Eng., and L.S.A., and have now established myself in private practice in Ramsgate, and reside at Gertrude-villa, Ramsgate. I did not know the deceased. I was called in yesterday morning about half-past ten; he was then at his residence at Picton-road and lying on the sofa. He was in much excitement. He told me he had been out for a walk. He was very evidently suffering from alcoholic stimulants, and he told me he had already had some whisky and brandy that morning. I examined deceased, and ordered him to his bed, and I prescribed and gave him a pill containing a grain of opium. I then left him, but saw him again in the afternoon, when he was in a high state of excitement, but had had some sleep. I wrote a prescription for him, of which I have a copy. Deceased took some medicine in the middle of the day, which had a very good effect, and gave him about an hour's refreshing sleep, and he awoke much better. The visit to which I am alluding was my second call. In the evening, about 8 o'clock, I visited the deceased again. He was again in a state of much excitement. I then prescribed for him, which prescription Mr. Fisher refused to dispense; my object being to give deceased some hours of refreshing sleep, so that he might get up comparatively well. By way of diet I ordered him eggs and brandy. The direction on the prescription was that "at 10 o'clock this draught is to be given." From what I heard I understood Mr. Fisher had said no chemist in the town would make up the prescription, as anyone taking it would be a dead man (or words to that effect). The dose I prescribed was half-an-ounce of digitalis and $1\frac{1}{2}$ ounce of distilled water, which I intended to repeat in four hours' time if it failed in producing the desired effect. (The Coroner here interposed, and stated what he found prescribed in Squire's Pharmacopœia for a dose in similar cases.) I was told afterwards that the chemist had refused to make up the prescription; and therefore the onus of deceased's death must rest with Mr. Fisher. (The Coroner thought this was a mere question between witness and the chemist.) I wish this to be inserted. For an ordinary case of *delirium tremens* it is by no means an uncommon dose, and, in sober truth, it is considered efficacious. I ordered a rump steak to be provided for deceased when he woke up after a few hours' good sleep. At about half-past ten I was again sent for, and was told that the medicine prescribed had not been given, as no chemist would make it up, and that the chemist had said if anyone took it he would be a dead man. Instead of deceased sleeping, he was in a state of greater excitement in consequence. After half-past ten, knowing that the medicine could not be procured, I gave him something out of my own medicine chest—a dose of morphia; the only fault of which was that it was not strong enough, and had no effect. I then left him, but did not afterwards see him alive. About one in the morning I was summoned again to the deceased. I forgot to state that when I was summoned about eleven o'clock, in consequence of the message from Mr. Fisher, and from what had been stated, deceased's mother told me she had lost all confidence in me. In consequence of the medicine not being made up, I could give no more assistance in the case; but at half past eleven I was called up, and was told that the draught I had given deceased had not produced sleep, and I said that nothing else could be done for him. On inquiry, I was told that my directions were thoroughly disregarded.

The foreman: Is any case known in which a person has taken the dose you prescribed with good effect?

Witness replied in the affirmative, and even larger doses; and stated he had read a paper before the Medical Association at Leeds on the subject, and that it was quite an ordinary dose, and which he could prove from several medical authorities.

The foreman: And you have known it to have the desired effect?

Witness : Yes ; but this was an extreme case, and required an extreme remedy. The person responsible is the person prescribing, but I don't think chemists should dictate to physicians what should be prescribed.

Witness, in addition to the above, said : I refused my certificate in order to give Mr. Fisher an opportunity of explaining his conduct in the case ; considering it also due to the public and to the medical profession generally, and to my own reputation in particular.

The Coroner : It is your opinion that death was occasioned by natural causes ?

Dr. Leake : In my opinion he would have lived if he had taken what I prescribed. He died from exhaustion of the brain, in consequence of not having necessary sleep.

The Coroner : It appears to be a matter of opinion between two persons.

In reply to a juryman, witness said deceased's was an extreme case, and required an extreme dose. He had visited deceased five times during the day.

Witness further expressed his opinion that Mr. Fisher ought to be visited with censure, as the same thing might occur again. His clear duty was to have sent a messenger to his (witness's) house to make inquiry. In his opinion, if the medicine had been administered deceased would have lived.

The witness Turner was re-called, and in answer to a question from the Coroner, stated that the deceased was 34 years of age.

The Coroner stated that he understood Mr. Cresswell was deceased's ordinary medical attendant, but that he was in London on the previous day. They wanted to know the occurrences of yesterday and last night. Therefore, if they wanted further evidence, they must wait for the arrival of Mr. Cresswell ; but he did not think it would lead to anything useful.

Mr. Fisher, who was present, wished to ask the coroner's opinion as to whether he could say what he knew relative to that prescription.

The Coroner : I do not call upon you to do so.

Dr. Leake quoted the following authority in confirmation of his view, as one amongst many others :—"Mr. Jones, of Jersey, stated that for the last twelve years he has treated all his cases of *delirium tremens* by large doses of digitalis with a remarkable degree of success. He gives half-an-ounce of the tincture with a little water for a dose. In some few instances one dose is sufficient, but generally a second is required four hours after the first. Very seldom a third dose of two drachms is called for owing to the absence of sleep. The effect of this drug is to produce a warm skin, a more regular and fuller pulse, and six or eight hours' good sleep."

The Coroner informed Mr. Fisher that if he wished to make any statement he must be sworn.

Henry Augustus Fisher, on being sworn, said : I live in High street, Ramsgate, and am a registered chemist and druggist. (The Coroner here handed him the prescription, asking him to look at it.) Witness then proceeded : The prescription now produced is the one that I had handed into me last night, shortly after nine o'clock. The dose being a very excessive one of digitalis—eight times the dose recognized by Mr. Squire in his Pharmacopœia, and the same in the British Pharmacopœia—I inquired of the messenger who brought the prescription whom it was for. He replied that if I particularly wished to know he would tell me ; this he uttered in a most impertinent manner. (Witness, on being asked who the messenger was, said he believed it was the first witness, but he was a perfect stranger to him.) I told him it was a very strong dose, and sufficient to kill anybody, and, as he was so very impertinent, I refused to give it, and returned the prescription to him. Had I even known it was for Mr. Davidson I should have refused to give it. In answer to a question, witness said : My reason for so doing was simply that digitalis is a medicine of very uncertain result. I handed the messenger the prescription back again, as I did not like the responsibility of making it. Any medical man wishing to give such a dose as here indicated ought to wait on a chemist and state the case. The prescription was only signed with the initials of the medical man, and not in his full name.

The Coroner told witness that the inquiry was merely as to the cause of the death of the deceased.

Mr. Fisher : I have attended here voluntarily. But before the jury come to any decision I think I ought to call upon two chemists present to say that I was perfectly justified in refusing to make up the prescription.

The Coroner said it was not an inquiry into the particulars of the case. If deceased had died from taking poison they would have had to go into the medical evidence ; but this was a negative affair.

Mr. Fisher : My conduct has been called in question, and I think I ought to be in a position to call witnesses.

The Coroner did not concur in this view, remarking that it would have been otherwise if witness had laid himself open to a criminal prosecution. Witness could leave it to the press to give publicity to what he had said.

Witness's attention being called to the fact that Mr. Davidson's name appeared in the prescription, he replied he did not observe it, and it was the dose that attracted his attention.

The Coroner : This is irrelevant.

John Pearson Cresswell said : I am a surgeon, practising at Ramsgate. I knew the deceased, and was his medical attendant. I had attended him up to yesterday morning. I saw him the last time on Tuesday, and I prescribed for him yesterday morning. He was then suffering from a slight attack of *delirium tremens*, threatening to be very severe if he was not careful. I was not in Ramsgate yesterday ; and I did not see the deceased again alive. His habits of life were such as would tend to shorten his days. Deceased had two or three attacks of it, but there was nothing to lead me to the supposition that the symptoms which I saw on Monday and Tuesday would have been fatal, as deceased had been better. I learn that he went out yesterday morning, and that was what brought on the severe attack which caused his death. Deceased was perfectly convalescent from a case of that kind when I saw him.

The Coroner here handed witness the prescription, asking him, as deceased's medical attendant, whether he had any observations to make.

Witness replied that in some extreme conditions he would have no objection to prescribe or to give it. It was not an ordinary dose, but in the case of the deceased it would have been like throwing feathers upon him. He maintained that a large dose at once was far better than allowing him to sink from exhaustion ; but in such a case as the deceased's you must bring the man under its influence at once.

The foreman : You think the dose ought to have been administered ?

Witness : Most decidedly. In a case of that kind the dose ought to have been given at the time it was ordered him, as it would have been the only hope of saving his life. A man not taking it, the thing takes its own course, and the man dies from it, there being no help for it. It is not a remedy I should rely upon myself ; but different medical men have different opinions.

The Coroner asked Mr. Fisher if he had any questions to put to witness.

Mr. Fisher : As my character is at stake I should like the jury to hear what I have to say. I could bring sufficient evidence. I have two gentlemen here whom I beg you will hear. They would have refused to dispense the prescription ; but there is a difference of opinion. I was not bound to dispense that prescription by law.

A juror wished to ask, through the Coroner, as Dr.

Erratum.—Page 114, col. ii., line 26 from top, for *Leeds* read *Hull*.

Leake was a stranger in the town, whether a chemist would dispense the prescription.

The Coroner: Of course a chemist must use his own discretion in the matter.

The Coroner, in summing up, remarked that the first thing they had to consider was the cause of death. He thought they could have but little difficulty in arriving at the conclusion, on the evidence of the medical testimony, that the deceased had died from exhaustion and from natural causes. But if they gave any rider they were perfectly at liberty to do so. It was a question of a very delicate nature, and one they would hardly go in to. There was certainly a startling difference between ten to thirty minims and half-an-ounce. It was for them to consider whether they would put a rider to their verdict or not. They would consider the evidence; and if Mr. Fisher incriminated himself in any way, but certainly he did not think he had done so. He thought they would have no difficulty in arriving at a verdict, and that deceased had been suffering from *delirium tremens*, and that since last Tuesday he had brought on another attack which ended in his death.

The jury were left alone to consider their verdict, and after a short deliberation returned the following:—"That the deceased died from natural causes, accelerated by excessive drinking; and the jury are of opinion that the chemist should have dispensed the prescription of the physician."

*** In reference to this case the following correspondence has appeared in the *Thanet Advertiser*:—

"Sir,—Having been present during the inquest held at the Elms Hotel yesterday, as to the cause of the death of the late Mr. Davidson, and it having transpired in evidence that in the opinion of a medical witness that had the draught which he had prescribed been administered death would not have taken place, and that consequently great responsibility rested on the chemist to whom the prescription was sent, for refusing to dispense it; and upon such distinct evidence the jury felt it to be their duty to add a rider to their verdict to the effect that the chemist ought to have compounded the draught.

"Will you allow me, as the oldest chemist practising in Ramsgate, to say that in my judgment no chemist is justified in dispensing any prescription where unusually large doses of a strong preparation of a poisonous herb like foxglove, is ordered, without a *real* understanding of the intention of the prescriber; and one of the most important qualifications required of chemists is that of being able to detect *at a glance* unusual doses. Here was an unusual dose, 240 minims of tincture of foxglove in one draught, the ordinary dose of which, according to Squire, ranges from ten minims to a maximum of thirty minims. Dr. Pereira gives the dose as follows:—'The usual dose of the tincture for an adult is ten minims, cautiously increased to forty.' It is, however, well-known that tincture of foxglove has been given, in exceptional cases, even in larger doses than ordered in this draught. The late Dr. Pereira says:—'I have myself exhibited the tincture to the extent of half-an-ounce—240 minims—(never more) in not more than two or three instances. To my surprise there was no striking effect produced by it, but I did not venture to repeat the dose.'

"The prescription was written with the usual symbolic character for ½oz., and as the difference between the character used to denote the maximum dose in Squire—viz., thirty minims—differs only by a minute additional stroke of the pen from the character denoting 240 minims, it would be a tremendous responsibility indeed upon the chemist who, without understanding the full and indubitable intention of the prescriber, should supply to anyone in a single draught *eight* times the recognized maximum dose, especially when a less than a shorthand writer's stroke is all that distinguishes the symbols. If the writer's hand and pen were infallible, and could never make a minute mark in error, then it would have been the clearest duty of the dispenser to have fully ascertained the intention of the prescriber before entrusting the medicine to a patient. (Chemists usually take counsel with each other on prescriptions from a distant prescriber where a perilous doubt exists.) Some physicians write their intentions in plain figures and words, and trust not unusual doses to a symbol which might embarass the dispenser.

"If this draught had been dispensed, and the patient should not have recovered, what would have been the position of the dispenser, who, on the characteristic only, had caused to be taken 240 minims of tincture of foxglove, without having previously ascertained the intention of the prescriber to have ordered so large a quantity. Any medical practitioner can obtain whatever preparation he may need, and administer whatever amount his judgment may indicate, but a chemist who understood his duty could not, and ought not to dispense unusual doses without, by some means, previously ascertaining that the extraordinary quantity was intended to be administered.

"I am, sir, your obedient servant,
"Hy. Morton,
"Hon. Local Secretary of the
"Pharmaceutical Society.
"Ramsgate, August 8th, 1873."

"Sir,—The coroner's jury, which met yesterday on the occasion of the death of the late Mr. Davidson, having, on the *ex parte* statement of the medical men who attended, chosen to attack me for declining to make up a prescription containing a most extraordinary quantity of a virulent poison, viz., ½oz. of tincture of digitalis, I beg you will favour me by inserting in your paper the accompanying document.

"The handwriting was entirely unknown to me, and initialled only.

"Yours obediently,
"H. A. Fisher.
"August 8th, 1873."

[copy.]

"Ramsgate, Aug. 8th, 1873.

"We, the undersigned, think Mr. Fisher was quite justified in refusing to make up a draught containing such a very large dose of a poisonous drug without a further communication with the medical man prescribing. The prescription being initialled only.

Cases under the Adulteration Act.

At Lambeth Police Court, Mr. William Parnell, baker, George Street, Camberwell, was summoned for selling bread containing rice. Mr. Clarke was for the prosecution, and Mr. Straight defended. The present proceeding was taken under the second part of the second section of the Adulteration of Food Act (35 and 36 Vict., c. 74), which provides that any person selling as unadulterated any article of food or drink which is adulterated shall be liable to a penalty not exceeding £20. A loaf purchased at the defendant's shop was found to contain a quantity of rice. A witness for the defendant stated that the flour was used as received from the miller's. Mr. Clarke relied on the case of "Fitzpatrick v. Kelly," in the *Weekly Reporter*, where a person was convicted of selling for butter an adulterated article at a small sum. Mr. Straight submitted that the case cited was not analogous to the present. It was not intended by the Legislature that a tradesman should be liable for selling an article which he believed to be genuine, but which happened to be adulterated. If the magistrate held this to be the law the sooner it was

amended the better. Mr. Ellison was of opinion that the offence was proved; to hold otherwise would open a wide door to offences. He imposed a fine of 10*s*.

George Orgle, milkman, Summer Road, Peckham, was summoned for selling adulterated milk. It was proved that the pint of milk purchased contained water and was very poor. The defendant said it was sold by his wife as a "mixture." The inspector said it was sold as milk and he knew nothing of a "mixture." The defendant said it was sold at 3*d*. per quart in a poor neighbourhood. Mr. Ellison fined the defendant £2 and costs.

Three Deaths from Poison.

The following inquests were held in Liverpool on the 26th July :—

On the body of Frederick Green, 22, who died on Thursday morning. The deceased was a chemist, residing at 22, Wavertree Road, and it appeared from the depositions that he had been in the habit of taking opiates. On Wednesday he took some laudanum to make him sleep, and after doing so said he had taken enough to kill six men. On the following morning he was found in his bed insensible, and black in the face. Medical assistance was of no avail. A *post-mortem* examination of the body showed that the deceased had died from narcotic poison, and the jury returned an open verdict.

On the body of Malachi West, who died on Thursday. The deceased resided at No. 41, Kirkdale Street, and was an engineer on a steamer. Recently he had been subject to pains in his head and chest, and he occasionally took laudanum for relief. On Thursday last he went home about two o'clock, and three hours later he was found insensible on the sofa. Efforts were made to restore him to consciousness, but without effect. The jury returned an open verdict.

Also on the body of David Herbert, son of the late H. B. Holmes, bookkeeper. The deceased child was five years of age, and recently had been staying at the house of Charles Percival, Queen's Road—a relative. On Thursday morning Mrs. Percival saw him asleep and in good health, but in a short time she saw him lying in a room insensible. It was afterwards discovered that he had drunk a small quantity of oil, which he had got from a bottle which had been standing on the bedroom shelf. The child died the same day. At the inquest it was stated that the oil had been purchased to use for rheumatism, and Mr. Percival was not aware that it was poison. The jury returned a verdict to the effect that the deceased had been accidentally poisoned, and expressed regret that such dangerous articles should be placed within the reach of children.

Infringement of Proprietary Rights.

Lancashire Chancery.

In the suit F. J. Clarke, Lincoln, *v*. Geo. Clarke, Manchester, Vice-Chancellor Malins has awarded a perpetual injunction, restraining the defendant, or his servants and agents, from using the words "Blood Mixture," or any other colorable imitation of the plaintiff's trade mark ("Blood Mixture,") in or upon any bottles, labels, handbills, or advertisements sold, printed, and used, or issued by the defendant, and from in any other way representing any medicine, compounded by or for him, to be "Blood Mixture."

Dispute about a Cholera Mixture.

Mr. Thomas Martin, chemist and druggist, Copperas Hill, applied to the Court for an order to restrain Messrs. William Jones and Co., chemists, Great Howard Street, Liverpool, from selling a cholera mixture in bottles with labels bearing the words, marks, and description of a cholera mixture of which Mr. Martin had the exclusive right of sale. Mr. Robinson appeared for the applicant, Mr. Martin. It was stated that Mr. Martin had the exclusive right to sell "Priest Parker's Cholera Mixture." It came to his knowledge that Messrs. Jones were selling a mixture with a label the same as that used by Mr. Martin, with the exception that instead of being described as "Priest Parker's Mixture," it was called the "Rev. Mr. Parker's Mixture." As this was an imitation of the article sold by Mr. Martin, and, as he contended, an infringement of his rights, he asked the court to make an order preventing Messrs. Jones from continuing the sale.—After the reading of some affidavits, his Honour said it did not appear that a bottle had been opened to try the merits of the mixtures. (A laugh.)—Mr. Robinson: We have had no experiments upon that. (Laughter.)—His Honour: I should have some evidence upon that point.—An affidavit by Mr. Martin was read, in which he stated that he exported considerable quantities of Priest Parker's Mixture; that it had become very well known and highly valuable, and that it was of great importance that he should obtain the exclusive right of selling the mixture.—An affidavit was read from a person (sent by the plaintiff) who went to the defendants and asked for "Priest Parker's Mixture." He got some bottles of the defendants' mixture, bearing the labels complained of, a person in the shop saying, "I am much obliged to you for the number of bottles you have purchased, and for pushing the business. I will not forget you hereafter." (Loud laughter.)—His Honour: In his prayers?—After some conversation his Honour made an order as asked for, and it was understood that the defendants would have leave to come before the court to answer the allegations made against them. Since then, however, an arrangement has been come to between the parties in the matter, and will receive the sanction of the court: —"The defendant agreeing to cease using the labels which he has hitherto used on bottles of his mixture called 'Cholera Mixture'; to destroy all such labels in stock, and all the bottles which bear upon them the words 'Rev. Mr. Parker's Cholera Mixture,' or other words referring to the Rev. Mr. Parker, or the words 'Priest's Mixture'; to destroy all handbills, signboards, and documents used by him or in his possession bearing the name of the Rev. Mr. Parker, or the words 'Priest's Mixture,' and hereafter in all respects to comply with the injunction granted in this case; to pay all costs incurred by the plaintiff as between solicitor and client; the plaintiff also agrees to discontinue the proceedings without prejudice, however, to his right to recommence or continue such proceedings, and to take all legal steps for enforcing the injunction, in the event of the defendant at any time hereafter failing to comply strictly with all the terms on his part." The defendant also adds:

"To Mr. Thomas Martin.

"Sir,—In consideration of your withdrawing the proceedings you have taken in Chancery against me, I have to-day entered into an agreement not again to use the name of the Rev. Mr. Parker, or to call any mixture which I may sell the "Priest's Mixture;" and I admit that the preparation which I have hitherto sold in the name of the Rev. Mr. Parker's Mixture is a preparation of my own, and that I do not know the component materials of your "Priest Parker's Cholera Mixture." I regret having sold my mixture under labels which might cause the public to mistake it for your mixture.—Yours respectfully, "(Signed) William Jones.

"Liverpool, Aug. 12, 1873."

Review.

Marienbad Spa and the Diseases Curable by its Waters and Baths. By A. V. Jagielski, M.D., Berlin. Late Physician to the Prussian Army. London: Trübner and Co.

This work is published with the intention of extolling the waters of Marienbad, which lies in the district Eger, Bohemia, about 108 English miles from Prague. According to Dr. Jagielski, "the air of Marienbad is not relax-

ing in the summer, and is, moreover, rich in ozone, which, with the healthy exhalations of the surrounding coniferous forests, favours increased activity of the vital forces." Thus Marienbad is truly favoured. The two chief springs are Ferdinandsbrunnen and Kreuzbrunnen; from these alone, in 1872, 800,000 bottles of the waters were exported. The virtue of the springs lie in being sulphatic and chlorinated alkaline. Ferdinand's spring contains :—

Per kilogramme.	Grammes.
Sodic sulphate	5·0477
Potassic sulphate	0·0424
Sodic chloride	2·0048
Sodic bicarbonate	1·8229
Lithic ,,	0·0144
Calcic ,,	0·7840
Strontic ,,	0·0010
Magnesic ,,	0·6900
Ferrous ,,	0·0850
Manganous ,,	0·0216
Basic aluminic phosphate	0·0018
Neutral calcic ,,	0·0019
Silicic acid	0·0965
	10·6140
Compounds of fluorine and bromine } soluble organic matter	Traces.
Free carbonic acid	1·972

Another speciality at Marienbad are the mud-baths. "The mud consists of a wet, soapy, smeary substance, blackish-brown colour, of a particular, bituminous, slightly sulphurous odour, and astringent bitter taste." Ten cubic feet, the quantity used for one bath, when dried by air exposure, contain chiefly from ten to twelve pounds of "Iron vitriol," fourteen drachms of formic acid, and seventeen drachms of other volatile substances. Its other peculiarities are its tough, fatty, smeary consistency, like an emollient poultice; its specific gravity, which increases the skin action and indirectly influences the deeper-lying organs; its development of gases giving it the properties of a gas and vapour bath; its retention of warmth keeping the longer so on account or its being a bad conductor of heat. Also in the neighbourhood there is abundance of gas issuing from the ground having the composition per 1000 cubic centimetres :—

Co_2	990
N	7·4
O	2·6
SH_2	traces.
	1000·0

When collected, the gas is used by persons suffering from nervous or from skin diseases; the application of the gas giving a varying feeling of warmth and of pricking to the members.

If, as Dr. Jagielski says, "*Epidemics never approach, and cases of severe or dangerous illness usually terminate favourably*," then surely a course of water at Marienbad is a *sine quâ non* for all patients.

Notes and Queries.

PERCHLORIDE OF IRON AND GLYCERINE.—Dr. Snow, in a letter to the *British Medical Journal* (June 28) calls attention to the fact that a small quantity of glycerine covers the astringent metallic taste which remains in the mouth after tincture of perchloride of iron has been taken. Dr. Boggs, in the issue of the following week, corroborates this statement, and adds further that glycerine counteracts the astringent action on the bowels where this is not needed, and suggests that it might be substituted for syrup as a vehicle for the various preparations of iron, cinchona, rhatany, etc., which have a tendency to constipate.

TESTS FOR PURITY OF IODIDE OF LEAD.—P. Carles reports (*Bull. Soc. Pharm. Bord.*, XIII., 171) that he has met with specimens of iodide of lead containing as much as 30 per cent. of oxyiodide of lead, the therapeutic action of which would be far inferior to that of the pure iodide. The contamination is the result of the use by some manufacturers of a basic acetate of lead, instead of the nitrate in its preparation. He therefore proposes the following tests :—(1.) When the iodide has a dull whitish yellow appearance, raising doubts as to its purity, 5 decigrams should be suspended in distilled water, and a few drops of acetic acid added. If the iodide be pure there will be no change of colour; but the yellow colour will immediately become brighter if any oxide be present. (2.) The second process is to exhaust the iodide by treating a grain of the suspected iodide with two or three successive quantities of boiling distilled water. If pure it will dissolve entirely, but should there be a dull yellow residue it will consist of the oxyiodide, which may easily be collected, dried and weighed.

BLACK ALDER BARK.—It having been suggested by Professor Maisch that the yellow colour of the bark of *prinos verticillata* (black alder or winterberry) might be due to the presence of berberine, a series of experiments was undertaken by Mr. William J. Lerch with a view of clearing up the point. The result being (*Amer. Journ. Pharm.* [4], iii., 255), that he failed entirely to detect any trace of berberine in the bark. The bark of *prinos verticillata* is in the secondary list of the United States Pharmacopœia.

[349] IROCH ACIDI CARBOLICI.—Would any reader kindly oblige me with a formulæ for the above ?—*W. N. G. L.*

Benevolent Fund.

Sir,—In looking over the weekly numbers of the Pharmaceutical Journal composing the last volume, one of the first thoughts that arises (with me) seems to be a feeling of indebtedness to the Editor for the amount of information and instruction therein contained, and for his courtesy in allowing so free a discussion of so many important subjects, each more or less bearing upon the true interests of our trade.

Some of the proposed alterations and improvements seem to have been satisfactorily carried out, others appear to be left in abeyance, or to have been quietly shelved.

Among the latter is a subject of great importance, and one which I should like to see kept constantly before our notice, until it receives something like a satisfactory adjustment. That subject is the "Benevolent Fund," and although we were treated to some very spicy and quite sensational articles upon the matter, all ended in sound, the fund itself seems to be neither better nor worse for all that was said about it.

Now, were I even possessed of the pens of these ready writers, on the present occasion I should not think it needful to put forth their powers.

In your last weekly issue, something is said of a principle in mathematical science, called the "principle of least action," and it seems to me that if this principle were more extensively *understood*, even amongst some of your numerous correspondents, neither the pages of the Pharmaceutical Journal would not suffer in consequence, nor the cause they have at heart.

We will, therefore, come to the point at once by saying that the present available resources of the Benevolent Fund are very inadequate for meeting the claims made upon it. And as this will not be disputed, we shall pass it as *proven*.

We then go on to say that it is our firm conviction that the fund can and may be made sufficiently strong to meet all legitimate demands.

And further still, that this may be accomplished by first allowing the present funded capital to remain as it is, and as regards the future, adding all donations to this reserve, but allowing all annual subscriptions to be made use of for the year's requirements, merely putting by the surplus, should there be any.

If this can be decided upon then let an appeal be made (through the local secretary) to every member of the trade for a contribution, and if this be properly carried out, there need not be much fear of being obliged *in the future* to reject four out of five approved candidates for want of funds.

I mention the local secretaries as the most proper persons, because they are in the position of being the accredited agents of the Society, but they would easily find others to help them, where by reason of the size of the town the labour might be too great for one.

I could say a good deal upon the subject of "Local Secretaries," but will satisfy myself with saying that there ought not to be a town or city in the kingdom (of any importance) where a chemist could not be found ready to take the office and to carry it out efficiently, and that those who feel but little or no interest in the Society do injustice to its interests by continuing to hold, or by accepting the office.

I do hope this matter will receive the thoughtful attention of the Council and of the trade at large, and that something may be done (as it easily might) largely to extend the benefits of this much needed fund, for meeting the wants of all deserving cases.

One who has known the Drug Trade more than Thirty Years.

The Examinations.

Sir,—I see that in the meeting of the Council last week, Mr. Schacht makes a comparison between the numbers attending the Sessional Examinations at Bloomsbury Square and those attending at Bristol, greatly to the depreciation of the former.

May I draw attention to one or two features in connection with the fact? First, the examinations are held at the end of the session, when a very large number of students have left town. I believe the numbers 82 and 107 represent all the students at the respective courses, though several only enter for one or two of the three parts; and practically, the number attending the last two or three weeks was only twenty, or less, in each class.

Further, the examinations take up the whole (almost) of two days, and a good many of the students are in employment, and would be unable to obtain leave for so long a time.

The large attendance at several of the written examinations which Professor Bentley gave this session tends to corroborate my solution of the question.

Edmund J. H. Thring.

August 11th, 1873.

Excessive Competition.

Sir,—I read the letter by "A West-End Chemist" with much interest. I knew that the trade was cut up largely by the co-operative stores and interfered with seriously, though perhaps to a less extent by the grocers, but now a new enemy seems to have entered the lists against us, the drapers, who, with their characteristic fondness for farthings, ticket a 1*s.* 1½*d.* "article" 10¾., 1*s.* bottle of citrate of magnesia 6¾*d.*, and so on, *ad nauseam*.

Registered chemists may sell the dangerous compounds, which do not bear a larger profit than the most innocuous drugs, and take all the responsibility, while these vampires pursue the "even tenor of their way" with perfect safety.

The question is: Are we to be put to the trouble and expense of passing compulsory examinations and yet be at the mercy of every trader who may choose to cut in at us?

I think the same law which protects the public by allowing none but properly qualified men to swell the ranks of chemists and druggists should, at least, by preventing undue competition, allow them to pursue their arduous calling with a fair prospect of success.

J. R. Place.

Highgate, August 6th, 1873.

Dispensers.—Army Hospital Corps.

Sir,—Will you kindly grant me space in your columns to say a few words with regard to the advertisement that appeared in the Journal of a short time back, and brought forward the letter of "Indignans" in your issue of July 26th.

I myself have been one of the many deceived ones, and when reading the advertisement, thinking it such a good opportunity for improving my position, I resolved to apply personally at Whitehall Yard, and find out what were the duties, etc.

In the course of the following week, I carried out my intention, and, upon entering, was received by the sergeant, who, when informed of my business, told me that the staff officer was not at the office, but that he would give me all necessary information. I was told that I should be required to enlist for a term of twenty-one years, do the drilling, and perform all the duties of a common private, and also be required as well to attend in the hospital, and perform the duties of a kind of assistant-surgeon in the way of attending to any accident, not of a serious kind, that might be brought in; after having been in that way engaged for a time, I should have to undergo an examination on bandaging, strapping up wounds, etc., and if found competent would then be allowed to enter on the duty that, from the advertisements, anyone would think they had solely to perform, viz., "dispensing," and moreover I should then have to wait my chance of being promoted in the ranks by degrees before I attained the rank of sergeant, and then get the pay of £60 a-year.

This, I was given to understand, was the German mode of selecting dispensers, which was found of so much service in the late Franco-German war.

A Deceived One.

London, August, 1873.

Arthur Cooper.—See "Notes and Queries."

George Brown.—Decidedly not, nor do we think any one would be.

Mr. Abraham.—Received with thanks.

G. V. Druce.—Your request shall have attention.

Ovis.—We are not aware whether the composition you refer to contains a poison included in the schedules of the Act.

mental lens of three feet diameter and three feet focal length, after one or two unsuccessful attempts, was able to detect a heating effect due to the moon's rays collected at its focus. Then about ten years later (Aug., 1856), Mr. Piazzi Smyth, while on Teneriffe, on directing his pile armed with its polished conical reflector alternately towards and away from the moon, satisfied himself that the radiant heat was appreciable.

In 1861 Professor Tyndall experimented with a thermopile armed with a large tin conical reflector; but the smoke and heated air from the surrounding chimneys, which were rather less numerous in the direction of the moon than in that to which he turned away his pile, completely masked, or rather overpowered, the heating effect from the moon.

Professor Joule, in 1863, by means of a cylindrical glass vessel, divided in a vertical direction by a blackened pasteboard diaphragm, which extended to within one inch of the cover and of the bottom of the vessel, and in the upper of which spaces was delicately suspended a magnetized sewing needle furnished with a glass index, was able to detect the heat from a pint of water heated 30°, placed in a pan at nine feet distance, also that of a moonbeam, admitted through an opening in a shutter, as it passed across the apparatus.

In the autumn of 1869 M. Marie-Davy, with a refractor of nine inches aperture, detected the moon's heat in the focus, and estimated the rise of temperature of the face of his thermopile at about twelve-millionths of a degree (Celsius); and a little earlier Mr. Huggins worked with the thermopile, but directed his attention more to the fixed stars than to the moon.

During the course of the year 1868* an arrangement was prepared for measuring the heat in the image of the moon formed by the mirror of the three-foot reflector at Parsonstown. For the purpose of further concentrating the heat of this image of 2·9 inches mean diameter on to the face of a thermopile $\frac{1}{3}$ of an inch diameter a concave mirror of $3\frac{1}{2}$ inches diameter and 3 inches focal length was employed; a rock-salt lens being objectionable from its condensing moisture on its surface, and, moreover, being hardly procurable of sufficient size.

To secure greater steadiness of the needle than was otherwise obtainable, a second similar concave mirror and thermopile were placed by the side of the first, the similar poles of the thermopiles being connected with each other, and the others with the terminals of the galvanometer. Thus the deviations due to the moon's heating effect were proportional to the *sum* of the effects due to each pile separately, and those arising from disturbing causes, acting on the two piles, to the *difference* of the effects due to each pile. To secure still greater steadiness of the needle, the two piles of four pairs each which, having been made at *different* times by Messrs. Elliott, were not of equal power were replaced by two more equal thermopairs constructed on the spot.† The apparatus was enclosed on all sides, except on that towards the mirror of the telescope, with a box of tin and glass, and the lattice-tube was covered with a cloth to keep draughts of air from the piles. Two covered wires led from the thermopiles to the galvometer in the observatory, and the heating effect was determined by directing the telescope so that the moon's image fell alternately for the space of one minute on each of the two small concave mirrors.

The observations made during the seasons 1868-69 and 1869-70, were found to follow pretty well Lambert's law for the variation of light with phase. It was found also that a piece of glass which transmitted 80 per cent. of the sun's rays suffered only about 10 per cent. of the moon's rays to pass through; thus a large amount of absorption before radiation from the moon's surface was shown to take place.*

In the earlier experiments no attention had been paid to the correction to be applied for absorption of heat by the earth's atmosphere; but, as the apparatus was gradually improved, it became indispensable to determine the amount of this correction before attempting to approach more nearly to the law of variation of the moon's heat with her phases than had been done in the earlier investigation.

By taking long series of readings for lunar heat through the greatest ranges of zenith distance available, a table expressing the law for decrease of heat with increase of zenith distance, closely following that deduced by Siedel for the corresponding decrease of the *light* of the stars, was obtained.† By the employment of this table, the determinations of the moon's heat at various moments of the lunation were rendered comparable and available for laying down a more accurate "phase-curve" than had been previously obtained. This curve was found to agree more nearly with Professor Zöllner's law for the moon's light, on the assumption that her surface acts as if it was *grooved* meridionally, the sides of the grooves being inclined at the uniform angle of 52° to the surface, than with Lambert's law for a perfectly *smooth* spherical surface.

The distribution of light on two white globes, constructed in accordance with Lambert's and Zöllner's hypotheses, on which a beam from the electric light was thrown, was shown to be very different in the two cases; the brightest spot on the former being at the centre, and on the latter at 52° on each side from the centre at the time of full moon, and at other times on the former at the bright limb, from which it gradually decreases towards the terminator; while on the latter there is a rapid decrease from the bright limb to a minimum about half-way to the terminator, after which it increases again, and then fades away on approaching the terminator.

On examining the phase-curve which had been obtained, a certain want of symmetry on the two sides of full moon was perceived, which was ascribed to the unequal distribution of mountain and plain on the lunar surface, as was shown by a rough diagram of the lunar surface with its so-called "seas." It had also been found that the percentage of the moon's heat transmitted by a sheet of glass diminished from 17·3 per cent. at full moon to about 13·3 per cent. at $22\frac{1}{2}$°, 11 per cent. at 45°, and 10 per cent. at $67\frac{1}{2}$° distance from full moon; a circumstance which might have been accounted for by supposing that there is

---

* See Proc. Royal Soc., 1869.

† In the construction of the thermopairs which were substituted for the thermopiles previously employed, the requisite sensitiveness was obtained by making the cross-section of the two elements small compared with the area of face, so that a smaller proportion of heat might be lost by conduction along the bars. On being compared with two of the ordinary construction they were found to be of about equal power, and, therefore, from the simplicity of construction they would appear to be deserving of the attention of physicists. (See Proc. Royal Soc., 1870.)

* Assuming Wollaston's estimate of 800,000 : 1 to be the correct value of the proportion between sunlight and that of full moon, and the percentage of heat transmitted by glass to be 10 per cent. for the moon's rays, and 80 per cent. for the sun's (the difference being due to absorption before radiation from the moon's surface), the corresponding ratio for solar and lunar heat deduced was 80,000 : 1. The later observations on lunar heat would require some modifications of this value, but in the present uncertainty as to the value for the proportion between sunlight and moonlight for which

Woolaston gives the value	. . . .	801,072
Bouguer ,,	. . . .	300,000
Bond ,,	. . . .	470,980
Zöllner, 1st method ,,	. . . .	618,000
2nd method ,,	. . . .	619,000

further examination of the question would appear unprofitable.

† Following the reasoning from which Pouillet concluded that the earth's atmosphere absorbs solar heat as if it were a medium of uniform density of height equal to $\frac{1}{10}$ of the earth's radius, we deduced from the measurement of the moon's heat, a height of $\frac{1}{50}$ of the earth's radius.

a constant amount of radiant heat coming from the moon in addition to that which, like the light, varies with the phase, had it not been found that as the moon approached tolerably near the sun, as, for instance, on March 27th, 1871, when her distance from full was 138°, no perceptible amount of heat radiated from her surface.

The less rapid decrease of the moon's heat than of her light on going farther from full moon, and the increase of percentage of heat transmitted by glass towards the time of full moon, may probably be explained on the assumption that when the sun's heat and light strike the moon's surface the whole of the former and only a certain proportion of the latter, depending on the intrinsic reflecting power or "Albedo" of the surface, leave it again, and consequently the shaded portions, which are inclined more towards the position of the earth at quadrature than at full moon, reflect a larger amount of heat as compared with the light at the former than at the latter time, and a greater flatness of the heat- than of the light- phase-curve is the result.

With the view of obtaining a decisive result on the question, whether or not the moon's surface requires an appreciable time to acquire the temperatures due to the various amounts of radiant heat falling on it at different moments, simultaneous determinations of the amount of the moon's heat and of her light were made, whenever the state of the sky allowed of it, during the eclipse of November 14th, 1872. The eclipse was a very partial one, only about $\frac{1}{40}$ of the moon's diameter being in shadow; but although this circumstance, coupled with the uncertain state of the sky, rendered the observation far less satisfactory than it would otherwise have been, yet it was sufficient to show that the decline of light and heat as the penumbra came over the lunar surface and their increase after the middle of the eclipse were sensibly proportional.*

Rather with the view of finding the value of the galvanometer readings in terms of the radiation from a surface of known temperature, and capable of being reproduced by any one at any future time, than in the expectation of getting more than the roughest approximation to the temperature of the lunar surface, readings of the galvanometer were taken when the faces of the piles were alternately exposed for periods of one minute to the radiation from two blackened tin vessels filled with water of different temperatures. It was thus found that were the atmosphere removed, the surfaces of new and full moon might be respectively replaced by blackened tin vessels of equal apparent area to that of the moon, and at temperatures of 50° and 247° Fahrenheit.†

In conclusion, Lord Rosse expressed a hope that among the many subjects which engage the attention of astronomers that of radiation of heat from the moon might not be entirely lost sight of, more especially by those who live in a more favourable climate for such observations than that of the British Isles.

CHLORIDE OF MERCURETHYL.‡

BY J. M. MAISCH.

This compound, it appears, has recently been introduced in Europe into medicine, and it is claimed for it that it may be used in the same doses and for the same purposes as corrosive sublimate, over which it has the advantage of not precipitating albumen, no matter in what solution the latter may be, whether as egg albumen, in the serum of blood, in urine, etc. Schering and Co. have introduced it under the name of *Hydrargyrum æthylochloratum.*

It was discovered by Strecker* and by Dünhaupt† in 1854. The former chemist started with iodide of ethyl, preparing therefrom as the first step the iodide of mercurethyl; the process of the latter involves the previous preparation of bismuth-triethyl, which, being decomposed by corrosive sublimate, yields the compound in question, besides chloride of bismuth-ethyl. Whichever course is followed, the process, or rather series of processes, are tedious and complicated; but that of Strecker appears to offer better advantages in utilizing all the material.

Iodide of ethyl or hydriodic ether (C_4H_5I) was discovered by Gay-Lussac in 1815, and prepared by distilling absolute alcohol with hydriodic acid, and separating the compound from the distillate by water. Serullas‡ subsequently improved the process by using iodine and phosphorous with alcohol, and Personne§ found the use of amorphous (instead of ordinary) phosphorus very advantageous, using again absolute alcohol. The latter process was rendered more practical in 1862 by Reith and Beilstein,‖ who proposed to put one part of red phosphorus into five per cent. of alcohol, spec. grav. 0·83, placing the flask with the mixture into cold water, adding 10 parts of iodine, distilling after 24 hours, shaking the distillate with soda solution, and removing the oily liquid which is rendered anhydrous and rectified. Lieben communicated, in 1868, to the Vienna Academy of Sciences, his observations that the chlorides of the alcohol radicals are converted into the iodides on being heated to about 130° C., with an excess of concentrated hydriodic acid. Wanklyn¶ and De Vrij** have simplified the preparation of iodide of ethyl very much by using absolute alcohol, to which a little more than one molecular weight of iodide of potassium is added, after which dry hydrochloric acid gas is passed into the liquid; or the hydrochloric acid is first passed into the alcohol and sufficient iodide of potassium added afterwards; after 24 hours the mixture is distilled, the iodide of ethyl separated by water and purified by washing, drying and rectifying.

Iodide of ethyl is a colourless oily liquid of 1·93 spec. grav. at 15° C. (60° F.), of a strong and peculiar odour, and boiling at about 70° C. (158° F.) When digested with mercury or some other metals, ethyl compounds of the metals are obtained. In this manner and by taking advantage of the influence of diffused light, Strecker prepares the iodide of mercurethyl, recrystallizing the product from alcoholic ether. It forms then colourless iridescent scales, subliming at the temperature of boiling water, fusing at a higher temperature, of an unpleasant odour, and being decomposed by direct sunlight finally into mercuric iodide; its composition is C_4H_5HgI. If its alcoholic solution is precipitated by nitrate of silver and the filtrate carefully evaporated, crystals (or a crystalline mass) of nitrate of mercurethyl are obtained, which are readily soluble in water and almost as freely in alcohol.

This nitrate is easily converted into the chloride by adding to the aqueous solution of the former muriatic acid or chloride of sodium, nitric acid, or in the latter case nitrate of sodium being separated in the aqueous solution.

Chloride of mercurethyl has the composition of C_4H_5HgCl; it forms white thin scales with an almost silvery lustre, and of a peculiar ethereal unpleasant odour; it is very sparingly soluble in cold water, little in ether and cold alcohol, but freely in boiling alcohol, crystallizing again on cooling; it sublimes at 40° C. (122° F.) without fusing previously, and condenses in thin laminæ; exposed to the air it evaporates completely, and heated in a water-bath it may be fused to a clear oily liquid, which evaporates without leaving any residue. When rapidly heated upon platinum foil it burns with a

* Both were reduced to about one-half what they were before the eclipse.

† In fact, assuming Dulong and Petit's law of radiation to hold, the change of radiation on going from new to full moon was the same as that produced by raising the temperature of the water through 197°, the initial temperature being 50° Fahrenheit.

slight flame, the vapours having a disagreeable odour and a metallic taste. Being very poisonous, it must be handled with great care on account of its ready volatility. Schering regards it as pure if it is readily and completely volatilized, dissolves without residue in boiling alcohol, yields in alcoholic solution but a faint reaction of chlorine, and, with alkali, does not produce a precipitate.

It remains to be seen whether its inactivity upon albumen renders this new claimant for medical favour so much superior to corrosive sublimate and similar mercurials that its good qualities would more than outweigh the dangers and uncertainties that must result from its ready volatility at our usual summer temperature.

CAMPHOR.*

The camphor of commerce comes from Formosa, Sumatra, Borneo, Japan, and China. It is obtained in crystalline masses already formed, and also in grains by distillation. The tree which produces the former kind is a near relative of our basswood, which we know as a charming tree, perfuming the air and yielding the finest honey in the world. It grows on the Diri Mountains in Sumatra, and in Borneo. It towers upward more than a hundred feet, and has been known to obtain a girth of fifty feet. The spirited persuasion of the axe draws from this forest monster the white treasures secreted in longitudinal fissures in its heart wood, sometimes, though rarely, in a layer as large as a man's arm, but more frequently in small fragments to be carefully extracted by some sharp-pointed instrument. It is not an abundant bearer. Twenty pounds is a rare yield for a great tree; ten pounds is a good harvest from one of medium size, and many are felled and split that furnish no camphor. This, however, is not an entire waste, since the wood is easily worked and is never attacked by the voracious myriads of Eastern insects which destroy all other varieties except the teak and calambuco. House and ship timber are made from it, besides many articles of furniture, and the aromatic trunk is extremely valuable to the housekeepers of our colder climate. This kind of camphor seldom finds its way to Europe and America. The Chinese ascribe to it marvellous medicinal properties, and pay for it enormous sums, thereby securing the entire yield.

Common camphor is obtained by distillation from the root, stem, and leaves of certain species of *Lauraceæ*, but more especially from the *Laurus camphora*. This tree is of good height but not gigantic, is many-branched, with evergreen lanceolate leaves on short stalks, and small yellowish blossoms in long clusters at the end of the flower stems. Of this, also, there are two varieties. The Chinese or Formosa camphor is carried in junks to Canton, and there packed in square chests lined with lead, whence it is sent to the different Eastern ports, where we procure it. It is of a grayish colour with a grain like sugar, and usually unattractive in appearance. The Dutch or Japan camphor is prepared in Batavia, is packed in tubs securely matted, is pinkish in hue, and coarser than the Chinese.

Both kinds need purification before using. The Venetians first and afterwards the Dutch monopolized the labour and profit of refining it for a long period, and it is only of late years that other nations have succeeded in obtaining it in its crude state.

Camphor is slightly soluble in water, but yields freely to alcohol, acetic acid, ether, and the essential oils. A pretty experiment may be tried with it which the young people will find amusing. Scatter a few pieces of clean camphor upon pure water, and they will whirl and sail about, keeping up the dance sometimes for hours. Drop among them some greasy matter, and the merry little performers will stop on the instant.

The loss of refining runs from 8 to 16 per cent. In a camphor refinery at Rumney, New Hampshire, United States, where from six to seven hundred pounds of camphor are refined daily, there are two large furnaces, the tops of which are covered with heavy iron plate, and about an inch of sand to regulate the heat. There are also 56 square and 38 round pans, which are filled every morning, and in twenty-four hours are ready to be emptied. These have tin globe-shaped covers, with a tubular vent in the centre, and as the heat dissolves the camphor into a liquid, it rises in the form of vapour, and attaches to the covers, the impurities falling to the bottom of the pans. It requires long experience to know just the amount of heat required so as to secure the purest article with the least loss.

It requires about one quarter of a cord of wood per day to run these furnaces, a day's work averaging 15½ hours. After cooling, the contents of the square pans, clear as crystal, are packed in boxes of one hundredweight each, and those of the round ones into barrels carefully lined, and are then sent to market, and from thence into every dwelling in the land.

* From an article on "Camphor Refining," quoted by the *Boston Journal of Chemistry* from *The People*.

CLINICAL TEST FOR THE DETECTION OF MERCURY IN URINE.*

BY MM. MAYENÇON AND BERGERET.

The analytical process adopted by the authors consists in placing in the urine an iron nail, suspended from a platinum wire, and adding a few drops of sulphuric acid. After half-an-hour's contact, the mercury, if present, is deposited upon the platinum. The platinum and iron couple is then taken from the urine, washed with pure water, and after being dried in the air, is plunged into an atmosphere of chlorine. The couple is afterwards agitated in the air, to rid it of chlorine, and the platinum wire is then passed over a sheet of cigarette paper, slightly moistened with an aqueous solution of iodide of potassium at 100° C. If there be any mercury, a brick-red ray of biniodide of mercury is produced. According to the authors, this process allows of the recognition of $\frac{1}{150000}$ part of a soluble compound of mercury.

The authors have experimented upon patients, and upon rabbits, and find as the result of their experiments, (1) that mercury or mercurial salts, taken in a single small dose, are eliminated promptly (four days) and completely from the organism; (2) that mercury or salts of mercury, taken during a certain time, even in small doses, require several days for their complete elimination; (3) that bichloride of mercury, injected under the skin, spreads through the whole organism in half an hour; (4) that the kidneys and the liver appear to be the organs where the mercury is found in the greatest abundance. The elimination of the mercury appears to take place in all the excrementitial humours. Iodide of potassium has a marked action in clearing the system of the mercury which it may contain.

BROMINE.

The following particulars respecting the production of bromine in the United States, which has during the last few years become of considerable importance, are quoted from the *Boston Journal of Chemistry* :—

The first bromine discovered in this country was detected by Professor Silliman in the bittern of the salt-works at Salina, New York.

At the salt-works near Freeport, Pennsylvania, the first attempt was made to manufacture it on a large scale, and for many years proved a profitable undertaking to the projector. The next factory was started at Natronia, Pennsylvania, by a Swedish chemist, but by this time the demand for the article was so great that the facilities then possessed proved insufficient to meet the demand, and under the auspices of one of our great manufacturing

firms, a systematic search was made for it, which resulted in the location of several extensive establishments for its manufacture, in the great salt regions along the Ohio River, both in Ohio and Western Virginia. The bittern at these wells is of such richness, that this region alone can supply the market of the world, and at a price that renders competition from other quarters impossible.

The factories established in this region are very extensive, and their united production does not fall far short of 5000 lbs. of bromine per week. Their bearing upon the business done in this article can be judged from the fact that since their establishment the price of the article has declined from six dollars and eight dollars per pound to less than one dollar per pound. The fact is that the Ohio River salt regions alone can more than supply the entire consumption of this article, and unless it should find some new and unexpected application in the arts, even the factories already established can supply the demand without increasing the present facilities.

It seems almost incredible that such an enormous amount of this article should be consumed as a remedial agent alone, yet such is the case; for, excepting the trifling amount annually used in the art of photography, it has as yet found no application in the arts.

In the form of bromide of potassium, large quantities are annually exported from this country, as the danger, risk, and expense incurred in the shipping of the crude article make the bromide more profitable for the European consumer and manufacturer.

Before it is even properly concentrated, the bittern of this region yields as much as *one ounce to the gallon*. It further enjoys the advantage of being very fine, and almost wholly free from iodine. The process employed in the manufacture of bromine is a very simple one. The bittern, or uncrystallizable liquor left after the extraction of the salt, is taken by suitable pipes directly from the salt works to the adjacent bromine works, and, still hot, is run into shallow iron pans, where it is rapidly boiled down to a high gravity. During this operation a dirty, pasty, and very impure salt subsides, which is removed by means of iron shovels. Having been thus concentrated, the now highly caustic liquor, containing a large amount of the bromides of soda, lime, and magnesia, is run into leaden or earthen stills, and having been mixed with a fixed percentage of black oxide of manganese and oil of vitriol, the chlorine thus liberated sets free the bromine, which, by the application of a gentle heat, readily distils over into receivers of cold water.

THE OUTBREAK OF TYPHOID FEVER IN MARYLEBONE.

Another remarkable instance of a localized outbreak of typhoid fever, similar to that detected by the sagacity of Dr. Edward Ballard in 1870,* has recently occurred, the locality being again in the metropolis, but situated at Marylebone instead of at Islington. On this as on former similar occasions there is a tendency to connect the outbreak of fever with the distribution of infected milk.

The circumstances attending the present outbreak, as far as they may be gathered from published reports, are briefly as follows:—On July 22 some children belonging to the household of Dr. Murchison, residing in Wimpole Street, Cavendish Square, were taken ill. On the 25th July the two eldest children and a baby were sent into the country, and a few days afterwards three other children took the fever. Naturally after past experience attention was then turned to the milk supply; but as the younger children who drank the largest quantity of milk were attacked after the elder ones this did not at first appear to be the cause. Closer inquiry however revealed the fact that milk had been daily received from the dairy in separate cans, one sealed and containing "nursery milk," which had been used for the baby and younger children; the other containing milk for the ordinary house supply. When it was found that after the baby had left town the supply of "nursery milk" had been stopped, and that the younger children of the family who had previously drank it, had instead drank that supplied for the household and six days afterwards had sickened with typhoid fever, the coincidence of the change and the seizure was too striking to be overlooked.* Dr. Murchison made inquiries and in one day found that ten neighbouring households, wherein cases of typhoid fever existed, had been supplied with milk from the same dairy. Dr. Whitmore, the Medical Officer of Health for Marylebone, was communicated with, and he in turn informed the managers of the dairy of the suspicions attached to their milk. Confirmatory information became plentiful, and soon two hundred cases of typhoid had been reported, all of which with one exception occurred in households that had been supplied with milk by the same company.

Whilst this information was being collected the distribution of milk from the inculpated dairy still went on. Although repeated notices had been sent to the managers to suspend the sale they evidently did not feel convinced by the evidence placed before them that it was their duty to make the sacrifice. Mr. Simon, the Medical Officer of the Local Government Board, having been appealed to, promptly dispatched Mr. J. Netten Radcliffe to make an investigation into the occurrence. Mr. Radcliffe immediately arranged to inspect, with Dr. Whitmore, the eight farms from which the milk company obtained their supplies, and at the request of the company Dr. Corfield and Mr. Henry Morton accompanied them. After six farms had been inspected with only negative results, one was found to be situated in a neighbourhood where enteric fever had been epidemic. More than this, the late proprietor of this farm had died in the early part of June under circumstances that, although they at first led to his death being attributed to heart disease, leave little doubt that it was due to collapse during convalescence from typhoid fever. Dr. Corfield's report states that the well from which the water used for washing the cans and similar purposes was drawn is lined with uncemented bricks, and situated at the lowest part of the yard, eight feet from a ditch which receives the drainage of the yard itself, the privy if it should overflow, the pig-sties, the dairy, and a manure-heap, into which the house slops were thrown. The privy itself is situated at the highest portion of the yard, 56 feet 6 inches from the well, and has the ordinary privy pit, which is perhaps as much as two or three feet above the level of the top of the well.

Such being the facts of the case, and supposing the poison of enteric fever to be upon the premises, it was considered that there were several ways in which it might have got into the milk. Before visiting this farm, upon becoming acquainted with some of the above details, the inspectors on behalf of the company had sent a telegram to the proprietors of the dairy in London, advising the immediate cessation of the distribution of milk from that farm, a request that was immediately complied with, the milk on hand being disinfected and thrown away. Credit is due to the owners of all the inspected farms, as well as the proprietors of the dairy, for the assistance and facilities offered to the inspectors. It is worthy of remark that Dr. Corfield states that, without exception, it was "apparent to the inspectors that no intentional admixture with water took place at any of the farms, at any rate, with the consent or knowledge of the farmers themselves."

Some of the circumstances recorded in connection with this typhoid epidemic are very remarkable. In one house, where four servants had been left upon board wages, two of them had purchased milk from the company, and

* See PHARM. JOURN. [3] vol. i. p. 617.

* It is worthy of notice however that Dr. Corfield, in his report upon the visit to the farm from which the suspected milk was supplied, states that all the "infants' milk" came from that particular farm, and connects this with the fact that it is children who have been so especially attacked in London.

two used condensed Swiss milk. The former were attacked by the fever, the latter were not. A young lady on a visit to Seymour Street drank freely of the milk, returned home to Gipsy Hill on the 23rd July, and was taken ill on the 26th. In one family, where there are three children, the eldest drank tea in the morning and orange wine and water at night, the younger two had bread-and-milk in the morning and cold milk at night; both the latter have typhoid fever, the former, who takes no milk, has escaped. Again, two families living next door to each other were supplied with milk from the same can, yet while in the one there have been two cases (one fatal) of fever, in the other there has been none. The explanation appears to be that in the latter case the whole of the milk was boiled before being used. Besides these, several cases of fever have occurred in houses not supplied with the suspected milk, but the patients have been found to have drank it in some other place.

This frequent coincidence between the occurrence of typhoid fever and the consumption of milk admittedly derived from a source where it was liable to infection is, at any rate, startling, more especially since it is consistent with prevailing views as to the communication of typhoid fever.

In reference to this subject, Mr. Alfred Smee, F.R.S., has addressed a letter to Mr. Simon, suggesting the existence of a connection between the use of sewage-grown grass as fodder and the production of milk which readily becomes putrescent and capable of causing disease. The appearance of this letter in the daily papers naturally brought forward Mr. W. Hope, as being prominently connected with schemes of sewage irrigation, and also with the Dairy Reform Company, to controvert the opinion expressed by Mr. Smee; but his criticism is even less conclusive in disproving the connection between epidemic typhoid and unwholesome milk than Mr. Smee's argument in favour of it, or the coincidence above referred to. Several further letters have since appeared, but they do not throw more light on the question that is of public importance, though they bear evidence that the discussion now opened will not be a mere "milk and water" controversy. Possibly it may at last add a feature of interest to the report of the British Association committee on the treatment and utilization of sewage, which may be looked for at the coming meeting at Bradford.

From the mass of correspondence on the subject that has appeared in the daily press, we extract the following letters, which have been addressed to the *Times* by Mr. Sedgwick:—

"Sir,—The attention which has been directed, since the publication of Dr. Edward Ballard's paper on a Localized Outbreak of Typhoid in Islington in July, 1870, to milk as the vehicle by which the poison of typhoid fever is often conveyed into the system, has served to elicit some valuable information on the mode in which epidemic diseases may be spread in districts where sanitary rules have been neglected; and the present outbreak of typhoid fever in Marylebone, which to some extent appears to be in like manner connected with milk supplied from a well-known dairy, will probably tend to confirm the general correctness of the observations made on that occasion. It was satisfactorily established by Dr. E. Ballard that, while the milk supplied to the families who suffered from typhoid fever at Islington was obtained from a particular dairy, the radical source of contamination was the water supplied from an underground and defective tank. This dairy tank was found to be constructed of wood which had become rotten and burrowed by rats, in consequence of which there was communication established between it and some old drains. The milk in this case might have been contaminated either by direct admixture with the polluted water used for the purpose of adulteration, or by the water being simply used for cleansing the milk cans. But, apart from such direct contamination, it is not unreasonable to assume that milk may be rendered injurious from the cows having been allowed to drink the tank water.

"In one of my papers on Cholera, which was read at a meeting of the Royal Medical and Chirurgical Society, November 12, 1867, attention was specially directed to this source of danger, and I had occasion to state that "it is a curious fact that even milk itself, the secretion of which is commonly supposed to be altogether exempt from any choleraic influence, may in like manner undergo some unrecognizable change by which it acquires deleterious properties capable of producing symptons of poisoning, which are sometimes analogous to, and even identical with, those of cholera. Among the more noticeable cases of this description is that which occured in 1826 at Aurillac, a village in France, and which Professors Orfila and Marc were commissioned by the French Academy of Medicine to investigate. In this case 15 or 16 customers of a particular dealer in goat's milk were attacked on June 13 with all the symptoms of cholera. Professors Orfila and Marc, in their report, stated that in parallel cases which had been reported to them by the police of Paris they had been unable to detect any mineral poison; that none of the received explanations were, in their opinion, satisfactory; and that they were disposed to ascribe the poisonous alteration of the milk to new principles formed by a vital process. As an appendix to this case, it may be mentioned that on Oct. 13, 1856, about twenty persons in Malta were seized with violent vomiting and other symptoms of cholera, ascertained by the police physician, Dr. Felice Calleja, to be caused by drinking the milk of two goats."

"It has been observed that the milk of cows kept in stables attached to distilleries is very often injurious, and in certain parts of North America, to the east of the Alleghanies, milk at certain seasons of the year produces a disorder which is popularly known by the name of "milk sickness," or "trembles." It is not necessary, on these occasions, to assume that the animal from which a noxious secretion has been obtained has been itself injuriously affected. Poisonous honey may be secreted by bees which have fed with impunity on certain flowers; and there is no physiological reason why milk capable of developing either typhoid fever or cholera should not be secreted by cows which have drunk with impunity water unfit for our own use."

"Sir,—Since public attention was first called to the connection between typhoid fever and impure milk, there have been eight local outbreaks of the disease in this country within the brief interval of three years, all of which have been more or less successfully traced to this source; and it may now be hoped that the anxiety and alarm caused by the present wide-spread occurrence of the disease, together with the frequency with which these outbreaks occur, will prevent the subject from being, on this as on former occasions, altogether shelved as soon as it has been proved that the milk was contaminated with impure water. I have stated, in my former letter that there is reason to believe these limited outbreaks of typhoid fever, analogous in their occurrence to many correspondingly limited outbreaks of sporadic cholera, are at least to some extent due to milk as it comes from the cow, apart from any fraudulent mixture with contaminated water, being occasionally unfit for our use; and I am glad to see that the subject is likely to attract further notice; for there seems to be in some quarters a tendency to discredit the opinion which has been advanced, that local outbreaks of typhoid fever, as well as of other diseases, may be due to an infected secretion, as distinguished from an artificial contamination, of milk.

"I have referred to cases in which outbreaks of sporadic cholera were due to goat's milk which had acquired poisonous properties, and I have no hesitation in stating, from a somewhat extensive acquaintance with the literature of this subject, as well as from personal observation, that the poisonous properties of the milk, in a large proportion of such cases, are due to something ex-

ceptional and injurious in the animal's food. If your well-known and distinguished correspondent, Mr. Alfred Smee, will consent to direct his attention to the remarks of M. Beaugrand on "Milk rendered toxic by poisonous plants," in the '*Dictionnaire Encyclopédique des Sciences Médicales*,' art. "Lait," he will find much curious and useful information on this subject. The inquiry is of the very highest importance as regards public hygiene; and great as our progress undoubtedly has been, during the last few years, in this as in other directions, we appear as yet to have reached only the threshold, so to speak, of the temple devoted to sanitary science.

"Goats, as rule, are allowed more liberty than cows in selecting their food, and it is probably owing to this fact that the milk of the former is more liable than that of the latter class of animals to acquire in this way injurious properties. Previous to the year 1870 little if any attention had been paid in this country to cow's milk as a cause of disease, while for many years previous to that date the use of goat's milk had been observed to be not unfrequently followed by dangerous symptoms. In a case, for example, of a woman and five children, which occurred some years since, choleraic symptoms showed themselves soon after drinking buttermilk obtained from a goat which appears to have fed on fool's parsley; and Dr. Mackay has published a report of some cases of poisoning by goat's milk to which it may be useful on this occasion also to refer. It appears that on the 27th of November, 1861, some ten or eleven of the ward-room officers of Her Majesty's ship Marlborough, including Dr. Mackay himself, were simultaneously attacked with symptoms which were at first supposed to be attributable to some poisonous matter having been accidentally mixed with some of the dishes of which they had partaken at breakfast. Among the symptoms described were extreme faintness, nausea, violent bilious vomiting, and diarrhœa; coldness of the extremities and cramps. They were found to be referrable to goat's milk, rendered poisonous by the animal having fed on the common sea-spurge. Many similar cases could be cited, if necessary, to prove that not the milk only, but also the flesh of these animals, may, through improper feeding, become unfit for our use; and, as such is the case with regard to goats, it would be a very curious and a very exceptional fact in physiology if it should be discovered that the milk of cows is seldom, if ever, liable to be injuriously affected in this country by bad water or by improper food.

"As regards local outbreaks of typhoid fever, primary importance has already been assigned to direct admixture of the milk with contamimated water; but it is important, at the same time, to bear in mind that milk may be injuriously affected through something wrong in the food or drink supplied to the animal by which it is secreted. Before the Royal Commission on the utilization of sewage, it was, I think, elicited that typhoid fever was produced by milk from certain dairy farms to which sewage had been applied. The grass crops on these farms were unusually rich, but the cows, in feeding on them, had probably swallowed some of the sewage matter with the grass, and yielded milk similar to that described by Mr. Smee; similar also to that which has been lately supplied to some of the customers of the London dairy referred to in connexion with the present outbreak of typhoid fever.

"The practical conclusion to be drawn from such observations is that, in order to secure wholesome milk, cows should be protected from contaminated water and improper food as well as ourselves. Science, like fashion, seems to be occasionally liable to excess; and in the fertile, but as yet imperfectly cultivated department of sanitary science there has lately been a somewhat overzealous search after contaminated water used simply for adulteration as the exclusive cause in these cases of disease; and attention has in consequence been diverted from other, and, in some respects, not less important, sources of mischief."

THE PREPARATION OF GELATIN.*

In the ordinary manner of making light-coloured gelatin, thin skins, sinews, cartilages, and bones are employed, which must be treated with muriatic acid and lime before being dissolved. These have furnished a good article, but at a high price. The expense of this process therefore induced F. Hense, of Berlin, to thoroughly investigate the subject of its manufacture in the hope of producing an equally good article at a lower price. The material employed was the brown, or almost black, glue of very poor quality, which is a by-product in a Berlin neatsfoot-oil manufactory, and which sells for five dollars per hundredweight. This substance does not swell up in cold water like glue, but forms a gummy mass, dissolving as a thick, syrupy liquid, not very adhesive, but resembling that of which printers' rollers are made. It is now used only in making cardboard and as a dressing for very dark-coloured fabrics.

In preparing this glue, the feet are first freed from hoofs and the more solid bones of the leg, which are used for turning into buttons and ornaments, and washed. They are then exposed for three hours to the action of superheated steam under a pressure of two atmospheres in a closed vessel; and after standing quietly half an hour, the liquid is drawn off. After skimming off the supernatant grease, the strong ammoniacal glue solution is strained and evaporated on a steam bath, and then furnishes the before mentioned blackish glue. When perfectly dry, it is very brittle and easily rubbed off between the fingers. Attempts to bleach it have yielded unfavourable results. It shows that it is already decomposed and is no longer gluten, or contains only very little of it. A large quantity of sulphurous acid partially bleaches it, but to employ this on a large scale would involve many technical difficulties. The fragile apparatus for making sulphurous acid would soon be broken in the hands of the workmen. Sulphite of soda could be dissolved in a very dilute glue solution, and muriatic acid added to decompose this salt, if the quantity of the sulphite of soda required were not too large; but fifty kilograms of glue would require at least 2500 grams sulphite of soda and 2250 grams muriatic acid. The salts formed, which are sulphate of soda and chloride of sodium, as also the free acid, would in no case improve the quality of glue, but on the contrary would render it utterly useless for many purposes in the arts. The process of bleaching with mineral acids would also destroy the iron evaporating pans, so that this method must be given up entirely.

All attempts at giving to the glue, when finished, the colour desired having failed, no other course remained but to ascertain the cause of its becoming so dark-coloured. The presence of sulphur and of considerable quantities of ammoniacal salts in the glue solution was too striking to escape notice very long. They could only have been caused by allowing the steam to act too long and too violently, whereby not only were the cartilages and gristle converted into glue, but the hair too had been dissolved, and thus caused the dark colour. In order to reduce the decomposition of the glue and formation of ammonia to a minimum, the process may be varied in such a manner that, instead of drawing off the contents of the digester once at the end of every three hours, they shall be drawn off hourly. On standing a little the grease rises to the top and can be skimmed off, and then a quantity of fresh wood charcoal mixed with 25 per cent. bone black is put into the liquid and left overnight for the purpose of absorbing ammonia and other impurities. The following morning it is heated to a temperature at which gelatin melts, about 70° to 85° Fahr., strained and evaporated to the desired consistency. The amount of charcoal necessary is about four per cent. of the quantity of glue in solution.

The Pharmaceutical Journal.

SATURDAY, AUGUST 23, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BRADFORD MEETING OF THE CONFERENCE.

THE Local Committee for the Pharmaceutical Conference meeting at Bradford have requested us to impress on intending visitors the desirability of early application being made to the Local Secretary for lodging accommodation, and that it would facilitate their efforts to secure such if their friends would state whether or not they propose remaining for the meeting of the British Association. This is necessary, as the hotel and lodging accommodation in Bradford is very limited, and the necessity is especially felt at a time when so large a number as usually attend the British Association have also to be provided for.

We desire to draw the especial attention of our readers to these very reasonable demands of the Bradford Local Committee, and may refer to the recent experience of the British Medical Association Meeting in London as a justification for doing so. On that occasion the attendance of members was so far in excess of any anticipation entertained by those whose duty it was to organize the proceedings, that it proved impossible to accommodate more than a fraction of the visitors. To distribute tickets for the dinner it was necessary to have recourse to drawing lots, and in the several excursions there was almost an equal difficulty in providing for all who wished to join.

Under such conditions there must of course be a considerable amount of individual dissatisfaction, and those who chance to be disappointed are often much disposed to censure sorely-taxed officials rather than admit that they are themselves to a great extent to blame for not having adopted the obvious plan of intimating their intention to take part in the proceedings.

On the same day (Tuesday, September 16) on which the British Pharmaceutical Conference is to commence its proceedings at Bradford, the twenty-first annual meeting of the American Pharmaceutical Association will commence in the city of Richmond, Virginia.

As this will be the first meeting of the kind held in the Southern States, there is a great desire that the several sections of the country may be fully represented, so that there may be evidence of the national character of the association, and of a continued growing interest in it.

An exhibition of objects relating to pharmacy is to be held in connection with this meeting, towards which contributions of articles to be exhibited in the following classes are solicited:—(1) Crude Drugs and Derivatives; (2) Pharmaceutical Preparations; (3) Chemical Preparations; (4) Pharmaceutical and Chemical Apparatus and Appliances; (5) Shop Fixtures, Soda-water Apparatus, etc.; (6) Druggists' Sundries, New Toilet and Fancy Articles; (7) Plants, officinal, useful, and ornamental; (8) Pharmaceutical Literature: New and Rare Books. A similar coincidence in the time of meeting of the two Societies occurred in 1870, and was then the occasion of the exchange of some pleasant courtesies by submarine telegraph.

THE WORKING OF THE ADULTERATION ACT.

IN the article which appeared under this heading two weeks ago we expressed the opinion in reference to the Glasgow butter case that there was either great want of care in taking the samples or else serious error in the analytical operations they were subjected to. Objection has been taken to this by Mr. A. H. ALLEN, the analyst for Sheffield, in a letter to be found in our correspondence columns, and he writes to correct what he believes to be an erroneous view of the question.

We regret that we cannot agree with Mr. ALLEN or accept his intended correction. If Mr. ALLEN will refer to the report of the case published in the Glasgow papers and extracted thence into our columns, he will find that two separate half-pounds of the butter were handed, sealed up, to Dr. THORPE for examination. One of those samples still sealed up was produced in court; the other was examined by Dr. THORPE who reported it to contain 19·5 per cent. of curdy and farinaceous matter, and 19·4 per cent. of water. At the same time Dr. WALLACE had examined two other samples of butter from the same kit and he found in them respectively only 1·1 and 1·5 per cent. of curdy matter without any farinaceous matter. There might be some doubt whether these different samples represented the same butter, and the magistrates reasonably enough took that view.

But there still remained the question, fairly put by Mr. ALLEN, whether the two samples of butter examined were adulterated with some curdy and starchy matter, and to solve that question the Glasgow Police Board directed the sanitary inspector to forward to Professors ANDERSON and MACADAM one half of each of the identical samples of butter produced in the case against GIBSON.

The reports of these gentlemen agree in representing the amount of curdy matter to be only about 1 per cent., as well as in affirming the total absence of farinaceous matter, thus corroborating the report of Dr. WALLACE in these respects. So far, therefore, it seems to us impossible to avoid the alternative conclusion to which we came when commenting on this case, and there does not seem to be any foundation for Mr.

Allen's opinion that the evidence of Professors Anderson and Macadam and Dr. Wallace proves nothing but variation in the samples, for their analyses agree in regard to the only points in which comparison is possible, viz., the amount of curdy matter and of water.

Some clue to the discrepant results might perhaps be found in Professor Thorpe's statement that he purposely selected that portion of the butter in which the white substance very irregularly distributed throughout the mass seemed present in largest quantity, but we purposely refrained from any allusion to this remarkable admission, since our object in drawing attention to this case was merely to show the importance of extreme care not only in the analytical operations to which articles are subjected for the purpose of the Act, but also in the taking of samples in the examination of which the reputation of dealers is at stake no less than the rights of the public.

FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Our readers can hardly have forgotten the brilliant success with which the French Association for the Advancement of Science was held last year at Bordeaux. The first volume of the Transactions, a portly octavo of some thirteen hundred pages, is just out, and contains some of the more memorable papers read and discussed before the meeting, notably Dr. Alphonse Guérin, "Sur la Communauté du Sang," M. Levasseur "Sur la Géographie commerciale," M. Paul Broca "Sur l'Homme préhistorique," and others hardly less attractive. The only objection to the meeting was that its sections were overweighted with matter in the form of papers and their inevitable discussion, so that scarcely two-thirds of the programme was carried out.

This year the Association meets at Lyons, a city selected, and justly so, over its two competing rivals, Lille and Havre. Lyons, besides its commercial importance, has the additional claim that it contributed twenty foundation-members to the Association, while its number of adhesions increases almost every day. The bureau of which M. Quatrefages, the distinguished naturalist, is president, and M. Adolphe Wurtz, the still more distinguished chemist, vice-president, includes some of the most eminent *savants* in France. Their exertions for the accommodation and entertainment of visitors have been unwearied, and all their arrangements give promise of a gathering even more successful than its immediate predecessor at Bordeaux. They have procured from the municipality the temporary use of the Palais de Saint Pierre and the Hôtel de Ville *ad hoc*, while they have so contrived as to limit the number of papers to a manageable amount. In addition to the general conferences and the detached sections, the guests will be invited to assist at a series of excursions well-devised to suit the tastes of the different schools of *savants*. There will be excursions to spots rich in geological and botanical features; excursions to the industrial basin of the Loire; excursions to the various iron-mines and foundries in the Ardèche. Add to this that the railway companies have reduced the fares for the meeting of the Association, and have also arranged with other lines for cheapening the cost of communication with Vienna and its Exhibition—and the attractions of the Lyons meeting of the French Association for the Advancement of Science will prove neither few nor small. The only point in which the bureau have laid themselves open to criticism is their tardiness in announcing the date of the sittings, the opening day having been fixed for Friday, the 22nd (yesterday).

EUCALYPTUS GLOBULUS.

Mr. Broughton, the Government quinologist at Ootacamund, in a report to the chief secretary of Government, Fort St. George, makes the following remarks on the supposed value of the *Eucalyptus globulus*. He says, "Much has lately appeared in the papers and quasi-scientific journals concerning the valuable qualities of the *Eucalyptus globulus* as a febrifuge. In the *Lancet* for April 20th, 1872, a notice is given of the uses of this tree medicinally, in which it is stated that all parts are most valuable as a febrifuge medicine, and also that the leaves, when smoked, are most efficacious in allaying pain, calming irritation, and procuring sleep. This article furthermore informs us that Professor Vauquelin obtained an alkaloid from the bark which crystallized like quinine as a sulphate, and which yielded the ordinary reaction of quinine with chlorine water and ammonia." Mr. Broughton further says: "I have examined the bark and leaves of the *Eucalyptus globulus*, and have the honour to state that neither quinine, quinidine, cinchonidine, nor cinchonine is contained in the plant in any proportion."

In the Journal of the Austrian Apotheker-Vereines there is a report of the results of some experiments made to ascertain the resistance to melting of ice from different localities and artificial ice. From these results it appears that blocks weighing two hundredweight melted under like conditions as follows:—

Ice from Switzerland	107 hours.
„ Norway.	115 „
Artificial ice made in Carre's machine	150 „
„ „ „ Tellier's „	144 „

Previous experiments have also indicated that artificial ice melts less freely than the best kind of natural ice.

Mr. John Wiggin, Pharmaceutical Chemist, has been appointed, under the provisions of the Adulteration of Food, Drugs, etc., Act, public analyst to the Corporation of Ipswich. The salary is to be £25 *per annum*, and a payment of 10*s.* for each analysis.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.—SESSION 1873-4.

The Council of the Bristol Pharmaceutical Association announce that they have made arrangements by which they are enabled to offer to their fellow members and associates the following complete course of instruction in Chemistry, Botany, and Materia Medica.

CHEMISTRY.—A course of thirty lectures, by Mr. Coomber, F.C.S., on *Inorganic Chemistry*, every Tuesday, at 8 p.m., commencing October 14th. A course of thirty lectures by Mr. Coomber, F.C.S., on *Organic Chemistry*, every Thursday, at 8 p.m., commencing October 16th.

BOTANY.—A course of sixty lectures, by Mr. Leipner, on *Botany: Elementary, Systematic, and Physiological*, every Monday, at 7.30 p.m., commencing September 8th.

At the conclusion of the session in May next, an examination will be held in each subject, at which every student is required to present himself. In connection with that examination the Council offer a series of prizes, particulars of which are appended.

Tickets for either of the two subjects—Chemistry or Botany—will be five shillings for members and associates, provided the holder complies with the condition of presenting himself for examination, and shall have attended not less than twenty-five lectures in each course, in accordance with the regulations of the classes; otherwise the fee will be ten shillings. Students are earnestly advised to abstain from entering for more courses than they can reasonably expect to follow up.

Tickets for the above lectures may be obtained of the following gentlemen:—Mr. Boorne, 4, Union Street; Mr. Stoddart, North Street; Mr. Schacht, Clifton; Mr. Martin, White Ladies' Road; Mr. Pitman, Redcliff Hill, who will give any further information which may be desired.

The kindness of Mr. Stoddart enables the Council again to announce a course of lessons on the Materia Medica of the Pharmacopœia. Mr. Stoddart declines, as heretofore, to accept any payment for his labours, but concurs in the propriety of requiring a fee of £1 1*s.* for attendance, the proceeds to go to the augmentation of the museum and library fund. An examination will be held, and prizes awarded, at the conclusion of the course. The lessons will be on Friday evenings, at nine o'clock, commencing October 3rd. Tickets to be obtained only at Mr. Stoddart's, North Street.

A course of practical laboratory instruction will be conducted by Mr. Coomber on Friday evenings, at the Laboratory, in Nelson Street. The fee (inclusive of apparatus and chemicals) will be £1 1*s.* per quarter. Tickets to be obtained of Mr. Coomber only.

As the lectures will soon commence, it is hoped that every principal will at once acquaint the assistants and apprentices of his establishment with the facilities offered for their scientific culture, and will do his best to further the efforts of the Council, some member of which will shortly call respecting this announcement.

Arrangements are also being made for the renewal of the monthly evening meetings, which appeared to give general satisfaction in previous sessions. The first of the series will be held in October.

SCHEME OF PRIZES FOR SESSION 1873-74.

The Council announce their intention to offer the following Prizes for competition among the students attending their classes in Chemistry, Botany, and Materia Medica:—

Chemistry (Inorganic.)

A prize to the student who passes the best examination in the elementary grade.

A prize to the student who passes the best examination in the advanced grade.

Chemistry (Organic.)

A prize to the student who passes the best examination in the elementary grade.

A prize to the student who passes the best examination in the advanced grade.

Botany (Elementary and Systematic.)

A prize to the student who passes the best examination in the elementary grade.

A prize to the student who passes the best examination in the advanced grade.

Botany (Structural and Physiological.)

A prize to the student who passes the best examination in the elementary grade.

A prize to the student who passes the best examination in the advanced grade.

Only those students who obtain a first class in their respective grades will be eligible for the above prizes.

Materia Medica.

A prize to the student who passes the best examination.

A prize to the student next in merit.

The examinations in Chemistry and Botany will be those of the Science and Art Department, ordinarily held in May.

The examination in Materia Medica will be conducted under the direction of the Council.

The prizes will be presented at the annual meeting in July, and will consist of books, apparatus, or instruments, at the option of the successful candidates.

Students are also reminded that in connection with the examinations in Chemistry and Botany, the Science and Art Department awards annually medals and prizes of books, particulars of which are fully described in the Science and Art Directory.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

ON THE ENERGIES OF THE IMPONDERABLES, WITH ESPECIAL REFERENCE TO THE MEASUREMENT AND UTILIZATION OF THEM.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture III.

On the Energy of Vitality, with especial reference to the Measurement and Utilization of it.

(*Continued from page* 135.)

Put the first finger of each hand to the ears, not pressing them tightly, resting the elbows on a table thus, and then clench the fists firmly, you will immediately throw the muscles of the arm into action, and as soon as they are brought into action there is a peculiar humming sound perceptible. That is a sound caused much as the sound of flies, when buzzing about, is caused, or as humming birds cause their sound; it is caused by an intermittent action; in this case of the muscles, and upon that action the rest of this lecture will turn. There is, however, a better plan even than that for observing this phenomenon. When you go to bed, if you are particularly bent on scientific research, and will lay your head on the pillow so as to entirely exclude all external sounds from the ear, then clench the teeth firmly; those muscles which are concerned in masticating the food are brought into play, and you hear the sound most distinctly. Now, that sound gives a musical note, and from that musical note all our knowledge of muscular action springs. All musical notes are caused by the frequent repetition of a vibration at equal intervals. Take a glass tube of some length, and a little jet of lighted gas. If the tube be placed over the gas light you hear a musical note. That is caused by the light being extinguished and relighted a certain number of times per minute, as you can see by watching the reflection in the mirror. If, now, the mirror be shaken behind the light, a number of separate flames appear; if these are counted, we can ascertain how often they occur in a minute or an hour. Therefore, we know the number of

* Cantor Lecture, delivered February 17.

beats which produce that musical note. Here is an instrument for causing a sound by the frequent interruption, at equal intervals of time, of a stream of air. The number of interruptions in a given time are recorded by the wheel-work and indicated on these dials. It is called a "Siren." Again, here is a gyroscope, which does the same thing. If some string be wound round, and it is set in rapid rotation, and then a piece of cane or quill be pressed against the little wheel at one end of the axle, the note produced will vary according to the speed of the rotation. Another illustration may be had from the heating of metals of certain peculiar shaped surfaces, and laying them on cold metal, sometimes a peculiar humming sound is heard.

When Dr. Haughton was suffering from a singing in the ears after an attack of fever, he produced a sound by exercising the muscles of the jaws; this sound was in unison with the singing in the ears, but separated from it by several octaves. Dr. Haughton was struck, like Dr. Wollaston, with the resemblance of the sound to distant cabs. He measured the intervals of the granite pavement, and found them about four inches apart. This gave three impulses in the foot. If the cabs were driven at eight miles per hour, we have 35·2 impulses per second. An organ-pipe with a moveable stop was tuned in unison, and thus 35 1-3 vibrations per second were deduced.

From this rate of muscular contraction Dr. Haughton deduces the amount of work stored up in human muscles. It may facilitate a more thorough comprehension of the subject, if, in as simple and clear a manner as in my power, the mode of conducting the experiments is described. Remember, the object is to make clear to all not only the mode, but also the principles on which these experiments rest. Therefore, every technical or professional term must as far as possible be avoided.

If the arms be held out horizontally, being raised direct from the sides, and not brought forward, they will be supported in that position by two muscles in each shoulder—or rather the portions of the two shoulder muscles which support them can be clearly defined and measured. The length of time for which this position can be maintained will of course vary considerably. The other evening I could hold mine in this position for only six minutes, that is to say, they became exhausted in that space of time. Therefore the sole power of the muscles employed was expended in maintaining the arms in that position for six minutes. Eight minutes will be found more near to the average.

Now let us consider what was happening whilst the arms were so held out. Clearly the muscles were giving off this note, that is to say, they are always giving it off when they are in action, and, therefore, the arm literally was swinging up and down, or vibrating, though to a very small and invisible extent. It would do so much more but for this peculiar arrangement; whilst the muscle contracts and produces the action that we usually call muscular action, that contraction does not take place through the entire mass of muscle at the same time. Each fibre contracts, but not in the same portion of the muscle and at the same time; there are waves succeeding waves, and the consequence is that there is, to all appearance, a steadiness in the arms through the continuity of these waves. But, as regards the action, it is the same as though that wave passed along at once. Now, if the wave passed along at once, then the arm would fall, because it would oscillate or move up and down as a wave does. Knowing how often that wave passes, you would know how often the arm fell. The arm falls thirty-two times per second. It falls as if it were perfectly free, and if perfectly free we can easily calculate the space through which it would have fallen in the 32nd part of a second, namely, the $\frac{1}{64}$th of a foot; in other words, we have reached this stage, that the action of a muscle is such that it allows the arm to fall through the 64th part of a foot in the 32nd part of a second. Now let us get to another stage. The cause of its falling is the action of gravity upon the whole mass of the arm. You may remember that when dealing with the pendulum, it was explained that in a compound pendulum different portions fell through different spaces, but that there is one point which we call O, termed the centre of oscillation, which may be regarded as representing the whole mass. Now, assuming a shoulder to be the point of suspension of the pendulum, it is the point O in the arm which would fall through the 64th part of a foot in the 32nd part of a second, and that point O, by a mathematical calculation, can always be found. Regarding the arm as a perfect cylinder, this point is at two-thirds of the length of the arm from the shoulder.

Again, the work done depends on the mass moved, or supported, and the mass moved is that which is calculated as at the centre of gravity, which for this purpose is about the elbow—about eleven inches from the shoulder. Therefore, assuming the arm to be twenty-four inches, then the point O, at sixteen inches from the shoulder, falls through the 64th part of a foot, in the 32nd part of a second, and it is very easy from that to ascertain how far the point at eleven inches from the shoulder, representing the whole weight of the arm, would fall in the same interval of time. We have, therefore, got the centre of gravity, the weight of the arm, and the distance it falls.* We consequently have all the elements wanted. We have the mass, the weight of the arm, the space (the 1-64th of the foot), and the time (1-32nd of a second). Without going into the question of mathematics, the work done under these circumstances, as regards my own arm, was this, that I was able to do with both arms 1980 lbs. in the six minutes that elapsed before fatigue came on; in other words, the work done was the same as though I had lifted 1980 lbs. one foot high—1980 lbs. is very nearly 18 cwt. That is to say, the work that these two arms did in falling through that space, and being lifted back again, was very little short of a ton. If any one wants to know how much work the human arm is capable of doing when working on its own account, he may raise weights amounting to 9 cwt. on to a stool, a foot high, and he would then ascertain the exact work that each arm did when left to support itself. Such is an outline of the mode in which the calculation is made. If there are any persons interested in it, as a question of actual calculation, a table in the foot-note may be of interest.†

---

* Dr. H. calls his and many other similar experiments "Statical," although reference is made to motion, because the muscles are kept in continued contraction until tired out, and undergo no translation in space, although a rapid and active molecular movement takes place within the muscles to which the work done is altogether due.

† To find the work done in holding the arms horizontal, time before exhaustion being six minutes:—

From measurement, length of each arm is 24 inches.

From weighing, weight of each arm is 8 lbs.

From muscular note, vibration of each arm is 32 times per second.

From tables, centre of oscillation of each arm is $\frac{2}{3}$ of 24 inches, or 16 inches from shoulder.

From inspection, centre of gravity of each arm is 11 inches from shoulder.

Now from the usual expression—

$$S = \tfrac{1}{2} G T^2$$

$$\text{In this case } S = \tfrac{1}{2}\, 32 \left(\frac{1}{32}\right)^2$$

$$= \frac{1}{64} \text{ foot.}$$

Therefore centre of oscillation falls through $\frac{1}{64}$ foot in $\frac{1}{32}$ of a second, or centre of oscillation falls through $\frac{60\ 32}{64}$ *i.e.*, 30 feet in one minute.

If at 16 inches from the shoulder there is a fall of thirty feet per minute, then at 11 inches from the shoulder there is a fall of $\frac{11\ 30}{16}$ feet per minute.

The arm in this case was held steady, and doing what may be called static work, as distinguished from that which is dynamical or kinetic. Dr. Haughton took very great pains to ascertain the exact weight of these muscles in the shoulder. This was done thus :—There is a large muscle called the "deltoid" muscle; a portion only of this muscle is engaged in the work. After careful examination in various ways Dr. Haughton concluded that 10-36ths of this muscle is employed in the experiment. It would be out of place to enter into these details here ; it may, however, be of general interest to place this investigation before you in a tabular form.

	oz. avoir.
Average weight of superspinatus muscle	1·671
Average of portion of deltoid.....	2·830
	4·501

Therefore 4·5 oz. perform, on an average, 1206·5 ft. lbs.
" 1 oz. performs 268 ft. lbs. before being exhausted.
As this exhaustion is complete in 8·29 minutes, the average duration of endurance, 1 oz. in 1 minute does $\frac{268}{8{\cdot}29} = 32{\cdot}3$ ft. lbs.

On one occasion these muscles were weighed and measured within 40 minutes after the execution of a criminal, so as to ascertain the exact size of them under circumstances where there had been no wasting from exhaustion. With the shoulder unloaded, the muscle was tired out in 8·29 minutes on an average of experiments. The weight of the muscles employed was 4½ oz., and the work they did on an average was equivalent to the lifting of 1206 lbs. through a foot. The weight lifted through one foot for one ounce of muscle would be 32 lbs. He then put a weight of 2 lbs. in each hand, and held them out as before until fatigued, and he found the muscles were exhausted in four minutes, but the amount of work which each ounce of muscle did was 46 lbs., so that it did more work than it did before. Now, the power of the heart to send blood into the muscles, to keep up the action there, is not, in this case, equal to the action or work required from them ; hence they began to fail in four minutes, whereas, in the other case, they kept at work for eight minutes. In fact, the power exactly balanced the work in the eight minutes; but it fell rather short in four minutes. An experiment was tried in another form, namely, hanging a weight on the wrist and keeping the elbow close to the side, a different muscle (biceps) came into play. This muscle weighs about eight ounces ; the power lasted 9¼ minutes, and the weight, per ounce of muscle, lifted was 41.

Statical Work done by Muscles.

Muscles used.	Work in foot pounds.	Duration of labour, in minutes	Weight of muscles in ounces avoir.	Rate of work in foot lbs. per oz. per min.
Unloaded muscles of shoulder.....	1206	8.29	4.50	32.3
Loaded muscles of shoulder	842	4.05	4.50	46.2
Loaded muscles of forearm	3170	9.29	8.21	41.5

Now, coming to dynamical work, when the muscles are engaged in producing motion, the muscles of the trunk of the body are employed simply in supplying the other muscles with that upon which they live during the time they are at work; they do no external work themselves. This was alluded to in an early part of the lecture, when it was said that there are certain muscles which act involuntarily; for example, if the heart cannot propel blood as fast as the muscle needs it, and if the will insists upon that muscle doing further work, then the heart is called upon to do what it cannot do, and death ensues. The two must be harmonized ; and where this harmony is broken, as sometimes happens in a boat race and other cases of violent exertion, accident or death results.

Dynamical Work done by Muscles of the whole Body.

Kind of Work.	Quantity of work in foot pounds.	Duration of labour in minutes.	Weight of muscles in oz. avoirdupois.	Rate of work in ft. lbs. per oz. per minute.
Boat race	61,040	7	575	15·17
Barrow lift.....	2,038,400	480	575	7·39
Running with load	10,091	155	575	35·11
Day labour.....	792,400	600	575	2·30

This table shows the results of experiments on different kinds of work. First, there is the case of a boat race which was rowed in seven minutes. The whole weight of the muscles employed in actually doing the work, viz., those in the arms and legs, was 575 ounces ; the work done, making all allowances for the weight of the boat and the people in it, etc., was equivalent to 61,040 lbs. raised through a foot, giving an average of only 15 lbs. per ounce per minute, so that the contrast is very great between static work and dynamical work, the former being three times as great. Next comes an instance bringing into play all the active muscles of the body. It was a plan adopted in some railway works, raising rubble from a great depth. There was a pulley at the top of a shaft, over which passed a rope, and a stage at each side large enough to carry a barrow. One barrow was filled at the bottom, then a man stepped into the empty barrow at the top, and his weight in falling to the bottom of the shaft lifted the barrow full of earth. He then ran up a ladder to the top, and was ready to descend again. By that means his own weight lifted up the full barrow of earth. With work like that a man worked for 480 minutes; and he did two millions of units of work. Compared with the boat race he was only half as industrious, and the length of time was very much greater, but he only did 7·39 foot lbs. per oz. per minute. In the next case a man ran with a load upon his shoulders, and his muscular power was knocked up in half a minute, but the work he did was 35 foot lbs. per minute, approaching very nearly the static work. Last comes a day labourer, who generally takes it very easy, and it appears he only does 2 foot lbs. per oz. per minute, so that if he complains of getting small pay he does little work for it ; it must be remembered, however, that he works for 10 hours a day at it.

Time warns me to close. It may, however, be of interest to state that, calculated as machinery would be calculated, the heart receives and propels the whole amount of blood in the human body in forty-two seconds.

To those who care for the subject of the present lecture, and have not altogether laid aside their mathematical knowledge, the information in Dr. Haughton's book will prove both instructive and interesting. To follow up the investigation, they may study the action of a horse in walking and drawing a load, also the construction of carriages so that the animal may most easily raise a loaded cart over an obstacle on the road, and, further, decide upon the inclination of the traces to the roadway. These being done the investigator will find much

Therefore the work done by one arm is $\frac{8{\cdot}11{\cdot}30}{16}$ ft. lbs. per minute.

Therefore the work done by one arm is 165 ft. lbs. per minute.

Therefore total work by both arms before exhaustion is 165.6.2 ft. lbs., or 1,980 ft. lbs., that is nearly 18 cwt. lifted through one foot in six minutes.

scope for original works in examining the various ways in which horses are harnessed so as to utilize their vital energies. This done, boats and bicycles, as means of utilizing muscular energy, are worthy of thought. Perplexity and confusion seem to be stamped upon modern usages in these matters, and the conclusion is forced upon us that the utilization of the vital energies has not yet been reduced to a system.

Parliamentary and Law Proceedings.

The Dispute about a Cholera Mixture.

The following correspondence respecting the Cholera Mixture, which, as reported in last week's Journal, was recently the subject of an injunction, has appeared in the *Liverpool Daily Post* :—

"THE REV. MR. PARKER'S CELEBRATED CHOLERA MIXTURE.'

"Sir,—You report to-day an application by Mr. Thomas Martin asking the Chancery Court of Lancashire to restrain Mr. W. Jones, of Great Howard Street, from selling a mixture under the title of 'Rev. Mr. Parker's celebrated Cholera Mixture.' Mr. Martin stated that it was a colourable imitation of a medicine prepared by himself; that he had the only recipe for it, and had prepared it for twenty years. If you think it is a matter of sufficient interest to your readers, we beg to furnish you with a copy of the prescription, which we have been in the habit of preparing and supplying for a period much longer than that named by Mr. Martin under the name quoted, and also under that of 'St. Mary's Powder.' It was prescribed by the late Dr. Murphy, of Upper Parliament Street, for the Rev. Mr. Parker, a Catholic priest. It is a very good remedy for diarrhœa and for the premonitory symptoms of cholera, and is as follows :—Take,

Confection of Opium	1oz.
Aromatic Confection	1oz.
Precipitated Chalk	½oz.
Powdered Gum Arabic	½oz.
Carbonate of Ammonia	¼oz.
Oil of Peppermint 60 drops.	

"Make a powder. Dose : A teaspoonful in a little cold water every four hours.

"Yours, etc.

"CLAY AND ABRAHAM.

"Liverpool, Aug. 12, 1873."

"PRIEST PARKER'S CHOLERA MIXTURE."

"Sir,—In your issue of to-day there appears a letter from Messrs. Clay and Abraham, with reference to an injunction in Chancery which I obtained, restraining Messrs. Jones and Co. from selling or preparing Priest Parker's cholera mixture. This letter appears to me so utterly uncalled for, and the information it purports to give so erroneous, and calculated (whether intentionally or not) to do me serious injury in business, that I am sure you will do me the justice of permitting this reply. And first I may be permitted to ask what Messrs. Clay and Abraham have to do with the legal proceedings which I successfully took to prevent Messrs. Jones infringing my rights? If their object was to do public good and not private wrong I could honour them; but whilst they are generous enough to give the public the recipe, they take care to inform them that they prepare it, thus advertising themselves as the vendors of Priest Parker's mixture, of which composition I am about to prove they are as ignorant as Messrs. Jones themselves, who admit they don't and never did know the compound.

"The first requisite in a dispensary chemist is accuracy, and when there is so much inaccuracy as is shown by Messrs. Clay and Abraham in the present instance, one does not wonder that gross and sometimes *fatal* errors in compounding are made. Had Messrs. Clay and Abraham had the ordinary precaution to have a bottle of my medicine before them they could not have failed to see that the compound of which they gave the recipe was in no respect like mine.

"To begin with, theirs is a powder, whereas Priest Parker's mixture is a liquid containing several active tinctures, which are entirely absent from their preparation, and the one principal ingredient is absent. To prove the simple truth of my statement, I have placed my mixture in the hands of the corporation analyst, Dr. Brown, and have had it also analysed by three competent chemists. Their testimony tends to establish my statement.

"I must further add that the powder known as 'St. Mary's Powder' was not written for the Rev. Mr. Parker, nor by Dr. Murphy, but was written by a Yorkshire physician for the Rev. Mr. Shepherd, at St. Mary's (hence its name), but is in no way identical with the cholera mixture made up by me, according to Dr. Murphy's own instructions, for Father Parker.

"Yours, etc.

"THOMAS MARTIN.

"Liverpool, Aug. 14, 1873."

"PRIEST PARKER'S CHOLERA MIXTURE.

"Sir,—Mr. Thomas Martin is good enough to inform your readers that the mixture which he sells under the above name is different from that of which we gave you the prescription. The conclusion which we draw is that he gives his medicine a *wrong name*. To prove that his is different he gives—not the prescription for his mixture to compare with ours, but—his assurance that he has placed his medicine for analysis in the hands of four competent chemists.

"It appears that Mr. Martin's preparation is a liquid mixture; that which we call by the same name is a powder. Any chemist could convert the powder into a liquid, and it may be more convenient in that form, but the question put forward was the use of the name, and to that question only we have addressed ourselves.

"What we have said, and what we repeat, is that we have for twenty or thirty years made a powder which has been known as 'St. Mary's Powder,' 'Priest Parker's Powder,' for cholera and diarrhœa, etc. We could have told more about it twenty years ago than we remember now; but we find a note that, for the precipitated chalk, Dr. Murphy sometimes substituted compound chalk powder.

"Yours, etc.,

"CLAY AND ABRAHAM.

"Liverpool, 15th August, 1873."

Prosecution of a Chemist and Druggist under the Medical Act.

At the Ipswich Police Court, on Thursday, August 7, Mr. James John Young, registered chemist and druggist, of Carr Street, was charged by Dr. B. Chevallier with "unlawfully, wilfully and falsely taking and assuming the name of surgeon contrary to law."

On behalf of the prosecution it was stated that Dr. Chevallier,—who on the passing of the Medical Registration Act in 1858 was requested to act as Secretary in Suffolk,—had in December last called upon Mr. Young and asked him if he was qualified to assume the name of Dr. Young and to practise as he was doing, and whether his name was registered. Mr. Young admitted that he was not registered, but said he was trying to be. On the following day he saw Dr. Chevallier and promised not to circulate any more handbills stating that he was a registered surgeon. About two months after that Mr. Young exhibited in his window a paper on which he styled himself a practitioner, and gave the public to understand that he was fully qualified to act. A few days after that he took that paper down and put another up, which stated that he was not only a surgeon and practitioner, but that he was a registered practitioner. Under those circum-

stances Dr. Chevallier felt that, as secretary, he had no other course open to him than to issue a complaint against defendant, who was liable to a penalty of £20.

In defence it was acknowledged that an irregularity had been committed, but it was urged that Mr. Young was studying for the medical profession, and that through the loss of some documents at sea he had been prevented from being registered. It was also stated that the business did not really belong to the defendant but to a Mr. James Young, who was then in Scotland on business.

The magistrates suggested that the solicitors should come to some arrangement, and, after a short consultation, the defendant pleaded guilty, and was fined 40*s.*, and 20*s.* costs.—*From the Suffolk Chronicle.*

Prosecution under the Adulteration Act.

At the Greenock Police Court, on Monday, August 11, Robert Rennie, a dairyman, was charged with selling milk which had been adulterated with skim milk and water. After the purchase of the milk had been deposed to, Mr. Ogilvie, public analyst, read a report of an analysis of the milk, stating that it was adulterated with 36 per cent. of skim milk and 14 per cent of water, and that these adulterants though not such as to injure the health of persons partaking of the milk, yet by increasing its bulk without proportionally increasing the normal constituents deteriorated the value of the milk as food for infants or young children. The standard adopted was 87½ per cent. of water in pure unadulterated milk. For the defence it was contended that the milk was sold as it was received from the farm, and that the poorness of the pasture upon which the cows fed might affect the quality of the milk. The adulteration was held to be proved and the defendant was fined 10*s.* 6*d.* and 12*s.* costs.—*From the Greenock Telegraph.*

Reviews.

On the Dissemination of Zymotic Diseases by Milk. By John Dougall, M.D., Medical Officer of Health for the Burgh of Kinning Park, Glasgow. Reprinted from the *Glasgow Medical Journal.* 1873.

Dr. Dougall's intelligent paper appears opportunely. Starting from the position which he regards as being sound, that enteric fever may be disseminated over wide areas by the milk supply, he proceeds to consider the probability of zymotic poison being generated in milk *de novo*, the probable nature of zymotic poisons, and the questions whether milk affords a congenial *nidus* for the propagation of such poison, and how it may become infected with the same.

Milk, he holds, cannot generate zymotic poison *de novo*. There is no instance of its producing the symptoms either of fermentative poisoning on the one hand, or of narcotico-irritant poisoning on the other. On the contrary, an eminent Glasgow practitioner is in the habit of feeding his enteric patients with butter-milk, or, as it might be called, fungoid milk—a beverage often used in Scotland to allay the thirst in other zymotic diseases—and actually preferred as an aliment in the preparation of home-made bread. The milk, moreover, supposed to have caused the outbreaks of enteric and scarlet fever was not fermented but fresh.

As to the probable nature of zymotic poisons, Dr. Dougall maintains that while they must be animal or vegetable solids, it does not follow that they must be either fungi or microzoa, or both ; nor, because they are neither gaseous nor liquid, that they are incapable of suspension in air or in fluids. In spite, however, of incessant observation and discussion, the nature of zymotic poison has yet to be ascertained, the only contribution to our knowledge of it being that of Chaveau and Burdon Sanderson, who proved that in vaccine or variolous matter the only contagious part is not the liquid but the solid particles, not larger than $\frac{1}{20000}$ of an inch in diameter.

Unfermented milk is a congenial *nidus* for the propagation of zymotic disease. The mammalian offspring, subsisting solely on mother's milk, rapidly increases in weight during the first few months after birth. The liquid, in other words, containing as it does all the elements, and in the due proportion and combination, for building up the tissues of the young animal, is simply a solution of the young animal's body as regards the identity of all their chemical elements and also as regards most of their chemical compounds. This being postulated, it follows that just as a child or adult is susceptible of being poisoned with small-pox, with scarlatinal, or with enteric virus, so also, and in a much higher degree, must milk when subjected to the same influence ; for while the living organism has vital force to resist the toxic attack, the absence of that *vis vitæ* in milk, which is dead organic matter, renders it peculiarily non-resisting and open to contagia. The readiness with which milk will contract the odour of any article which happens to be near (boiled fish, for example, tainted meat, onions, and so forth) is thus explained, while its fluidity greatly enhances its fertility as a zymotic soil. Now, of the milks sold, that mixed with colostrum or "beasting milk," and diseased milk or that from a diseased cow are the most congenial *nidi* for zymotic putrefacts, butter-milk being the least so.

Such being the case Dr. Dougall comes to the last question he puts to himself—"How may milk get infected with zymotic poison ?" First, he answers, by impure water ; secondly, by impure air. Water is so commonly and easily tainted from the infiltration of organic matter (call it liquid manure, human excreta, or sewage) that its addition to milk whether intentionally for adulteration or unintentionally for rinsing the milk cans, cannot fail to impregnate the fluid with zymotic germs. Impure air, suspending certain specific contagia, also infects the milk, as in the Leeds outbreak of enteric fever, when the water was found blameless and nothing but a reeking mass of liquid manure in the vicinity could evolve the poisonous particles.

What is the practical deduction from these facts? To keep the zymotic seed from the milk *nidus*, and the milk-*nidus* from the zymotic seed. Easy in farm-houses, this precaution is very difficult in large towns. It is common in these life-centres for parties to live and rear families in rooms behind shops, through which the sole access lies, and in which groceries, milk, provisions, fruit, sweetmeats, and so forth are sold. When infectious disease enters such a family, can it fail to be the source of quite peculiar risk to the public ?

It is much, however, to know the cause of danger ; the remedy will follow in time. In England alone 100,000 deaths are annually due to the zymotica ; but, thanks to the refined modes of modern research, higher microscopical powers, and the mutually assisting sciences of chemistry and physiology, we may ere long be able to put our finger on every source of such poison, and anticipate its developement without waiting to destroy it in the germ.

Memoir of Sir James Y. Simpson, Bart., M.D., D.C.L. Oxon., One of her Majesty's Physicians for Scotland, Professor of Medicine and Midwifery in the University of Edinburgh. By J. Duns, D.D., F.R.S.E. Professor of Natural Science, New College, Edinburgh. Edmonston and Douglas. 1873.

Simpson's life had much to attract and not a little to repel the biographer. He was, as Macaulay says of James the First, "made up of two men." One was the indomitable surmounter of obstacles, social and scientific ; the versatile, much-contriving questioner of Nature ; the devoted teacher and the public-spirited townsman ; the genial friend, and the affectionate husband and father The other was the intermeddling schemer, the vindictiv

enemy, the mischief-making colleague, and the inveterate notoriety-hunter. In the first aspect the biographer's task is a delightful one. He has only to narrate and he is sure to please. Humble as to birth, though respectable as to parentage, young Simpson soon gave evidence of the stuff he was made of. The scantling of classics and mathematics which the Scotch parish school places within the reach of every boy, prepared him for the University of Edinburgh, where, thanks to the generosity of a brother, he was enabled to enter in his fifteenth year. That brother, by-the-way, is one of the noblest figures in the present book—a true Proculeius :—

" Notus in fratres animi paterni,
Illum aget penna metuente solvi ;
Fama superstes."

At the classes Simpson took a place inferior to that of duller lads whose opportunities had already been greater. He never made himself a scholar in the strict sense of the word. He could grope his way through an ordinary Latin author, and, with the help of the dictionary, construe a bit of Greek ; but it was with no more culture, if, indeed a smattering of mathematics and moral philosophy can be called such, that he began the study of medicine. Here, however, he could cope with his fellow-students on equal terms. Level at the start, he soon made the running, and came in in a canter. He was fortunate, moreover, in his companionship with John Reid, also a "Bathgate bairn," whose counsel, and still more whose example, kept him straight. His teachers, too, were men of vigour, whose intellectual touch was inspiration. Knox made anatomy and physiology a romance, while Liston impressed all his pupils with his power ; and Thomson's fine analytical talent fostered inquiry and induced reflection. Simpson became a member of the Royal College of Surgeons, and at once sought practice ; but in vain, though the situation he aspired to was that of a country practitioner. Returning to the classes he graduated as doctor of medicine in 1832, and by his thesis was lucky enough to attract the attention of Thomson, who made him his assistant. He settled in practice in Edinburgh—the field of his choice being Obstetrics ; and rapidly drew to himself the regard, not to say the jealousy, of his compeers. A visit to London and Paris, described with animation in his diary, broke agreeably the dull routine of practice. Then came an extra academical lectureship, followed by marriage—a step in all respects advantageous to him—and finally his election to the chair of midwifery by a majority of one. Up to 1840—the date of this triumph—his career commands nothing but admiration. It flows purely and sparklingly. But as it widened it took in grosser ingredients till, broad and imposing as it grew, it ran turbidly and chafingly, reflecting much sunshine and many a cloud.

Now begin Dr. Duns' difficulties, and, we must say, he gets over them with tact, if not always with complete success. The jealousy of Simpson's colleagues, undisguised during the election struggle, were but thinly veiled under collegiate relationship. Squabbles deepening into feuds quickly cropped up. Amidst it all, however, Simpson buckled manfully to his work ; made his class the most attractive in the University ; and extended his *clientèle* day by day. So numerous indeed were his patients that he often failed to attend them, thereby incurring much censure not always undeserved. A fierce controversy with Professor Syme came in to complicate his anxieties. But his rise was steady and sure till in 1847 he was made one of her Majesty's Physicians for Scotland. That year, however, was memorable for a far greater episode in his career : his discovery of the anæsthetic virtues of chloroform. Previously to this, sulphuric ether had been employed to induce anæsthesia. But there were serious objections to it, and Simpson deeply impressed with the conviction that other agents would be found capable of being introduced with rapidity and success into the system, through the channel of pulmonary absorption, had directed his attention especially to this subject, trying among other things upon himself and others the inhalation of volatile fluids, in the hope of finding some one with the advantages of ether and free from its disadvantages.

The trial of chloroform appears to have been almost accidental according to the following account of the first occasion on which Simpson detected its anæsthetic effects :—

"The scene was an odd one. I had had the chloroform beside me for several days, but it seemed so unlikely a liquid to produce results of any kind, that it was laid aside, and on searching for another object among some loose paper, after coming home very late one night, my hand chanced to fall upon it, and I poured some of the fluid into tumblers before my assistants, Dr. Keith and Dr. Duncan, and myself. Before sitting down to supper, we all inhaled the fluid, and were all 'under the mahogany' in a trice, to my wife's consternation and alarm. In pursuing the inquiry thus rashly, perhaps, begun, I became every day more and more convinced of the superior anæsthetic effects of chloroform, as compared with ether."

This conviction was also shared by his butler Clarke, who seems to have had a high opinion of the properties of "chlory," for on finding Simpson one day lying apparently unconscious from the effects of a recent experiment, he remarked to some friends who were watching him with a good deal of alarm, "He'll kill himsel' yet wi' thae experiments ; an' he's a big fule, for they'll ne ver find onything better nor chlory." This appreciation had indeed gone so far as to lead the butler into trouble, for among other experiments, Dr. Simpson had got an effervescing drink prepared with chloric ether in aerated water. At a dinner party this was brought forward and tried, pronounced to be very pleasant, but rather heady. The butler took the remains of this new beverage down-stairs and gave it to the cook, saying it was champagne. Shortly after drinking it, she fell on the floor insensible. The butler rushed into the dining-room, saying, "For God's sake, sir, come doun ; I've pushioned the cook." Dr. S. with some others ran down-stairs, and found their patient lying on the floor, snoring heavily. The butler explained that he had given her a glass of "the new champagne chlory." As there was no danger, the incident created a hearty laugh.

"Claimants" to the discovery, however, were not slow in presenting themselves. Objectors on theological grounds (*credite posteri !*) to its use lifted up their voices. Among the former was Dr. Glover of Newcastle ; but he was soon disposed of. In a letter to him Simpson showed unanswerably that his previous experiments with chloroform had nothing to do with "its anæsthetic properties as produced by inhalation." More formidable was Dr. Morton, of Boston, U.S., who had employed sulphuric ether for anæsthetic purposes ; but, in spite of persistent and *ex parte* "vindications" on the part of his friends, notably Dr. Bigelow, Morton's claim amounts to no more than having superseded nitrous oxide. Dr. B. W. Richardson in the *Lancet* (May 1870) sums up the whole controversy in a lucid and exhaustive paper, and concludes with the verdict that, "all told," the palm of merit in anæsthetic discovery rests with Simpson. The subject occupies a lengthy chapter in Dr. Duns' book but Dr. Richardson's essay might have absolved him from the unwelcome task of re-opening it. He might with still more propriety have dismissed the religious—or rather the "religiose"—cavillers from his pages. But Dr. Duns is a clergyman and cannot be expected to share Lucretius' contempt—

" Tantum Religio potuit suadere malorum."

By this time Simpson's fame was world-wide, and his society courted by *savants* and physicians, European and Transatlantic. Honours showered upon him

" Thick as leaves in Vallombrosa."

Scarcely a learned society but made him an associate or corresponding member. Controversy, however, dogged him like a sleuth-hound. Like Dr. John Brown's "Rab,"

it seemed as if he never could get "eneuch o' fechtin'." His chief encounter was with the homœopathists, notably his colleague, Professor Henderson—a man of sterling talent, of whose trenchant style Simpson had a salutary appreciation. On the whole, the victory rested with the latter, whose ingenuity and fecundity of resource came out wonderfully on the occasion. Scarcely, however, had he emerged from this struggle, when he again became involved in collegiate bickerings, and was alienated from men whom he had every reason to respect and even admire. Quite gratuitously, moreover, he intermeddled with the election to the Practice of Physic Chair, and established enmities which death itself did not close. From these it is quite refreshing to turn to his professional pursuits, and even to his dabblings in antiquarianism, for which he had a considerable aptitude and a strong liking. His device of acupressure attracted much attention, but, ingenious as it is, it seems destined to be superseded by the antiseptic ligature of Lister. His doctrine of the evils of "hospitalism," novel and striking as they are, have awakened a discussion which must end in seriously modifying the practice of congregating large numbers of the sick and hurt under the same roof. His paper on "How to stamp out the small-pox" was, perhaps, the latest contribution he made to medicine; but by that time his strong and elastic frame was showing signs of decay. Bitter disappointments, private losses, domestic and financial, above all the animosity evoked by his candidature for the post of principal of the University of Edinburgh were telling visibly on him, in spite of the gratifying honour of a baronetcy, and the recognition everywhere accorded to his genius. Angina pectoris, the agonizing symptom of fatty degeneration of the heart, had once and again betrayed itself; but still he struggled on, concealing his pain, though it must have torn him like the vulture of Prometheus. In the spring of 1870 he broke down, and before the summer set in he was confined to his room. On the 6th of May he expired, in the arms of that brother who had tended him in childhood, fostered him in youth, and stood by him through good report and bad report during his manhood. Regret at his loss was universal, and a public funeral signalized the "last scene of all."

Dr. Duns has performed his task well. As a writer he has no pretensions to style, and sometimes expresses himself with a looseness (as in the opening sentence of chapter sixth) which is surprising in a gentleman of undoubted accomplishments. There is, moreover, an unctuous religiosity of phrase running through the book which savours of "Little Bethel" rather than of the educated churchman. But with all these reservations, his biography is an interesting and instructive one, redounding much to his credit, if the extreme delicacy and difficulty of his task be held in account. An admirable photograph preserves his subject's lineaments in most characteristic form, and the external accessories are all that could be desired from the respectable firm of Messrs. Edmonston and Douglas.

A Manual of Practical Hygiene; intended especially for Medical Officers of the Army and for Civil Medical Officers of Health. By E. A. Parkes, M.D., F.R.S. Fourth edition. London: J. and A. Churchill. 1873.

To answer correctly, and at some fair length, as to wherein consists Hygiene, has become of late no light task. The necessity for providing pure air, the relation of the air to the soil, the study of its impurities (either suspended or gaseous matters), the system of properly estimating these impurities, the measurement of air necessary in certain conditions for men and animals, the study of climatology, and the instruments used by pathological men, the choice of sites for dwellings, the selection and examination of soils, the proper allotment of rooms in houses, the obviation of over-crowding, the providing against rising and drifting dampness, natural and artificial ventilation, normal heating and the degrees and kinds of warmth, the effects of exercise and training, proper lighting, the water supply, its collection and distribution, the best methods of ensuring commensurate supplies, the storage and filtration of this element, and its analysis, its impurities in transit, the construction of cisterns, the fouling of watersheds, the percolation of fæcal matters in wells, the general question of alimentation and articles of food and beverages, the quantity, quality, and digestibility of dietary matters, the detection of adulteration, the diseases consequent upon tampering with food, milk especially, the proper cooking of meat and vegetables, scientific baking, baths, their use and abuse, clothing, and the best materials for making them, the drainage of districts, and the collection and removal of excrement and dust, sewer ventilation, disconnection of drains, the proper construction of cesspools, privies, ash pits, water, earth, or ash closets, the best sanitary fittings for the house, the offices, and the stables, the utilization of sewage by filtration, precipitation and irrigation, the perfect inspection of nuisances, the disposal and burial of the dead, the disinfection and purification of the house and clothing in cases of epidemics, the duties of medical officers of health for civil, naval, or military communities, the study and classification of specific and non-specific ailments, and the prevention of diseases by precautionary measures, the arrangement of health statistics, death rates, and sanitary reports generally; these and a hundred other items of value would crowd upon the mind whilst endeavouring to reply to the apparently simple question.

After listening to the well deserved applause which followed the delivery of the address in medicine by the author of the book now under review, and the expression of thanks which it met with at the hands of the British Medical Association only the other day, it would and does appear quite supererogatory to recommend this volume to our readers in any formal way. The labours of our author in the sanitary vineyard, and the many useful things he has grafted upon the branches of the social tree, are known wherever English is understood or translations made. He is easy to understand, and temperate in all he says, simply because he is master of his multitudinous subjects, and he is precise in his deductions because he has arrived at his results after many years of elaborate observation and research. Seldom, if indeed ever, have we perused a work in which we have noticed less inflation of style, or more purity of diction, backed by such wealth of ideas.

A medical journal in reviewing a short time ago the 'Diseases of the Ovaries,' by Mr. T. Spencer Wells, observed that it was the best monograph that existed in our language, or perhaps in any other, and this is precisely what we we would say of the book before us—it is the most complete and best treatise on sanitation that has ever been issued from any press, home or foreign. The subjects which we began by enumerating, and many more, find here ample treatment; and a very complete index brings up the rear of things to commend. It must become the text book of the science in all our universities and public institutions, and it will deservedly find a place in the library of every medical man, sanitary officer, and landed proprietor.

Advice to Sanitary Authorities and to Individuals on the Threatened Approach of Asiatic Cholera. By John M. Fox, Medical Officer of Health to the Rural Sanitary Authority of the Cockermouth Union and to the Urban Authorities of Cockermouth, Wokington, and Keswick. London: Simpkin, Marshall, and Co. 1873.

Within the compass of some twenty pages, Mr. Fox presents a graphic view of how cholera is propagated, and of the means by which its propagation may be prevented, and its attack resisted. He writes intelligently,

clearly, and vigorously, and his views are not only in accordance with those of modern science, but they have borne the practical tests of experience in two former epidemics of cholera. The pamphlet is plain enough to be understood and cheap enough to be bought by every one.

Obituary.

Notice has been received of the death of the fol lowing :—

On the 25th December, 1872, Mr. John Stathers, Pharmaceutical Chemist, of Notting Hill. Mr. Stathers, joined the Pharmaceutical Society in 1858.

On the 28th June, 1873, Mr. William George Tryon, Pharmaceutical Chemist, of Landport. Mr. Tryon joined the Pharmaceutical Society in 1841.

On the 26th July, 1873, Mr. William Jabez Halliday, Pharmaceutical Chemist, of Bury New Road, Manchester. Mr. Halliday joined the Pharmaceutical Society in 1860.

On the 10th March, 1873, Mr. Richard Ellis, Chemist and Druggist, of Thornbury, Gloucester.

On the 26th June, 1873, Mr. James Collins, Chemist and Druggist, of Tewkesbury.

On the 8th July, Mr. Enos Andrews, Chemist and Druggist, of Newton-le-Willows, Lancashire.

On the 21th July, Mr. John Wray Rawling, Chemist and Druggist, of Hackney Road.

On the 30th July, Mr. Joseph Massey, Chemist and Druggist, of Oldham.

On the 11th August, Mr. Edward Sutton, Chemist and Druggist, of Sutton Bridge, Long Sutton.

Notes and Queries.

EUPHORBIA IPECACUANHA.—The properties of the root of this plant, which is officinal in the United States' Pharmacopœia, have been investigated by Mr. Christopher Petzelt, and form the subject of his inaugural essay in connection with the Philadelphia College of Pharmacy. He reports (*American Journal of Pharmacy* [4], iii., 255) that the emetic and carthartic properties of the root of *euphorbia ipecacuanha* are due solely to its resin. This resin may be prepared by exhausting a moderately fine powder of the root with alcohol, distilling off the menstruum, adding the residue to water, and washing and drying the precipitate. The resin is soft and of a yellowish colour. Exhausted with acidulated water, the solution gave no precipitate with iodohydrargyrate of potassium, but, redissolved in alcohol, a copious precipitate was formed on addition of a solution of subacetate of lead. Half a grain of the resinous matter acted as a carthartic, producing watery stools ; one-and-a-half or two grains produced nausea and vomiting. The constituents of the root were found to be resin, fixed oil, wax, starch, glucose, and inorganic salts.

COD LIVER OIL BREAD.—With a view of overcoming the repugnance of some patients to cod liver oil, M. Bouchut has sought to mask the taste of the oil by incorporating it with flour and making a kind of bread of the mixture. This bread is described (*Répertoire de Pharmacie*, N.S., i., 425) as not in any way disagreeable, and its success during several weeks is stated to have been very encouraging.

SPIRIT OF LEMON.—The following is the formula for Spiritus Limonis (Spirit of Lemon, Essence of Lemon) of the United States Pharmacopœia : —

"Take of—

Oil of Lemon, two fluid ounces,
Lemon Peel, freshly grated, a troyounce,
Stronger Alcohol [sp. gr. 0·817], two pints.

Dissolve the Oil in the Stronger Alcohol, add the Lemon Peel, macerate for twenty-four hours, and filter through paper."

[350.] ERASMUS WILSON'S HAIR WASH.—In reply to *A. C.* I send the following, which has been represented to me by one of the surgeons of St. Mary's Hospital as

Erasmus Wilson's Hair Wash.

Aqua Mellis	½ oz.
Liq. Ammoniæ	½ oz.
Spirit. Rosmarini	1 oz.
Ol. Olivæ	1 oz.

W. T.

[351] CHRISTISON'S PILLS.—In reference to a notice which appeared in the PHARMACEUTICAL JOURNAL of last Saturday I may mention that the pill so long known here as Christison's Pills, and prescribed by Sir Robert up to the present time, is really the colocynth and hyoscyamus pill mass of the *present* pharmacopœia, *but in pills of two grains each.*

At a time when Socotrine aloes was used in forming the compound colocynth pill mass, the following was the form written by Sir Robert Christison for compounding his pills :—

℞. Mass. Pil. Coloc. c. Aloes Barbad. gr. xvj.
Ext. Hyoscyam. gr. xviij.
Ft. Mass. et divide in pil. xij.

JOHN MACKAY.

[352.] ETHER BOTTLES.—Could any one suggest the best means of capping small bottles containing ether (corked bottles) ? Is there any gum, *easily melted*, that is insoluble in ether ? My present plan is to dip in melted sealing-wax and afterwards in plaster of Paris. It answers pretty well, but I would like something better.—"*Collodion.*"

[353.] LACE STIFFENING.—Will some correspondent kindly give a recipe for French stiffening for lace collars ?—*W. P. Swift.*

The following journals have been received :—The 'British Medical Journal,' August 16; the 'Medical Times and Gazette,' August 16; the 'Lancet,' August 16; the 'London Medical Record,' August 16; 'Medical Press and Circular,' August 16; 'Nature,' August 16; 'Chemical News,' August 16; 'Gardeners' Chronicle,' August 16; the 'Grocer,' August 16; 'Journal of the Society of Arts,' August 16; 'Grocery News,' August 16; 'Produce Markets Review,' August 16; 'The Practitioner,' for August; 'Liverpool Daily Post,' August; 'Journal of Applied Science,' for August; 'British Journal of Dental Science,' for August; 'Food, Water, and Air,' for August; 'Educational Times,' for August; 'Brewers' Guardian,' August; 'Scientific American,' August 16; 'Neues Jahrbuch für Pharmacie,' October 1872 to January 1873; 'Journal de Pharmacie et de Chimie,' for August; 'Moniteur Scientifique Quesneville,' for August; 'L'Union Pharmaceutique,' for August; 'Répertoire de Pharmacie,' for August; 'Boston Journal of Chemistry,' January to August; 'Pharmacist,' for August; 'American Journal of Pharmacy,' for August; 'Chemist and Druggist,' for August 15; 'Chemist and Druggists' Advocate,' for August; 'New York Medical Journal,' for July; 'Madras Medical Journal' (Index); 'Medical Notes and Queries,' August 16; 'Revista Farmaceutica,' for July; 'American Chemist,' for July; 'Zeitsch Allg. öster. Apot.-Vereines,' for August 10.

perties of this plant are not very marked. It has been used in a number of diseases.

Helianthemum.—Frostwort is considered to be a valuable remedy in scrofula, and like many other alteratives in large doses will cause vomiting. It is sometimes used externally also, in the form of a poultice made of the leaves, for scrofulous swellings, etc.

Phytolacca.—Poke root possesses powerful properties, causing vomiting and purging, together with symptoms of narcotic action. Its action in large doses is not only violent but long continued. It is generally used in small doses (one to six grains) as an alterative, and appears to produce beneficial effects by its stimulating action upon the glandular system.

Xanthoxylum.—Prickly ash bark is a stimulating alterative, and is used in rheumatism, torpor of the liver, and languid states of the system. It appears to act as an arterial stimulant, causing a determination to the skin, and an increased secretion from the various glands ; hence, it acts powerfully as a sialogogue.

Anthelmintics.

Chenopodium anthelminticum.—Wormseed is used chiefly for the expulsion of round worms in children. Its properties depend upon a volatile oil, which is the form in which it is generally administered. Its nauseous odour and taste, however, render it rather objectionable.

Asclepias incarnata, which belongs to the secondary list, possesses anthelmintic properties, but is not much used.

Astringents.

Geranium maculatum—Geranium is one of the most powerful of the indigenous astringents. In common with *Heuchera americana,* it is sometimes called alum root. On account of its freedom from unpleasant taste it is much used for children and delicate persons.

Quercus alba and *tinctoria.*—White and black oak barks are chiefly used externally for lotions and injections. The black oak yields the quercitron bark of commerce, and contains a bitter principle, which is apt to disagree with the stomach, and renders the bark unfit for internal use.

Rubus canadensis and R. villosus.—Blackberry root is astringent and tonic, and is employed as a popular remedy in infantile diarrhœa, when accompanied by atonicity of the bowels.

Statice limonium, var. Caroliniana.—Marsh rosemary is used in diarrhœa, etc., and as a gargle or wash for ulcerated mouth and throat.

In the Secondary List occur—

Diospyros virginiana.—The unripe fruit of the persimmon is a pleasant astringent and tonic used in similar cases to those in which bael is used in India.

Heuchera americana.—Alum root.—A very powerful astringent, generally used as a topical application.

Lycopus virginicus.—Bugleweed is used as an astringent in hæmoptysis and in incipient phthisis.

Rhus glabrum.—Sumach.—The berries are used as a gargle in quinsy and sore throat, and as a lotion for ringworm, etc.

Spiræa tomentosa.—Hardhack leaves are used as an astringent tonic in the diarrhœa, accompanied with indigestion, frequent among children, for which this remedy is peculiarly fitted by its freedom from unpleasant taste.

(To be continued.)

THE STASSFURT POTASH INDUSTRY.*

Stassfurt, the seat of an industry which has revolutionized the manufacture of the salts of potash, is a small town containing a few thousand inhabitants, situated about twenty kilometres from Magdeburg, and on the frontier line which divides Prussia from the principality of Anhalt. The geological bed upon which it stands is the new red sandstone. Not until 1838 was it suspected that beneath this sandstone bed there existed a layer of rock salt. Borings however were then immediately ordered by the Prussian government, and in 1851, after many difficulties, the existence of a layer of salt at least 330 metres thick was ascertained ; shafts were sunk, and in 1857 the working of the mines was commenced.

To arrive at the saline bed it was necessary to penetrate to a depth of 200 metres through the red sandstone and less important layers of gypsum and marl. The saline bed may be divided into four portions. The lower portion, about 240 metres, forms the greater part of the bed and is composed of rock salt, intersected by thin veins of *karstenite.* Next comes the region of *polyhalite,* 64 metres thick, composed still of rock salt, traversed by veins two or three centimetres thick of a salt which has been named "polyhalite." This mineral is a compound of the sulphates of lime, magnesia and potash, and answers to the formula $2(CaSO_4)+MgSO_4+K_2SO_4+2H_2O$. The mean composition of this layer is 91·20 per cent. of chloride of sodium, 0·66 per cent. of karstenite, 6·63 per cent. of polyhalite, and 1·51 per cent. of hydrated chloride of magnesium. To this layer succeeds another of different composition and characterized by the presence of a salt to which the name of "kieserite" has been given. Kieserite consists of hydrated sulphates of magnesia ($Mg\,SO_4, H_2O$) in small microscopic crystals. It gives its name to the layer in which it is found, which is 56 metres thick and contains 65 per cent. of chloride of sodium, 17 of kieserite, 13 of carnallite, 3 of chloride of magnesium, and 2 of karstenite. Finally, the upper portion is formed of a group of salts known by the name of "waste" salts, because at first they were not utilized, and were only removed in order to get at the rock salt that lay beneath. These salts have principally magnesia or potash for their base. Although this layer was unemployed at first, and was only removed to enable the miners to get at the rock salt beneath, it contains the salts which at the present day form the basis of the industry at Stassfurt. Of these the principal is carnallite, a chloride of potassium and magnesium answering to the formula $KCl+MgCl_2+6H_2O$. It is ordinarily coloured red from the presence of oxide of iron in microscopic scales. The other of these salts are "sylvine" or "howelite" (chloride of sodium containing often small quantities of sulphate of potash and sulphate and chloride of magnesia), "tachydrite" (carnallite in which chloride of potassium is replaced by chloride of calcium), and finally, "boracite," a combination of borate of magnesia and chloride of magnesium.

As before mentioned Stassfurt stands upon the frontier line which separates Prussia from the duchy of Anhalt ; the Prussian explorers were consequently unable to extend their galleries towards the south-east, although the geological indications were most favourable on that side. Hence in 1855 the government of Anhalt also undertook the exploration of the salt beds in its territory. The enterprise was completely successful. The saline layer was reached at a depth of 145 metres, and it was soon

* Abstracted from a paper in the *Moniteur Scientifique* for June.

ascertained that it was in no way inferior in richness in potash salts to that previously explored on Prussian territory. Indeed the search quickly led to the important discovery of a considerable layer of another salt, which gave a new direction to the industry of the country. This salt was the "kainite," a compound of sulphate of magnesia and chloride of potassium. Its discovery enabled the manufacturers to extend their operations beyond the preparation of chloride of potassium to that of pure sulphate of potash, which has now become an important article of export to England and the United States.

The salts obtained from the mine find after purification numerous applications. The chloride of potassium is employed in the fabrication of saltpetre: the sulphate of potash finds an important market in the alum and glass manufactories. The Stassfurt manufacturers send into commerce sulphate of magnesia, chloride of magnesium, bromine (in quantities nearly equal to the European consumption), and boric acid. Finally, the impure salts left as residue in the different processes of purification, and consisting principally of salts of soda, potash and magnesia, are skilfully combined and offered to agriculturists as a mineral manure.

To give an idea of the importance of the potash production at Stassfurt it may be mentioned that it occupies ten large manufactories, and that in 1869 the Prussian mines alone yielded 109,075,000 kilograms of potash salts, and 56,332,000 kilograms of rock salt, representing a value of 916,960 francs.

In a memoir by M. Becker some interesting details of the manufacture are given, from which the following is taken. In the preparation of the chloride of potassium the "waste" salts are received at the manufactory either in powder or in small fragments. In the first case they are dissolved in large closed vessels; in the second the solution is effected in open cylindrical boilers. These boilers are furnished at a short distance from the bottom with a plate pierced with holes, and between this plate and the bottom is a steam pipe twisted in a spiral and pierced with holes in its upper part. The boilers are from 2 to 3·5 metres in diameter, and 1·5 to 2 metres high. When the solution is made it is drawn off either by a lateral robinet placed immediately below the double bottom, or by a kind of head of a watering-pot placed in the centre of the bottom.

For each part of the "waste" salts two-fifths, in round numbers, of water is used; this is agitated constantly and concentrated until the solution marks 34·5° Baumé. It is then allowed to stand two hours to allow of the deposition of argillaceous matters. As during this time the temperature is lowered a little, there is also deposited a little marine salt, which carries down with it more argillaceous particles, and thus assists to clarify the liquid.

When the solution is sufficiently clear it is passed into the crystallization pans; the residue is then treated once or twice with boiling water, after which there remains at the bottom of the vessel a mixture of kieserite, rock salt, clay, and a very small proportion of chloride of potassium.

The clear solution naturally presents a variable composition—especially in the relative proportions of the chlorides of sodium and potassium which it contains—according to the composition of the crude salt. The following analyses, made at different times, will give an idea of its composition and the variations it presents :—

	I.	II.	III.
Chloride of Potassium .	9·65	10·24	9·96
Chloride of Sodium . .	6·89	6·22	2·48
Chloride of Magnesium .	14·62	15·73	19·67
Sulphate of Magnesia .	4·11	3·74	4·26
Total	35·27	35·93	36·37

The first crystallization of this liquor is effected in cylindrical sheet-iron vessels, 2·30 metres in diameter and 1·80 metres in height, the bottoms of which are inclined and have at the lowest part a hole which is used for running off the various portions of mother liquor, and can be closed by a wooden peg. A siphon is also used in the decantation of the liquors. In such a vessel the solution is first left to cool to 58° C. The proportion of chloride of potassium deposited varies with the temperature. It is between 50° C. and 60° C. that this salt commences to deposit. Above that temperature chloride of sodium is deposited. The following table illustrates the crystallization of the different salts from a solution having the composition of analysis III. :—

Temperature.	K Cl.	Na Cl.	Mg Cl.	Mg SO_4.	Water.	Quantity of salt per cent. of solution employed.
108-100° C.	3·15	92·78	0·51	0·69	3·95	0·78
100- 90	1·35	94·84	0·78	0·69	2·24	0·61
90- 80	1·63	95·61	0·83	0·57	2·65	0·47
80- 70	0·86	96·64	0·58	0·43	2·25	0·50
70- 60	3·70	92·70	0·76	0·63	2·68	0·40
60- 50	25·16	70·56	0·12	0·72	3·04	0·57
50- 40	72·01	23·49	0·32	0·50	3·11	1·91
40- 30	75·75	19·07	0·87	0·42	3·76	1·16
30- 20	74·51	21·05	0·80	0·89	2·15	1·03
20- 10	25·77	8·62	1·42	29·46	34·62	2·25
10- 0	11·91	7·18	3·34	36·77	40·93	4·88

It is shown by this table that it is between 60° C. and 50° C. the chloride of potassium commences to crystallize in notable quantity, and that between 20° C. and 10° C. the deposit of common salt becomes again more abundant, at the same time a large proportion of sulphate of magnesia separates.

When instead of the crude salts being dissolved in water they are dissolved in the mother liquor of a former crystallization a solution is formed that varies from the former both in composition and in the crystallizations it yields at different temperatures. It has a density of 1·273 at 100° C., and gives upon analysis the following figures :—

Chloride of Potassium . . .	12·28	per cent.
Chloride of Sodium	4·97	,,
Chloride of Magnesium . . .	17·93	,,
Sulphate of Magnesia . . .	2·28	,,
Total	37·46	,,

The following table, compared with the former one, will indicate the variation in the crystallization :—

Temperature.	K Cl.	Water.	Quantity of salt per cent. of solution.
98-90° C.	6·61	16·67	1·12
90-80	3·45	4·19	0·38
80-70	24·64	3·07	0·61
70-60	76·92	4·19	1·03
60-50	78·52	5·38	1·50
50-40	80·40	4·75	1·46
40-30	94·57	3·50	1·23
30-20	68·50	2·96	2·03
20-15	86·71	2·42	0·52
15-10	87·54	2·97	0·81

The mother liquor of this crystallization would contain 2·10 per cent. of chloride of potassium. It would appear therefore that it would be better to effect the solution with a mother liquor than with a fresh quantity of water. But when this is done so much carnallite remains in the residue as practically to nullify the advantage; in fact, only

two-fifths of the crude salts employed can then be dissolved.

In practice, the salts deposited in the crystallization vessels are richer in potash than might be supposed from the table. These salts, taken as anhydrous, contain from 15 to 22 per cent. of chloride of potassium. The proportion of water is, on the average, 30 per cent. This large proportion of water proceeds from the rapid cooling of the sides of the vessel, and especially of the surface. When the temperature approaches 60° C. the deposit of water on the sides becomes more manifest and at the same time the salts deposited are richer in potash. Below this temperature only isolated but voluminous crystals of chloride of sodium characterized besides by their whitish aspect are deposited upon the sides of the vessel. Indeed, the workmen are guided as to the time for transferring the solution to a fresh vessel less by the thermometer than by the appearance of the salts deposited upon the sides. This fractional crystallization has the advantage of yielding a purer crystal, since nearly all the earthy matters are carried down by the first crystallization of common salt. After the solution has been transferred to the second crystallization vessel it is allowed to cool to 15° C., though in summer it is frequently necessary to decant it at a temperature above that point. As it is more important to cool rapidly than to obtain large crystals the buildings where the crystallizations are effected require to be very airy; the exterior walls to the height of two metres have a great number of openings which in winter time can be closed with wooden shutters. This method of operating is gradually extending in the manufactories, but in some, when the deposit of the richer salts commences, the workmen throw into the crystallization vessels a quantity of fagots upon which the crystals are deposited. These are afterwards collected, together with those formed on the sides and the upper part of the layer formed at the bottom. The residue is either used for manure or submitted to a refining precess.

The composition of the mother liquid of this first crystallization is represented in the following two analyses :—

	a.	*b.*
Chloride of Potassium	4·89	5·41
Chloride of Sodium	4·83	5·50
Chloride of Magnesium . . .	17·58	15·55
Sulphate of Magnesia	3·66	3·78

This liquor is concentrated in a large boiler over a lignite fire; during the evaporation some crystals are deposited, and when the boiler is emptied these are thrown into boxes with perforated bottoms and left to drain. In the crystallization which follows a product is obtained containing 6 to 14 per cent. of chloride of potassium which is utilized for manure. The mother liquor of the second crystallization is, in its turn, concentrated, and again allowed to crystallize. The mother liquor now contains only from 0·5 to 1·5 per cent. of chloride of potassium, and is not again concentrated.

To return to the crystals produced in the first crystallization. These cannot be sent into commerce as they are deposited, since they contain too much chloride of sodium and too little chloride of potassium; the proportion most often required being 80 to 85, or even 95 to 97 per cent. of chloride of potassium. To remedy this inconvenience the product is digested in large wooden vessels with a small quantity of water, the process being based upon the greater solubility of common salt than of chloride of potassium. After a single digestion in water of the yield of the first crystallization, and calcining the product, it usually contains about 80 or 90 per cent. of chloride of potassium; the yield of the second crystallization, treated in a similar manner, contains about 50 or 60 per cent.

The foregoing details refer chiefly to the preparation of chloride of potassium, which is the principal product, but there are other secondary products. Thus, the residue from the first treatment by water is composed mainly of common salt and kieserite. The latter, after separation by levigation, is used in the preparation of sulphate of magnesia; the former is sold in powder, or in lumps for cattle. The salts deposited in the boilers during concentrations consist principally of a double sulphate of potash and magnesia: they are mixed with other salts deposited at different stages of the operations, calcined, ground, and sold for manure. This branch of the Stassfurt industry, originated in 1864, has become so prosperous that last spring the larger establishments were scarcely able to satisfy the demand. Lastly, the final mother liquor is used in the preparation of bromine. This operation is conducted in a large stoneware apparatus of peculiar construction, in which the mother liquors are heated, together with binoxide of manganese and sulphuric acid, by means of a steam pipe open at its extremity. The bromine which distils with the vapour of water is condensed in a leaden or earthenware worm, from whence it passes into a Woulf's bottle containing water, and then into two others containing an alkaline solution. It is afterwards distilled in large glass retorts, and then can be sent into commerce completely free from iodine. When the mother liquors are not used for the extraction of bromine they are concentrated to dryness over a fire, and the residue is gently melted and run into blocks that contain about 55 per cent. of magnesium. The greater part of this product is sent to England, where it is used in the cotton manufacture. In this manner the whole of the products of the Stassfurt mines are utilized.

THE LAVENDER-FIELDS OF HERTFORDSHIRE.

The following interesting sketch of the Lavender fields of Hertfordshire appeared in *Chambers's Journal* for August 16 :—

Comparatively few persons are aware to how large an extent the culture of lavender for commercial purposes is carried on within a radius of thirty miles from London. In the county of Surrey alone, there are nearly three hundred and fifty acres of land devoted to its growth; and the total extent of the lavender-fields in the London district cannot fall short of five hundred acres. Although it is only of recent years that the culture of the plant in England has been sufficiently extensive to raise it to the dignity of a recognized industry, the dried flowers have been used from time immemorial as a perfume; indeed, it acquired the name given to it by the Romans, *lavandula*, from the use to which it was applied in scenting the water of the bath.

The lavender plant grows wild in some part of Italy and the island of Sicily, but it is uncertain at what period it was introduced into England. Shakspeare, in the *Winter's Tale*, puts these words into the mouth of Perdita :

> "Here 's flowers for you;
> Hot lavender, mint, savory, marjoram;
> The marigold, that goes to bed with the sun,
> And with him rises weeping: these are flowers
> Of middle summer."

True, the scene is laid in Bohemia; but it is evident by the context that the plants named were such as were usually to be found in an English shepherd's garden as early as the time of Elizabeth.

Passing over the intervening three centuries, let us come at once to the subject of our sketch, the lavender-fields of Hertfordshire. An hour's journey by the Great Northern Railway, through a charming tract of country, past the historic houses of Hatfield and Knebworth, which lie hidden by trees on the traveller's right hand; over that grand engineering mistake, the Welwyn Viaduct, beneath which trickles the tiny river Mimram, through Stevenage, where Lucas the hermit, wrapped in his dirty blanket, still remains as when he served Charles Dickens as a model for his Tom Tiddler—passing all these, we at length find ourselves, as the train slackens its speed, at the bot-

tom of what seems to be an extensive chalk-pit. This is the northern outcrop of the London basin; and the station at which we alight as soon as the deep white cutting is passed, is Hitchin.

At this place, some fifty years ago the experiment was first made by a Mr. Perks of growing lavender as a source of profit. So well did it succeed, that there are now about thirty-five acres of land in Hitchin devoted to its culture, yielding sufficient essential oil to produce upwards of two thousand gallons of lavender-water annually. A visit to the fields and laboratory, during the latter part of July or the beginning of August, when the flowers are in full bloom, is in itself worth the trouble of a journey to Hitchin; to say nothing of the special attractions which the neighbourhood offers to the botanist, geologist and antiquary.

The largest field is situated at the western side of the quaint old town, near the house in which George Chapman, the friend of Shakspeare and Ben Jonson, completed his translation of Homer. The young plants are bedded out in November, at a uniform distance of one yard apart. Formerly, they were placed at only half that distance; but it is found that a heavier yield is produced from plants set a yard apart, than from double the number at only eighteen inches. When three years old, the plant is at its best; and when it reaches the age of seven years, it has made so much wood that it is more profitable to uproot it, and set a fresh plant. The harvest-time depends much on the state of the weather, but it usually commences about the first week in August. The flowers are cut with a sickle, bound up in small sheaves, and immediately carried to the distillery. There the stalks are cut off, leaving but little more than the flowers, by which the bouquet of the oil afterwards extracted is much improved, though the quantity of the oil is sensibly diminished. Much care is needed on the part of those who handle the sheaves in the distilling-house to guard against being stung by the bees which remain attached to the flowers. The temperance, industry, and providence of these insects are proverbial; yet their behaviour in lavender-fields, especially towards the end of the season, when the flowers are fully developed, cannot be too severely reprobated. So careless are they of the good reputation they have earned, that they refuse to leave their luscious feast even when it is laid on the trimming bench; and hundreds are thrown into the still, notwithstanding the efforts to dislodge them, n a state of helpless intoxication.

After the flowers are separated from the stalks, they are put in the still, which is a copper vessel holding about two hundred gallons, beneath which is a furnace. The flowers are pressed down tight, after which the still is filled with boiling water, and the head carefully fitted on and luted with clay or linseed meal, so as to prevent the escape of steam. The head somewhat resembles an enormous tobacco-pipe, the bowl being placed over the still. The stem of the pipe, called the worm, is coiled round and round in a vessel of cold water known as the worm-tube. As the steam is driven off through the head of the still, it is condensed in passing through the worm-tube, and runs into a vessel beneath. The essential oil is brought away with the condensed steam, and floats on the top. A siphon sucks out the water beneath; and as, in its passage through the worm, it has become impregnated with the oil, it is utilized by being made hot, and again put into the still, to boil the next batch. As the water in the worm-tube becomes heated by the steam-tube passing through it, cold water is injected from beneath, which forces off the upper portion of the water, which has become too hot to perform its task of condensation. In about four hours the still has given off all its steam, and the result is about a pint of essential oil, of a light yellow colour. In some seasons, it will fall far short of that quantity, while at other times it will greatly exceed it. When the condensed steam and oil have ceased to flow, the head of the still is hoisted off, the sodden mass of flowers is taken out with long forks, and the still is refilled. The refuse is taken back to the fields, and there allowed to remain, until it is used as manure for the next year's crop.

When the oil is first distilled, it has a peculiar empyreumatic odour; but by being kept in bottles for twelve months it loses much of its harshness. It is still, however, unfit to be used as a perfume in its natural state. In order to convert the essential oil into what is known as lavender-water, it is mixed with from twenty to forty times its bulk of spirit, and with just a trace of neroli, or other essential oil, according to the taste of the compounder.

Some idea of the enormous consumption of lavender-oil may be gained from the fact, that there is annually produced in England sufficient oil to produce nearly thirty thousand gallons of spirit of lavender. A large quantity is used in the production of other perfumes of more pretentious names. Soaps and toilet-washes are chiefly scented with French and Italian oil, which is worth but from eight to ten shillings a pound, while the English oil is valued at four times that price. The difference in the value is chiefly due to the fact, that in the foreign distilleries the whole of the stalks, and even the leaves, are put in the still, whereas in England, particularly at Hitchin, where even more care is taken than in the Surrey fields, nothing but the choicest blossoms is used.

THE COLLECTION OF GUM SENEGAL IN SENEGAMBIA.*

BY DR. BÉRANGER FÉRAUD.

Since the discovery of Senegambia, the gum of the country has been one of the principal objects of exchange between Europeans and the indigenous blacks, and the traffic has been so extensive and important that even the policy of the country has sometimes been subordinated to it. Senegal gum is yielded by several trees of the same genus (*Acacia arabica*, *A. Seyal*, *A. Verek*, *A. Adansonii*), and it cannot be pretended that all the species are yet known. These gum trees, which grow in the Sahara regions, are cultivated by the Moors and some black tribes, who carry the product to the various markets scattered along the banks of the Senegal. The trees also grow spontaneously in many parts of Senegambia, especially on the right bank of the Senegal; it is there that the forests of gum trees occur, if such a term can be applied to the very thinly sown agglomerations of these trees.

The forests of gum trees from which the products are sent into Senegambia are three in number:—(1) that of Alfatak, or Afatac, which is situated about fifteen leagues from the river, opposite Podor, and extends to Lake Cayar, occupying a large portion of the country of the Brakna; (2) that of Liebar, or El Ebiar ("the wells"), situated thirty or forty leagues from the river, in the country of the Darmancour Moors, and containing many small red gum trees (*A. nilotica*); (3) that of Sahel, in the territory of the Tararza Moors, the product of which is carried to Gahé. The latter forest consists exclusively of white gum trees, and it is the gum from these trees which is carried to Portendick to supply the demands of English traders.

The following details are given on the authority of M. Carrière. A gum forest is looked upon as a sacred place, where no stranger dares break off a branch or carry away the gum, under pain of celestial in addition to terrestrial punishments. Each of the members of a tribe which possesses a gum forest has the right to collect gum in it, and his share depends upon his activity, he having a right to that only which is collected by himself or by his slaves. The first collection of gum commences in

---

* *L'Union Pharmaceutique (Bulletin)*, i. 67, from a memoir on the natural products of Senegambia, published in the *Moniteur Officiel de Sénégal*, Sept. 3rd, 1872.

October, at which time those of the tribe who intend collecting the gum establish themselves in huts on the outskirts of the forest, and within reach of the wells. The collection of gum is very laborious, for the forest abounds in climbing and prickly plants, so that the trees are not gained without infinite trouble and numerous punctures and excoriations; but the appetite for gain overcomes all obstacles. The master is stimulated by the wants of his family and by pride, the slave is driven by hunger and the fear of beatings; thus all labour with sustained ardour, and little by little the gum is collected.

For the removal of the gum from the branches of the acacia whence it exudes, the Moors arm themselves with long sticks crooked at the end, by the aid of which they remove the tears of gum, which collect in balls of varying size. When the work to be done lies within so small a compass that in the middle of the day the collectors can return to the wells without too much loss of time, they carry only a small bag made of skin, into which the balls of gum are placed. But if the outskirts of the forest have been explored, and it be necessary that the collectors penetrate further into the interior, another bag containing a small provision of water is also taken. But the master never allows the slave to carry any food with him, stimulating him to greater exertions by the promise, too often broken, of a good feast on his return. Should the unfortunate captive not have gathered the prescribed quantity by the evening, and, exhausted by hunger and the burning heat, dare to eat any of the gum he has collected, he is mercilessly beaten. The first collection of gum finishes in December; a second is made in March. The latter is more abundant in proportion as the winds have been stronger and more prolonged during the year; that is to say, the branches previously distended by the humidity of the rains have become more thoroughly dried, and crack more deeply and in a greater number of places. The trading in the gum is effected in the months of January and March; the tribe abandoning the forest as soon as the collection is finished, and resorting to the market. In disposing of the gum the Moor shows a considerable amount of avarice, selling it in small portions at a time, and going from ship to ship on the chance of obtaining a better price.

In the time of Adanson, about 1760, the quantity of gum exported from Senegal was nearly 30,000 quintals, or 900,000 kilograms; in 1827, a very bad year for collection, the exportation amounted only to 613,500 kilograms. But since the Moors have taken more precautions for preserving the forests from fire the production of gum has greatly augmented, and in 1868, 2,763,618 kilograms were exported from Senegal. In fact, the amount of 3,000,000 kilograms has frequently been surpassed.

Probably it would be possible, with the aid of the blacks, to create plantations of gum trees in the vast extent of country which forms the centre of the Senegambian triangle. Such a result would have a direct effect on the amount of production, and would tend to prevent the sudden and unexpected rises in the price of gum which every now and then occur.

The vereck (*A. Verek*) produces a hard, black-veined wood, which could be used for ebony work; it is especially a gum-yielding tree and abounds in Senegambia.

AIR CONTAMINATION IN RELATION TO THE PUBLIC HEALTH.

The valuable contribution to chemical climatology which, in his book entitled 'Air and Rain,' Dr. R. Angus Smith last year presented to the public, was an unofficial account of the results of prolonged investigation respecting the state of the atmosphere in various parts of the British Isles. In the Ninth Annual Report, recently presented to Parliament by Dr. Smith, as Inspector under the Alkali Act, 1863, the subject is introduced into an official document. Being rather weary of the monotony of reporting only on the escape of muriatic acid from alkali works, he commenced inquiries into the amount of other gases, so as to give an idea of the extent to which the air of our towns is injured by manufactures. He has also included researches into the amount of organic and inorganic substances existing in the atmosphere in populous towns and in country places. The intention was to establish a method by which the condition of a place as to general health could be judged of definitely from the result of chemical experiment, without waiting for the evidence in the disease or death of human beings. Dr. Smith believes that, to a certain extent, that object has been reached. The health of a town has been in accordance with the chemical results obtained. No attempt has been made to find the nature of the disease which may affect any town, but the condition has been estimated by the number of deaths in the usual way.

This is entirely a new inquiry; at least it is new to have any steady success in the matter, and Dr. Smith says it is of great importance that such experiments should be continued, and so rendered available for regulating our opinions both of the health of individual places and the effect of individual causes. For example, if we wish to know whether a certain manufacture is injurious, it may be enough, and the experiments go to show that it is enough, to examine the air. If we wish to know whether a certain mode of drainage is sufficient, the experiments go to show the same, namely, that an analysis of the atmosphere near the spot will lead us to a true conclusion.

There is, however, a great deal to be done. The results, so far as towns are concerned, are decided enough, but results are required from places which have no manufactures, and which have very few human beings. The examination of such places would decide a very important point.

Dr. Smith has thus extended his work from the inspection of alkali works to the examination of air generally for sanitary purposes, so far as chemical means are concerned; and he holds that it is of great importance that a chemical branch for such inquiry should exist, as would be in accordance with the spirit in which the Alkali Act was conceived. The medical methods of examination not being all that are required, the chemical must supplement, as far as it is in its power, taking probably out of the hands of medical men some of the work, according as experiment becomes more and more definite.

Another branch towards which Dr. Smith has devoted himself in the reports given in has been the climatological; he has brought chemical agency into that department also, a little more decidedly than has before been attempted, making a foundation for future efforts. In this not much has been done, if we speak of places quite freed from the influence of human beings; but there has been a beginning made, and it will be of great importance to continue it. It is clear from the first inquiry, that wind which blows from inhabited places differs from that which blows from uninhabited places; and it is clear from the second part or the meteorological that wind which blows from certain directions differs from that blowing from others; that air too which comes slowly over the ocean is not the same in quality as that which comes with violence, and that air which comes up rivers and from lakes is not the same in quality as that which comes from the sea. The influence of the different directions of winds has also to be considered—whether they be from an eastern or other sea; and a great deal has yet to be done in the examination of air at different heights. The word meteorological is not yet applied to these inquiries, but they may be extended so as to have it applied to them. The word climatology has been used as referring to artificial as well as to natural climates.

The examination of the rain as a means of knowing the

air has also been made to give us much more information than hitherto by the analyses of numerous specimens from various parts of Great Britain.

Considering all these things, Dr. Smith comes to the conclusion that the examination of the physical phenomena of metcorology, as hitherto carried on, has too little to tell us regarding the influence of the atmosphere on health. The force and direction of the winds are observed, and they are expected to produce every time similar results. But these expectations have an imperfect foundation. The winds may come from the same quarter, and still be different in composition. The true quality of the wind must be sought partly in the chemical examinations. By its examination we may learn the true origin of many commotions in the atmosphere. It is, therefore, important to the medical man and to the meteorologist that chemistry should be added to the other sciences which have hitherto been made to contribute to meteorological observations.

The medical man tells of disease rising from certain noxious substances. The chemist is expected to define the class of these substances, to say whether putrefying bodies exist,—bodies containing nitrogen, and capable of forming very noxious compounds,—or whether sulphuretted hydrogen or other gases are the true sources of the evil complained of. As he cannot, however, say what is the character of the disease that is in the atmosphere, that must be left to some other of the sciences, which must come in to assist the observation of the medical man. Man himself is so complicated, and the agencies which affect him are so numerous, that no one science can contain him ; and medicine, to be perfect, would seem to demand universal knowledge. Every science must come to its aid,—that is, every science which treats of any agent which affects man.

The coincidence between an improved state of the atmosphere and the lowering of the death rate is remarkably illustrated in the appendix to the report by some statistics respecting the town of Chorley, and although Dr. Smith points out that the effect is probably an exaggerated one from a large quantity of rain during the time referred to having flushed the sewers and also from many sanitary improvements having been effected, the instance given is a very striking one. The whole of the figures cannot be quoted here, but some idea of the facts may be gathered from the following comparison between the air at Chorley in January to March, 1872 and September, 1872. Taking Blackpool as a standard for hydrochloric and sulphuric acids at 100, and Inellan as a standard for free ammonia and albumenoid ammonia at the same number, we get the following comparative results :—

Locality.	Hydrochloric Acid.	Sulphuric Acid.	Free Ammonia.	Albumenoid Ammonia.
Blackpool	100	100	—	—
Inellan.....	—	—	100	100
Chorley (Jan. to March, 1872).....	1391	609	517	237
Chorley (September, 1872)	200	38	37	101
London	320	361	117	116
Underground Railway ...	974	1554	138	271
A midden	—	—	644	302

Coincident with the great improvement in the Chorley air, the death rate, which had usually been 24, fell to 18, and the manufacturing town assumed almost the health condition of a country village.

In anticipation of the inquiry, Why does not Dr. Smith proceed with his investigations if he considers them so important ? he replies that the work has not become official, and individual work must be intermittent ; but he is decidedly of opinion that the introduction of more chemical investigation into the sanitary and meteorological departments is desirable.

As to the more immediate subject matter of the report, —the escape of hydrochloric acid from alkali works—it is satisfactory to learn from Dr. Smith, with respect to a complaint often made that the manufacturers wait to be found erring instead of finding out their own mistakes, that now the better class of manufacturers look after the matter by means of their own chemists.

The smaller works are generally not so liable to escapes, because they work more quietly. Still this is not an absolute rule, and there are large works which have small escapes from close furnaces caused by their peculiarity of management. The open furnaces are usually more regular.

There have been many opinions as to the distance that gases will travel. Dr. Smith thinks we may be sure that sulphuric acid does not remain any perceptible time as a gas when it comes into the open air. It seems to travel only a short distance ; but the wind varies, and so must the distance. Muriatic acid will go several miles ; and sulphurous acid of necessity goes further, but dilutes more rapidly than the former, and will therefore be less perceived. Chlorine, it is known from a remarkably complete observation, will go four miles, and be quite distinct to the smell, so as to enable one to speak with certainty. But to obtain this the ground or space must be smooth ; if it is roughened by trees or much vegetation the air passes through as water through a stream filled with water-plants, which very readily clear the muddiest. The trees obstruct the motion of the air and gases, and the absorbable portion is removed,—not without damage, of course, to vegetation.

Chemical works generally are greatly on the increase, and the power to repress escapes of gases does not increase with them. The Alkali Act, which was excellent for a time and has done some good, is becoming less valuable daily. When alkali works accumulate in one place they make even one per cent. of escape a great evil, and it is impossible practically for all injured persons to receive compensation. It is true, or it may be true, that compensation comes to the nation, but what is that to him who loses his paternal estate or good tenants. Something more is required. All the usual gases are escaping in increasing quantities, and the actual increase of muriatic acid from alkali works is considerable, although not the percentage.

The method of measuring by percentage is becoming insufficient, unless supplemented by other methods of detection. For example, excessive escapes may take place in an irregular way that cannot be measured, and the inspector can bring no action. He may be sure that a work has done much harm, but he can only remonstrate, unless he has measured the gas.

Dr. Smith suggests that some relief would be found in having the air examined when new manufactories are proposed, and if the atmosphere is already injured to a certain extent, to allow no more of the same manufactories at the place. This would give a maximum limit of bad air.

AROMATIC TINCTURE OF ASSAFŒTIDA.

BY L. MYERS CONNOR.

Tincture of assafœtida has such an unpleasant smell and nauseous taste that it is sometimes difficult to administer. Mr. L. M. Connor, of Dallas, Texas, publishes in the *American Journal of Pharmacy* a formula based on some experiments he has made, in which he claims that the difficulty is removed. He states that the preparation keeps well.

℞.	Tinct. Assafœtida	℥viij.
	,, Orange Peel.	℥ij.
	Ess. Peppermint	℥iij.

Mix. Dose one and a half to two fluid drachms without the addition of water.

The Pharmaceutical Journal.

SATURDAY, AUGUST 30, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE UNJUST CENSURE OF A DRUGGIST.

IN the few remarks we ventured to make in reference to the case at Ramsgate, reported at page 135 of this Journal, we endeavoured as far as possible to keep within the limits of the pharmacist's functions and duties ; in fact, to mind our own business without criticizing the doings or shortcomings of others. In pursuance of that aim we expressed an opinion that the jury were wrong in appending to their verdict that Mr. DAVIDSON died from natural causes a rider throwing the onus of his death on a Ramsgate druggist who refused to supply Mr. DAVIDSON'S porter with a draught containing eight times the recognized maximum dose of tincture of digitalis, and we stated reasons for this opinion.

In taking this course, which we believed to be due to the class we represent, as well as modest in its pretension, we were supported not only by the facts of the case, but also by the remarks of the CORONER, who in his summing-up directed the jury that their whole business was to determine the cause of death. In regard to that point, he expressed his opinion that they could have but little difficulty in arriving at a conclusion. At the same time, he told them that the question whether the chemist was bound to make up the prescription was a delicate one, and he further told them he thought it was a question they ought not to go into, since, in case of necessity, any culpable error committed by the druggist could afterwards be dealt with by the proper tribunals. To our apprehension, nothing could well be more fair and reasonable, and we still think the opinion expressed by the jury was not only uncalled for by the facts of the case, but also unwarranted by the *ex-parte* evidence of the medical men.

It must always be a trying and sometimes a dangerous position for a medical man to appear at an inquest to account for the death of a patient before a jury more likely to be influenced by prejudice than to be capable of appreciating fairly the merits of a case, and it was from a sense of this fact that we abstained from criticizing the conduct of the medical man who prescribed this unusual dose of digitalis, or the evidence he gave. We hoped that this task might be left to those journals which deal more especially with medical affairs, and that the case would there be treated of fairly and equitably. But though we have heard on the part of medical men frequent approval of the course taken by Mr. FISHER, it is with no little disappointment and surprise that we find an opposite proceeding adopted by a medical journal which aspires to be a leading representative of the profession. The *Lancet* instead of realizing our anticipations in this respect, and consistently confining itself to criticism of the medical aspect of the case, has chosen to ignore this legitimate exercise of its influence and, constituting itself a censor of pharmaceutical practice, to combine a palpably disingenuous representation of the facts with abusive censure of the druggist, who is stated to have acted very wrongly, is accused of "ignorance of medical science," scornfully reproached with having no ideas beyond the range of 'Squire,' and grandiloquently told that medical practice is not to be limited by the druggist's opinion of a prescription.

At the same time we are informed that the prescriber of the half-ounce of tincture of digitalis naturally threw the onus of the man's death on the druggist, since he justified his prescription before the CORONER, and that he was "ably supported" in doing so by the ordinary medical attendant of the patient. With regard to the former point we may remark that the justification of any prescription in the eyes of a non-medical coroner would not go for much. In the present instance the justification was—apart from the example of Mr. JONES, of Jersey—merely self-justification, and the effect it produced upon the CORONER'S mind may be estimated from the fact that in his summing-up he remarked that there certainly was a startling difference between the half-ounce dose prescribed by Mr. LEAKE and the dose indicated by the British Pharmacopœia as ranging from ten to thirty minims. So much for Mr. LEAKE'S "justification" as a matter of fact, it is not our province to discuss it as a matter of medical theory or practice. But how was the extremely qualified justification so "ably supported" by the other medical man? Why, by representing the utility of administering such doses of digitalis as mere matter of opinion, and by the statement "It is not a remedy I should rely upon myself." We are here addressing ourselves to the question whether, from the facts in evidence, there was any foundation either for the statement of Mr. LEAKE that the man's death was due to his not having the medicine, or for the jury's censure, based as it was solely upon that statement and we may say instigated by it. We venture to think there was, so far, no adequate foundation for either, and if we go to medical authorities for aid we find opinions differ. Mr. CRESSWELL'S evidence moreover was distinct that the deceased had been suffering from repeated attacks of *delirium tremens* and that his habits of life were such as would tend to shorten his days. Equally explicit was his evidence that half an ounce of tincture of digitalis was not an ordinary dose.

All these facts were ignored in the *Lancet* article, and if they were not studiously ignored, at any rate the omission to mention them admits of suspicion that the writer was so prejudiced against druggists as to be incapable of taking a fair view of the case, and was consequently incompetent to write upon such matters in a leading medical journal.

Let us turn now to another aspect of the case. It is admitted by the *Lancet* that the case was a very urgent one, that there was also a corresponding responsibility attaching to the prescription—*extremi morbi extrema remedia* is the explanation given for the large dose—and then the writer goes on to say that "*in the absence of the medicine the patient speedily died.*" We italicise these words, for they are important in various ways. Without attempting to offer the opinion on medical grounds, we do not hesitate to declare this statement to be a most unwarrantable assumption. But however this may be, the *animus* we have above referred to again becomes manifest here. Why should the absence of the medicine be ascribed solely to the druggist? Is the *Lancet* writer so dull that he could not perceive the possibility—not to say the propriety—of a medical man in such a case of urgency going himself to the druggist, in the first instance, with his own prescription, and making it clear to the dispenser that the unusual and exaggerated dose of medicine prescribed was intentionally designed to meet a pressing emergency? Can he be ignorant that this is constantly done by medical men in the interest of their patients and themselves? Here was precisely a case in which such a plan should have been adopted. Mr. LEAKE, as a new comer, probably may not have been very well known in Ramsgate; his mere initials on the prescription gave no guarantee that it was written by a medical man, considering the unusually excessive amount of the dose ordered and the possibility that ℥ss. might be regarded as having been written in mistake for ʒss. These were all circumstances which might have induced Mr. LEAKE to make sure that the medicine should be supplied which he held to be of vital importance; and we venture to think that a medical journal would have rendered greater service, not only to the profession but also to the public, if it had directed its comments to this aspect of the case rather than indulged in acrimonious censure of a class with which medical men have intimate relations.

Among the letters which have appeared in reference to this case, one of the most remarkable bears the signature of J. COLLIS BROWNE. Adopting the view that the life of the patient depended on immediate treatment, the writer seems unable to perceive any cause of death but the refusal of the druggist to supply the medicine. Apart from what we have already said on this point, we may remark, that Mr. FISHER was not the only druggist in Ramsgate, and that his refusal was no absolute bar to obtaining the medicine. Undoubtedly it is the duty of the druggist in case of doubt to communicate with prescribers, but we cannot regard impertinence on the part of messengers sent for medicine, as being conducive to the performance of that duty, nor are we aware that it is any part of the druggist's business to submit to such treatment.

The writer of this letter, however, considers the druggist is merely a machine to carry out the physician's orders, and that, being properly a person ignorant of the quality and requirements of medicine, he should not have any opinion as to the limits of dose. To those who hold such views, or incline to endorse them, we will suggest for consideration the probable result of carrying out this principle in the case of a prescription now before us, in which Liq. Strychniæ ʒvj. is ordered in an ℥viij. mixture, of which two large tablespoonsful were to be taken three times a day.

Fortunately for the public and for the medical profession at large, dispensing druggists are neither so ignorant nor in so degraded a position as the writer of this letter would have them; fortunately also, as we have reason to believe, his sentiments would find but feeble echo amongst medical men.

UNIVERSAL PHARMACOPŒIA.

WE have received a circular signed by Dr. DE CRISTOFORIS MALACHIA, Chief Physician in the Milan Hospital, and LUDOVIC ZAMBELETTI, pharmacist in Milan, in which those gentlemen announce their intention to present a proposal of a Universal Pharmacopœia before the medical congress which will assemble in the course of this year at Vienna.

THE MILLER MEMORIAL.

THE friends of the late Professor JAMES MILLER, who for many years occupied the Chair of Surgery in the University of Edinburgh, have raised by private subscription the sum of £1600, to be devoted to the perpetuation of his memory. Knowing the deep interest he took in medical missions it has been determined to devote the money to the purchase of a house in George Street, Edinburgh, and its conversion into a "Home" for students while being trained by the Edinburgh Medical Missionary as medical missionaries. A sum of £1000 is still required to complete the arrangements.

AWARDS AT THE VIENNA EXHIBITION.

IN the award of prizes in connection with the Vienna Exhibition recognition is made not only of positive excellence in the articles exhibited, but also of actual progress made in the various arts. We are informed that "medals of progress" have been awarded to Messrs. T. and H. SMITH for their display of chemicals, and also to Messrs. DOWS, CLARK, and Co., of London, for their Soda Water and Ice Cream Soda Water machinery, and for their aërated mineral waters.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

At the half-yearly meeting of the above Association, held at the rooms, Halford Street, on Tuesday, August 5th, Mr. W. Thirlby, President, in the chair, the following report was read, and unanimously adopted :—

"The Committee, in presenting their usual half-yearly account of the proceedings of this Society, submit to the members what has been carried on during the past session.

"The meetings of the classes marked out by the programme have been held with nearly unbroken regularity. The attendance, which has been as good or even better than in any previous session, is a sufficient proof that the interest in this part of the Society's operations does not diminish. The average number of members attending each class has been as follows :—Chemistry, 10·1 ; Botany, 11·3 ; Materia Medica, 11·8 ; and Dispensing 7·1.

"Papers of interest have also been read by different gentlemen, including one at the opening of the session, on 'The Classification of Plants,' by F. T. Mott, Esq., F.G.S. ; and later on, J. E. Weatherhead, Esq., favoured the members with a lecture on 'The Microscope.' The Committee take this opportunity of thanking those gentlemen for their kindness.

"The preliminary class was conducted during the first part of the session by W. Walker, Esq., and the committee desire to express their high appreciation of that gentleman's long-continued and honorary services.

"In addition to the evenings devoted to the classes, the rooms have been opened every night for the purposes of study and practical work, and a good number have availed themselves of the advantages offered by this arrangement. One evening a week has been set apart for members who are specially preparing for the Minor examination.

"The committee desire to express their thanks to the Council of the Pharmaceutical Society for their donation of £10 towards erecting a case for specimens, a well-made, and in every way suitable cabinet having been put up at a cost of £12. This is being filled with specimens and articles of materia medica presented by many wholesale houses.

"The library continues to be of great use, both for the purposes of home study and reference.

"In concluding the report of the ninth session of the Society, the committee cannot but view, with considerable pleasure, the progress which has been made during the period it has been in existence. It is a matter of congratulation that one of the leading trade journals was pleased to speak of it in terms of high approbation, terming it a 'Model Association,' and the committee hope that this will be a sufficient inducement to the honorary members to continue that support which they have always so liberally afforded."

The President announced that valuable presents of drugs, chemicals, etc., had been received from the following houses,—Messrs. Hodgkinson, Stead, and Treacher ; Davy, Yates, and Routledge ; Barron, Harvey and Co. ; Langtons, Scott, and Edden ; Dunn and Co. ; and Harker and Co., of London ; Messrs. Wyllys and Co., Coventry ; Messrs. Clarke and Co., Portsmouth ; Messrs. Matthews Bros., Bristol ; Messrs. Beatson and Co., Rotherham ; Messrs. Robinson and Co., Chesterfield ; and a cordial vote of thanks was accorded to these firms for their kindness and liberality.

It was also announced that several other donations had been promised, but had not yet been received.

A vote by ballot for the election of a new committee was then taken, and the officers were chosen as follows : Mr. T. Wright, P.C., President ; Mr. S. H. Cadoux, A.P.S., Vice-President ; Mr. E. H. Butler, A.P.S., Treasurer ; Mr. C. B. Lomas, A.P.S., Hon. Secretary ; Mr. E. J. Bishop, Mr. A. Shakespeare, Mr. A. Chamberlain.

STATEMENT OF ACCOUNTS FOR THE SESSION ENDING AUG. 4, 1873

RECEIPTS.

	£	s.	d
Feb. 4th. Cash in hand	10	2	8
Cheque from Pharmaceutical Society	10	0	0
Subscription from 19 assistants at 3s. each	2	17	0
Rent from Civil Service Dramatic Club	2	0	0
Subscription from 18 apprentices at 2s. each	1	16	0
Library pence last session	0	8	6
,, ,, present do.	0	7	9
Extra cash for prizes from E. J. Bishop	0	3	10
,, ,, ,, for J. M. Butler	0	3	3
,, ,, ,, for C. B. Lomas	0	2	4
Discount...	0	2	10
	£28	4	2

DISBURSEMENTS.

	£	s.	d.
Bill for Glass Case	12	2	0
Rent and Water Rate	5	14	0
Bills for Stationery	3	7	4
Poor Rates	1	2	0
Refreshments and Incidental Expenses	1	2	0½
Bills for Chairs	1	16	0
Gas Bills	0	10	5
Coal	0	5	0
Sundries	0	7	0
Cash	1	18	4½
	£28	4	2

A programme of lectures for the tenth session (from Aug. 14, 1873, to Feb. 3, 1874) has been issued.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The following prize scheme for the session 1873-74 has been issued in connection with the Assistants' Section of the Glasgow Chemists and Druggists' Association :—

The committee have much pleasure in announcing to the assistants and apprentices connected with the trade that a sum of money has been placed at their disposal to be offered as a prize or prizes among the assistants and apprentices who are members of the Chemists and Druggists' Association, on the following conditions, viz.—

First.—Competitors shall not be in business on their own account, shall be under twenty-five years of age, and members of the Glasgow Chemists and Druggists' Association.

Second.—The names of intending competitors, together with the subject of the paper, shall be given in to the secretary (Mr. J. Murdoch), *on or before the 1st of November next.*

Third.—The subjects of the papers shall be left open to competitors ; but they must have a bearing upon the practice of pharmacy.

Fourth.—Each competitor shall read his own paper at a stated meeting of the Assistants' Section in the course of the ensuing session.

Fifth.—At the close of the competition it shall be the duty of the secretary to call a special meeting of the members of the Assistants' Section, to judge of the merits of the various papers read, and whether there shall be one prize for what may be considered the best paper, or several prizes, distributed according to the merits of the respective papers considered entitled to a prize.

Sixth.—In giving their decision, the members shall vote by ballot. The ballot papers to be examined and counted by three scrutineers, to be appointed by the members at the special meeting. The result to be final. Competitors shall not be allowed to vote.

Seventh.—The members shall decide at their special meeting when and how the prize or prizes may be presented.

The committee earnestly trust that those members of the trade eligible will *at once* prepare to enter upon the competition. Those who are not yet members of the Chemists and Druggists' Association will have an opportunity of joining during the month of October, when it is

expected the general meetings will be resumed; or at present, by applying to the secretary.

The annual subscription for apprentices is one shilling; for assistants, two shillings and sixpence. All assistants and apprentices members of the association being entitled, by virtue of that membership, to all the privileges of the Assistants' Section without further fee.

Further information may be had from Mr. J. Murdoch (Secretary, Assistants' Section, Glasgow Chemists and Druggists' Association), 47, Eglinton Street, Glasgow.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture IV.

The Energy of Affinity, especially with reference to considerations for the Measurement and Utilization of it.

The energy of affinity assumes many protean forms, embracing facts in very opposite phases. At one time it seems to hold elemental matter in adamantine chains so firmly that no appliances, such as heat or light or electricity, can undo the bonds; at another time there seems to be a repellant power of affinity (contradictory though the expression may sound) so influencing, that though every facility for voluntary combination be presented, yet none of these inducements accomplish this combination. For example, the oxygen and nitrogen in the atmosphere, which for all general purposes may be said never to enter into combination whilst acting as atmosphere. Again, oil and water—neither shaking nor heating can cause mixture, let alone combination. This repellant power is utilized in vitality thus: The fluid which lubricates the eyeball would continually pass over the edges of the lids, and so run down the cheeks, were there not glands upon the edge of the lids that secrete a very little oil, and so by virtue of this "repellant affinity" the ordinary fluid is confined to its appointed channel. If this fluid be excessive, the oily boundary is overflown, and tears trickle down the cheeks.

The energy of affinity is manifested in mechanical action, and it is probably the source of the mechanical power utilized by men for manufacturing purposes. We find affinity operating under all circumstances in which the character of a resulting compound is different from that of the elementary bodies which constitute the compound. Affinity may be said to be kinetic when converted: and potential when in molecular relation. In other words, all the molecules of one body are somehow or other related by affinity to the molecules of another body, either directly or indirectly, when states of change are occurring. Under these circumstances, until the new molecular relations are called forth there is potential energy, as these are brought about we get kinetic energy.

The term "Affinity," as employed in this course of lectures, needs an explanation. As a term in science it is fairly derived from that sense in which it ought to be used in conversation or ordinary writing. The word, when properly applied, is in reference to those connections which a marriage may have established between the relatives of the wedded pair. Prior to that marriage there were no relationships; after it, relationships enter by *affinity*. The relatives of the husband are connected to him by consanguinity, so are the relatives of the wife to her, but after the marriage these two sets of relatives are connected each to the other by affinity. This distinction makes clear that affinities are regarded only as between different bodies. No affinity can exist between lead and lead, or between oxygen and oxygen. As in social life, the legal relationships resulting from affinity and consanguinity are very different, so in science life, the atoms which constitute the elementary parts of a simple body, and the molecules which constitute the elementary parts of a compound body, are tied together in bonds of different kinds.

Between atom and atom, or molecule and molecule of a like nature, there are no affinities. True, these are held together, but it is by what is sometimes called the force of cohesion. If atom or molecule of one nature is, thus unchanged, held to an atom or molecule of another nature, then the bond is one of adhesion. If, for example, two plates of smooth glass be slid one over the other and pressed together, they cohere. If gum be dropped on one and the other pressed upon it, they then adhere. Water adheres to many substances of very different constitution.

To cohesion we are indebted for the strength of solids. The cohesive force operates, but in marvellously different degrees, in ice, water, and steam. To adhesion we are indebted for those unions effected by cements, etc. With the intensity of these two subsidiary agents in the work of affinity this lecture is not concerned, although they perform no unimportant parts.

Between affinity, if used as a term in physics, and if used as a term in chemistry, there is this distinction:—Students in physics might classify cohesion and adhesion as branches of affinity. Students in chemistry would not admit the term (affinity) unless the composing elements after the influence of affinity have undergone such a change as to obliterate all traces of the originals. Hence the phrase "chemical" affinity, thus, by the prefix "chemical," excludes the physicist's views.

An experimental illustration may make clear the use of the term "affinity," by the respective students in physics and chemistry.

Here are two solutions, the one of gum dissolved in water, the other of camphor dissolved in spirits of wine. These two are respectively mixed, nevertheless there is in neither case any chemical affinity. If we add pure spirits of wine to the mixture of gum and water, we should destroy what the physicist might call the affinity, but which the chemist does not admit to be such. On the other hand, if we add water to the solution of camphor we destroy the mixture there; a separation takes place, and in one case the gum, and in the other the camphor, is precipitated. The term "affinity," applied to the unions thus separated, would not to a physicist seems improper; the chemist would not permit the use of this word. It is in the chemist's sense that the word is used in the phrase "energy of affinity." He distinguishes thus—the term "combination" is applied by him to the results of affinity, and to that which has just been described as a phenomenon in physics the chemist applies the term "mixture."

These preliminary distinctions prepare us for an explanation of what we are to understand by those affinities whose energies are to be considered. Used, in a chemical sense, affinity is that power which influences bodies dissimilar in composition, form, and character to combine. The consequence of this union is the formation of new compounds, which may or may not be dissimilar in colour, form, and even fashion, to any of the composing bodies, which may or may not be possessed of properties and characters that are even traceable in the originals. These compound bodies, thus, unlike their progenitors, also establish relationships of affinity, and we are soon surrounded with numerous compounds, so diverse that all traces of the originals are to ordinary apprehensions totally obliterated.

There is, however, amongst the bodies a kind of clanship or caste, similar to that amongst the people of India. Thus, simple or elementary bodies combine only with simple or elementary ones; compound bodies only with compound ones.

For example—Oxygen, which is a simple body, enters

* Cantor Lecture, delivered February 24, 1873; reprinted from the *Journal of the Society of Arts*.

into the alliance of affinity with the metals, which are also simple bodies.

Here is some pûre metal—lead—in a state of very minute subdivision. It is enclosed in an air-tight glass tube. This lump of lead is exactly the same material. The difference is that in the finely subdivided metal in the glass tube combination with oxygen will take place the moment it is exposed to the air, so that the atoms of lead which are soon to be shaken out are brought into contact with the oxygen—atom with atom.

Thus, on breaking off the end of the glass tube and shaking out the contents, you see the black particles as they fall glow with heat owing to their rapid combination with the oxygen of the atmosphere. Here is a case of affinity, consequent on a state of subdivision—a case of affinity proper. Mr. Wills, who most kindly this evening gives us the benefit of his chemical knowledge and experimental skill, will now show you how strong is the affinity of oxygen for the steel blade of a knife; when heated and placed in a stream of oxygen the ignited particles of steel in the blade rapidly burn away. The same thing happens if a stream of oxygen is directed on any of the simple metals when raised to a red heat. In a hollow on this tile are some iron nails; by directing a stream of ignited hydrogen in oxygen upon them, the affinity is so strong that they not only melt but boil, and the ebullition is so powerful that a brilliant shower of molten metal is scattered around. Similarly, a piece of zinc when exposed to oxygen is rapidly consumed.

But when we deal with acids which are compounds, they do not ally themselves by affinity with the simple metals, but only with the oxides of the metals which, like themselves, are compound bodies.

The range of the energies of affinities is very great. For example, oxygen and the metals. Oxygen can with difficulty be induced to unite with gold and platinum, hence these metals do not tarnish in the air; with sodium and potassium the affinities are so strong that the union is rapid enough to generate both light and heat. Either to facilitate or prevent such union, and so promote or retard the energy of affinity, has led to the adoption of various compounds, under the name of fluxes.

It may be well to explain that to this energy of affinity we may be said to owe the variety which the earth possesses. Reduce its compounds into their elements, and a sample of each of all of which the world is made might be arranged on this table. There are now only 63 reputed elements: from the affinity amongst these 63, whether taken by twos, or threes, or fours, or more, everything is made. Indeed, $\frac{99}{100}$ths of the earth is made of 13 elements; the mathematician's calculation is an easy one which could tell the number of articles that might be formed by combining these 13 by twos, then by threes, then by fours, and so on to 13. There would thus out of these elements be eight thousand one hundred and ninety-one different compounds. This number is very naturally increased from the operation of what may be called the law of combination in multiple and sub-multiple proportions. Allowing another 8191 for these multiples and sub-multiples, there would be in the world composed of these 13 elements 16,382 articles. Such a calculation as this is exceedingly simple, and the mathematician would say must be correct. Affinity, however, enters with a "veto." It claims the right to determine the nature of any combination or set of combinations, and in the exercise of this claim the character and constitution of the combining elements are so completely altered as to have lost all obvious trace of their original, and, therefore, when the combination by threes takes place the result does not partake of the character of any one of the components. This change of character is what the mathematician's calculation does not reckon upon, indeed such a calculation is based upon the physicist's interpretation of the word affinity, and it ignores the chemist's views.

The problem which is now before us is to define a mode of measuring the transformations in every shape introduced by affinity amongst these thirteen elements; a problem very simple, as thus stated, but wondrously complicated, in fact only capable of an approximate or inferential solution, which is, practically, no solution at all.

In a homely way this difficulty may be illustrated within the walls of many a house. Assume the residents to be a father and mother and thirteen children. Who can tell the combinations consequent upon what may be called the mutual affinities existing amongst these thirteen children? Even from day to day the stability of that family cannot be ensured. The combinations of twos and threes, which yesterday gave promise of permanency, is to-day dissolved, and these molecular children form other alliances. This microcosm of a world is under the influence of new feelings, changed tastes; indeed, it passes, with more than electrical rapidity, from a summer-like happiness to a wintry gloom—from a peaceful calm to lurid flashes—sad forebodings of domestic storms!

Well, amongst the affinities of the thirteen terrestrial elements similar changes and relations are induced. Whilst we may be able to tell with unerring exactitude how any *two* can act, if left to settle themselves under the sole influence of their dual affinities, when three or four, or more, come together certain perplexity results.

To progress from simple to compound is a most satisfactory procedure. Adopting this plan, and dealing with only two of the thirteen elements—ignoring the others—placing the two in such a relation that their mutual affinities may be fully exercised, the law as regards these two, and (as we shall see afterwards) the energy consequent upon this law, may be made fairly evident, and utilized in manufacturing industries as well as calculated with mathematical precision.

Let two be taken—any two—say, the gases oxygen and hydrogen. Place what we may call equal quantities of each apart from all other elements. Cause them to combine. It would be soon observed—*i.e.*, if the experiment were repeated frequently—that this combination is not arbitrary, it is not at the experimenter's option. Although he may put different quantities of these gases in juxtaposition, yet by some means, and for some reasons unknown to us, they unite only in definite proportions. If more than 11 oz. of hydrogen be offered to 88 oz. of oxygen, the excess of hydrogen will be left uncombined, also the reverse.

As a case of estimation by measure, the nature of the affinities, their intensity and the inexplicable results produce a comparison which is very striking; *e. g.*, 24 parts, by measure, of common salt contain 25·8 parts of sodium, and 30 parts of liquid chlorine. Such condensation, that is the condensing into (say) 24 cubic inches of solid matter so much as nearly 56 cubic inches would require the exertion of a very great mechanical force. To appreciate this, it must be remembered that the salt, the sodium, and the chlorine are all under the same atmospheric pressure, and consequently were there not certain inter-relationships among their constituent elements, of which we know nothing, such change of volume could not be accomplished.

The exercise of affinity, although definite as regards the proportions of the bodies influenced by it, is not called into action without either previous certain surroundings or the creation of influencing surroundings, such, for instance, as the presence of moisture or heat, or light or electricity. If, for example, we take these two white powders which are here mixed together, and add a little water to them, their affinities begin to operate, and a violent effervescence takes place. Again, the states of solid, liquid, and gaseous vanish under the energies of affinity. Mr. Wills will mix two gases, and they immediately form a solid. Now we will put two liquids together, and we find that they become converted into solids. In another case you see that the contact of two bodies suffices to change their state. If a little iodine is put upon this plate, and then a little phosphorus is added, the affinities are manifested by ignition, and the solids pass into the gaseous state. Nor are

changes of state and temperature the only attendant phenomena of the energy of affinity. Electrical phenomena are often, if not always present, although not always observed.

It is not improbable that if the energy of affinity is ever measured and brought within our means of calculation, it may be done inferentially, through some of these collateral manifestations which have not yet been so carefully observed, employed, and tabulated, as their importance would seem to justify. What it is that influences these affinities is as far beyond our present knowledge as to tell what it is that influences many of the affinities of social life amongst the thirteen children. The chemist not only endeavours to establish new relationships, but also to disentangle the relationships which affinities have already established. He fails to-day, he succeeds to-morrow. With bodies thus by energy of affinity compounded and interlaced—

——"In mazes intricate,
Eccentric, intervolved, yet regular
Then most, when most irregular they seem"

—we all are concerned. Although we know not their laws, we do know that they partake of the Medo-Persian character—they change not—and therefore, if once discovered, they are to be relied upon under all circumstances.

This Medo-Persian character of the laws which govern the energies of the affinities introduces into any culculation of them, when and where they are known, a precision and means of repetition which give thus far to physical chemistry the character of an exact science. With a precision equal to that of the laws of gravity, it is found that in respect to combining proportions there is a mathematical order, perfect and exact. True, articles may be mechanically mixed in any proportions; they can be chemically combined only in definite proportions, and it is only when thus combining, in the chemist's sense of the word, that the "principle of least action" is brought into operation in affinity, and its results as economically utilized by men as the results of the energies of gravity and vitality were described to be in the last two lectures.

In mixtures the particles are still separate, and in many cases may be distinguished under a microscope. Here is an instance. If this bottle is opened, the character of the whole contents is changed. The mixture of the atoms of the air with the nitrogen gas changed the appearance of the mass instantaneously. Again, you are all aware that coal gas burns in air, but we can also make the air itself appear to burn. In the presence of such experiments, it might become a question whether we burn gas in air, or whether we burn air in gas. Here is a cork through which are passed two small glass tubes. One of these tubes is connected with the gas of the room by this flexible india-rubber pipe, the other is open to the air. Now, light the gas issuing from the small tube. Here is a glass chimney, similar to those used with paraffin lamps. The cork has been fitted into the chimney. Place the chimney on the cork, the jet of gas burns as before. Let the supply of gas be increased, the consequence is that the chimney is soon filled with an atmosphere of coal gas; and observe, when a certain quantity of gas has entered, the flame quits the glass tube and now appears upon the air tube. Apparently air is now burning with a pale blue flame in an atmosphere of gas, whilst the gas issuing from the top of the chimney may also be ignited, and will burn in the air of the room. At the top, then, there is coal gas burning in air, and within, air is apparently burning in coal gas.

Again, for example, if gunpowder be taken and well washed, the nitre may be dissolved in hot water, and if the water be evaporated the nitre will be found as ordinary crystals; further, if heat be applied, the sulphur may be sublimed, and then pure charcoal will be left, or the sulphur may be dissolved out by bisulphide of carbon. Thus we can get the three elements of gunpowder, and find they are what they were at first. On another process of manufacture, if the nitre be fused in a crucible, and sulphur added, there results an entirely new substance—sulphate of potash; if to the heated mass charcoal be added, there is formed carbonic acid, and this, with the potash, forms carbonate of potash. No washing or warming will separate these latter combinations. They are for all purposes entirely new substances; they are no longer a mixture, as gunpowder is, in which the affinities may by a spark be called into play, but they are in a combination in which the affinities have already done their work, and that under the influence of continuous heat and without explosive violence, and, therefore, no further development of affinities, either with or without the energy of explosion, can take place.

The utilization of gunpowder, then, is the result of a process of mixing, such mixing being designed to facilitate the action of several affinities, by placing the elements of the composition in close approximation, ready at a signal from a controlling agent to operate. It seems reasonable to say that the closer these elements are to each other the greater will be the facility with which combinations may take place, and, therefore, the more readily can the affinities be utilized. Such *à priori* reasoning is not confirmed; no simple mixture of impalpable powder, however intimately the dusty particles may have been mingled, fulfils the condition required in gunpowder. It is possible, however, so to diffuse such impalpable powder in the air of a room as that each minute portion is surrounded with an atmosphere of oxygen. If when thus diffused explosion by detonation of any group of particles takes place, the entire mass may explode. In mills for the grinding of madder this accident has happened so frequently as to require special precautions. Herein is an example of many cases in which, whilst admitting our thorough knowledge of the premises on which our reasonings are based, we are found at fault when we apply the knowledge: consequent, apparently, upon ignorance of certain even unsuggested peculiarities in the affinities involved.

Some of you may remember that in July last there was a very serious accident in a flour mill at Glasgow. Property was destroyed to the value of £18,000 or £19,000, and nineteen lives were lost. But how it happened or why it happened no one knew. The fire insurance companies deputed two scientific gentlemen to investigate the matter thoroughly, and they came to the conclusion, rightly or wrongly, that flour diffused through the air in the mill had become so uniformly or minutely mingled with the oxygen of the air, that the atmospheric contents of the room or rooms were in a state of what may be called gaseous gunpowder. The effect of a spark from the millstones or the machinery caused explosion of the aërial gunpowder by that most violent of all means—detonation. Such a conclusion of such a probable danger being only now surmised, shows how little we know of the energy of affinity. In this mill appears to be an example of the production of explosion from hitherto unsuspected sources.

We have in this bottle a diffused substance, and it is diffused in a liquid which rapidly evaporates. A piece of paper is immersed in the liquid, and we will now allow the paper to dry. When that is nearly accomplished the combustion of the paper with flame occurs, owing to the non-vaporizable solid being so minutely subdivided that the oxygen of the air is in contact with many atoms of the same material, and so energetically unites with them as to produce flame.

To apply to the information already communicated to gunpowder, may perhaps make as clear the influences which a more detailed knowledge of affinities would give than any other instance. The action of gunpowder is simply this: in a condensed material are many gases, we will speak of these gases as one—*a gas*. The utilization of gunpowder might at first sight appear to depend upon having the largest amount of gas in the smallest solid space.

Now, without entering upon any chemical question, it may suffice to say that in this mixture of nitre, sulphur, and carbon are all the elements for (what we may name) the completion of the energies, though every other sub-

stance were excluded. We have here a jar of water, and if into that we put a mixture of gunpowder which has been ignited, you will find that water has no power to put an end to the combustion; it takes place as well under water as in air. From such reasoning and experiments as these, it might be anticipated that the cubic inch of gunpowder which on ignition produced the greatest number of cubic inches of gas would be the most valued. This, so apparently satisfactory conclusion, is very seriously in error. The amount of heat developed, and the rapidity with which the gas is formed, are important elements in guiding as to the mode of utilizing the affinities called forth amongst nitre, sulphur, and charcoal. If the affinities are so intense that the development of all the heat and gas consequent upon the exercise of the affinities through the entire heap is instantaneous, then explosion of a very violent and destructive character takes place. Such an explosion for mining, and doubtless other purposes, would entail serious loss—the rock, or the shell, would be so shivered as to be simple dust; our coals would have to be as artificial fuel, for the powder produced must, by tar, rosin, or other ingredient, be formed into lumps. To loosen and disintegrate, but not to destroy, are the general requirements for blasting or mining. If the rate at which the affinities in the mass are permitted to come into play can be regulated, and so either retarded or accelerated, then the modes of utilizing them may be planned. For example, if a ball is to be sent from a gun, that law should, if possible, be impressed upon the affinities which nature has impressed upon the energy of animal vitality. A horse accomplishes the dragging of a load by slow beginnings, a locomotive does the same, affinities must do the same. Hence the development of the greatest intensity of affinity in the case of a gun should be progressive until it attains a maximum, and the time occupied in so doing should be determined by the rate of travel of the ball and the strength and length of the gun.

Other cases, such as the blasting of rocks, demand a very different exercise of affinities. Here the object is simply to disturb, to unsettle, to break up; motion of the pieces to a distance is not required. Considerations such as these, simple as they may appear, are full of perplexity, consequent upon our ignorance of that in which these affinities consist.

Similar remarks apply to gun-cotton, dynamite, nitro-glycerine, litho-fracteur, or any of the explosives which modern science has formed.

It is from an attempt to impress upon the affinities a law of time in their exercise that the various forms and compositions of gunpowder owe their origin.

We are much obliged to Mr. Abel, who has kindly lent the Society of Arts different samples of gunpowder. There is one bottle containing powder, the grains of which are nearly half an inch cube; there are various other forms, the object of these various forms being to develop the affinities at a rate to be determined by the purpose for which the respective gunpowders are to be employed.

The pressure at the time of explosion has been estimated at more than 4000 atmospheres, *i.e.*, more than 4000 × 15lb., or 60,000lbs. per square inch. This statical pressure being converted into a kinetic or velocity estimate, is more than 216 tons lifted one foot.

There are other substances on which this same law determining the rate at which the affinities are to operate, may be impressed. Gun-cotton is one. We are again obliged to Mr. Abel for two illustrations on the wall showing the destruction of the martello tower at Dimchurch, in Sussex. It was accomplished with 186lbs. of compressed gun-cotton. And the development of the affinities was such that the tower changed at once into the form you see in the second diagram. Had gun-cotton in the same state of combination and in the same character been put into a cannon, in all probability the cannon would have burst before the ball had time to move.

Some very peculiar and inexplicable affinities are presented by this ally or rival of gunpowder, viz., gun-cotton. In the first place, the rate of combustion and the consequences of it may be previously regulated, and that with much accuracy. Its energy may be mild or great, at the will of the operator. The result of numerous experiments is that to obtain the full power of gun-cotton it must be exploded in a close chamber, in order that the gases and heat generated by the first part of the explosion may penetrate the mass. The records of experiments with gun-cotton show very plainly the absolute necessity for considering how affinities comport themselves. A bag of gunpowder nailed on the gates of a city would blow them open. A bag of gun-cotton so nailed would fail. Put the gun-cotton in a box and it will shatter the gate to atoms. A box of gun-cotton flung down close to pallisades would open a passage for troops.

Spectrum analysis reveals the fact that the spectrum from the flame of a compound body, as chloride of calcium, is not the same as that observed in the electric spark passing over pieces of chloride of calcium. The explanation suggested is that certain chemical compounds, when they are heated above a given temperature, are decomposed into their constituent elements below that temperature. These compounds are capable of existing in a permanent state. It may be thus with the energy of gun-cotton. When discharged at the temperature of flame, the gaseous constituent elements are not formed, and therefore no explosion. When at the higher temperature producing concussion, then the constituents are formed, and explosion ensues.

You will find that the rate at which gun-cotton explodes depends upon the rate at which the affinities are called into play. Here is a specimen. If we bring the affinities of this gun-cotton into play by means of a spark, and thereby do not produce sufficient heat to develop its affinities rapidly, the rate at which the gun-cotton is consumed is comparatively slow. If we bring its affinities into a flame, the rate at which affinities are developed in consequence of the heat is great. If we bring them into play by means of detonation the rate at which they are developed is greater still. You see that when a flame is applied to this strip of gun-cotton it runs along it rapidly, whereas when a spark is applied to a piece of the same material, the combustion is slow, like touch-paper. If I hold up the string of spark-ignited gun-cotton, the heat gathers, the ignition becomes more rapid, the spark being converted into a flame. Now, if instead of allowing the affinities to be exercised at that slow rate we cause them to develop immediately, we should have had a very different result. Here is some pulp gun-cotton, the very form in which it was used for the destruction of this tower. If we detonated some of that, we should none of us be here to tell the tale of how it went off. There is enough in my hand to send the walls of this room in all directions, but it must be by detonation. The effect of what is something like detonation can be shown in a different form. You are aware that in a coal-mine there are fearful explosions. It has been found that these explosions often take place after a blast in a distant part of the mine. The question therefore is, what has that blast to do with the explosion, the two not being near together? Mr. Galloway, of the Meteorological Office, has been investigating this matter for some time past, and it has been found that these Davy safety lamps, of which specimens are on the table, are not, when within the influence of a reverberation of the air from the effects of a blast in a distant part of the mine, always as safe as they are supposed to be.

The lamp consists of a flame within gauze; and when surrounded by an explosive compound, owing to the inability of the flame to penetrate the gauze, the explosive gas does not ignite. If, however, detonation takes place, even at a distance from the lamp, then we shall produce those conditions which are favourable to the development of chemical affinity. Here is a Davy safety lamp, lighted, and now placed in an atmosphere of explosive gas. The question is, what will happen in case a shot is fired in a distant part of the mine? In the case before you the lamp is

placed at one end of a long tube, the other end of which is closed by a piece of india-rubber, and in continuation of, but detached from, the long tube there is a short tube of the same diameter. There is no communication whatever between the two tubes, and as you may notice there is a space between the ends of them. My intention is to fire a pistol at the open end of the short tube; the explosion will cause the india-rubber to be compressed, and so to act on the air in the longer tube. You probably know that if there were on the table a box with an elastic back, and a candle at the other end of the room, opposite to a hole in the front of the box, then by striking the box at the back, the candle would be blown out. Now, on firing the pistol, having its end in this short tube, the india-rubber is compressed, and the gas surrounding the Davy lamp, which is supposed to be in a distant part of the mine, at once bursts into flame. This is the same phenomenon that takes place when shots are fired in one part of a mine, and an explosion occurs in another part.

This is all well and good if it would help towards a solution of the question of regulation of the energies of these affinities if only we could delay the affinities as we delay them in gunpowder, because we might then do what Galileo did when he delayed the ball down an inclined plane; or what Kater did when he caused the pendulum to repeat itself frequently, and so record the effects of gravity; or what Atwood did when he took a small weight and caused that to fall by gravity, but distributed its effect through a large mass. The consequence was that they were enabled to observe what the law of gravity is. If, now, we could rely upon such a process of delaying the affinities as has now been mentioned, we should then have a chance of ascertaining their energies; but we cannot rely upon it for two reasons. In the first place there are a number of phenomena classed under the head of nascent actions, which constantly interfere. Let me explain what that is. At the time that certain substances are being formed, certain affinities exist which do not exist afterwards. If, for example, you manufacture hydrogen and then bring nitrogen, from another process of manufacture, into contact, they do not combine. If, however, you manufacture them both in the same vessel, they combine and form ammonia, NH_3; and hence, in the case of putrefying vegetables, there arises that peculiar ammoniacal smell. Here is some permanganate of potash, which, when dropped into this tube of coloured liquid, will produce certain phenomena, which take place owing to this nascent action—the colour will be discharged.

(*To be continued.*)

Parliamentary and Law Proceedings.

The Dishonest Dipsomaniac in Trouble.

At the Marylebone Police Court, on Thursday, August 19, James Reed, 34, described as a gentleman, living at 23, Nutford Place, Marylebone, was charged with stealing a shirt, pair of sheets, and a coat and scarf. Some two months ago the prisoner was charged at the same court with obtaining chloroform under false pretences, from a chemist in the Edgware Road, and it was then stated that he was in the habit of frequenting chemists, taking chloroform, and not paying for it. It was also stated that he had been a surgeon in the army, but on his return home from India had met with an accident and injured his right arm, and at times had fits. He had a pension of 9*s.* 6*d.* per day. The prisoner had been lodging at 23, Nutford Place for ten days, and a pair of sheets were missed last Saturday, and they were found on the previous morning at the shop of a pawnbroker, near the Edgware Road. The sheets were pawned by the prisoner last Saturday for 3*s.* 6*d.* Mr. D'Eyncourt said when the prisoner was previously before him he thought he was not in his right mind, and he would not have been discharged had not his friends given an undertaking to take care of him. The prisoner would be remanded for a week.—*Marylebone Mercury.*

Alleged Poisoning by Fungi.

On Wednesday, August 18th, Dr. Diplock concluded an inquiry at Acton Bottom respecting the death of Ruth Brooks, a domestic servant at the King's Arms Tavern. The deceased, it is said, was poisoned by eating some fungi given her for mushrooms by a gardener named George Hunt, who had a few days before threatened the inmates of the house. The evidence taken at the first hearing was to the effect that Hunt was in the habit of going to the King's Arms for his beer, and he frequently made the barmaid and the deceased presents of vegetables and flowers. On Wednesday previous he brought what he said were some mushrooms. He gave them to the barmaid over the counter, telling her at the time how to cook them. The deceased, who acted as cook, fried them as recommended, and ate some for her breakfast. She died in great pain the same evening. A *post-mortem* examination showed that she had taken an irritant vegetable poison, such as is found in various fungi. Other persons who ate of the supposed mushrooms became very ill, but recovered. Hunt, upon being cautioned, said he did not know that what he gave the girls was poisonous. Upon being questioned by a juryman he admitted that he had been refused admission to the house on Sunday morning, but he denied using threats. A lad named William Lowe deposed that about three weeks ago, on a Sunday morning, Hunt applied at the house for some beer but was refused. He then made use of bad language and said, "I'll remember you." The second witness was Mr. Thomas Slattery, a builder, who, one day prior to the eating of the fungi, went to the house where Hunt was employed. He noticed some "mushrooms" growing in the meadow, and asked Hunt whether they were good ones. He at once replied, "No they are not; they are poison." These were seen upon the spot where Hunt admitted he picked those he gave to the barmaid. The Coroner, in summing up, informed the jury that if they considered Hunt gave the fungi with a malicious motive—that was to say, for the purpose, not necessarily of causing death, but of causing pain or illness—then they must return a verdict of murder against him. The jury, after a brief consultation, returned a verdict of "Wilful murder" against Hunt, who was committed upon the coroner's warrant.—*Times.*

Wholesale Poisoning by Arsenate of Soda.

Two children have died at Blackburn from the effects of eating arsenate of soda. At the inquest it was proved that a quantity of ashes had been carted from the manufactory of Messrs. Jackson Bros., George Street West, and with these ashes there had been intermingled a quantity of arsenate of soda which in 1866 had been supplied to the Messrs. Jackson for manufacturing purposes. The deceased and twenty-eight other children had picked up the salt in question under the impression, from its crystallized appearance, that it was alum, and had sucked it. The deceased had died from its effects, and the others had also been suffering from the effects. The jury returned a verdict that the deceased had been accidently poisoned. Some of the other children were not expected to recover, but the majority are out of danger.

Prosecutions under the Adulteration Act.

The Sale of Tea and Mustard.—Conflicting Evidence.

At the Court House, Epsom, on Monday, August 18, Mr. Burnett, grocer, of Sutton, was summoned for having sold tea alleged to be adulterated. Evidence was given as to the purchase of a quarter of a pound of black tea, price 6*d.* The packet was not labelled and the buyer was not informed that it was an admixture. A certificate of Dr. Stevenson, the analyst, was produced stating that the tea was adulterated with iron filings and earthy mat-

ter to the extent of about 3 per cent. by weight, but that the adulteration would not be injurious to the health of a person drinking an infusion of the contents of the packet. For the defence it was urged that the tea was in the state in which it was imported, and that Mr. Burnett ought not to be made responsible for an adulteration, if any, that had been effected across the seas. Further it was contended that the tea was not adulterated. Witnesses were called to prove that a sample of the same tea had been forwarded to Professor Campbell for analysis, and Professor Campbell deposed that in that sample he had found no trace of filings or sand, and that it appeared to be precisely similar to the packet of tea produced in Court. The Bench then ordered that a joint analysis should be made by Dr. Stevenson and Professor Campbell and the further hearing of the case was adjourned for the purpose.

Another summons, also against Mr. Burnett, was for selling mustard alleged to be adulterated. The local inspector deposed to the purchase, at the defendant's shop, of two ounces of mustard which Dr. Stevenson's certificate now stated to be adulterated with wheaten flour and turmeric, but not injurious to the health of the consumer. Mr. C. L. Price said he had been with Messrs. Colman sixteen years. He had seen the mustard, the subject of the present inquiry ; it was known as a double superfine mustard. He said it was the custom to mix the flour of black seed and the flour of white together with a portion of wheaten flour, varying from 5 to 10 per cent., and a very small portion of matter was added to give it a uniform colour. The Government, in mixing their mustard, used black and white mustard, rice, flour, ginger, and chillies. Mustard as a condiment and food was always mixed ; it was supplied pure to hospitals ; it was not acceptable to the public when pure. Dr. T. Redwood deposed that he had analysed a portion of the mustard, and found it to contain 5 per cent. flour, and a very minute portion of turmeric ; the remainder was white and black mustard seed. He should not say it was adulterated. He thought flour improved the mustard as a condiment. For medicinal purposes mustard should be pure. When he received the portion he gave part of it to Mr. Campbell. During the twenty years he had been an analyst he had known mustard to be mixed with flour as a condiment. He believed its quality to be thus improved. He considered that flour with black and white mustard seed improved the flavour, and a little turmeric improved the colour. French mustard contained many more ingredients than English mustard. The quantities used in this mustard were beneficial. He thought it a legitimate mixture. Mr. Dugdale Campbell said he received a sample of mustard from Dr. Redwood. It contained about 7 per cent. of wheaten flour. The mustard was a very good sample indeed. The quantity used was beneficial to the flavour of the mustard. The magistrates said they considered the case proved against the defendant, and fined him 3*s.* and costs 27*s.* A case was then applied for, which was granted.

Two other similar cases were heard, in which penalties of 3*s.* fine and costs were inflicted.—*Grocer.*

At the Southwark Police Court, on Monday August 25, Charles Johnson, grocer, of Kent Street, appeared to a summons taken out against him by the Vestry of St. George the Martyr for selling adulterated mustard. The officer appointed by the Vestry stated that some mustard was purchased at the shop of defendant, which, on being examined by Dr. Muter, was found to contain flour and turmeric. The defendant said he was not aware that the mustard was adulterated. Mr. Partridge informed him that if he had bought the article as the best and genuine mustard, he would have right of action against the sellers, and there was little justice to the public if such cases were lightly passed over. The defendant had rendered himself liable to a penalty of £20. He would, however, have to pay a fine of £5 and 4*s.* 6*d.* costs. The defendant urged the magistrate to reduce the penalty, but Mr. Partridge declined to do so.

At the same Court, on the following day, James Henry Herbert, milkman, of King Street Borough, was summoned for selling milk which, upon analysation by Dr. Bianchi, had been found to be adulterated with three-tenths of water, and to be deficient in fat and cream. The defendant's brother appeared to the summons and pleaded guilty. Mr. Partridge imposed a penalty of £5 and 4*s.* 6*d.* costs. Benjamin Kirkham, milkman, of Great Charlotte Street, Blackfriars Road, appeared to answer a similar complaint. Dr. Bianchi stated he examined about a pint of what was termed milk, and found in it three parts water. Such stuff was injurious to health and particularly to children. Mr. Partridge fined defendant £5 and costs. Evan Jones, milkman, of Little Guildford Street, was also summoned for a like offence. In this case the milk was half water, and very deficient in cream and fat. Mr. Partridge fined the defendant £5 and costs, and stated his intention to deal severely with all such cases. He regarded the act as a most beneficient one for the public.—*Standard.*

Reviews.

NOTES OF A COURSE OF NINETEEN LECTURES ON NATURAL PHILOSOPHY, delivered at Guy's Hospital during the Session 1872-73. By G. F. RODWELL, F.R.A.S., F.C.S. (Churchill).

These lecture-notes are very well drawn up, and are likely to do good service, both to lecturers in the arrangement of their courses, and to students as memoranda and summaries of the facts and principles of the several branches of natural philosophy to which they refer. The definitions and theorems are plainly and concisely stated, and very clear explanations and illustrations are given of many important laws. It is needless to go into details, but we would especially direct attention to the excellent advice which Mr. Rodwell gives to the student regarding experimental proof. He says : "Let him never forget to prove a thing experimentally, remembering that a law, coupled with its practical experimental proof, is infinitely more valuable as an inducer of the proper attitude of scientific thought than fifty laws which are simply remembered without demonstration. Finally, let him strive to attain that *summum bonum* of the natural philosopher's life, the enunciation of some law of nature ; commenced by steady and laborious original experimental research ; continued by generalization and the application of suitable mental processes ; ended—*finis coronat opus*—by the development of the law."

In conclusion, it will perhaps be thought worth while to direct the author's attention to a few points which may admit of modification in future editions.

Pages 74-77.—The subject of "Light" is treated, as stated in the preface, somewhat more shortly than the other subjects ; nevertheless, we think room might have been found for a short exposition of the very important phenomenon of *total reflection ;* also of *spherical aberration*, lest the student should carry away the notion that parallel or divergent rays falling on a concave mirror, are all reflected to the same point, whatever may be the aperture of the mirror.

On page 86 it is said : "The amount of heat produced by the stoppage of a moving mass is *equal* to the mass of the moving body multiplied by the square of its velocity." Instead of "equal" we would suggest "proportional."

P. 87. "Heat having been defined as a motion of the small particles, or molecules, of matter, it is obvious that the addition of this motion to a congeries of molecules must cause them to occupy a greater space than before." We cannot see the obviousness of this conclusion. On the contrary it appears to us that a collection of particles might spin round their own axes, vibrate in straight lines, revolve round one another, and perform an endless variety of gyrations, without increasing the mean distances between their centres.

P. 114. "The neutral (magnetic) fluid of a steel bar may be decomposed *either* by powerful induction, *or* by stroking the bar in one direction with one pole of another magnet." Surely this latter method is itself inductive.

P. 115. "The magnetic meridian of a place will obviously not coincide with its geographical meridian." This is not only not obvious, but it is not even universally true : for the magnetic *does* coincide with the geographical meridian on certain points of the earth's surface, viz., all those which are situated on the *line of no declination*, which was the case with London in the year 1660, as stated on the following page.

These however are minor matters, and we end as we began, by cordially recommending Mr. Radwell's book to teachers and students.

THE AIR IN RELATION TO CLOTHING, DWELLING, AND SOIL. By Dr. MAX VON PETTENKOFER. London. 1873. Trübner and Co.

The translator of the above little book of ninety-four pages, Dr. A. Hess, has conferred a positive boon, not only upon medical men, but also upon architects and engineers. The work consists of a reprint of three lectures delivered before the Albert Society at Dresden by the author, who is Professor of Hygiene at the University of Munich. The Albert Society is a ladies' association, which chiefly aims at the preparation of capable female sick nurses and other beneficences.

Were all the many useful papers upon sanitary matters which appear in the *Revue des deux Mondes*, in *Dingler's Polytechnical Journal*, and other kindred foreign publications translated regularly and in full in papers like the *Medical Record*, the *Practitioner*, and the *Journal of Public Health*, etc., the benefit would be considerable ; but we are afraid that this is not likely to come to pass, and that we must be content with the eclectic cream of these publications. Happily an education in French and German is now almost universal, and yet, despite this, there are so many drawbacks in connection with technical nomenclature, so many idioms to master, and so on, that the best of us would perhaps prefer a reliable translation ready to hand. It would be also a decided saving of time, we would then not require to convert, for ourselves, Reaumur or Centigrade into Fahrenheit, or look up our foreign tables ; above all, we should see in pride of place our own familiar ℈ ℥ ℥ and ℔. One of the wisest things which the Commissioners of Patents could do for the technical education of the country would be to employ an extra staff of competent clerks, and, not content with giving us a translation of merely the *titles* of the articles in the foreign journals, accord us a complete interpretation of their pages, good, bad, or indifferent. They could compass this with very little extra trouble, whilst private enterprize might hesitate to cross the inky flood. The *Index to Foreign Scientific Periodicals* is, as every one knows, published every fortnight at the low sum of twopence, but how many of our readers would willingly pay twenty times the amount to have their favourite sections done in full into plain English, *Non cuivis homini contingit adire Corinthum*. By all means, therefore, let us have photographs of Corinth brought to our albums.

The first lecture treats of the relations of the air to the clothes we wear, and will be found to contain some very interesting matter. In it the subject of loss of heat is also deftly handled, loss of heat by radiation, such as follows when sitting near a cold wall, or close to a window ; loss of heat by evaporation, as when our bodies are subjected to draughts, or when one side of us faces the wind ; and loss of heat by conduction, as when our warm bodies serve but to heat the constantly impinging air. This last particular cause of loss is, of course, greater in the open air than in a room, just as the loss of heat by radiation and evaporation is greater in a room than in the open air. When persons blush they give off heat, because their cheeks are dilated with warm blood, and there is more heat to be radiated, conducted away and evaporated with the watery portion of the blood. When we fan ourselves in a hot atmosphere, the benefit which accrues in the sense of coolness, is brought about by the increase of the velocity of the air, and the consequent greater abstraction of heat by conduction. We wear clothes, too, to prevent the heat of our bodies from radiating towards the colder surroundings ; in fact, our clothes absorb this heat, and also warm the air which lies between them and the skin. In the coldest day of winter, provided we are suitably clad, we feel no sensation of cold, for the heat of our live bodies is given off to the air through the medium of the dead cloth. The nerveless feathers of birds, and the insensitive fur of animals serve the very same purpose. We lose heat therefore by all three of these natural laws, and often by a conjunction of them. When we are bathed in perspiration, for instance, there is an increased assignment of heat to the enveloping air by both conduction and evaporation.

The chapter upon the influence of the air upon our dwellings, and the dangers which attend dampness, is somewhat out of the stereotyped way, and will very amply repay perusal. So will the last chapter, which treats of the ground-air, or the relations of the air to the soil. We are inclined on the whole to consider this as the most original of the series. But it would be manifestly unfair, even if our space would allow us, to condense its matter, with the risk of spoiling it, and we therefore refer our readers to the book itself.

THE MINERAL SPRINGS OF THE UNITED STATES AND CANADA, WITH ANALYSES AND NOTES ON THE PROMINENT SPAS OF EUROPE. By GEO. E. WALTON, M.D., Lecturer on Materia Medica in the Miami Medical College, Cincinnati. New York : Appleton and Co., Broadway.

"For many years," writes Dr. Walton, "he has desired to know whether there are any medicinal virtues in mineral waters. Between the incredulity of the profession, and the credulity of the public he has thought there may be a medium of truth." Hence, this work as a result of the inquiry, and the conversion of the author from being a neutral to be an advocate of the sanative power of mineral waters.

The States and Canada are rich in mineral springs, and Dr. Walton has been to much labour in gathering the particulars of the characteristics of each, together with their chemical analyses. However, we are told that whatever the chemical analysis may show as the principal constituent, the properties of the water can only be judged by clinical experience. In the words of Trousseau, "Mineral waters are not simple medicaments ; whatever may be the predominant mineralizing agent as demonstrated by analysis, it acts not alone. Nature, in combining with the more or less notable elements which chemistry may isolate other exceedingly variable ingredients and principles which have not yet been discovered, has done for this mineralized agent that which we seek to imitate each day in our prescriptions when we endeavour to reinforce or diminish the effect of a medicinal substance by associating others with it."

"Mineral waters are only applicable to the treatment of chronic diseases," and the fact seems to the author to be incontestable that they prove more beneficial than the active ingredients given in the usual way ; but why, it is not understood.

It may be interesting for our readers to recapitulate a a few of the many virtues ascribed to them by the author :—

Alkaline waters :

(Those rich in sodic carbonate.) For uric acid gravel ; catarrh of the bladder ; chronic bronchitis ; diabetes mellitus ; they afford relief to the passing of gall stones ; and to dyspepsia accompanied with acidity.

ANALYSIS OF SOME BARKS OF CINCHONA OFFICINALIS AND ITS VARIETIES CULTIVATED AT OOTACAMUND.

BY DR. J. E. DE VRIJ.

In the beginning of this year I received from Mr. McIvor twenty-five samples of bark with the request to give him my opinion about their chemical composition. Notwithstanding the great sacrifice of time and labour, I eagerly undertook their investigation as I am firmly convinced that a great number of analyses will yet be required before we become acquainted with all the conditions required by every species of cinchona to produce the largest amount of quinine. Whilst I am still occupied with the analysis of the samples of bark belonging to other species of cinchona, I now publish the results obtained from the barks of *C. officinalis* which I have recently terminated. The numbers and descriptions assigned to them are the same as given to them by Mr. McIvor.

No. 1 is a specimen of *C. officinalis*, var. *angustifolia*, grown at Dodabetta elevation. Original bark (*lancifolia* No. 2 of Mr. Broughton's Reports) :—

19·25 grammes of dry bark yielded 1·95 grammes of mixed alkaloids = 10.13 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{6·1}{0·281}$; l=200 mm.; $a° = 18°$ ↖, was $[a]j = 195°·3$ ↖.

1·669 grammes of mixed alkaloids treated with ether yielded 1·536 grammes of alkaloids soluble in ether = 9·32 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{38·14}{1·536}$; $l = 100$ mm.; $a° = 8°$ ↖, was $[a]j = 198°·6$ ↖.

1·06 grammes of alkaloids soluble in ether yielded 1·624 grammes of herapathite = 0·917 gramme of quinine = 8·06 per cent.

19·25 grammes of bark yielded 0·178 gramme of quinovic acid = 0·92 per cent.

No 2 is ditto ditto (*lancifolia* No. 3 of Mr. Broughton's reports) :—

17·85 grammes of dry bark yielded 2·135 grammes of mixed alkaloids = 11·96 per cent. The molecular rotation, through an accident, has not been determined.

1·7558 grammes of mixed alkaloids treated with ether yielded 1·5192 grammes of alkaloids soluble in ether = 10·34 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13}{0·7096}$; $l = 100$ mm.; $a° = 12°$ ↖, was $[a]j = 219°·84$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{4·9}{0·12}$; $l = 200$ mm.; $a° = 6°·5$ ↖, was $[a]j = 132°·7$ ↖

0·805 gramme of alkaloids soluble in ether yielded 1·267 grammes of herapathite = 0·71 gramme of quinine = 9·1 per cent.

17·85 grammes of bark yielded 0·136 gramme of quinovic acid = 0·761 per cent.

No. 3 is a seedling of *C. officinalis*, grown at an elevation of 6200 feet; this is a very distinct variety, with a fine habit of growth :—

48·85 grammes of dry bark yielded 2·958 grammes of mixed alkaloids = 6·05 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·3}{0·489}$; $l = 100$ mm.; $a° = 5°·5$ ↖, was $[a]j = 150°$ ↖.

2·483 grammes of mixed alkaloids treated with ether yielded 1·565 grammes of alkaloids soluble in ether = 3·81 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·8}{1·565}$; $l = 100$ mm.; $a° = 15°$ ↖, was $[a]j = 132°·2$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{13·6}{0·786}$; $l = 100$ mm.; $a° = 7°·5$ ↖, was $[a]j = 130°$ ↖.

1·093 grammes of alkaloids soluble in ether yielded 1·161 grammes of herapathite = 0·656 gramme of quinine = 2·286 per cent, and 0·437 gramme of amorphous alkaloid = 1·524 per cent.

As this amorphous alkaloid proved to possess a lævogyre rotation, whilst the amorphous alkaloids which I examined before were dextrogyre, it follows that the amorphous alkaloidal matter obtained in analysing cinchona barks is not always identical, and that, therefore, more than one alkaloid must be comprehended under the general name of *amorphous alkaloid*.

The alkaloids insoluble in ether after having been transformed into neutral sulphates yielded with bitartrate of sodium 0·297 gramme of bitartrate of cinchonidine = 0·2 gramme of cinchonidine. From the mother liquor of this bitartrate I obtained by caustic soda a precipitate consisting of two alkaloids, of which the one was cinchonine, whilst the other was a new alkaloid very soluble in cold alcohol and lævogyre.

48·85 grammes of bark yielded 0·092 gramme of quinovic acid = 0·188.

No. 4 is a similar variety to No. 3, but with hairy leaves while No. 3 has smooth leaves.

46 grammes of dry bark yielded 4·91 grammes of mixed alkaloids = 10·67 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13}{0·539}$; $l = 100$ mm.; $a° = 6°$ ↖, was $[a]j = 144°·7$ ↖.

4·427 grammes of mixed alkaloids treated with ether yielded 1·995 grammes of alkaloids soluble in ether = 4·808 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{20}{1·995}$; $l = 100$ mm.; $a° = 17°·5$ ↖, was $[a]j = 175°·4$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{13·2}{0·562}$; $l = 100$ mm.; $a° = 5°·5$ ↖, was $[a]j = 129°$ ↖.

1·795 grammes of alkaloids soluble in ether yielded 2·45 grammes of herapathite = 1·384 grammes of quinine = 3·707 per cent.

The mother liquor of this herapathite did not yield any amorphous alkaloid; but instead of this 0·485 gramme of a crystallizable alkaloid, together with a dark brown resinous matter.

The alkaloids insoluble in ether, transformed into neutral sulphates, yielded by bitartrate of sodium 0·945 gramme of bitartrate of cinchonidine = 0·635 gramme of cinchonidine. From the mother liquor of this bitartrate I obtained by caustic soda a precipitate consisting chiefly of a new lævogyre alkaloid very soluble in cold alcohol and containing only traces of cinchonine.

46 grammes of bark yielded 0·115 gramme of quinovic acid = 0·25 per cent.

No. 5 is renewed bark of *C. officinalis*, eighteen months old and grown at an elevation of about 7800 feet.

41·2 grammes of dry bark yielded 1·91 grammes of mixed alkaloids = 4·63 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{7·2}{0·305}$; $l = 200$ mm.; $a° = 11°$ ↖, was $[a]j = 130°$ ↖.

1·616 grammes of mixed alkaloids treated with ether yielded 1·301 grammes of alkaloids soluble in ether = 3·727 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·6}{0·46}$; $l = 100$ mm.; $a° = 6°·55$, was $[a]j = 193°·6$ ↖.

0·841 gramme of alkaloids soluble in ether yielded 0·987 gramme of herapathite = 0·557 gramme of quinine = 2·47 per cent.

The mother liquor of the herapathite contained chiefly amorphous alkaloid with a trace of brown resinous matter.

41·2 grammes of bark yielded 0·4344 gramme of quinovic acid = 1·05 per cent.

No. 6 is the same renewed bark but only fifteen months old.

20 grammes of dry bark yielded 1·628 grammes of mixed alkaloids = 8·14 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{7·2}{0·305}$; $l = 200$ mm.; $a° = 9°$ ↖, was $[a] = 106°·2$ ↖.

1·289 grammes of mixed alkaloids, treated with ether, yielded 1·0566 grammes of alkaloids soluble in ether = 6·672 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·5}{0·5016}$; $l = 100$ mm.; $a° = 5°·5$ ↖, was $[a]j = 137°$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{12·6}{0·4726}$; $l = 100$ mm.; $a° = 0°$, was found to be $[a]j = 0°$.

1·522 grammes of alkaloids soluble in ether yielded 1·83 grammes of herapathite = 1·034 grammes of quinine = 4·53 per cent.

The alkaloids insoluble in ether yielded no reaction with bitartrate of sodium, but proved to consist of cinchonine and a lævogyre alkaloid, very soluble in cold alcohol.

The determination of the quinovic acid was lost by an accident.

No. 7 is renewed bark of *C. officinalis* twenty-eight months old; elevation 7800 feet.

38·7 grammes of dry bark yielded 3·875 grammes of mixed alkaloids = 10 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{20}{1·1054}$; $l = 100$ mm.; $a° = 5°$ ↖, was $[a]j = 90°·4$ ↖.

3·52 grammes of mixed alkaloids, treated with ether, yielded 1·903 grammes of alkaloids soluble in ether = 5·406 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{20}{0·853}$; $l = 300$ mm.; $a° = 19°$ ↖, was $[a]j = 148°·5$ ↖.

1·06 grammes of alkaloids soluble in ether yielded 1·012 grammes of herapathite = 0·572 gramme of quinine = 2·917 per cent.

The alkaloids insoluble in ether yielded no reaction with bitartrate of sodium on cinchonidine; but caustic soda precipitated from their solution a mixture of cinchonine, and the before mentioned lævogyre alkaloid.

38·7 grammes of bark yielded 0·624 gramme of quinovic acid = 1·612 per cent.

No. 10.—Dodabetta original *C. officinalis*. Branch bark.

58 grammes of dry bark yielded 1·807 grammes of mixed alkaloids = 3·115 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{20}{1·807}$; $l = 100$ mm.; $a° = 10°·5$ ↖, was $[a]j = 116°·2$ ↖.

1·609 grammes of mixed alkaloids treated with ether yielded 1·355 grammes of alkaloids soluble in ether = 2·617 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{20}{1·355}$; $l = 100$ mm.; $a° = 12°·5$ ↖, was $[a]j = 184°·5$ ↖.

1·287 grammes of alkaloids soluble in ether yielded 1·532 grammes of herapathite = 0·8656 gramme of quinine = 1·76 per cent.

58 grammes of bark yielded 0·232 gramme of quinovic acid = 0·4 per cent. of herapathite = 0·8656 gramme of quinine = 1·76 per cent.

Although this amount of quinine is not great, I consider it to be relatively very large, as this was branch bark, which consisted of thin quills not thicker than a goose-pen.

No. 11.—Ditto ditto, small branch bark, but the quills still thinner than the former bark.

40 grammes yielded 0·385 gramme of mixed alkaioids = 0·948 per cent. The molecular rotation calculated from the observation $\frac{V}{p} = \frac{12·5}{0·385}$; $l = 300$ mm.; $a° = 10$ ↖, was $[a]j = 108°·2$ ↖.

0·385 gramme of mixed alkaloids treated with ether yielded 0·302 gramme of alkaloids soluble in ether = 0·743 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{16·6}{0·302}$; $l = 300$ mm.; $a° = 10°·5$ ↖, was $[a]j = 192°·3$ ↖.

The amount of alkaloids at my disposal was too small to determine the quantity of quinine.

40 grammes of bark yielded 0·092 gramme of quinovic acid = 0·227 per cent.

No. 12.—Dodabetta original *C. officinalis*. Stem-bark mossed.

40 grammes of dry bark yielded 2·914 grammes of mixed alkaloids = 7·285 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{7·6}{0·319}$; $l = 200$ mm.; $a° = 13°$ ↖, was $[a]j = 154°·8$ ↖.

2·573 grammes of mixed alkaloids, treated with ether, yielded 2·162 grammes of alkaloids soluble in ether = 6·121 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{20}{2·162}$; $l = 100$ mm.; $a° = 20°·5$ ↖, was $[a]j = 189°·6$ ↖.

2·097 grammes of alkaloids soluble in ether yielded 2·9 grammes of herapathite = 1·638 grammes of quinine = 4·781 per cent.

40 grammes of bark yielded 0·329 gramme of quinovic acid = 0·822 per cent.

No. 13.—The same, but unmossed.

40 grammes of dry bark yielded 1·914 grammes of mixed alkaloids = 4·785 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·3}{0·799}$; $l = 100$ mm.; $a° = 10°$ ↖, was $[a]j = 166°·4$ ↖.

1·893 grammes of mixed alkaloids, treated with ether, yielded 1·645 grammes of alkaloids soluble in ether = 4·16 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·5}{0·479}$; $l = 300$ mm.; $a° = 20°$ ↖, was $[a]j = 187°·9$ ↖.

1·16 grammes of alkaloids soluble in ether yielded 1·28 grammes of herapathite = 0·723 gramme of quinine = 2·6 per cent.

40 grammes of bark yielded 0·157 gramme of quinovic acid = 0·4 per cent.

No. 14 is a large-leaved seedling of *C. officinalis*, elevation, 8200 feet; a fine strong growing variety, of which we have only a few plants.

38·6 grammes of dry bark yielded 1·1054 grammes of mixed alkaloids = 2·86 per cent.

1·1054 grammes of mixed alkaloids, treated with ether, yielded 0·728 gramme of alkaloids soluble in ether =

1·886 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·6}{0·728}$; $l = 100$ mm.; $a° = 3°$ ↗, was $[a]j = 56°$ ↗.

By adding an alcohol solution of iodine to a solution of these alkaloids in acidulated spirit, I did not obtain a trace of quinine-herapathite. The amorphous alkaloid which I obtained from this solution, after treating with sulphurous acid gas, etc., did not contain any trace of resinous matter, as almost always happens, more or less, but was almost colourless, and yielded, with oxalic acid, a neutral oxalate, which, placed above sulphuric acid, dried like a varnish, without yielding any trace of crystallization. My opinion that this amorphous alkaloid might be quinicine was thereby proved to be unfounded, as Mr. D. Howard has demonstrated that the oxalate of quinicine can be crystallized.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{6·8}{0·273}$; $l = 200$ mm.; $a° = 15°·5$ ↗, was $[a]j = 193°$ ↗.

Their neutral solution did not give any reaction, either with iodide of sodium or with bitartrate of sodium; it contained therefore neither quinidine nor cinchonidine. I conclude from the observed facts that the mixed alkaloids of this bark consist chiefly of cinchonine and amorphous alkaloid.

38·6 grammes of bark yielded 0·1332 gramme of quinovic acid = 0·345 per cent.

The results of my analysis of this bark lead me to the conclusion that it *cannot* be produced by a variety of *C. officinalis*. My esteemed friend Mr. J. E. Howard, to whom I communicated the results obtained from this bark, replied to me—"I am interested in your analysis of the strong growing variety, which from the results shows pretty distinctly that it is not a variety of *C. officinalis* at all, but not improbably one which I set down as *C. erythranta*."

No. 15.—Dodabetta *C. officinalis*, from an exposed place, 8400 feet of elevation :—

50 grammes of dry bark yielded 4·46 grammes of mixed alkaloids = 8·92 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·3}{0·52}$; $l = 100$ mm.; $a° = 0°$, was $[a]j = 0°$.

3·94 grammes of mixed alkaloids, treated with ether, yielded 1·669 grammes of alkaloids, soluble in ether = 3·78 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{20}{1·669}$; $l = 100$ mm.; $a° = 10°$ ↖, was $[a]j = 119°·8$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{12·8}{0·544}$; $l = 100$ mm.; $a° = 3°·5$ ↗, was $[a]j = 82°·3$ ↗.

1·44 grammes of alkaloids, soluble in ether, yielded 1·581 grammes of herapathite = 0·8932 gramme of quinine = 2·345 per cent. From the mother liquor of this herapathite I obtained 0·468 gramme of a dextrogyre amorphous alkaloid, and also a trace of orange-yellow resinous matter.

1·845 grammes of the alkaloids insoluble in ether, transformed into neutral sulphates, did not give any reaction with iodide of sodium, and proved therefore to contain no quinidine. After this negative reaction I obtained, by the addition of bitartrate of sodium, 0·519 gramme of bitartrate of cinchonidine = 0·409 gramme of cinchonidine. From the mother liquor of this bitartrate caustic soda precipitated cinchonine containing only a trace of the often mentioned lævogyre alkaloid, which was chiefly separated by washing the dry precipitate with a little cold alcohol.

The molecular rotation of the thus purified precipitate, calculated from the observation $\frac{V}{p} = \frac{13·6}{0·843}$; $l = 100$ mm.; $a° = 13°·5$ ↗, was $[a]j = 217°·9$ ↗, which, though not identical, approaches very much to that of pure cinchonine.

50 grammes of bark yielded 0·85 gramme of quinovic acid = 0·17 per cent.

No. 16 is the same, growing on a sheltered position.

50 grammes of dry bark yielded 4·212 grammes of mixed alkaloids = 8·424 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{15·1}{0·7}$; $l = 100$ mm.; $a° = 8°$ ↖, was $[a]j = 172°·5$ ↖.

3·448 grammes of the mixed alkaloids treated with ether yielded 2·684 grammes of alkaloids soluble in ether = 6·557 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{15·5}{1·133}$; $l = 100$ mm.; $a° = 14°$ ↖, was $[a]j = 193°·2$ ↖.

1·557 grammes of alkaloids soluble in ether yielded 2·242 grammes of herapathite = 1·267 grammes of quinine = 5·34 per cent.

From the mother liquor of this herapathite I obtained a mixture of an amorphous with a crystalline alkaloid, which were both lævogyre.

The molecular rotation of the last one, calculated from the observation $\frac{V}{p} = \frac{6·1}{0·255}$; $l = 200$ mm.; $a° = 3°$ ↖, was $[a]j = 35°·9$ ↖.

50 grammes of bark yielded 0·342 gramme of quinovic acid = 0·684 per cent.

No. 17. Neddiwattum *C. officinalis*, from an exposed position; elevation, 5800 feet :—

50 grammes of dry bark yielded 2·863 grammes of mixed alkaloids = 5·726 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·7}{0·594}$; $l = 100$ mm.; $a° = 4°·5$ ↖, was $[a]j = 103°·7$ ↖.

2·734 grammes of mixed alkaloids treated with ether yielded 1·525 grammes of alkaloids soluble in ether = 3·194 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{14·5}{0·609}$; $l = 100$ mm.; $a° = 7°·5$ ↖, was $[a]j = 178°·5$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{13·5}{0·928}$; $l = 100$ mm.; $a° = 3°$ ↖, was $[a]j = 43°·6$ ↖.

0·928 gramme of alkaloids soluble in ether yielded 0·725 gramme of herapathite = 0·4096 gramme of quinine = 1·41 per cent.

From the mother liquor of this herapathite I obtained 0·467 gramme of an amorphous alkaloid, which was almost colourless.

Its molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·7}{0·467}$; $l = 100$ mm.; $a° = 3°$ ↖, was $[a]j = 81°$ ↖.

The alkaloids insoluble in ether, transformed into neutral sulphates, proved to contain no cinchonidine, as they showed a negative reaction with bitartrate of sodium. They consisted chiefly of the before mentioned lævogyre alkaloid, very soluble in cold alcohol, and a little cinchonine.

50 grammes of bark yielded 0·31 gramme of quinovic acid = 0·62 per cent.

No. 18. Dodabetta *C. officinalis*. Manured :—

50 grammes of dry bark yielded 5·83 grammes of mixed

alkaloids = 11·66 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·3}{0·6}$; $l = 100$ mm.; $a° = 8°·5$ ↖, was $[a]j = 188°·4$ ↖.

3·589 grammes of mixed alkaloids treated with ether yielded 3·082 grammes of alkaloids soluble in ether = 10·01 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{13·5}{0·969}$; $l = 100$ mm.; $a = 15°$ ↖, was $[a]\ j = 208°·9$ ↖.

1·245 grammes of alkaloids soluble in ether yielded 1·53 grammes of herapathite = 0·8644 gramme of quinine = 6·95 per cent.

From the mother liquor of this herapathite I obtained 0·344 gramme of lævogyre amorphous alkaloid.

50 grammes of bark yielded 0·475 gramme of quinovic acid = 0·95 per cent.

No. 19. The same unmanured.

50 grammes of dry bark yielded 4·183 grammes of mixed alkaloids = 8·366 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{12·7}{0·503}$; $l = 100$; $a° = 7$ ↖, was $[a]j = 176°·7$ ↖.

3·59 grammes of mixed alkaloids treated with ether yielded 2·703 grammes of alkaloids soluble in ether = 6·3 per cent. The molecular rotation, calculated from the observation $\frac{V}{p} = \frac{14·3}{1·157}$; $l = 100$ mm.; $a° = 15°$ ↖, was $[a]j = 185°·4$ ↖.

The molecular rotation of the alkaloids insoluble in ether, calculated from the observation $\frac{V}{p} = \frac{13·3}{0·806}$; $l = 100$ mm.; $a° = 6°$ ↖, was $[a]j = 99°$ ↖.

0·887 of these alkaloids yielded 0·372 gramme of bitartrate of cinchonidine = 0·25 gramme of cinchonidine. From the mother liquor of this bitartrate I obtained by caustic soda a precipitate consisting of the oft-mentioned lævogyre alkaloid, very soluble in cold alcohol, in which I could not find with certainty any trace of cinchonine.

0·962 gramme of alkaloids soluble in ether yielded 1·013 grammes of herapathite = 0·572 gramme of quinine = 3·75 per cent.

From the mother liquor of this herapathite I obtained 0·338 gramme of almost colourless amorphous alkaloid, and a trace of orange-coloured resinous matter.

The molecular rotation of the amorphous alkaloid, calculated from the observation $\frac{V}{p} = \frac{10}{0·338}$; $l = 200$; $a° = 6°·5$, was $[a]j = 96°·1$ ↖.*

I conclude this series of investigations by putting the results into a tabular form, in which, however, I have omitted the results obtained from No. 14 as that bark is considered by me not to belong to *C. officinalis*.

* I wish it to be understood that I do not and never did consider the alkaloid designed by me under the name of *amorphous alkaloid* to be a definite pure substance. As I never had more than a fraction of a gramme of it at my disposal, every one acquainted with this kind of investigation will easily comprehend that it was impossible for me to do more than to state its presence and its quantity. In the present investigation I went a step further and determined in some cases its molecular rotation. But this also I consider only of a relative and not of an absolute value. So for instance I found dextrogyre, lævogyre and inactive amorphous alkaloids in the course of my investigations, and it is very possible that a bark may contain more than one of them, which mixtures will naturally possess different rotations and sometimes none at all.

Amount of mixed alkaloids and of quinine contained in sixteen specimens of bark, from C. officinalis, *and its varieties, grown under different conditions, by Mr. W. McIvor, at Ootacamund* :—

100 Parts of Bark, dried at 100° C., contain :

No.	Mixed alkaloids.	Molecular rotation lævogyre.	Alkaloids soluble in ether.	Molecular rotation lævogyre.	Pure quinine.	Crystallized sulphate of quinine.	Quinovic acid.

THE "PITURI": A NEW NARCOTIC.*

Dr. G. Bennett, writing in the *New South Wales Medical Gazette*, vol. iii. no. 8, May, 1873, some notes on Queensland, says that Mr. Hill gave him a preparation obtained from the leaves of a plant named by the aborigines of the interior "Pituri." It was obtained by Mr. James Gilmour, when in search of Dr. Leichhardt, from the natives, in the form of dried leaves, and was used by them as a stimulating narcotic, in a similar manner to the betel of the East, and forming a substitute for tobacco. It was erroneously labelled on the bottle containing the preparation "Pituri Oil," for, on examination, it was found to be spirituous, as if the leaves had fermented in the act of distillation. The botanical character of the plant could not be ascertained, from the leaves received being dried and in so pulverized a state that a perfect leaf could not be found. Mr. Hill stated that he had found that the effects of a teaspoonful of this liquid in a glass of water was to produce a burning sensation in the stomach, followed by a vomiting and giddiness.

The following is an abstract of a paper read before the Queensland Philosophical Society, March, 1872, on the Pituri, by Dr. Bancroft :—

"On February 9th of this year I obtained from Mr. Gilmour a quantity of dried leaves, and the particulars here narrated, of a plant used by the natives as a stimulating narcotic. These leaves, called "Pituri" were obtained in the neighbourhood of the waterhole Kulloo, eight miles beyond Eyre's Creek.

"The use of the pituri is confined to the men of a tribe called Mallutha, all the males of which tribe are circumcised.

"The pituri is carried in neatly made oval pointed bags, specimens of which Mr. Gilmour has brought.

"The old men, before any serious undertaking, chew these dried leaves, appearing to use about a tablespoonful. A few twigs are burnt, and the ashes mixed therewith. After a slight mastication, the bolus is placed behind the ear, to be again chewed from time to time, the whole of which is at last swallowed. The native after this is in a sufficiently courageous state of mind to fight or undertake any serious business.

* From the *London Medical Record*.

"One old man, with whom Mr. Gilmour and party fell in, refused to have anything to say or do until he had chewed the pituri; after which he rose and harangued in grand style, ordering the explorers to leave the place. The pituri caused a severe headache in persons who tried it. The dust given off in examining the leaves causes sneezing."

The above is the information supplied by Mr. Gilmour. Mr. Wills' diary from Cooper's Creek homeward (p. 283) has the following:—"May 7, 1861. In the evening various members of the tribe came down with lumps of nardoo and handfuls of fish, until we were positively unable to eat any more. They also gave us some stuff they call bedgery or pedgery; it has a highly intoxicating effect when chewed even in small quantities. It appears to be the dried stems and leaves of some shrub.

"The pituri consists of leaves broken into small particles, and mixed with acacia leaves, small dried berries containing reniform seeds, and unexpanded flower-buds of the shape of a minute caper."

After describing in detail some experiments he made with an infusion of the pituri, Dr. Bancroft thus enumerates its effects:—

"1. Period of preliminary excitement from apparent loss of inhibitory power of the cerebrum, attended with rapid respiration; in cats and dogs, with vomiting, and profuse secretion of saliva.

"2. Irregular muscular action followed by general convulsion.

"3. Paralysis of respiratory function of medulla.

"4. Death, or

"5. Sighing inspirations at long intervals.

"6. Rapid respiration and returning consciousness.

"7. Normal respiration and general torpidity, not unattended with danger to life."

The poison given by the mouth acts with less vigour; when it is injected into the intestines the results are more certain. The animal has a longer stage of excitement, the convulsive fit is not so severe, and recovery is more certain. Torpidity remains for some hours.

A quarter of a drop injected under the skin of a rat causes excitement; the animal starts with slight noises, may fall over a few times from very strong muscular irregularities, remains excitable for some time, then gradually becomes torpid.

In small medical doses we may expect to find the period of the excitement and the torpidity to be the only marked symptoms. In cats and dogs the excitement is not marked, but vomiting of a violent kind occurs.

Some leaves of a tree of the natural order *Lauraceæ*, and of the genus *Tetranthera*, used medicinally by the aborigines of New South Wales, were given to Dr. Bennett, which had been brought from the Bogan and Darling, where they are smoked by the aborigines for pains in the head and other ailments. It is called by them Yarran. The leaves have also been smoked by Europeans, and found beneficial in cases of asthma. The tree grows from twelve to fifteen feet high; the wood is hard, and used by the aborigines for clubs.

The editor of the *New South Wales Medical Gazette* adds that at the Cape of Good Hope there is a Composite plant, the *Parchonanthus camphoratus*, Linn., the leaves of which, when dried, are smoked by the Hottentots and bushmen instead of tobacco, exhibiting slight narcotic effects. In the form of infusion they promote perspiration, and are said to be useful in spasmodic asthma. The wild dagga (*Leonotus leonurus*, R. Brown), which bears very beautiful flowers and belongs to the order *Labiatæ*, is abundant at the Cape, and is also smoked by the Hottentots instead of tobacco, with similar narcotic symptoms to the preceding.

OIL OF CHAMOMILE.*

BY E. DEMARÇAY.

Having had occasion to prepare angelic acid by means of the essential oil of chamomile, the author collected a quantity of the liquid which Gerhardt considered to be a carbide of hydrogen, and to which he gave the name of camomillene. Having noticed that it presented characters differing from those attributed to it by Gerhardt, M. Demarçay made a closer investigation of the substance, the results of which he has recently communicated to the French Academy.

According to Gerhardt, the oil would be a mixture of a small quantity of resinous matter, of hydride of angelyl, and a carbide of hydrogen, boiling at 175°C., isomerous with oil of turpentine. He supposed that the hydride of angelyl would possess a boiling point approaching closely to 175° C., and that that circumstance, added to the presence of the resinous matter, would explain, on the one hand, the impossibility of separating the different principles of the oil, and on the other the gradual elevation of its boiling point. He based his conclusions on the disengagement of hydrogen when the oil was heated with potash and the production of angelic acid.

This conclusion M. Demarçay holds to be incorrect, the disengagement of hydrogen being a pure illusion. In fact, the oil can be decomposed without the least trace of gas being observed, while the same products of decomposition are obtained.

The oil yielded the following relative results at the boiling points of its different portions:—

At 150° C. ebullition commenced, but up to about 173° C. only a few drops passed over.

From 173° to 185° C. there passed over 32 per cent. of the oil.

From 185° to 200° C. there passed over 40 per cent. of the oil.

From 200° to 250° C. there passed over 17 per cent. of the oil.

The distillation was then stopped, the brown oily residue, which formed about one-tenth of the oil, appearing to decompose.

In re-distilling the fractional portions, a slight lowering of the boiling points was observed, and also points of stoppage between 177° and 184° C., about 194° C. and 200° C.; above 230° C. a very few drops passed, the retort then containing a small proportion of a thick liquid. Operating upon small quantities of the oil, the author was able to collect the peculiar products at the above temperatures, but found it difficult to isolate them in a state of purity.

The action of alcoholic potash and fused potash upon the oil produced identical results, provided the latter was shaken with the oil several times, or until it had no further action. This latter process, however, occasioned considerable loss of the volatile products, leading the author to prefer the former. To the oil dissolved in its volume of alcohol, its weight of potash was added in small fragments, and the whole was shaken together in a well-stoppered bottle until the potash was dissolved. After thirty-six hours the liquid had formed a mass, to which was added its volume of water. It was then distilled, first in a water bath and next over a flame, until nothing but water passed over, and the products of the two distillations were mixed. The residue was covered with a thin layer of liquid that solidified upon cooling.

The distilled portion, after the addition of carbonate of potash, separated into two layers, the upper of which, containing all the products of distillation, was dried over solid carbonate of potash, then over anhydrous baryta, and finally submitted to distillation. Ebullition commenced at 80° C. By fractional distillation a first liquid was obtained passing over at below 100° C., this was alco-

* *Comptes Rendus*, vol. lxxvii., p. 360.

hol; the remainder passed over between 105° and 160° C., and by repeated rectification was separated into two products, one boiling between 107° and 109° C., and the other between 129° and 132° C.

The first of these products gave an iodide boiling between 119° and 121° C. Examined comparatively with butylic iodide it presented exactly the same reactions. Analysis of the product showed that it possessed exactly the composition of butylic alcohol.

The second body formed an iodide boiling between 144° and 146° C. It proved by its reactions and by analysis to be amylic alcohol.

The oil when treated with fused potash gave exactly similar products, and the author was in this way able to ascertain the complete absence of ethylic and propylic alcohols.

A small quantity of distillate which passed over at above 135° C. had the odour of the residues of distillation of amylic alcohol, and presented the appearance of a mixture of alcohols, and a mixture of the iodides and acetates of those alcohols was obtained from it. These products had the odour of corresponding amylic compounds, but boiled at a higher temperature, the iodides rising to 170° C., which seemed to indicate the presence of a higher alcohol. In explanation of the difference of his results from those of Gerhardt, the author suggests that the presence of the alcohols escaped the notice of that chemist through the drying of his product over chloride of calcium, which combines with alcohols.

The mixture of potash salts remaining in solution after the distillation of the alcohols gave with sulphuric acid an oily layer equal in weight to nearly half the essential oil operated upon. This layer was composed of angelic and valerianic acids, very difficult to separate either by cooling or by distillation. The method that succeeded best was to etherify the mixture, and then to separate the two ethers. The valerianic acid which was present in smaller proportion than the angelic acid appeared to differ somewhat from the ordinary acid.

From the foregoing facts the author concludes that oil of chamomile is a mixture of several ethers among which the angelates and valerianates of butyl and amyl predominate. To control this hypothesis he prepared the angelates of butyl and amyl and also analysed portions of the essential oil. The angelate of butyl boils at 177° to 179° C.; its odour recalls that of the oil, but is not identical. The angelate of amyl boils at 198° to 200° C.; its odour much resembles that of the preceding compound. The analysis also confirmed the supposition, camomillene giving the figures of valerianate of butyl. Like the ethers also the oil combines with metallic chlorides.

Thus composition, boiling point, and manner of decomposition all agree in indicating that oil of chamomile should be looked upon as a mixture of ethers and not as an aldehyd.

PRELIMINARY NOTICE OF A NEW KIND OF PLASTER.*

BY L. E. SHAEL.

It is no uncommon practice among physicians to order an aqueous compound and an oily substance together in the form of a plaster. Commonly this case could be managed without producing serious complications, but when the mixture is to be applied upon another plaster, previously spread, then the skill of the dispenser is unduly taxed. Sometimes such directions could not be carried out by common means, and, therefore, it becomes optional with the compounder to change the character of the ingredients, or their proportion and quantity, as prescribed, or make additions which will afford the necessary consistency; or in the event of non-compliance with the indications, fail in the attempt, and without really good cause sacrifice his reputation.

When the prescription is impossible, according to its letter, a conscientious pharmacist will always reserve to himself the necessary license to construe and execute it according to the spirit, as prompted by the occasion, an action justified by common reason, and conceded by the interests of both professions, and hence an operator deficient in this amount of judgment and application is unqualified to serve at the dispensing counter.

The physician desiring a certain combination, writes for a number of ingredients, in the proportion desired; but being himself no pharmacist, and therefore utterly unskilled in the art, consequently expects that the operator, with the proper capacity, will elaborate the prescription, according to the art of pharmacy, and the spirit of the order.

This, however, does not imply uncalled for substitutions or mercenary interference with the quantities of expensive ingredients, neither does it confer the privilege of dispensing pills for powders, or liquid mixtures in the place of these, nor does it justify the dispensing of a greater quantity of medicine than the physician directs.

Utterly impossible combinations, or dangerous mixtures or doses, are, of course, from *primâ facie* evidence, referred to their author for correction or revision. A thoroughly competent pharmacist will never constitute himself the umpire in regard to the pathological merits of any case as appears from a prescription; a doubt in this regard does not find elucidation within the confines of the pharmacal art.

Now, however, if it is ordered to apply to the square inch of surface of a plaster of some particular kind, previously spread, an additional quantity of five to ten grains each of some solid extract and some fixed or volatile oil, then it requires the intervention of another agency which will harmonize these extremely heterogeneous elements. The solid extract must necessarily first be softened with a small proportion of water; it will even then adhere only with difficulty to the plaster, but much more so after the addition of the oily substance, which produces a mixture that in most cases instantly separates when in a state of rest, and possesses no adhesiveness whatever. More oil or more extract would avail nothing, neither would a more solid fatty ingredient be of much consequence, but the incorporation of a moderate quantity of powdered tragacanth affords the desired medium by which the mixture can be made to assume an adhesive, compact, and uniform character, and thus be easily applied upon the plaster, which by aid of its exposed margin will stick firmly and securely to the position in which it is placed on the skin.

Other plasters can be produced by the aid of powdered tragacanth, whereby large quantities of oil or extract can be employed, when spread upon sheets with an adhesive margin. In every case the extract is first liquefied with water and a small proportion of glycerin, the oily substance added, then thickened with powdered tragacanth, and finally spread upon any desirable base with an adhesive margin.

* From the *Pharmacist* for August, 1873.

NEW ZEALAND NATIVE DRUGS.

In an article upon the 'Useful Plants of New Zealand,' quoted in the *Gardeners' Chronicle*, from the *Auckland Almanac*, it is stated that many species of native plants furnish drugs which might be made serviceable articles of export. The "Supplejack" gives a good substitute for sarsaparilla; the gum of Phormium is invaluable for severe burns, scalds, and wounds; the gum of the Ponga (*Cyathea medullaris*) is a vermifuge; *Pelargonium clandestinum* (the Kopata) and *Geranium microphyllum*, both of which are common in the province, afford good substitutes for arnica; the inner bark of the Pohutukaua and Rata, and the root bark of the Bramble (*Rubus australis*), are of great value in diarrhœa and dysentery; but the want of space forbids mention of many interesting objects in this section.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 6, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BRADFORD MEETINGS.

AFTER fifteen years of wandering through Great Britain and Ireland, the British Association for the Advancement of Science will, in a few days, again visit the shire in which it first saw the light. When the Association held its inaugural meeting at York, in 1831, under the presidency of the late EARL FITZWILLIAM, few would have predicted for it such a development of vigorous scientific life. At each successive visit to the county,—again to York in 1844; to Hull in 1853; and to Leeds in 1858,—it has shown increased strength and vitality, fresh sections and subsections have indicated the widening of its grasp and the extension of its influence; and it will meet at Bradford with the prestige of a meeting last year at Brighton perhaps on the whole unparalleled in the history of science. The single source of regret is, that through the illness of the President-Designate, Dr. JAMES PRESCOTT JOULE, the Association will lose the inestimable services of a man whose work is appreciated far more widely than his name is known.

The British Pharmaceutical Conference, however, will now visit Yorkshire for the first time, and, under the presidency of its first treasurer, will gather within a few miles of the home of one of the gentlemen to whose early services, as general secretaries, the Conference owes so much of its prosperity. Bradford, *per se*, has perhaps little that would tempt the fagged pharmacist to spend a portion of his dearly-won holiday there. The seat of the worsted manufacture, with its "palatial warehouses," would fail to charm those who are weary of looking at similar sights, and who remember the last year's visit to London-surmer; but it stands within easy reach of much that is worth seeing in a county second to none in antiquarian, historic, botanic, geologic, or scenic interest.

But before proceeding further it is worthy of note that Yorkshire still carries off the palm for the number of its pharmaceutical organizations. Of the twenty-seven societies, more or less engaged in pharmaceutical education, reported on by the Provincial Education Committee of 1870, seven, or more than one-fourth, were situated in that county, namely, those at Bradford, Halifax, Hull, Leeds, Scarborough, Sheffield, and York. The societies at Scarborough and York have scarcely shown any further sign of their existence, but enough remain still to give to Yorkshire pharmacists the pre-eminence in this respect, although even here the provincial societies are in a somewhat drooping condition. At the last annual meeting of the Bradford Chemists' Association, the President regretted the slight evidence of progress, and that the only class formed—a botanical class—had been poorly attended. From a resolution passed, this Association appears to put a low estimate upon its innate educational powers, and favours the suggestion of teachers being employed by the Pharmaceutical Society to travel from town to town. It is to be hoped, however, that the Conference meeting will give a stimulus similar to that which it has hitherto given at every place of meeting, and leave the Bradford pharmacists with a better knowledge of each other, and a less desponding view of their qualifications. Ten miles off, at Leeds, the Association is in the eleventh year of its existence. The last report spoke of a decrease in the number of members; but the position taken by the Associates of this Society in the examination of the Science and Art Department has been very favourable. This seems to be worthy the notice of the Sheffield Pharmaceutical and Chemical Association, which expressed disapproval of Mr. SCHACHT'S scheme on the ground that the mere payment of £1 or £2 to students passing the local examinations would, in that locality, prove comparatively insignificant and totally inadequate. Here again the annual report speaks of indifference, shown by decrease in attendance at the meetings; but a redeeming feature is the establishment of a Pharmaceutical Students' Association, which it is pleasant to hear is in a prosperous condition. Seven miles from Bradford is Halifax, where the Chemists and Druggists' Association being recently in possession of a small financial surplus resolved to spend it in forming the nucleus of a library of reference. Stretching across the county eastward, Hull is reached with its Chemists' Association, whose late president, Mr. ATKINSON PICKERING, has more than once vigorously expressed his opinion upon the duty of the Council of the Pharmaceutical Society respecting provincial pharmaceutical education, and the manner in which it has been performed. Official *laches*, if any, have not prevented the Hull people from doing their duty; a system of education for pharmaceutical students has been provided by them, which is described as second to none in the kingdom, and, what is quite as much to the purpose, the students have availed themselves of it in numbers exceeding expectation. Should the Hull Association ever cease to run alone, may it still be able to make as satisfactory a report!

At present no intimation of the number or nature of the papers to be read at the Conference meeting has been given, though doubtless they will be well up to the mark, and will be heralded by an address from the PRESIDENT worthy of his established

reputation. In the absence of business, therefore, the thoughts may well be excused for foretasting the holiday which many have resolved shall follow this year's scientific meetings in the North.

Bolton Abbey is the spot to which the local committee of the Conference invite the members to accompany them on Friday, the 19th inst.; a place famous for natural beauty and traditional interest, the name of which, being linked with some of WORDSWORTH'S most beautiful poetry, will be remembered as long as the English language shall last. In his 'History of the Deanery of Craven,' Dr. WHITAKER thus paints it, in language which it would be a pity to curtail :—

"Bolton Priory stands upon a beautiful curvature of the Wharfe, on a level sufficiently elevated to protect it from inundation, and low enough for every purpose of picturesque effect. Opposite to the east window of the priory church the river washes the foot of a rock nearly perpendicular and of the richest purple, where several of the mineral beds which break out, instead of maintaining their usual inclination to the horizon, are twisted by some inconceivable process into undulating and spiral lines. To the south all is soft and delicious : the eye reposes upon a few rich pastures, a moderate reach of the river, sufficiently tranquil to form a mirror to the sun, and the bounding hills beyond, neither too near nor too lofty to exclude, even in winter, any portion of his rays. But, after all, the glories of Bolton are on the north. Whatever the most fastidious taste could require to constitute a perfect landscape is not only found here, but in its proper place. In front, and immediately under the eye, is a smooth expanse of park-like enclosure, spotted with native elm, ash, etc., of the finest growth : on the right a skirting oak wood, with jutting points of grey rock ; on the left a rising copse. Still forward, are seen the aged groves of Bolton Park, the growth of centuries ; and further, yet, the barren and rocky distances of Simon Seat and Bardon Fell, contrasted with the warmth, fertility, and luxuriant foliage of the valley below."

Is the visitor imaginative ? He may fancy he can hear still ringing through the air the puzzling question—

"What is good for a bootless bene ?"

which the LADY ALICE—bereaved mother !—answered by rearing the stately priory. He may wander up the river to the "Strid," where the "lordly Wharfe" is "pent in with rocks on either side," and see the tragedy enacted o'er again in which young ROMILLY lost his life :—

"He sprang in glee,—for what cared he
That the river was strong, and the rocks were steep ?
But the greyhound in the leash hung back,
And checked him in his leap.

"The boy is in the arms of Wharfe,
And strangled by a merciless force ;
For never more was young Romilly seen
Till he rose a lifeless corse."

Past the chantry door, looking through the "chink in the fractured floor," he may conjure up the CLAPHAMS and MAULEVERERS—

"Buried upright;
There, face by face, and hand by hand;"

or go out into the churchyard and see the white doe of Rylstone loitering there. To Bolton Priory, too, came the good HENRY CLIFFORD the "Shepherd-lord," who—to save his life from the Yorkists, after the bloody field of Towton, upon which his father fell—was put to lead the lowly life of a shepherd. When King HENRY VII. came to the throne the estates were restored, and although CLIFFORD was then thirty-one, and could neither read nor write, he worked with such good purpose as to win a reputation for learning in astronomy and alchemy.

"Choice of studious friends had he
Of Bolton's dear fraternity ;
Who, standing on this old church tower,
In many a calm propitious hour,
Perused, with him, the starry sky;
Or, in their cells, with him did pry
For other lore—through strong desire
Searching the earth with chemic fire."

But Bolton Abbey is not the only place in the county associated with letters that the world will not willingly let die. Haworth, the home of the BRONTE family, is not far from Bradford. EUGENE ARAM'S crime, the theme of BULWER'S tale and HOOD'S poem, was committed near Knaresborough, and he himself was tried and executed at York. And away in the north, near the borders of Durham, are Rokeby, and Bowes, where it is said the original Dotheboys Hall stood. Yorkshire is also the scene of many of ROBIN HOOD'S exploits. JAMES MONTGOMERY was educated at Fulneck and imprisoned in York Castle for libel. EBENEZER ELLIOTT was born at Masborough.

One more name may be mentioned, for the sake of its associations, though not so well-known as several that are omitted. It is that of a friend of DRYDEN, POPE, and ADDISON ; of a man who was glad to die at forty-one to get rid of the trouble of taking off his shoes—Sir SAMUEL GARTH, the author of the *Dispensary*. At the end of the seventeenth century there existed a very pretty quarrel between the College of Physicians and the apothecaries. The latter had ventured to prescribe as well as to compound medicines, and the physicians to outbid them in popularity advertised that they would give advice gratis to the poor and establish a dispensary of their own for the sale of cheap medicines. Sir SAMUEL rushed into the fight with his satire, in which, not satisfied with speaking for his friends the physicians, he constructed speeches for his opponents. This is the strain in which he made COLOCYNTHUS, an apothecary, talk :—

"Couldst thou propose that we, the friends of fates
Who fill churchyards, and who unpeople states,
Who baffle nature and dispose of lives, . . .
Should e'er submit to their despotic will,
Who out of consultation scarce can skill ?
The towering Alps shall sooner sink to vales,
And leeches in our glasses swell to whales. . .
Our properties must on our arms depend,
'Tis next to conquer bravely to defend."

Had Sir SAMUEL GARTH lived in the present day he might have ranked as first pharmakophobist on the *Lancet* staff. Dr. PRIESTLEY—of whom it was said that "no one ever entered on the study of chemistry with more disadvantages and yet few have occupied a more dignified station in it"—was a native

of Yorkshire ; so also were Professor PHILLIPS and Professor SEDGWICK, both past Presidents of the British Association.

The numerous mineral springs constitute another feature in the county, not without interest to the pharmacist. The principal of these are—Aldfield (slightly sulphureous) ; Askerne (weak saline aperient, and slightly sulphureous) ; Boston Spa (saline) ; Bridlington Quay (chalybeate) ; Croft (strongly sulphureous) ; Filey (saline aperient) ; Guisborough, the first place in England where alum works were erected (sulphureous) ; Harrogate (sulphureous and chalybeate)* ; Horley Green (aluminous and strongly chalybeate) ; Hovingham (stimulating and aperient) ; Knaresborough (carbonated alkaline) ; Malton (strong saline chalybeate) ; Scarborough (saline chalybeate). Near Ilkley are two hydropathic establishments, one at Ilkley Wells, the other at Ben Rhydding, where there is also a compressed air bath. Those who enjoy the luxuriously appointed baths of the present day may contrast them with HUMPHREY CLINKER'S experience of those at Harrogate in his time :—

"At night I was conducted into a dark hole on the ground floor, where the tub smoked and stunk like the pit of Acheron in one corner, and in another stood a dirty bed, provided with thick blankets, in which I was to sweat after coming out of the bath. My heart seemed to die within me when I entered this dismal bagnio, and found my brain assaulted by such insufferable effluvia. After having endured all but real suffocation for above a quarter of an hour in the tub, I was moved to bed and wrapped in blankets. There I lay a full hour, panting with intolerable heat."

As to the many other objects of interest in the county : the battle-fields—such as Stamford Brig, where HAROLD fought and conquered before marching for Hastings ; Wakefield, Towton, and others associated with the white and red roses ; Marston Moor, fatal to royalists—do they not form part of the national history ? The dales and vales, the moors and fells, the abbeys and castles, the churches and towers ; Scarborough, "the queen of English watering-places," with her sisters from Redcar on the north to Withernsea on the south, are they not described in the Guide Books ? This "gossip" has lasted long enough. *Vale !*

ALEPPO DRUGS.

ONE of the points of interest in the recent report of Mr. SKENE, her Majesty's Consul at Aleppo, is that the seeds of the Palma Christi (*Ricinus communis*) have for the first time been brought forward as an article of exportation from that province. The plant has been cultivated there for many years, and is always sown in alternate rows with sesame, prospering equally well. In 1872 the produce was of such excellent quality and so abundant that with a hope of extending its cultivation should the consignment be as successful as similar ones from Egypt, 230 sacks of seed, weighing nine tons, were exported to France, Italy, and Germany, at a cost of 55,000 piastres.

Six-sevenths of the scammony exported from Aleppo in 1872 was consigned to England and the remainder to France, the whole amounting to 737 cases, weighing 1456 cwt., and costing at the shipping port 210,000 piastres. This was a low price and resulted from the dishonest cupidity of the collectors, who have adulterated the product more than ever. The *Convolvulus Scammonia* grows plentifully upon the slopes of Mount Amanus ; the scammony collected is of good quality and if it were not adulterated would command a much higher price.

As an illustration of the important modification which a branch of commerce may undergo through the influence of scientific discovery, the fact may be instanced that gall nuts, an article of local produce, no longer occupy the place in British trade with North Syria that they did before other chemical appliances had displaced them in the arts of tanning and dyeing in England. Only a quarter of the yield of 1872 was sent to this country. The quantity gathered from the dwarf oaks on the mountains of the province during the year, although more than double that of 1871, did not amount to one-half the product of former years, when the demand was greater than now.

The opening of European apothecaries' shops, in the place of those of the Asiatic drug-selling grocers in the bazaars of Aleppo has created a trade which is becoming prosperous. A large quantity of drugs was imported in 1872 ; but it is impossible to determine what proportion of them was sold, or at what prices, because they form a branch of the gains of the medical profession, each practitioner having his own dispensary, while the *ad valorem* import duty, registered at the custom-house, is entirely fictitious, representing, perhaps, only a small fraction of the real value.

It is also interesting to note that the use of henna is on the decline, that appearing in the markets of North Syria being inferior in quantity and quality, and the import of 1872 not having found a ready or remunerative sale. The use of it is thoroughly an oriental custom, and although women are still seen with their hands and horses with their tails dyed with henna, its use is rapidly going out like other Eastern fashions, which are receding as those of Europe advance.

MR. W. W. STODDART, Pharmaceutical Chemist, of Bristol, has been appointed, under the Adulteration Act, Public Analyst to the City and County of Bristol, at a salary of £100 per annum, and £50 per annum for laboratory expenses.

WE regret to learn that Mrs. HANNAH GREAVES, who was in 1870 elected as an annuitant on the Benevolent Fund, died on the 30th August, aged 80 years.

---

* A very interesting series of specimens, showing the saline residues of one pint (20 oz.) of each of the Harrogate waters, prepared by Mr. Davis, Pharmaceutical Chemist, of Harrogate, is exhibited in the Museum of the Pharmaceutical Society.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

September 3rd, 1873.

MR. JOHN WILLIAMS, TREASURER, IN THE CHAIR.

Present—Messrs. Betty, Greenish, Hampson, Owen, Robbins, Savage, Stoddart, Sutton, and Urwick.

The minutes of the previous meeting were read and confirmed.

The New Bye-Laws.

The Chairman reported on what had taken place between Mr. Simon and the deputation recently appointed to wait upon him. It appeared to be the opinion of the Privy Council that as they could not accept the Bye-Laws in their present form, on account of the alteration in the Bye-Law referring to the election of a President or Vice-President of the Society to the Board of Examiners within six months of leaving office, the whole of the Bye-Laws should be formally reconsidered and approved. This, however, would be a troublesome process, and the deputation suggested that the Privy Council should accept the new Bye Laws, with the exception of the one they objected to, which would simply leave the law as it stood at present in that respect. This, he believed, would be agreed to.

Mr. Savage thought the Council should now pass a resolution accepting the suggestion of the Privy Council, and then ask for the confirmation of the Bye-Laws.

Mr. Betty did not see how the difficulty of submitting the amended Bye-Laws to three meetings of the Council, and to a special meeting of the members could be avoided.

The Chairman said it was very desirable to get the Bye-Laws confirmed as early as possible, in order that the Council might be empowered to elect two additional examiners.

Some discussion ensued as to the necessity for again going through the form of submitting the Bye-Laws, when amended, to three meetings of the Council and a special meeting. Mr. Urwick thought the new Bye-Laws, which were accepted by the Privy Council, might be confirmed and come into force, without being re-approved in consequence of the omission of one amendment.

Mr. Betty, on the other hand, was convinced this would not be sufficient; *admissio unius exclusio alterius* was a well-known maxim of law, and clearly applicable to the present case. He suggested that the Bye-Laws, as amended by the Privy Council, be at once read a first time, and approved by the Council, in order not to lose time, and that the opinion of the solicitor be obtained as to the necessity of going through the whole process.

After some further conversation this suggestion was accepted, and a resolution passed, in the following form, on the motion of Mr. Betty, seconded by Mr. Sutton.

> "That in lieu of the amended Bye-Law, sec. 10, clause 6, as passed by the last special meeting, the following be now read a first time:—'*No person shall be appointed an examiner who, at the time of appointment, is, or who, during one year prior to the time of appointment, has been a member of the Council, and the election of any examiner to be a member of the Council shall vacate his appointment as an Examiner.*'"

Certain Members and Associates were restored to their status in the Society on payment of the subscription for the current year, and a fine of one shilling.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Grimsdale, James .....Uxbridge.
Mumby, Charles John Everitt...Gosport.
Saunders, Thomas Bealby .....Darlington.

Chemist and Druggist.

Wilkinson, William .....Colne.

ASSOCIATES.

The following having passed their respective examinations, and being in business, were elected "Associates in Business" of the Society:—

Minor.

Fairburn, Robert Waller.....Guisborough.

Modified.

Epps, Franklin .....London.
Evans, Roderick .....Lampeter.
Hurst, James.....Oldham.
Tily, Charles Alfred..... .....London.
Welton, Henry .....Coventry.

The following having passed the Minor examination were elected "Associates" of the Society:—

Brown, William Braithwaite ...Preston.
Lord, John Edward .....Rawtenstall.
Smithies, William Edward .....Elland.
Turner, William Spencer.....Hingham.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination were elected "Apprentices or Students" of the Society:—

Bell, Frederick Leonard .....Southampton.
Clayton, Thomas .....Malton.
Dowdeswell, Jonathan.....Tiverton.
Fisher, Sidney .....Wolverhampton.
Griffith, John .....Penycaeran.
Grimshaw, Thomas .....Preston.
Heading, Herbert Henry.....Ely.
Hooper, David .....Southwark.
Hugill, John Howden .....Edmonton.
Procter, Robert.....Kidderminster.
Sharp, John .....Sunderland.
Wood, James.....Devonport.

Election of an Examiner.

The Council next proceeded to elect an Examiner to fill the place vacated by Mr. Haselden, the late President, in consequence of his election not being approved by the Privy Council. Two or three names were mentioned, but on a ballot being taken Mr. Octavius Corder, of Norwich, was declared unanimously elected.

Finance Committee.

The report and recommendations of this Committee were received and adopted and sundry accounts were ordered to be paid.

Benevolent Fund.

This Committee had met as usual, but made no recommendations with regard to grants, the cases brought before them being still under investigation.

Unusual Doses in Prescriptions.

The Chairman said all the members were doubtless aware of the circumstances which had recently taken place at Ramsgate with reference to the refusal of a chemist to dispense a prescription containing an unusual dose of digitalis. He did not know whether the Council would take any steps to correct the erroneous impression which seemed to be entertained by the coroner and jury. He had no doubt in his own mind that Mr. Fisher of Ramsgate was perfectly justified in declining to dispense the prescription.

Mr. Savage hoped the Council would not move in the matter, being convinced if they once began to interfere in local matters there would be no end to it.

Mr. Hampson said he had thought a good deal upon this matter, and it was his intention to bring it before the Pharmaceutical Conference, so that, if possible, they might agree upon some sign to be recommended for the adoption of medical men when excessive or unusual doses

were ordered. When this was done, as he had no doubt it would be, by a unanimous resolution of the Conference, it would probably be well if the Council also recommended its adoption. He did not think it wise to enter into personal matters, but the general question was of great importance.

Mr. Owen said there were hundreds, if not thousands, of chemists throughout the kingdom who never saw the Journal, or any periodical of the kind, and therefore it would be useless to take any action of this kind unless they were prepared to send out a circular to every one in the trade. Two years ago, when in the West of England, he was astonished to find a chemist, doing a large business in a large town, who was totally ignorant that there had been any agitation with regard to the Poison Regulations.

Mr. Stoddart mentioned a case which had recently happened in his own experience where a young lady desired to have a prescription made up containing a large dose of strychnine, to be taken every four hours. She stated that her father was a physician, and desired the prescription to be made up as written, but as she would give no further details, he declined to dispense it, and never heard anything more of it.

Mr. Greenish was glad to hear that this matter was to be brought forward at the Conference by Mr. Hampson, and thought that any action taken by the Council should come afterwards. He thought dispensing chemists had a right to call upon medical men, for their own protection, to attach some sign to unusual doses. It was not the province of the chemist and druggist to determine whether any given dose was proper in any particular case, but where it was an unusually large dose it was the bounden duty of the medical man to attach some sign to it. That sign he thought should be his own initials, and then the chemist would be justified in dispensing it.

Mr. Betty had no doubt the matter would be fully discussed at Bradford.

Mr. Greenish added that in the New Pharmacopœia for Germany there is a table containing 86 articles, and in the Austrian Pharmacopœia there is a similar table containing 60 articles, to each of which the maximum dose is attached, and any prescription containing a dose beyond the maximum in those tables cannot be dispensed without the prescriber's sign, thus (!) opposite to it, nor is the chemist permitted to dispense the same prescription a second time without an additional guarantee of a similar character.

Mr. Robbins agreed that this was a very important subject, and one which ought to be taken up by the Council if they could do so effectively. It appeared to him, however, that the best course of action would be for the Council to communicate with the College of Physicians, and ask them to recommend some regular course of action in the matter to their brethren.

Mr. Savage thought this suggestion a very valuable one.

Mr. Betty agreed with Mr. Robbins that a communication should be sent to the College of Physicians. Confined to pharmacists, their labours would be futile, but as the Pharmacopœia was issued by authority of the Medical Council, on which the College of Physicians was represented, and as this Pharmacopœia contained the doses in which chemists were examined, they might fairly call upon the College of Physicians for support and assistance in this matter.

Mr. Hampson said it was his intention, if the Conference came to any decision upon this subject, to bring it before the Council, and afterwards it would be very advisable to send copies of the resolution—if it should be carried—to the Medical Council and the medical colleges, and ask them to move in the matter themselves. Strictly speaking it was the duty of medical men to take the initiative, but he hoped the ventilation of the subject at the Conference and a resolution of the Council would produce the desired effect.

The Chairman said he was sure even the present discussion would be serviceable, particularly after the remarkable letter of Dr. Collis Browne, which they had no doubt seen, stating in effect that chemists ought to be mere automatons, having no right to think for themselves, or do anything but blindly follow the prescriptions which were brought them. Such a notion could not be too strongly repudiated.

Mr. Betty felt sure there was not a man at the table who would not have poisoned two or three persons in the course of his life if he had followed the principle laid down in this remarkable letter. He himself could recall two or three instances in which he should have killed the patient as dead as a nail if he had followed literally the prescription sent him.

House Committee.

The report of this Committee was read. It stated that a special meeting had been called in consequence of a letter from the contractors whose tender for the alterations had been accepted, saying that they had discovered an important error in their figures and begged to withdraw the tender. Application was then made to the next lowest on the list, but he also declined to abide by his original tender, and the Committee therefore, acting under the advice of the Surveyor, had obtained and accepted a tender from Mr. Stanley Bird, and had given him directions to proceed with the work, although the total cost would be £96 above the amount sanctioned by the Council at the previous meeting.

After some conversation as to the details of the business, the report was unanimously adopted.

The Registrar was instructed to erase from the register the name of Annie Aspinall, of Over Darwen, Lancashire.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture IV.

The Energy of Affinity, especially with reference to considerations for the Measurement and Utilization of it.

(*Continued from page* 176.)

Then there are another set of actions which are more peculiar still, which manifest great energy, but which actions interfere with our measuring the energy of affinity as utilized by men. We have here a piece of platinum, and here is an argand burner, connected by a flexible tube with the gas-pipes of the room. Over the argand burner is placed this copper cylinder on three legs, having a wire-gauze top. The sheet platinum is now coiled, and placed on its edge on the gauze. The tap is opened, and the gas now burns with a lambent blue flame. Observe, the platinum is now being heated; now it glows. Let the gas be turned off. The flame is now extinguished; the once glowing platinum has become black. Thus far is nothing peculiar. Again, the gas is turned on. The black platinum is passing to a dull red; now it glows again, but the gas is not ignited, and the platinum remains at this red-white heat without any apparent cause. If a glass cylinder, to protect it from currents of air, be placed round it, this apparent burning without being consumed will continue during the remainder of the lecture, and, were conjuring tricks an object, it might be said that light and heat were here produced without the destruction of any materials. This is a case of what is called catalytic action. Phenomena like these perplex very much in estimating the energy of affinities.

Here is another case, of a like peculiar character. This is a coil of platinum wire, and you will find that if made

---

* Cantor Lecture, delivered February 24, 1873; reprinted from the *Journal of the Society of Arts*.

red hot, and then placed in a vessel of ammonia, although there is no gas in it, the platinum continues red hot. There is no reason, apparently, why it should continue in that red-hot state.

Gunpowder has been introduced solely for the purpose of illustrating the questions that might arise in reference to the physicist's and the chemist's views of affinity, and not for any purpose in reference to its use in mining or war.

If its introduction has made clear that the affinities amongst the atoms of which it is composed may be controlled, that the intensity and rate of its explosion (which is but another name for chemical combination) may be regulated—that it and its related explosive agents may exercise their affinities without danger—harmlessly and slowly, then the inquiry is at once suggested, on what elements do chemical combinations depend? Why are these combinations accompanied with devastation and ruin? Why are those peaceful and unperceived?

Those who were present at the first lecture will be prepared for the suggestion that these differences arise (in part, at least) from some of those results which in that lecture were said to be deducible from a consideration of the units of time, mass, and space. Those fundamental units form a combination on which all our knowledge of work and production of energy depends. It will probably be remembered, too, that in the lectures on gravity and vitality these units of measurement formed the object of research by the men who have given to society the mode of estimating these energies.

It may have been noticed that whereas in the other lectures of this series the titles have in them the words, "especially with reference to the measurement of it," these words are changed in the title of the present lecture, and there are substituted for them the phrase, "especially with reference to considerations for measuring, etc." It will now be not inappropriate if one or two of the causes which lead to this difficulty in estimating the energies of affinity be made as clear as the competency of your lecturer will permit.

Before entering upon this, it may be well to consider whether the actual putting forth of the energy of affinity is a phenomenon belonging to physics or chemistry. The answer, open to contradiction by many, is that the study of the energies of affinity is a purely physical question and not a chemical one. For this reason a chemist deals with those combinations in which the constituent elements have passed through such changes that their identity is lost. The chemist is ever dwelling upon changes, and his equations are not the equations of the physicist and the mathematician; they are, by the use of mathematical symbols, the representatives of change, of what affinity has done and completed, and not of that energy with which it has been done, and which is to be measured. The energy of affinity either causes or induces these changes, and until that energy has operated chemistry has no standing-ground. The energy of affinity opens the gate which separates the domains of the chemist from those of the physicist, and as the physicist is in possession of the matter the chemist must look there before he can take note of those changes he so loves to contemplate.

It is quite true that when the physicist and mathematician attempt to apply those principles which serve so well in investigating the measurement and utilization of the other imponderables, they are baffled. By the application and study of these principles it is moderately well known how to call forth that which we wish to call forth. The summons being issued, we can rely upon the same result, whatever may be the surroundings. Not so with the energy of affinity; it is now slow, now sudden, now destructive, now restorative, now brought out by heat, now by light, now by moisture, now by sound, now by time, now by the simple presence of another molecule.

It is similar to the other energies with which we are dealing, in that it seems to consist in a species of attraction or its opposite repulsion. Gravity has a power of attraction at all distances; electricity has both attractive and repellant powers, and we may say at all distances; but affinity is limited to molecules so near that we must say that the matters of which they consist are in absolute and perfect contact.

That there is what we call matter—that it is of such a character or nature as that no two particles of it can at one and the same time occupy the same space; that however much a lump of this matter be divided it may still by finer instruments be subdivided; that by neither mechanical nor chemical means has anyone ever yet obtained one such ultimate and indivisible particle of matter. These are assumptions generally received without controversy.

It is, however, in and amongst these ultimate and indivisible particles of matter, that the laws of affinity operate. If we could handle them as we handle the bulks, which the aggregation of these particles form, then, probably, all difficulties respecting the laws of affinity would vanish. We cannot handle them. The physicist gives it up in despair; the chemist, however, more venturesome, deals with them. In dealing with them he puts forth a proposition which the physicist knows not how to accept.

Such unions and interlacings as these seem to set at nought the postulate that no two particles of matter can occupy the same space. For the chemist recognizes two, three, four, or five particles of matter, seemingly rushing together, and, as far as we know, occupying the very space which a fundamental physical proposition states they cannot occupy. It may, however, be quite true, for telegraphic messages now-a-days run along the same wire in opposite directions at the same time.

If we could but reconcile these views (and they will be reconciled some day), what a change will come over the dreams of scientific theorists, and what a magnificent and splendid territory for scientific research will then be brought into possession!

To return to the difficulties which interfere with an enunciation of the laws of affinity.

It is plain that explosives, as they are called, vary in their manifestations to our senses in respect of intensity (the assumption that the energy of affinity always produces a species of explosion is not a very violent one). But it is not so plain that within themselves the intensity is a constant quantity, and admits of no variation—that whether gun-cotton causes a cliff to crumble as powder into the sea, or flashes harmlessly without even igniting the gunpowder laid on the palm of the operator's hand, the energy of the affinity in the two cases is exactly the same. In fact, affinity can neither be created nor destroyed—it may be resisted, and if the resistance could be measured at the moment affinity may be said to put forth its energy, and overcome the resistance; then this is the measure of the energy. Illustrations of this are numerous and convincing. Let a few minutes be given to one.

If a person raises 100 separate 1lb. weights off the floor on to a table three feet high, then, as a measure of the energy expended, we take the work that is done, viz., 100 separate lbs. raised three feet, and call the product 100×3, viz., 300, as the measure of the energy of vitality which thus raised the weights. Suppose now the man had been ten minutes in doing this work, then the energy per minute would be measured by the figures 30. Suppose that instead of working at this rate he had lifted all the weights in one minute, the energy per minute would be still measured by the figures 300, and if the rate of work were continued there would have been expended in ten minutes an energy represented by the figures 3000. Thus we may reason until the work originally done in ten minutes is done in one second. The measure of the energy in that one second is 300, and in one minute 18,000, and in ten minutes 180,000. The intensity of the energy in this last experiment is 6000 times as great as in the first experiment. Let this illustration suffice to show that to measure the itensity of an energy time must be taken into account if we wish to utilize that energy, or to bring it into calculations.

It will be within the memory of those present at a former lecture, that, in the case of the energy of gravity, Atwood brought time in by staying the sudden action of gravity, and distributing the fall of a weight through a large mass. Kater brought time in by causing a pendulum to record the number of its vibrations. They dealt with gravity alone, but we are dealing not only with the energy of affinity alone, but with such concealed and unknown energies as those which are taking place whilst the phenomena we are observing are going on. If we could put two substances together, and could guarantee that neither nascent nor catalytic action should be taking place, then we should have an energy responding as a unit to the energy of gravity. So, if we could prolong the time, we might, somehow or other, get a record of the energy. But that we cannot do, and with all our modern appliances it seems almost impossible to notice the time when affinity begins and ends its work. Under any circumstances it is difficult to notice time, but when the interval is short, what is called the personal error is as great as though the time were long.

A digression may make this clear. Suppose the eye sees an event, a nerve of sensation conveys the impression to the brain, and then a nerve of motion directs the muscles of the fingers to record it. Now, in the case of affinity, before the nerve of sensation has telegraphed to the brain the commencement of the event whose duration we wish to record, the end of the event is there, and the retina has impression super-imposed upon impression, and the fingers fail to enter the records. This leads to another difficulty—the nerves of different persons transmit impressions at different rates, hence observations and records of the duration of things seen and heard by two people do not agree, and certain corrections have to be introduced consequent upon these personal differences in the speed of these nerve-conveying telegrams.

As regards mass. Assuming that our investigations are carried on in the same locality, then, speaking generally, mass is fairly measured by weight in vacuo. If the bodies we see and handle were units, then we might recognize mass as the weight of the visible body. These bodies are composed of elemental units, the masses of which we cannot see, and affinity deals with these elemental unit masses and not with the bodies themselves. Certain considerations, based upon numerous observations, led Dalton and others to conclusions in regard to the weights of these ultimate unit masses. Admitting all to be correct, they are not sufficient for the purpose of estimating the energy of affinity through the fundamental units of time, space, and mass.

The failure is thus—Dalton finding hydrogen the lightest substance compared all others with it. But what is the actual weight of a hydrogen atom? That we do not know, therefore we cannot know the weights of the other substances which are recorded in this.

If the absolute weight of one elemental unit of any simple body could be had, then thanks to Dalton and others, the absolute weight of the unit elements of all other bodies is known.

For the purpose of making clear the value of these atomic or molecular elements in reference to their mass and the space between them, let me, at the risk of some repetition remind you that knowing the weight of one atom or molecule of each of the bodies, the energy of whose affinities is to be measured, and knowing the space between them and through which space these atoms or molecules pass before they coalesce, then the product of these two elements gives the value of the energy in the form of work done. If with this product the time is combined, then not only the energy but the intensity of the energy is also known.

Now, if we cannot get at the unit *masses*, how can we possibly get at the distance between them; yet this distance is the *space* through which these little masses must be carried by the influence of that affinity whose energy is to be measured by the work it does.

When, however, we consider that the waves of light have been measured, the number of them per inch stated, their velocity ascertained, we have good grounds for assuming that the masses and distances of the ultimate elements of matter will also be ascertained; then the laws which regulate the energies of such affinities will, most probably, be also ascertained.

Such are some of the preliminary difficulties which present themselves to those who look in hope to establish the laws which govern the energies of affinity from first principles.

If, however, these laws be enunciated—if they be even approximately attained—it will, most probably, be through some indirect means, through some other energies from which these energies of affinity may be deduced. In this indirect way the mechanical energy of heat has been measured, and its value is as generally received and acted upon as that twelve pence make one shilling and twenty shillings make one pound.

The source of mechanical power, so far as men utilize it, is in the energies of affinities. To these energies, as formed by the Creator (inherent and primordial), we owe the means by which work is done. Indeed, it is no very bold suggestion to make, that to the exercise, even now, of these inherent affinities, we owe much—it may be all—of terrestrial magnetism and internal terrestrial change and heat; the progress, in the depths of the earth, of these affinities, may be the cause of the variation of the compass; nay, we cannot tell where speculations such as these lead. How the atoms disport themselves we know not; this we do know, that when some atoms meet some other atoms they are as Greek joined to Greek, for "then comes the tug of war."

Parliamentary and Law Proceedings.

Alleged Poisoning by a Lotion.—Committal of a Chemist and Druggist for Manslaughter.

A lengthened inquiry has been held at Barnstaple by Mr. R. J. Bencraft, borough coroner, touching the circumstances attending the death of Mrs. Yeo, the wife of an innkeeper of that town. Mr. L. Bencraft watched the proceedings on behalf of Mr. Goss, chemist and druggist.

At the first meeting of the jury in consequence of a statement made by Mr. Fernie, the surgeon who had attended the deceased, it was thought desirable not to proceed further until a *post mortem* examination of the body had taken place. At the next meeting Mr. Fernie deposed that he had made such *post mortem* examination, assisted by Mr. Bosson, a duly qualified medical practitioner. He first examined the umbilical hernia, from which the deceased had suffered for several years; it was about as large as his two fists, and consisted of a quantity of omentum, softened by inflammation. He then proceeded to examine the stomach, between which and the hernia there were 16 feet of other intestine, which seemed to be perfectly healthy. He found that one-third of the inner surface of the stomach exhibited signs of inflammation, and fully one-third showed signs of intense inflammation, the colour being a deep crimson interspersed with streaks of a very dark colour. This part of the stomach was near the gullet or swallow. Upon examination of the rectum he found the lower part of its inner surface inflamed. The whole of the intestines were perfectly empty as regarded food. The liver was very large, and of a fatty texture; the heart and lungs were healthy, and so was the brain. Having made the *post mortem* examination, he imagined, in the first place, that the inflamed state of the intestines and partial strangulation of the hernia were such as would have caused death. In the second place, the state of the stomach was such as would also have caused death; yet, the two conditions seemed to be perfectly separate, because there was no continuation of the inflammation between the stomach and the hernia.

On thinking the matter over, it seemed to him not improbable that, supposing the deceased had vomited, as was stated she had done for two or three weeks, the repeated acts of vomiting would squeeze more and more of the intestines into the hernia, and so produce strangulation.

The Coroner: Can you give the jury any opinion as to how the inflammation of the stomach arose?—Witness: I can only surmise, knowing that there was arsenic in the lotion, that arsenic might have caused the inflammation.

Mr. L. Bencraft: You have expressed an opinion that the lotion contained arsenic.—Witness: Yes.

Did you receive one bottle or two?—Two.

Will you tell the jury whether you have submitted the contents of these two bottles to a chemical test?—Both have been tested, and I have no doubt that the lotion does contain arsenic. At the same time, if conviction is required, you must go further than me, and engage a professional analyst.

Having made these experiments, are you prepared to pledge your professional experience and reputation that the lotion contained arsenic?—I have no reputation as an analyst.

But you have stated that the lotion does contain arsenic?—And I firmly believe it does.

Of course you have the remains of it carefully preserved?—Yes; and I can show you the arsenic now, if you choose. I may add that I found evidence of sulphuric acid in the lotion.

I apprehend the theory is, that if this did cause death, it would have got into the stomach by absorption?—Yes; and would have produced the inflamed appearance of which I have spoken.

You think the condition of the stomach sufficient to have caused death?—Yes.

You spoke of a very large liver: I apprehend that betokens an intemperate person?—I am unable to form an opinion.

Might not the appearance be due to intense diarrhœa?—No; it is impossible. Inflammation of the stomach is a very rare complaint, unless it is the result of poison.

Notwithstanding all this, you hesitate to express a decided opinion as to the cause of death.—Yes; considering the condition of the hernia, I must. I can only say that the state of the hernia was such as would cause death, but at the same time I do not think the inflammation had been more than three days in existence.

Having regard to the mixture, do you think it could have been composed simply of sulphate of zinc and water?—My opinion is strongly against it. I still have the ingredients, and they can be tested.

The Coroner said he took it that at this inquiry the jury would not go immediately into what the mixture contained. It would be more for them to consider whether they thought any further examination of the lotion and the parts of the body referred to, was or was not necessary. They had had a general statement from Mr. Fernie as to the state of the stomach and intestines, and they had heard that gentlemen say what it was that led him to make the statement he did at the first inquiry, which statement he had reiterated on that occasion.

A juryman asked whether, at the previous inquiry, Mr. Fernie stated he had no doubt the deceased died from the application of arsenic?

Mr. Fernie said he did not go so far as that, and was not responsible for what had appeared in the newspapers. He did not go so far even as to say that the inflammation of the stomach was caused by arsenic.

Mr. Bencraft said he proposed calling the person who made the mixture.

The Coroner: I should not feel disposed to accept the responsiblity of taking his statement on oath even were he prepared to give it. The simple question for the jury was whether, having heard Mr. Fernie's statement, they thought it their duty to send the lotion to a professional analyst, in order that they might be perfectly satisfied as to what it did contain.

The court was cleared whilst the jury held a consultation upon the course to be pursued, and on the reporters being re-admitted the Coroner stated that they had come to the unanimous conclusion that they could not satisfactorily go further into the matter until an analysis of the lotion and certain parts of the body had been made by a competent person. He had undertaken to see that this should be done. The lotion and the parts of the body mentioned would be sent to Mr. Stoddart, of Bristol, who would report the result of his examination to the jury, and if upon that report he (the Coroner) thought it necessary to subpœna him he should do so.

Mr. Bencraft suggested that if Mr. Stoddart discovered arsenic he should be asked in what quantity, because he was told that sulphate of zinc did contain a quantity of arsenic. It was then decided to adjourn the inquiry for a fortnight.

On Saturday afternoon, August 30th, the adjourned inquest was held at the Guildhall. Mr. John A. Thorne was present to watch the case on behalf of Mr. Goss, of Braunton.

The Coroner opened the proceedings by stating that a fortnight ago an adjournment had been made to allow of parts of the stomach, etc., and the lotions used by the deceased, being examined by an analytical chemist. He had taken the subjects to be analysed, carefully sealed, to Mr. Stoddart, who had furnished him with a report, upon which he had subpœnaed him there that day. Mr. Stoddart was present to give any further evidence or answer any questions which the jury might wish to put to him.

The first witness called was Mr. William Walter Stoddart, analytical chemist, of Bristol, who, on being sworn, read the following report:—

"Western Counties Laboratory, 90, North Street,
"Bristol, August 22nd, 1873.

"I. Bencraft, Esq., Coroner for Barnstaple.

"Dear Sir,—I have completed the analysis of the contents of the hamper left by you on the 18th instant, viz.—jar containing part of mamma and ulcer; 2 ditto, stomach; 3 ditto, rectum; 4 ditto, liver and spleen; 5 ditto, kidney; 6, bottle of lotion, marked No. 1; 7, ditto, marked No. 2, bottle of mixture. All the above except mixture, contain zinc in large quantities. The several portions of the body are highly charged with that metal in the state of oxide combined with animal principles. The lotions are strong solutions of sulphate of zinc, commonly called white vitrol. They also contain oxide of iron and traces of lead. Both these are probably derived from the above-named salt. I have carefully and repeatedly tested each for the presence of arsenic by the processes of Reinsch and Marsh, without success. I am quite sure arsenic is not present in any of the tissues received, or in either of the lotions. I think the absorption of so much zinc would be likely to cause excessive sickness and diarrhœa, especially when accompanied with so much general derangement of the body."

Mr. Stoddart then proceeded to make some observations, and remarked that the inside of the stomach was in such a state of decomposition that, besides being very disagreeable, it was very difficult to tell what the appearances were like. It was the first instance he had experienced in which he had found zinc in such remarkably large quantity. He had tried fully five times to detect the presence of arsenic, but had failed. He showed the jury the porcelains upon which he had experimented; their surfaces were quite clean, while on another, on which he had placed a solution containing three grains of arsenic, there were three large-sized spots. He also exhibited the zinc which he had extracted from the ulcer, the liver, and the lotion. It appeared to him that the zinc had been absorbed into the system. He had tried two methods of testing the tissues; one, by boiling them in acid, and treating the solution with the usual

precipitant; the other by burning them. The zinc was separated in a pure state.

Dr. Thompson, of Bideford, was then examined. He stated that he was the coroner of Bideford, and a duly qualified medical practitioner. He had been in practice thirty years. He gave it as his opinion that the absorption into the system of a lotion containing zinc, in such large quantities as had been described, was likely to be attended with very serious results. On being asked what would be the symptoms resulting from absorption, he replied that he could not say, neither did he know of any recorded instance of poisoning by absorption of zinc, but he knew what the effects would be when taken into the stomach. It would produce irritation of the stomach and diarrhœa, but the effect it would have on the constitution would depend very much upon the time it was in the body. Zinc did not class amongst the most irritant of poisons, and therefore it would require a long time to effect a very strong impression on the system; the length of time would be the essence of its operation. If he were to keep a person under the influence of any medicine that would cause nausea and vomiting for a very long time, he should very likely kill him, whereas the use of the same medicine for a short time only would probably do no harm.

The Coroner: Having heard what Mr. Stoddart has stated that the lotion contained, do you consider that a large or small dose?—It might be used for a short period without harm, but I should not like to use it for many weeks together.

A juryman asked whether, the effect it would produce being so gradual, sudden death would be likely to ensue?

Dr. Thompson: If a person were gradually reduced by an irritant substance, such as sulphate of zinc, that person would be very likely to collapse, but at the same time, there was a case recorded by Dr. Barrington, in which sulphate of zinc was administered in doses of two scruples three times a day for a week, without an injurious effect upon the constitution. In his own practice he had frequently known persons suffering from cancer die suddenly.

The Coroner: Would it be a judicious thing to use zinc to the amount contained in the lotion, in the case of a person suffering from a disease of that sort?

Dr. Thompson: Certainly not; it would be highly dangerous.

By Mr. Thorne: Habits of intemperance would reduce a person and necessitate more caution as to what was administered. The fact of a person being fat, taken by itself, would not render sudden death more probable. Absorption of zinc, or any other soluble substance, was very likely to take place through a cancerous wound.

Supposing the lotion to contain the proportions of zinc mentioned by Mr. Stoddart, would that be likely to cause death?—I should think not. If, however, I were applying such a lotion, and found that diarrhœa ensued after three or four days, I should think that the zinc was causing it, and discontinue its use at once.

Just so; but you do not think it would cause sudden death, as in this case?—I should not think so. I have applied substances containing sulphate of zinc in large quantities to a woman's leg without any injurious effect upon her constitution.

Mr. Andrew Fernie, surgeon, was again called, and asked by the foreman why he had spoken so positively as to the presence of arsenic in the lotion. He replied that when he stated to the jury there was arsenic in the lotion he was expressing the result of an analysis made by Dr. Kemp, who he thought was a competent person for making such an analysis, and who wrote to him stating that he had discovered a considerable quantity of arsenic in the lotion. Dr. Kemp did produce arsenic, and Mr. Stoddart was of opinion that the spot on the porcelain was arsenic, but he was of opinion now that the chemicals used were not pure, and must have contained arsenic. He spoke strongly on this point, because the appearance of the stomach induced him to believe that some irritant had been applied.

The Coroner said they must have all seen the importance of the inquiry, and that the case demanded careful and rigid investigation. He commented on the evidence at great length, and said it was for the jury to determine whether death was caused by the ailments from which the deceased was suffering, or from a complication of them; or whether it resulted from the unskilful treatment of the person who attended her. He noticed that Mr. Goss, of Braunton, was a registered chemist. Well-known remedies were sometimes used by unskilful persons, sometimes with good effect, but of course greater responsibility rested on unqualified persons. Any fair and reasonable doubts should be given in favour of the person implicated. If, however, they thought death was accelerated by unskilful treatment, that would amount to a verdict of manslaughter, a rather high-sounding word, but one which sometimes implied but very little culpability.

The jury retired, and, after an hour-and-a-half's absence, gave it as their opinion that there was no positive evidence as to the immediate cause of death, but they believed it to have been accelerated by the unskilful treatment of Mr. Goss, of Braunton. The Coroner said this would entail upon him the necessity of recording a verdict which, in effect, would be that of manslaughter.—One of the jurymen remarked that a censure was all that they had intended their verdict to convey.

Mr. Goss at once came forward and voluntarily surrendered, and the Coroner intimated his willingness to accept bail, Mr. Goss in £50, and two sureties in £50 each. Messrs. John and J. P. Seldon immediately offered themselves as securities for Mr. Goss's appearance at the assizes.—*From the North Devon Herald.*

Sending Dangerous Acids by Railway.

William Warden, sen., and William Warden, jun., of Gordon Terrace, Gordon Road, Peckham, were summoned before Mr. Cooke, sitting at the Clerkenwell Police Court, by Mr. Richard Williams, superintendent of police of the Great Northern Railway Company, for sending by rail a box containing three bottles of sulphuric and nitric acid, without distinctly indicating their dangerous nature. It was stated that on the 31st of July, the younger defendant took to the King's Cross Station a large box, labelled for Scarborough. As it was being put into the train a liquid was observed running from the box, smelling very strongly and giving off vapour. The defendants, who were in the employ of Messrs. Brock, the firework makers, denied having any knowledge as to the contents of the box.

Mr. Hopkinson, chemist, of Swinton Street, Gray's Inn Road, examined the bottles and found they contained nitric and sulphuric acids.

For the defence it was submitted that there was no evidence against the elder defendant, and that no offence within the statute had been proved against the younger defendant, inasmuch as it had been proved that he did not send the goods at all, but intended to take them with him as luggage. As to notice not being given, there was time to declare the nature of the goods before the train by which the defendant was going started.

Mr. Cooke said that he should dismiss the summons, against the elder defendant. With regard to the other defendant, he was of opinion that the delivery of the vitriol to the company's servants to be sent by train was a sending within the meaning of the Act of Parliament. If he was wrong in that view the defendant could appeal. He fined the defendant £5 or, in default, imprisonment in the House of Correction for two calendar months. He might say that the offence was a very bad one; and had it not been for the youth of the defendant he should have inflicted a penalty in the fullest amount.—*Standard.*

Review.

LECTURES ON PRACTICAL PHARMACY. By B. S. PROCTOR, Lecturer in Pharmacy at the College of Medicine, Newcastle-upon-Tyne.

We are very glad to be able to welcome the appearance of Proctor's 'Practical Pharmacy,' not only because it supplies a volume for which there is and has been for some time past an undoubted demand, but also because the work is from the pen of one of ourselves—a pharmacist *pur et simple*.

It is remarkable that, although during the past ten years we have had many manuals and text-books upon chemistry proper, and chemistry as applied to pharmacy, and, in addition, books which are little better than paraphrases of the pharmacopœia, still we have not, as far as our memory serves us, had a single work devoted to the "art and mystery" of pharmacy from a British pharmaceutist.

First let us be just to the provinces, and not only congratulate but compliment them in having thus taken the initiative.

Zealous men and teachers are on all sides to be found, but it is to be feared that in pharmacy such men are almost as numerous as the younger ones who are desirous of obtaining a complete knowledge of their profession, for even in Newcastle-upon-Tyne, the stronghold of enthusiastic and scientific pharmacists, we are told that a lecturer—the author—found himself discoursing upon sulphur to *one only*—the last student left to him.

It does not transpire what followed after sulphur, amorphous, octohedral, and prismatic, had been dilated upon, but we imagine that the solitary student could hardly have been treated as was once described by Tom Hood in his poem of "The Last Man," and sent to breathe sulphur in its gaseous form.

Since the passing of the Pharmacy Act, 1868, there seems to have been more organization than in former years, and, through the good offices of the author, assisted by his brethren of Newcastle, the wants of the pharmaceutical student have been provided for at the College of Medicine, where lectures are now delivered upon pharmacy.

In the "prefatory letter," our author lays claim to being "by nature a student;" we, in our turn, will make out his claim as a teacher, a position to which he is fairly entitled after the exposition of practical pharmacy he has placed before us.

We are aware as the author intimates that occasionally "professed teachers" ride their hobbies of nomenclature, notation, etc., most unmercifully, but we overlook their infirmities when we see that by system, and sometimes by system only, pupils can be taught. Even upon weights, measures, and thermometers, we must confess we are wedded to a system, and we are not quite sure that our ideas upon almost anything and everything that bears upon instruction to youth are not also based upon system.

Of course it may happen that in some so-called systems there will be no true system at all.

Who, for instance, does not remember the tortures of committing to memory weights and measures, and the attempt to understand divisions in the scale of thermometers, which were evidently compiled in days when the metric system was not the prevailing notion. Upon this point therefore our views are, we regret, diametrically opposed to those of the author.

Do not let us be misunderstood in this matter, but point to an illustration from the details of an experiment made with a view of determining moisture in squills and senna (page 11), in which the weight of the substance taken is first described in grams and the loss in drying in grains. We hold that much more would have been conveyed to and impressed upon the mind of the student if the weight taken had been described as one, ten, or one hundred grams, and the loss as so many decigrams, centigrams, or milligrams; or, if we must have our subdivision of the avoirdupois pound, then as one hundred or one thousand grains, and the loss in grains.

In one case the percentage loss is instantly apparent, whether reading or listening to a lecturer, while in the other, to make the matter intelligible, calculation is required, and if listening, the ordinary mental calculator is in a maze as the figures pass in at one ear and out of the other.

The work before us is first of all subdivided into three parts—viz., abstract or general pharmacy, official pharmacy, and extempore pharmacy, these subjects being severally treated in a series of lectures numbering in all twenty-nine.

Under the head of drying medicinal plants, by no means an unimportant topic to the pharmacist, some very excellent suggestions are given for the drying of leaves, and these directions have not been inserted without the *rationale* of the process accompanying them; they also are followed by a woodcut of a very excellent and simple drying stove, which we consider well worth the attention of the pharmacist.

The comminution of drugs is not confined to a description of the simple machines used for incising and contusing, but the more complicated and ponderous mills used for producing powders of extreme fineness on the large scale are fully described. We should have been glad to have seen appended to the very excellent cut and description of sifting apparatus a table of the various degrees of fineness of sieves through which powders must pass before they can be termed coarse, moderately fine, fine, superfine—indeed, if the description of powders given in the U.S. Pharmacopœia had been copied here, it would have been a valuable guide, although perhaps not identical with the degrees of fineness commonly accepted in this country.

In the lecture apportioned to "Solutions" we have tables of density of liquids in constant use, such as caustic soda, acetic acid, details of experiments to determine the solubility of salts and gases, under ordinary circumstances and under pressure, and in addition, some interesting remarks on supersaturated solutions, with Mr. Tomlinson's theory of the phenomenon of supersaturation appended.

Crystalline and amorphous salts, groups of isomorphous salts, the separation of crystals from liquors both amorphous and crystallizable, notes upon certain salts which appear in crystalline forms with variable amounts of water of crystallization, with a table of the amount of water in certain common pharmaceutical salts, occupy the lecture devoted to crystallization.

It is to be regretted that the notation used to describe the composition of these crystals is almost wholly upon the old system; occasionally it happens the two are side by side. Not only do we regret it because it makes the work appear (what it really is not) ten years behind the times, but because to students who know little or nothing of chemistry, the composition of the salts may seem obscure when reading this work alternately with a modern manual of chemistry. We are therefore tempted to question the policy of the arrangement, for we well remember our own confusion and embarassment during the transition period from the old to the present system of notation.

The evaporation of liquids either with a view to concentration or of finally producing extract is well described, as is also the use of steam heat applied under ordinary atmospheric pressure and by means of vacuum pans, the temperature of the former being wisely stated as such as would be produced by a heat of four or five pounds pressure to the square inch, a point too often lost sight of by manufacturers who work frequently with pressures ranging from one to two atmospheres, thereby partially charring many vegetable substances. Illustrative of this lecture is also a cut of Reynolds' mechanical stirring apparatus.

Under the lecture upon distillation we have descriptions and cuts of stills and condensers, as well as very practical remarks upon the processes usually resorted to for the production of essential oils, followed by tables giving the boiling points of many such oils, and also another very valuable table illustrative of the amount of essential oils yielded by materials commonly distilled. In passing we would just remark that some of the oils there enumerated, for instance almond and caraway, are certainly yielded in larger proportions than the maximum there stated.

Under filtration and percolation, embracing among other arrangements Schacht's filter, described some few years since in the PHARMACEUTICAL JOURNAL, of which a cut is given, is one of the author's filters for oil, which although tolerably well adapted for filtering oil on a miniature scale, would require to be materially altered before it could be made to filter anything but small quantities.

Of the several varieties of percolators illustrated and described, we must confess that we prefer Deane's, and agree with the author that the great secrets of percolation are undoubtedly to be found in the comminution of the drug and the proper packing in the percolator. Upon this subject we think our transatlantic brethren can, and do give us some practical hints; we are sure also that they would support the author in denouncing the attempt to economize spirit by using water to displace the last portions of that menstruum, and more especially the idea that spirit so displaced is of full strength. With this lecture (the tenth) the section of the work devoted to Abstract or General Pharmacy is concluded.

Official Pharmacy opens the second part, upon which, we think, little can, or indeed is necessary to be said, for if the pharmacopœia processes from which these are abstracted are faithfully followed, in the majority of cases good and reliable preparations will result. The directions for the manufacture of all preparations seem, as far as they go, to accord with the officinal processes, even to the errors which have from time to time been pointed out as existing in the Pharmacopœia. In many cases the author has, for the sake of brevity, omitted most important details, such for instance as the temperature at which the operator is to work.

We must not pass by the very excellent paragraphs upon Spirits of Wine, fully explaining (without errors so common under this head) its relation to the excise and pharmacy.

The directions for making the scale preparations of iron well describe the various stages of manufacture, and as much may be said for the resinoids. Upon resin of podophyllin, however, the author describes the U.S. process as being different to our own, inasmuch as hydrochloric acid is not used to precipitate the bebeerine. This certainly was the case formerly, but in the recent U. S. Pharmacopœia the process is identical with our own.

With the lecture upon dispensing commences an all important section of the work, one perhaps more than any other, upon which the knowledge of the many special subjects with which a pharmacist has to become acquainted is brought to bear. The author evidently holds the same views, for he has devoted no less than about one-sixth of the whole work to dispensing and comments upon doubtful prescriptions, upwards of thirty excellent lithographed facsimiles of which are inserted as illustrative of his subject.

He commences with excellent hints, and to those about to be initiated into pharmacy we cannot over-estimate the value of his advice—"There is no department of business in which the formation of good habits is so important as in dispensing. Let it be your habit—a habit so strongly formed as to be your second nature—to be orderly, neat and quick, attentive to little things, observant of everything," and last, and not least, "the dispenser should be an accomplished man and a gentleman, up to every duty and above none."

After first noting the various mixtures, salts, etc., in daily and almost hourly use, that may be kept in a concentrated form or in solution, in order to expedite work at the dispensing counter, and after giving a few simple, but none the less all sufficient directions for labelling, weighing, and measuring, the author passes to doubtful doses in prescriptions, a subject at the present time most interesting to dispensers, as the medical journals are expressing somewhat strong opinions upon it.

Emulsions, the terror of juvenile pharmacists, are here explained, and formulæ given upon which students may experiment. We cannot comment upon the dissection of, and rendering clear, the doubtful points in the autograph prescriptions to which we have before alluded, being unable to reproduce them here, for it would be but a repetition of playing a tragedy with its chief character omitted. In order, therefore, that our readers may form a just appreciation of their style and value, we must refer them to the work itself, and its accompanying notes and explanations. The making of pills with various excipients, not only from ordinary ingredients, but from those bodies which it is generally acknowledged are most difficult to turn into elegant masses, forms the subject of a whole lecture. The student would do well to try many of the formulæ, as well also as the various powders for covering, and the process for coating pills there given.

One topic more, in connection with the dispensing counter, one that cannot, all will agree, be learned by "cramming," viz., plaster-spreading. Here, if knowledge is to be imparted and acquired, it must be by practical demonstration on the part of the teacher, and practical experience on the part of the learner.

Lectures twenty-four and twenty-five are solely devoted to the chemical examination of officinal salts; such a subject we think should have been omitted from a manual like the present. Its legitimate place would be in a treatise upon pharmaceutical chemistry, where, in order to make every point intelligible to the student, each reaction would be explained and the decomposition illustrated according to the notation used among modern chemists.

The pharmacy of special drugs to which the latter pages of the volume are devoted is certainly a novel and praiseworthy idea; the effect evidently intended to be brought about by the author, is to induce students to take a drug and work at it and its preparations step by step, until a thorough knowledge of its character be acquired.

Although the author's experiments upon Cinchona Bark and other special drugs are not such as we ourselves or other pharmacists might have chosen to have carried out, still they are valuable as an indication of the manner and style of work necessary to decide the queries of pharmacy.

The calculation given for determining worth of quinine as based upon the value of Cinchona Bark is not by any means clear. We question the accuracy of the starting point, for according to our own ideas a bark yielding two per cent. of quinine would for the purposes of quinine manufacture be commercially worth about three shillings per pound, provided that the whole or greater part of that quinine was crystallizable as sulphate; if not, it would be worth even a less sum.

We quite agree with the author that our Cinchona preparations are eminently unsatisfactory. The fluid extract although much approved by the medical profession is one that cannot upon the completion of its manufacture be viewed with satisfaction by the operator; for in the first place he finds he has at the least 25 per cent. less fluid extract than the Pharmacopœia says he should have, that the amount of water (and consequently the evaporation required) has been something enormous, unless indeed he has resorted to the special device recommended by Giles and others (overlooked by the author), and, finally although the bark to all appearance is exhausted, upon making a chemical examination of it he finds at least half the quinia is left untouched.

To devise a good and economical process for the production of fluid extract of Cinchona is a field in which a student might work with advantage.

We would not for one moment advise any one to try to make a concentrated decoction, either with or without

acid, as Mr. Proctor did, to attempt to accurately represent and at the same time be eight times the strength of the officinal decoction, for time is valuable and it has long since been decided that concentrated decoctions and infusions do not represent with accuracy when diluted the officinal preparations.

The chapters specially devoted to opium and aloes contain much information, both for students and those of maturer years, such, indeed, as is not to be found in any one published work. The author has taken advantage of recent investigations by Deane and Brady upon the former drug, and the researches of Tilden and Flückiger upon aloes and its crystalline principles.

The final lecture, devoted to iron preparations, is replete with that sound judgment and plain speaking so characteristic of the entire work.

We quite agree with the author, and most heartily endorse his opinions by quoting from this section :—"There is no article of materia medica which has been administered in so many different forms as iron, and none which threatens to go on multiplying and replenishing our shelves with such frightful fecundity.

"To stay this plague, to increase the death rate and diminish the birth rate of iron remedies, is the one thing most highly to be desired."

"The granular effervescing preparations known as citrate of iron, citrate of iron and quinine, carbonate of iron, and iodide of iron, form a little family. It were better they had never been born. Their birth showed but the folly of their parents, and their decay shows that they did not possess the stamina for a useful existence."

Notwithstanding the different opinions we have held upon some points, we feel that we should not be doing justice to ourselves and to the author if we did not record the great pleasure the perusal of his manual has afforded us.

We have no hesitation in recommending Proctor's 'Practical Pharmacy' as a text-book for those who during their apprenticeship have not only to acquire business habits, but also to obtain such information as will enable them to understand the *rationale* of the various pharmaceutical processes they are daily called upon to perform. To more advanced students, who are preparing for examination, we think this volume will supply a want that has often been felt, when such information is required as can only be obtained from practical men.

We shall not be surprised to find this work taking its place side by side with the manuals now recognized as being specially adapted for pharmaceutical students.

Obituary.

Notice has been received of the death of the following :—

On the 26th July, 1873, Mr. William George Jones, Pharmaceutical Chemist, of Staines. Mr. Jones had been a member of the Pharmaceutical Society since 1852.

On the 11th August, 1873, Mr. Edward Earl, Chemist and Druggist, of Sutton Bridge, Long Sutton.

On the 21th August, 1873, Mr. Alexander Forbes Allan, Chemist and Druggist, of Fyvie, Aberdeenshire.

On the 31th August, 1873, Mr. William Chellew, Chemist and Druggist, of Breck Road, Liverpool.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer ; not necessarily for publication, but as a guarantee of good faith.*

UNJUST CENSURE OF A CHEMIST.

Sir,—If you think it worth while you can add this contribution to the discussion raised by Mr. Fisher's case.

In the matter of etiquette the fact seems to be lost sight of that the dispensing chemist, if he attends to his business, is nearly always to be found "at home," while the medical man, if he attend properly to his practice, will spend nearly as much time perhaps "abroad."

Some twenty years ago I made up a series of boxes of pills to which, each time the prescription was presented, successive additions and subtractions were made, *something like this* (I have now no copy to refer to) :—

℞ Quinæ Bisulph. . . gr. 6, 12, 18, 24, 30, 36, 6
Ferri Sulph. . . . gr. 36, 30, 24, 18, 12, 6, 48

These figures represent the successive alterations that had been made, and had all been marked through except the last in each line.

Thinking it quite possible that the prescriber might have committed the error of mistaking the line to which he added the figures, I called upon him at once, a mile and a-half off. He was not in, and I was briefly told to "come again at 6 in the morning." I did so, and found the gentleman in full career with a hall full of patients. Mr. —— was very courteous, but asked me if I thought the dose poisonous. I said, "No." "Well," said he, "I meant it ; but"—looking at the paper—"I might as well have written a fresh prescription." So I thought ; since it caused a delay of more than twenty-four hours, the patient residing in the country.

Now, it is continually urged even among ourselves that it is the chemist's duty in each case of doubt to call upon the doctor, and ask an explanation. I used to do this, but so often found the gentleman out on his rounds (as on the face of the thing is extremely likely) that repeated disappointment and delays tired me out. I now but rarely give myself this trouble, not unlikely to be worse than useless, but instead, confining myself to no rule however, say perhaps,—"I suppose the doctor said he particularly wished to know the effect of the first dose or two of the medicine ?" "No. He did not." "Well, tell him the chemist made the remark : he will be all the more satisfied of the medicine being carefully prepared." I have then made the correction in pencil which I thought was obviously needed, and dispensed the medicine. The doctor discovers the correction, and thanks me next day. At least, I have been so far so fortunate.

The alternative is—wait upon, send or write to the prescriber, and hours may pass ere communication is effected. Meanwhile the patient grows *im*patient and suspicious. And every chemist must have experienced how very difficult it often is to satisfy a party who *intends to wait*—and to whom the doctor may himself have said, "This is a simple thing, and won't detain your messenger more than a few minutes"—with excuses for delay, without in some degree compromising himself or the medical man.

Once I received "℞ Liq. Plumbi Acet. ℥j" which by mere accident I learned was not intended for outward use, but to be taken. The paper was duly signed, but without either directions for use or name of patient. The doctor had actually written "Tinct. Ferri Mur.," but had taken up in mistake from off his desk or table another slip of paper. In this case I saw and asked the gentleman : but it suggests a dilemma.

Suppose such a prescription were brought from a distance by rail, as concentrated formulæ often are. What then would be the wisest course to pursue ? It is clearly the chemist's duty not merely to refuse to dispense the medicine himself but to prevent its being dispensed at all as written, and it is only "doing as one would be done by" to screen the practitioner. I have had also good reason to know that patients will sometimes rely implicitly on the word of mouth instructions perhaps of a friend and regard the chemist as over, if not absurdly, cautious for putting upon it a poison label.

THOMAS LOWE.

Liverpool, Aug. 30th.

Sir,—It being an open question among the medical profession as to whether the dose of digitalis was a safe or

proper one, for convenience sake I will assume that it was both.

The question then arises how for the future a prescription ought to be written that the chemist may have the confidence to dispense doses when ordered eight times the maximum strength of the B. P.

When shall he know that the time has arrived to cast aside his knowledge of doses and the action of medicines—a knowledge that has cost him much time and money to acquire; a knowledge that by Act of Parliament he is now bound to possess before he is permitted to carry on a business as a chemist and druggist; and a knowledge that he is supposed to exercise for the safety of the patient in any instance of glaring error?

It is proposed by some of your correspondents to append (*sic*) to unusual doses, but this would not ensure the detection of error where ℥ is written for ℥, or ℥ for ℈, or ℈ for gr. or guttæ.

If the suggestions in my letter at p. 520, vol. iii. had been followed they would have met this case.

If the prescribing had been correct a life might have been saved, if wrong, the chemist could not have been to blame.

I now append another note to the same plan, which will obviate any mistake: it is (where possible) to write the first line of the active ingredient in its highest terms, and the next in a lower one, thus—

Tinct. Digitalis . . . . . ℥j.
2 (℥ ss. + ℥ iiiss.)

It is surprising that the jury should go out of its way to censure the chemist for his carefulness and yet could not discover much serious neglect in other quarters.

As to whether the surgeon has been guilty of culpable supineness we need not discuss.

It is our duty to carry out the physician's intentions, when clearly defined, and it is also our duty to endeavour to have laid down such rules as will for the future prevent any dispenser from becoming the victim of a vindictive persecution.

H. Simpson.

Regent's Park, September 3rd, 1873.

Sir,—In Dr. Farre's 'Abridgment of Dr. Pereira's Elements of Materia Medica' (1865), under the head of "Tincture of Digitalis," is the following note by the editor:—

"It would remove all doubts about the real intention of the prescriber, and would relieve any scruples of the dispenser, if the prescriber when ordering *unusually* large doses of this or any other medicine would *write his initials* above the dose, or above the quantity of the active ingredient."

Had Mr. Leake adopted this reasonable precaution Mr. Fisher would have *at once* dispensed the prescription, but he did nothing of the kind. Surely the *Lancet* will not deny that Dr. Farre's opinion ought to have weight with members of the profession.

As a pharmacist of forty years' experience in business, I have frequently had to submit to the prescriber what *appeared* to me to be an overdose or a wrong quantity, and *in almost all cases they proved to be so*, and I have been repeatedly thanked for doing it. In some cases most certainly death would have resulted had the prescription been made up as written. When the prescriber could not be communicated with, I have positively refused to dispense the medicine, and would do so again, and I hope the improper finding of the jury will not deter any pharmacist from doing the same.

An Original Member of the Pharmaceutical Society of Great Britain.

Edinburgh, 30th August, 1873.

Sir,—Allow me to call the attention of the readers of the Pharmaceutical Journal to a leading article in the *Lancet* of August 30th, on the duty of druggists in general, when any unusual dose of a powerful drug is prescribed, and on the conduct of Mr. Fisher, of Ramsgate, in particular, in not dispensing a prescription containing half-an-ounce of tincture of digitalis for a dose.

We readily grant that the usual mode of procedure in the first dispensing establishments in London, when such cases occur, is to consult the physician or surgeon, *if known* and *if possible*, but be it understood that such a course is always considered as a *courtesy* rather than a *duty*.

Again, the article in question has the following sentence—"We think it would have been more creditable to the druggist in question *if he had known that the administration of large doses of tincture of digitalis has been a recognized practice* since the discovery, twelve years ago, of its usefulness by Mr. Jones, of Jersey, who treated sixty-seven cases in this way."

Now, I have no hesitation in saying that no house of business, in London or country, would have dispensed a prescription ordering half-an-ounce of tincture of digitalis for a dose (unless acquainted with the physician's intention) even if they had known of all the large and unusual doses administered during the last two centuries.

It is very evident that the writer is ignorant of the rules of a strictly conducted dispensing establishment, and of the care requisite to ensure what he terms "the wonderful accuracy with which medicines are dispensed," and, whatever may be the "notoriety of prescription," I venture to assert that, however well acquainted the writer of the article in the *Lancet* may be with instances of half-ounce doses of tincture of digitalis, not one chemist in five hundred has ever seen such a prescription, although they may have lived in houses where a hundred or a hundred and fifty prescriptions were dispensed daily.

And, sir, I think "things will come to a fine pass" if medical men allow their patients to die for the want of proper instructions to the dispensers of medicine.

Proctor Jones.

August 30th, 1873.

Chemists' Responsibilities.

Sir,—In reference to the case of Mr. Fisher, of Ramsgate, permit me to say that as a chemist of more than thirty years' experience, I should neither accept the dictum of Mr. Leake nor the preposterous assumption of the *Lancet*, that a dispensing chemist is to be allowed no freedom of action, but is bound to dispense (without questioning) any prescription containing even the most unusual doses of the most powerful or even deadly remedies, and, as it often happens (as well as in the case of Mr. Fisher) without knowing anything of the qualifications of the writer of it.

It would be a waste of time to attempt to convince either Mr. Leake or the writer in the *Lancet* as to what is to be expected from one educated man of another, and as every disinterested person must consider that Mr. Fisher was entirely free from blame, I will allow the Ramsgate case to pass without further notice.

Now, after asking two or three questions springing out of the point at issue, I shall endeavour to answer the same from my own experience, and as briefly as the importance of the subject will admit of.

Well, then,—Is a dispenser always able to know whether an unusually large dose of a medicine be really intended by the prescriber or whether it be an oversight?

To this I most decidedly answer, He is not able.

For several years the superintendence was in my hands of a dispensing department where considerably more than a thousand prescriptions per week were made up, from some of the principal physicians and surgeons in London. Whenever an extreme dose was ordered my attention was directed to it, and it generally turned out to be an error of the prescriber's, proving the force of the old saying to hold good with doctors as well as with others, "Nemo mortalium omnibus horis sapit." Can the writer of a prescription always be communicated with when doubts do arise? In very many instances he cannot, as I well know at the cost of considerable trouble and anxiety.

Now, without being tedious, perhaps it will be allowed me to give a few results of comparatively recent experience which will demonstrate, I hope, the truth for which I contend, that the dispenser is called upon not only to have an opinion as to doses, but to act upon it.

℞. Hydrarg. Chlorid.
Pulv. Opii āā . . . . . gr. ij.
Ft. pil., 4tis. horis sumend. Mitte vj.

In this case the prescriber, a physician of considerable practice, was found, and at once altered the Pulv. Opii to gr. ¼.

℞. Hydrarg. Bichlor.
Ammon. Hydrochlor. āā . . gr. iss.
Pil. Ferri Comp. . . . . gr. v,
Ft. pil., ter die sumend. Mitte xxiv.

This was also the prescription of a medical man of great practice, and most precise in everything. The first time the pills were made the Pil. Ferri alone was ordered, the mistake had occurred through writing the doses of the Hydrarg. Bichlor. (when the prescription was altered) for twenty-four pills instead of one. The prescription was brought to us in the middle of a busy market, the doctor was not found, and the patient was going a long distance into the country. So without a word to the patient (which always causes alarm), I took the liberty to erase the the gr. iss. and put gr. $\frac{1}{16}$.

A prescription containing Liq. Strychniæ ♏ xv. for a dose was brought me by a lady from a medical man of celebrity thirty miles from this; she was to take the medicine for ten days or a fortnight, and see him again. Now I feel pretty sure that many, not being so conversant with the effects of strychnia as myself, would have made it up as ordered, but I ventured to reduce the dose to half that quantity, until I could communicate with the prescriber, who at once wrote to say the dose was intended to be ♏ v., not xv.

Only a very short time since, during my absence for a short period, a prescription was made up by my young man, and on my entering the shop about a quarter of an hour after, he at once asked me if ♏ xv. of the Acid. Hydrocyanic. P.B. was not a large dose; my reply was that it was, and on looking at the copy of the prescription in our book, felt certain that Acid. Hydrocyanic. was not intended.

I sent off at once with the best excuse I could for the medicine, and found on looking at the prescription that it was decidedly written Acid. Hydrocyan. dil., although it appears, as I at first knew, Acid. Hydrochlor. dil. was intended.

But I will go further than this, and state most unhesitatingly that doses are ordered which are dangerous (and sometimes even would be fatal) through the *sheer ignorance* of the prescriber, and this is why I affirm that in the case of a large dose being ordered it is not only necessary to be assured that such dose is intended, *but on public grounds*, to satisfy oneself as to the qualification of the prescriber, or, as Mr. Fisher did, refuse to dispense it; in such a case full name and address being requisite.

It is most essential at all events that in the case of unusually large doses being ordered, some distinct mark should be given to show that such is intended. And I should much prefer to *(sic.)* it being written thus:—

℞

Tinct. Digitalis . . ℥ iv. (4 drachms.)

Statim sumend.

℞

Tinct. Opii. . . . ♏ lx. (60 minims.)

Statim et post horas duas si opus sit.

℞

Ext. Belladon. . . grs. 80 (80 grains.)
Aqua. . . . . ad ℥ iv. (4 ounces.)

One tablespoonful three times a day.

I hope my desire to occupy as little space as possible will not prevent my letter from being intelligible, and sincerely hoping the Council of the Pharmaceutical Society will take action in the matter, leave it in their hands and in that of the trade at large,

ONE WHO HAS KNOWN THE DRUG TRADE MORE THAN THIRTY YEARS.

Sir,—A delicate question arises out of the Ramsgate case—How is the pharmacist to know whether prescriptions, in the manner they are now written, come from legally qualified practitioners or not, when they are merely signed with initials, as physicians' prescriptions usually are? Of course many are known to be genuine by their handwriting, but, as regards nearly half the prescriptions dispensed in London, the dispenser cannot be certain about their genuineness, and if a prescription written by an unqualified practitioner, say for *Acetum Cantharidis* or *Extractum Ergotæ Liquidum*, were dispensed by a pharmacist, and the medicine were used feloniously, would the pharmacist be actionable for supplying it? There ought to be a remedy for this, and I would suggest that each qualified practitioner should write his prescriptions on paper bearing his address, or some reference to the medical register, so that their authenticity could be ascertained and reference to the writer rendered comparatively easy, which is not the case at present.

WM. MARTINDALE.

10, *New Cavendish Street, W.*,
Sept. 1st, 1873.

"PRICE LISTS."

Sir,—Will you allow me a small space in your valuable columns to draw attention to a contemptibly low and mean practice carried on here through the medium of the price list?

A few days ago a woman called at our establishment with a prescription to get dispensed, and in handing it to me remarked that the doctor had recommended her to patronize Mr. ——, and had had it there three or four times, but supposed she could get it from me all the same. On examining the prescription I found it could have been dispensed by any chemist and druggist, as it merely contained bromide and iodide of potass. After dispensing it I stated that the charge would be 2*s.*, which was the price marked on the margin in the authorized characters of the price list, when, to my astonishment, she remarked that she had only paid 1*s.* 10*d.* for it before, at the same time adding that she had been told, on complaining of it being so expensive, that she would pay two shillings at any other shop. Now, sir, this is a very deplorable state of principles in our ranks, and more especially as the case in point emanates from a Pharmaceutical Chemist.

AN ASSISTANT.

Edinburgh, August 27, 1873.

Inquirens.—(1) Yes. (2) The new regulations of the Board of Examiners are to come into force after October 1, 1874.

"*A Registered Student.*"—Only Registered Students and Apprentices of the Society are eligible to compete for the Jacob Bell Memorial Scholarship.

"*Fidelio.*"—Several recipes for sauces were given in vol. i. of the present series, p. 1043.

J. Attenburrow.—Hypericum androsæmum.

S. H.—The expressed oil is meant, and the quantity printed—half a drachm—is correct.

"*Student.*"—See a note to Mr. Greenish's paper on Mustard (vol. iii., p. 783) respecting a pure article supplied by Messrs. Dewar, of Newcastle. We believe that unadulterated mustard is supplied also by Messrs. Sadler, Frith, and Ross, of London.

"*Inquirer.*"—We do not know of any published book upon the subject.

Errata.—In consequence of two misprints that occur in the letter from "One of Twenty Years' Experience," on p. 180, the following corrections become necessary:—col. i, line 19 from bottom, *for* "Acid. Sulph. ℥ ss." *read* "Acid. Sulph. ℥ jss."; line 5 from bottom, *for* "℥ j. tr. digital." *read* "℥ ss. tr. digital."

A. E. P.—(1) We cannot name this plant from the specimen sent, send another specimen, and mention locality where gathered. (2) *Aster Tripolium.* (3) *Suæda maritima.* (4) *Hydrocotyle vulgaris.* (5) *Cochlearia officinalis.*

"*Carte.*"—No such photograph has been advertised, but one might perhaps be obtained from Messrs. Maull and Polyblank, Piccadilly, or from the Royal Exchange Photograph Company, Cornhill.

R. H. C.—The 'Elements of Materia Medica,' edited by Bentley and Redwood, is an abstract of the original work by Dr. Pereira. We know of no other that has been published recently.

J. W. Ellis.—Stachys sylvatica.

T. M. D.—It is probably a misnomer for "oleic."

The following journals have been received:—The 'British Medical Journal,' August 30; the 'Medical Times and Gazette,' August 30; the 'Lancet,' August 30; the 'London Medical Record,' August 30; 'Medical Press and Circular,' August 30; 'Nature,' August 30; 'Chemical News,' August 30; 'Gardener's Chronicle,' August 30; the 'Grocer,' August 30; 'Journal of the Society of Arts,' August 30; 'Grocery News,' August 30; 'Produce Markets Review,' August 30.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. N. Moore, Mr. H. W. Howse, Mr. E. B. Storm, "Assistant," "Kilburn," E. W., W. E. G.

MATERIA MEDICA OF THE UNITED STATES' PHARMACOPŒIA.

BY E. M. HOLMES.

Curator of the Museum of the Pharmaceutical Society of Great Britain.

(*Concluded from page* 163.)

Demulcents.

Sassafras pith.—Two drachms of the pith to a pint of water forms a pleasant mucilaginous liquid which is used as a drink in catarrh and in irritation of the bladder, and as a lotion in ophthalmia.

Ulmus fulva. Slippery elm.—The inner bark is a favourite remedy in the United States, and is used for several purposes. It is a valuable demulcent and emollient. In a coarse powder it is used as a poultice to allay inflammation. In fine powder it is used to form a kind of gruel, or boiled with milk to form a nourishing food for infants. In mucous inflammations a drink formed by infusing the bark in water is found to be very useful. The taste of the bark resembles that of fenugreek seed, but is without the bitterness of the latter.

Viola pedata belongs to the secondary list. It possesses similar properties to the *Viola odorata.*

Emetics.

Euphorbia corollata. Large flowering spurge. The root bark possesses emetic properties in doses of 15 to 20 grains, but in large doses produces cathartic effects and sometimes inflammation of the mucous membrane of the alimentary canal.

Euphorbia ipecacuanha, or American ipecacuanha, resembles the last in its effects, but in a lesser degree, and is used for the same purposes as ipecacuanha.

In the Secondary List occur—

Apocynum androsæmifolium, or dogsbane, and *gillenia*, both of which resemble ipecacuanha in their action. The former is generally used in chronic liver complaints.

Diaphoretics.

Eupatorium perfoliatum. Thoroughwort, or boneset, as it is more commonly called. It is much used in colds, influenza and febrile diseases, to produce profuse perspiration. This is frequently accompanied by vomiting and relaxation of the bowels. Its action does not appear, however, to be attended with any injurious effects.

Sambucus canadensis is used in America for the same purposes as elder is used in England.

In the Secondary List are found—

Asclepias tuberosa. Butterfly weed, or as it is more frequently called, pleurisy root. It is a popular remedy for colds, etc., and possesses somewhat similar properties to boneset, but is of a much milder nature. It is said to have proved very useful in the treatment of prolapsus uteri, when mixed with half its weight of the root of *Aletris farinosa*, and given in drachm doses of the powder three times a day.*

Nervines.

Cimicifuga racemosa. Black cohosh. The special action of this drug appears to be to allay nervous irritability, and it has hence been used in a variety of diseases, more particularly in rheumatism. It should not be used when acidity of stomach is present.

In the Secondary List occur—

Cypripedium, commonly called American valerian, is used for the same purposes that *Valeriana officinalis* is in England. In conjunction with catnep and scullcap it is a popular remedy for neuralgia and nervous headache.

Scutellaria lateriflora.—Scullcap is by some authorities considered to be inert, and hence finds a place in the secondary list. By others it is highly esteemed as a nervine tonic and antispasmodic. In delirium tremens and in nervous excitability the infusion drunk freely is said to produce a calm sleep.

Rhus toxicodendron.—The leaves of the poison oak have been recommended as a nervous excitant in paralysis, but on account of the variable action and volatility of the active principle the plant is but little used.

Stimulant Carminatives, etc.

Gaultheria. — Gaultheria or winter-green. The leaves used to restrain chronic mucous discharges, and the essential oil as a stimulant and flavouring agent.

Hedeoma.—American pennyroyal is used for the same purposes as *Mentha Pulegium* or English pennyroyal. The oil of pennyroyal of American commerce is obtained from the hedeoma.

Monarda.—Horsemint is used in flatulence, vomiting, and urinary disorders, and as an emmenagogue.

In the Secondary List occur—

Asarum canadense.—Wild ginger.—It is used as a stimulant and carminative and as an adjunct to other medicines.

Solidago odora.—Sweet-scented golden rod is used as a stimulant and a diaphoretic, and the essential oil to remove nausea, and as a flavouring agent.

Tonics.

Coptis trifolia.—Gold thread is a pure bitter tonic of a similar nature to calumba and hydrastis. *Xanthorrhiza apiifolia*, which occurs in the secondary list, has similar properties, and like coptis owes its usefulness to the presence of berberine. It is singular that this principle, the occurrence of which in so many plants seems to point out its usefulness, should not have been brought into use in an isolated state.

Cornus florida.—Dogwood bark is an astringent tonic, useful in those cases in which quinine cannot be administered without causing unpleasant symptoms. It also acts as a stimulant and antiperiodic. When fresh the bark will sometimes cause griping.

Sanguinaria canadensis, or bloodroot, is a stimulant tonic. When administered in small doses it increases arterial action and stimulates the liver and digestive organs, but in large doses it manifests acrid and narcotic properties. It is chiefly used in torpid conditions of the liver. Externally it is sometimes used as an escharotic for fungous growths, in which it seems to restore a healthy action.

In the Secondary List occur—

Cornus circinata, or round-leaved dogwood, and *Cornus sericea*, a swamp dogwood. The former possesses similar properties to *C. florida*, while the latter is more astringent and less bitter. The infusion of *C. sericea* is stated to be very valuable in the sickness of pregnancy and uterine diseases.

Frasera Walteri or American calumba, and *Gentiana Catesbœi*, or blue gentian, are used in the same cases as the *Gentiana lutea* *Sabbatia angularis*, another gentianaceous plant, resembles our English

* King's 'American Dispensatory,' p. 143.

centaury in appearance and properties, and is hence known as the American centaury.

Liriodendron.—Tulip tree bark is possessed of stimulant and aromatic as well as tonic properties.

Magnolia glauca possesses antiperiodic and diaphoretic as well as tonic properties. It is sometimes used as a substitute for Peruvian bark in cases where the latter causes unpleasant symptoms.

Polygala rubella is simply a bitter tonic without possessing the acrid properties occurring in other species of this genus.

Prinos verticillatus.—The bark of the black alder, a shrub belonging to the holly family, is used as an astringent and alterative tonic in cases in which there is considerable want of vital power, as in gangrene, dropsy, etc. The decoction is also used as a lotion for gangrene and skin diseases.

For fuller information concerning the above remedies, the reader is referred to the American Dispensatory, to which work I am indebted for some of the information here given, more particularly that relating to the articles of the secondary list, many of which are not much used by the medical profession, although they are largely used in domestic medicine.

In conclusion it may be remarked that there are comparatively few remedies in the U. S. P. of a nature altogether different to those which are to be found in the B. P. Among those which may be said to have no representatives in the B. P. are gelsemium, sanguinaria, stillingia, helianthemum, castanea, and *Iris versicolor*. Hydrastis is perhaps peculiar in its tonic action upon the mucous membranes, although it otherwise much resembles calumba. Sassafras pith affords a readier means than is presented by any article of the B. P. of making elegant mucilage; and slippery elm has an advantage over linseed meal in not being liable to cause irritation.

The reduction in the number of processes given for preparations which have a definite chemical composition, and which cannot be advantageously prepared by the retail pharmaceutist, and the increase in the number of processes for essential oils, and articles which cannot be readily tested and purified and which are very liable to adulteration, is a feature to which attention might be called in this country. Obviously, the processes given are not very likely to be followed by wholesale manufacturers who have processes of their own which are better, or, at all events, more convenient. For the articles of which the purity and strength can be readily ascertained by the retail pharmaceutist, it cannot be considered absolutely necessary that this should be the case, and all other preparations are best prepared by the pharmaceutist himself.

TARTRATES AND CITRATES OF IRON AND THEIR AMMONIACAL COMBINATIONS.*

BY C. MÉHU.

The use of ferrous salts, so justly lauded in the present day, has induced me to publish the following experiments, which had for their special object the preparation of one of the most stable ferrous salts, the tartrate, and of two double salts of peroxide of iron and ammonia, the tartrate and citrate, in such a way as that they should have a constant composition.

* *Journal de Pharmacie et de Chimie* [4], vol. xviii. p. 85.

Ferrous tartrate ($C_8H_4O_{10}$, 2(FeO).*—To obtain this salt perfectly white, permanent in the air, and of a constant composition, I place in a flask nearly equal weights of small iron tacks or iron wire cut small, tartaric acid and boiling water, and boil the mixture regularly over a gentle fire. Hydrogen is abundantly disengaged, and little by little, a perfectly white gritty deposit appears, which at length gives to the liquid the consistence of soup. By repeated additions of distilled water the liquid is maintained at the same level. When a sufficient quantity of ferrous tartrate is formed, it is collected on a filter of white paper or calico and washed with boiling distilled water. The acid liquid which passes through is again poured upon the iron and heated, it being still very acid and far from exhausted. The last washings may be used in a succeeding operation to replace the water which evaporates from the flask. The ferrous tartrate, well washed, forms a white gritty mass, which is divided into tablets upon filtering paper and dried quickly in a moderately heated stove.

The precaution most necessary to observe is that the washing should be sufficient, for if the salt retain a little tartaric acid it acquires after a time a green or even yellow tint, in proportion to the acid remaining. It is necessary, therefore, to thoroughly wash it with boiling water. This washing might be effected also with alcohol, which disappears more quickly in the drying, and easily dissolves the tartaric acid, but its use would be costly and unnecessary.

The iron not being chemically pure, there occurs, especially at the commencement of the action of the tartaric acid, a separation of usually a very thin layer of black carbonaceous impurities, which is easily removed by filtration just at the point when the deposit of ferrous tartrate commences to manifest itself.

It would be incovenient to employ only the exact quantity necessary of metallic iron, even though well divided; a large excess of iron renders the operation more rapid. The product separates very well from the metallic mass, as it remains suspended in the liquid upon the flask being shaken, provided that the liquid be in sufficient quantity and the iron not in too small fragments.

When the acid liquid, in the midst of which the deposit of ferrous tartrate is formed, is exposed to the air, it turns yellow through absorption of oxygen, and ferric tartrate is formed. Upon boiling this solution upon metallic iron in great excess it is rapidly decolorized under the influence of the hydrogen disengaged by the reaction. If the acid liquor and the iron be left in contact without boiling, the ferrous tartrate and the metallic iron after a time form a solid mass, upon which the acid liquor gradually ceases to act. It is therefore important not to interrupt the boiling of the liquid.

The composition of ferrous tartrate, perfectly dry and white, corresponds to the formula $C_8H_4O_{10}$, 2(FeO), which gives 39·2 per cent. of anhydrous peroxide of iron. Direct analysis of the product dried in a stove at 100° C. gave 38·99, 38·90, and 38·95 per cent. of anhydrous peroxide of iron, amounts very near to that indicated by theory.

Ferrous tartrate is a well defined white salt, in very clear microscopic crystals; it may be preserved in

* Throughout this paper the old notation (C=6; O=8; Fe=28), which is that adopted by the author, has been retained.

closed vessels indefinitely, even in the light, without any necessity for special precautions. The salt has no tendency to oxidize if it contains no free acid ; I have kept it thirteen years without undergoing any sensible alteration. One of the least perfect specimens, exposed to the sun in an unclosed bottle became at length slightly reddened ; but imperfect washing and the influence of ammonia in the air were probably the determining causes of this slight oxidation. Water strongly acidulated with tartaric, citric, or acetic acid, or saturated with chloride of ammonium, does not exercise any perceptible solvent action upon ferrous tartrate, even with heat. Water acidulated with hydrochloric or sulphuric acid dissolves it rapidly, the solutions being nearly colourless at first, afterwards gradually becoming yellow. Nitric acid reacts in a similar manner, but its oxidizing action is more rapid.

Hydrochloric solution of ferrous tartrate turns to the right the plane of polarized light ; it acts similarly to a solution of ferrous chloride with tartaric acid added. Ammonia separates from this solution a white precipitate, which in the air immediately turns green.

Tartrate of Peroxide of Iron and Ammonia.—$C_8H_4O_{10}$, Fe_2O_3, NH_3, 2HO, dried at 100° C. Brought into contact with an excess of ammonia solution, the ferrous tartrate is dissolved with a very perceptible evolution of heat, the liquor taking a greenish colour, and gradually acquiring a thicker consistence. The mixture absorbs oxygen from the air to form the tartrate of peroxide of iron with fixation of water. With the citrate the absorption of oxygen takes place more slowly ; the liquid, at first green, appearing nearly black in the mass, turning yellow slowly. The compound can then be dried in the open air, it not being deliquescent. At first the ferrous tartrate dissolved in the ammonia forms a fluid solution ; this in proportion as it absorbs oxygen thickens and finally solidifies if it be not diluted with water, even in presence of great excess of ammonia. As soon as the oxidation is complete the liquid again becomes more and more fluid, until, when it has acquired the colour of caramel, it has nearly the fluidity of water. This is due to the formation of an intermediate tartrate only slightly soluble in ammonia, which may easily be obtained upon evaporation in green crystals ; it is not, however, a stable or a well defined product. The tartrate of peroxide of iron and ammonia obtained without heat from the ferrous tartrate is not deliquescent ; it occurs in transparent plates, very soluble in distilled water, insoluble in alcohol. Alcohol is not even coloured by contact with it, and precipitates it from a concentrated aqueous solution. It is also insoluble in ether.

Simply dried in the open air tartrate of peroxide of iron and ammonia so obtained yielded upon incineration 27·09 and 28·2 per cent. of anhydrous ferric oxide, the figures varying with the hygrometric state of the air. Dried under a glass over sulphuric acid the salt gave 29·58, 29·19, and 29·4 per cent. of anhydrous ferric oxide ; these figures corresponding to the formula, $C_8H_4O_{10}$, Fe_2O_3, $NH_3 + 5\,HO =$ 29·19 per cent. of ferric oxide. Dried at 100° C., until it ceased to lose weight, and then incinerated, it gave 32·68, 32·53, and 32·59 per cent. of anhydrous ferric oxide, corresponding to the formula $C_8H_4O_{10}$, Fe_2O_3, $NH_3 + 2\,HO = 32{\cdot}38$ per cent. of ferric oxide. The oxide of iron was calcined several times, with the addition of a few drops of nitric acid, to destroy all trace of carbon, until the complete cessation of loss of weight during a fresh calcination.

Tartrate of peroxide of iron and ammonia is usually prepared with bitartrate of ammonia and hydrated peroxide of iron. In the reaction of these two compounds in the presence of water the oxide of iron is gradually but very slowly dissolved. Beside the difficulty of preparing *pure* hydrated peroxide of iron, the process has the inconvenience that the length of time required with the bitartrate, or even with the saturated tartrate of ammonia, tends to drive off all the ammonia and eventually to give a tartrate of peroxide of iron.

Ferrous Citrate.—$C_{12}H_5O_{11}$, 2FeO + 3HO.—"Metallic iron," says Gerhardt,* "dissolves in citric acid with disengagement of hydrogen. The saturated solution, precipitated with alcohol, gives white flocks of triferrous citrate." When the action of an aqueous solution of citric acid upon reduced iron is exhausted, the filtered liquor added to two or three times its weight of alcohol presents scarcely any turbidity. If, on the contrary, the liquor is still very acid, the precipitate is more voluminous, flocculent, and white. This soft mass may easily be washed with lukewarm water ; exposed to the air it becomes green, then dark-green, and finally a blackish-green when dried at 100° C. By this method only a very small quantity of more or less oxidized triferrous citrate, mixed with varying proportions of biferrous citrate, is obtained. The product gives 37 to 39 per cent. of anhydrous ferric oxide, after being dried at 100° C. It dissolves freely in ammonia, and the solution appears to have a greater avidity for oxygen than that of the biferrous citrate.

By proceeding as for the preparation of ferrous tartrate, that is to say, submitting to prolonged ebullition in a glass vessel a mixture of equal weights of small tacks or iron wire, citric acid, and water, hydrogen is given off, and a ferrous citrate is obtained perfectly white, gritty, crystalline, dense, and particularly easy to separate from excess of iron. This salt can be collected upon a calico filter, and washed rapidly with boiling water ; but when divided into squares on filtering paper and placed in the stove it is more unstable than the ferrous tartrate. It is only by taking great precaution that this salt can be obtained dry and white.

Citric acid appears to attack iron more readily than tartaric acid. The crystals of ferrous citrate are larger than those of ferrous tartrate, which allows of their being more rapidly washed. They are also more soluble in water than those of the tartrate, but a hot saturated solution does not deposit crystals upon cooling. Alcohol scarcely precipitates a saturated solution of this citrate unless there be excess of acid. Direct sunlight colours the crystals red upon the surface, but the oxidation penetrates only a little way below the surface, and is also very slow.

This ferrous citrate is a citrate with two equivalents of metallic base ; its composition corresponds to the formula $C_{12}H_5O_{11}$, 2(FeO) + 3HO, which gives theoretically 30·3 per cent. of anhydrous ferric oxide. Incineration of four specimens of good white ferrous citrate, dried at 100° C., left 29·97, 30·0, 30·4, and 30·3 per cent. of anhydrous ferric oxide. It may be noted that in using the citrates too finely divided it is difficult to avoid during calcination a projection of some portions of the iron beyond the platinum cap-

* 'Chimie Organique,' vol ii., p. 99.

sule even when it is covered. The tartrates do not present this inconvenience, and it may be avoided by using the ferrous citrate and the citrate of peroxide of iron and ammonia in large fragments. The citrate also was washed with nitric acid and dried before each calcination.

The ferrous tartrate is a salt in which the acid is completely saturated by the ferrous oxide. The citrate just described is not completely saturated, since the citric acid is trivalent; hence the heat produced by the action of solution of ammonia upon ferrous citrate is much greater than that which results from the action of ammonia upon ferrous tartrate.

Citrate of Peroxide of Iron and Ammonia.—$C_{12}H_5O_{11}$, Fe_2O_3, $NH_3 + 3HO$.—Ferrous citrate dissolves immediately in solution of ammonia, with great evolution of heat. The liquid which is at first dark green, nearly black in the mass, rapidly becomes yellow at the edges. The liquid state favours oxidation; it is only necessary to spread the ammoniacal solution upon a flat surface and in two days its oxidation will be complete. Dried in the open air or in a stove it then gives fine scales of citrate of peroxide of iron and ammonia, of constant composition, perfectly soluble, and easily preserved. If the oxidation be incomplete the scales will have a green colour; this intermediate citrate preserves well but is ill-defined.

The citrate of peroxide of iron and ammonia absorbs atmospheric moisture rather freely; hence it gives variable proportions of anhydrous ferric oxide, unless the precaution be taken of carefully drying it. Perfectly dried in a stove at 100° C. it gave 27·80, 27·78, and 27·70 per cent. of anhydrous ferric oxide. The formula given corresponds to 27·681 per cent. of ferric oxide.

This method of preparation presents no difficulty, and avoids the long and troublesome process of preparing pure peroxide of iron, so difficult when operating upon large quantities; it also gives a product of constant composition, and easily preserved. The solution of the citrate of peroxide of iron and ammonia resists ebullition well. It may be concentrated at will, for the salt is soluble in water in all proportions: one part of water and two parts of citrate give a solution that has not even a syrupy consistence.

Rectified spirit dissolves only traces of citrate of peroxide of iron and ammonia; more concentrated alcohol is not even coloured by contact, and the salt remains pulverulent at the bottom of the tube. Employed in sufficient quantity alcohol precipitates it from its aqueous solution.

OLIVE OIL FROM TUNIS.

An important division of the regency of Tunis, called the Sahil, is very largely devoted to the production of olive oil, and therefore, as little information with regard to this part of the country has been presented to English readers, we may shortly describe it, in so far as the oil trade is concerned. The sandy, calcareous soil of the Sahil is very suitable for the growth of the olive tree; it is soft, loose, and easily turned, and if stones are met with in some places, they are merely upon the surface. A little wheat and barley is occasionally sown, but it is exclusively the olive tree which forms the true riches of the country. The number of olive trees, as given for the entire Sahil, is about 5,000,000, which should, taking the average production (although there is great variation in this respect), produce an annual average of 2,000,000 metals of oil, or in other words, upwards of 44,000 tons. It is stated, however, that with a little enterprise on the part of the inhabitants, the production might be very materially increased, as there are large spaces of good land remaining unemployed, and from which consequently no benefit is derived. In point of fact, as mentioned before, the real wealth of the Sahil consists in the oil trade. Its development took place some twenty years ago, when the duty of 10 per cent. upon the produce, so universal in Mahommedan countries, was changed to a fixed duty upon the tree. Before this wise change was effected, the native labourer, having to pay away a tenth of his crop, was comparatively indifferent as to the amount yielded by his trees.

Under the present system, however, not only have the old and profitless trees been replaced by young fruit-bearing ones, and the sites more judiciously chosen, but a more equal distribution of property has ensued, by inducing land-holders to part with their lands. Indeed, the salutary consequences arising from this measure were rendered manifest by the results of the years immediately following its introduction. The duty, or kanoon, as it is called, varies, according to the tree, from 1½*d.* to 3*d.* From an official report for the year ending July, 1872, we learn that the revenue from this duty amounted to over £11,000, while another advantage of the new system is, that it yields the State a fixed, instead of an unknown and variable revenue, resulting from the uncertainty of the crops. In regard to the culture of the olive tree, the worst enemy against which it has to contend is the drought, and this unfortunately occurs with great frequency, inasmuch as the absence of natural springs renders the province entirely dependent upon the rains. The first of these are the winter rains, which predispose the trees to an abundant florescence; the spring rains force the fruit, while any subsequent falls assist in filling it out. Occasionally it happens that some of these periodical rains are wanting; at others, that they are all withheld, the latter having been unfortunately the case during the last three or four years, when the crops were reduced to a fourth, and even sixth, of an average yield. Considering how greatly dependant the native of the Sahil is upon these rains for the fruit of his trees, it is very unsatisfactory to find the great disregard he manifests in the way of guarding against the evils caused by a want of rain. He rarely loosens the earth around the base of the roots, to enable them to imbibe the atmospheric moisture of the nights, nor does he train them, as he might do, horizontally, to screen the roots, by means of the foliage, from the parching effects of the summer sun.

It may be interesting to shortly describe the *modus operandi* adopted in Sahil in the manipulation of the oil. The olives are gathered in the months of December and January, those who gather them having leather or horn casings on the fingers, and the fruit is collected on mats or on cloths spread around the trunk of the tree for that purpose. There are two kinds of oil—the masri, which is strong in flavour and smell, and the drub-el-ma, which is deprived of both by being passed through water. The mills, however, are rudely constructed, and very imperfect in their operation, the result of which is, that a great deal of the oil is not pressed, and consequently passes off with the refuse. In addition, the process is attended with a great deal of waste, and the presses certainly require improvement. They are composed of round blocks of stone, from three to four feet long, revolving on an axis fixed horizontally to a vertical stake, and put in motion by a mule or camel. By this roller the olives are crushed into a sort of paste, which for the drub-el-ma is precipitated into water, whereon the oil floats from the difference of its specific gravity, and is skimmed off. If the masri oil be required, this paste is submitted to pressure. After the extraction of the oil, the residue, which is called fittura, is given to camels. The purchases of the oil from the producers are effected by means of semsars or brokers, with whom the oil merchants contract for future delivery, and at prices mutually agreed upon. As the payments are always made in cash, the merchants are frequently

obliged to make heavy advances. In these transactions the system of advances in anticipation of a non-existent article cannot fail to be attended by considerable risk, to cover which the parties who make the advances can only afford to offer the lowest prices, and find it necessary to charge heavy interest. These transactions, in fact, are merely loans of money for a return with interest, in produce, when instalments become due. If the crops fail, the contract is renewed for the following year, after altering the conditions, to the advantage, in most cases, of the creditor rather than the debtor. For brokerage, 1 per cent. is charged, and the vendor pays the governmental duty of ½*d.* per metal of oil. Forty-five metals are equal to one ton.

According to official statistics published on the subject, it is calculated that during the past five years £300,000 worth of olive oil left the shores of Tunis, of which Great Britain took one-fifth, the rest being divided between France and Italy. Freights direct to the United Kingdom now range from 40*s.* to 50*s.* per ton, but for the latter rate vessels call at Italian ports for casks to contain the oil. It is only within the last few years that shipments have been made direct to ports in the United Kingdom, up to which period British trade was limited to the Island of Malta, and results show that it amounted, on an average, only to an annual value of about £20,000 for exports, and considerably less for imports. France and Italy, it is said, can always compete successfully with Great Britain in the oil trade of Tunis, as the demand for the article in the former countries is permanent, and the cost of transport much lower. It appears that the cost of the oil free on board is about £33 per ton, to which must be added the cost of casks, £2; freight, say £2; landing expenses, insurance, etc., 35*s.*, bringing up the total cost in London per ton to nearly £40.

THE ACTION AND RELATIVE VALUE OF DISINFECTANTS.*

BY J. A. WANKLYN.

If we heat the infectious material of, for instance, scarlet fever to a red heat, we destroy it. There can be as little doubt that, if we bring chlorine gas thoroughly into contact with infectious material, we destroy it likewise. If we boil it with oil of vitriol, or with permanganate of potash, we destroy it. Probably, too, if we soak it in concentrated carbolic acid, or treat it with excess of corrosive sublimate or arsenious acid, we render it inert. It is, indeed, highly probable that every kind of infectious material is capable of being rendered inert by thorough contact with any powerful chemical reagent.

But if the heat be only gentle, and if the chemical reagent be dilute, there is absolutely no reason for believing that, by the employment either of the one or of the other, we are so much as contributing towards the destruction of infection. There is a difference not only in degree, but even in kind, between the action of the same chemical when concentrated and when dilute. Concentrated sulphuric acid will convert cane-sugar into a lump of charcoal, but dilute sulphuric acid transforms it into dextrine and glucose, and, curiously enough, fits it for undergoing septic changes. So, again, very dilute bleaching powder has actually been found to favour the development of certain low forms of life; and Pettenkofer, as is well known, has found that germs whose development had been arrested by carbolic acid, start into life when the carbolic acid is still further diluted.

In the practical employment of disinfectants, the fact that dilution frustrates the action of a disinfectant has been very generally lost sight of. Attempts have often been made to disinfect the atmosphere. It is even said that, during the panic occasioned by the cattle-plague, the commissioners endeavoured to disinfect the general atmosphere of the agricultural districts by turning cattle adrift with towels soaked in carbolic acid attached to their horns. I need not insist on the futility of such a proceeding; or, indeed, on the necessary futility of any effort to eliminate anything by chemical means from the general atmosphere covering our fields or occupying our streets. But it will probably not be quite needless to insist upon the impracticability of attacking the very limited atmosphere of a dwelling-house by chemical means. Certain very simple considerations will, however, suffice to throw the utmost doubt on the utility of endeavouring to purify air which has suffered contamination.

In a well-known official memorandum, drawn up, I believe, by Professor Rolleston of Oxford, directions are given for the disinfection of a room with sulphurous acid. So much sulphur (the quantity proportionate to the size of the room) is to be burnt, and doors and windows are to be shut; and the memorandum winds up with the statement that, if a man be able to abide in the room for one instant whilst the disinfection is being carried on, then the disinfection is not to be depended upon. In other words, it is admitted that, not until you have put so much sulphurous acid into the air as to make it totally unfit to breathe, have you disinfected that air. The same certainly holds generally in regard to other agents; and, in short, we cannot hope to purify the air of a room by any chemical means without spoiling the air. It is therefore useless to try to disinfect the air. This is strikingly illustrated in reference to printed directions relative to the practice of disinfection. See, for instance, Dr. Wilson's little card, 'Disinfectants and how to use them.'

"Chlorine gas, poisonous and irritating to the lungs when in excess. For an occupied room, close fire-place windows, etc., as directed under F. Pour over a quarter of a pound of black oxide of manganese in a dish placed high half a pint of muriatic acid (spirit of salt), and leave for six hours. It bleaches, and is apt to make white-limed walls sweat—useful for cabs."

Now if we take a room, say 13 feet by 13 feet and 13 feet high, or of a capacity of about 39 cubic metres (and that is not a very large room), and if we calculate what proportion by weight the chlorine liberated by the quarter of a pound of oxide of manganese will amount to, we get about 3 parts of chlorine in 1000 parts of air. In point of fact, however, the proportion of chlorine in the atmosphere of such a room would never reach anything like 3 per 1000, inasmuch as walls are not impervious, and during the six hours the air would have changed, and 3 parts per 10,000 would probably be nearer the true proportion. But this is the room not fit to inhabit by reason of the presence of chlorine. The minuteness of the dose of chlorine which the inhabited room receives may be left to your imaginations. To me it seems that the wisdom of the physician who places his little saucer with bleaching powder and muriatic acid in the chamber of his patient, is comparable with that of the cattle-plague commissioners who tied the carbolized cloths to the horns of the cattle.

Experience confirms that which an appeal to first principles suggests; and we are informed that, during the Franco-German war, although the hospitals stank of carbolic acid, yet wounds were not healthy. Although I believe that the purification of air which has once been defiled is a hopeless task, yet it by no means follows that disinfectants have nothing to do with purity of atmosphere. It is open to us to abstain, in a very large degree, from rendering the air impure.

By the efficient application of disinfectants to foul surfaces, we may hinder defilement of the atmosphere of our dwellings. One of the main functions of a serviceable disinfectant is that it shall be antiseptic; that it shall postpone decomposition and putrefaction until a convenient season. A good disinfectant should not itself defile

* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in London, August, 1873, and printed in the *British Medical Journal*. The discussion upon this and the following paper will be found at p. 213.

air, neither should it be dangerously poisonous or corrosive. There is a very common substance which has long been used to hinder putrefaction. It does so only in a concentrated form. It has no smell; it is not poisonous. It can hardly be said to be corrosive. Its name is common salt. I hold that this substance and its analogues—the chloride of calcium and the chloride of magnesium—are the most available general disinfectants.

THE MODE OF DISINFECTING BY HEAT.*

BY W. H. RANSOM, M.D., F.R.S , F.R.C.P.,
Physician to the General Hospital, Nottingham.

As it is my desire to treat this question as a practical one only, I assume assent to the proposition that heat is a disinfecting agent of so much value as to justify public authorities in spending money to secure the necessary mechanical appliances. To this I venture to add, as an opinion which will, I think, receive general assent, that heat is, for a certain group of things, the best and almost the only known trustworthy disinfecting agent. Nor can I here, without violence to the memory of an able man who has passed away—I mean Dr. Henry of Manchester—omit to point out that almost all our knowledge of the facts upon which we rest the proposition to which I have assumed your assent is due to that gentleman. He alone, so far as I know, has had the courage to make the experiments so much needed ; and he has apparently proved that a temperature of 200° F., continued for not less than one hour, destroys the activity of the virus of scarlet fever.

My attention was first drawn to this matter about eight years since, when, being asked by a public body to advise them as to the best form of hot closet for disinfecting purposes, I was unable to find any one in use which I could recommend. I therefore commenced some experiments with the view of suggesting a pattern to be tried ; but the engineer who then kindly assisted me died, and the matter was put aside until 1870, when the occurrence of scarlet fever in my own family recalled my attention to this urgent public want.

Experiments made at home in 1870 with a hot closet, having a capacity of about twenty-five cubic feet, constructed upon the oven principle, heated by gas outside, and having its surfaces partly covered by a hot-air flue and partly backed with non-conducting material, led me to the conclusion that this form of hot closet could not be recommended. I was, however, enabled from these observations to form provisional opinions as to the temperature which might be safely used, the time that goods should be exposed, the need for ventilation in such a chamber, etc. I will not take up your time by stating in detail the results of these experiments, because, from the imperfection of principle in the closet, very few of the results were sufficiently exact. However, I found that clothes and bedding might be exposed to a heat of 250° to 260° F. for an hour and a half in such a chamber without much injury. As chambers made on this principle are much used, I will here briefly state the imperfections which were found out in working.

a. The chamber cannot be long maintained at a steady heat, however carefully you attend to the adjustment of the gas-tap ; and, were it heated by coal, I cannot think it could be so well regulated as by gas.

b. The temperature varies enormously in different parts of the chamber at the same time.

c. Being imperfectly ventilated, its drying power is insufficient, and the heat therefore penetrates slowly into the interior of beds, etc.

I decided, therefore, to endeavour to construct a new one, which should fulfil the following conditions.

1. The temperature should at all times and in all parts of the chamber be within certain known limits ; and it should be plain at a glance that they are not exceeded ; the maximum being determined by the singeing-point of the materials of clothes and bedding, and the minimum lying as close as possible to the maximum, but always ten or twelve degrees above 212° F. Thus one might feel assured that clothing put into such a chamber really was exposed to a sufficient heat, and yet not injured by too much, which would seriously deter the public from using it.
2. The temperature should be easily maintained within the required limits, for periods of time sufficient to ensure adequate penetration of heat into the interior of bad conductors, such as beds, etc.
3. The chamber should have a current of heated air passing through it, so as to favour penetration of heat by drying.
4. It should be so moderate in cost and so simple in use, that small institutions might avail themselves of it, and a fairly instructed nurse manage it.
5. It should be self-regulating.

Accordingly, in the winter of 1871-2, a hot closet was erected, under my directions, at the General Hospital, Nottingham, which to a great extent did what was desired to be done. In this contrivance, the heat is obtained by burning gas with smokeless flames, and conducting the products of combustion, mixed with the heated air, by means of a short horizontal flue, into a cubical chamber through an aperture in its floor, and out of it by a smaller aperture in its roof. Fixed thermometers show the temperature of the entering and outgoing currents, which represent the maximum and minimum temperatures of the chamber. A self-acting mercurial regulator, adapted to this stove from Kemp's regulator, maintains the temperature of the entering current at any required degree. A thick jacket of felt and wood economises the heat, and makes it steadier. A valve at the outlet of the chamber, together with another at the inlet of the furnace, enables the maker to regulate once for all the speed of the current passing through the chamber—an item of great importance in the endeavour to keep the temperature of the outgoing current as high as possible. To this, if it be desired, may be added a conical short chimney at the outlet, in which three or four small fish-tail burners may be lighted. By this method any active particles of poison which might, in the earlier moments of the operation, be carried up in the current, would be burned. Dr. Henry anticipated objections of this kind, and used in his apparatus a similar contrivance to that which is now employed in Fraser's disinfecting closet.

For about a year and a half this closet has been in use with but few interruptions, and, I think I may venture to say, has rendered important services to the hospital, especially during the recent prevalence of small-pox, when a number of cases were admitted to our fever-house. Whenever the fever-house is occupied, the hot closet is at work night and day, and ready at any moment for use. The sister in charge managed it without difficulty after a little instruction which I gave her. Although it has a cubic capacity of twenty-five feet only, and is chiefly used for the clothes of patients, it has sufficed to disinfect blankets and the contents of beds and pillows. Its average consumption of gas is nine cubic feet an hour, at a cost, assuming gas to be 4*s.* per 1000 feet, of 6*s.* a week, counting seven days a week, and twenty-four hours a day.

Records of its work have been kept, showing the maximum and minimum temperature, the consumption of gas, and the pressure of gas at various hours. From these I am able to say that the heat can be maintained for weeks at a stretch without any greater diurnal variation than 5° F., which is usually due to the increase of pressure at the gas-works in the evening.

The average reading of the maximum thermometer is 250-5° F. ; that of the minimum is 232° F., which I should like to see 10° F. higher. Nor do I doubt the possibility of making it so in any future closet which may be erected upon this plan.

* Read before the Public Medicine Section at the annual meeting of the British Medical Association in London, August, 1873, and printed in the *British Medical Journal*. The discussion upon this and the preceding paper will be found at p. 213.

Thus, it may be said the five conditions stated as desirable have been fairly well fulfilled by this stove. When a large experience shall have taught us more, I do not doubt that much better results may be achieved by improvements in the details of the construction of hot closets on the principle now described.

The chief advantages of this closet are, its moderate cost, its efficiency, cleanliness, constant readiness for use; its capability of being managed without the cost of an engineer or stoker by an intelligent nurse; and the facility which it offers for maintaining a steady known heat for the length of time necessary to ensure deep penetration into bad conductors.

The only disadvantages which I have noted are: (*a*) The necessity of having occasionally (perhaps four times a year) the services of an intelligent workman to look at and adjust the heat-regulator if necessary; (*b*) The action, which I think is occasionally though rarely seen, of the acid products of combustion upon some of the most delicate colours. This I will show you, and you will see how trivial it is. It would not be difficult to overcome this objection.

Before proceeding to draw up a card of instruction for the guidance of the sister in charge, I thought it prudent to repeat observations by the acid of this chamber on the singeing point of various textile fabrics, and on the time required for penetration of heat into beds, etc. First, as to the singeing point; here are tables recording these observations, not yet complete. I will sum up the results, so far as I have gone.

White wool, cotton, linen, silk, and paper, may be heated to 250° F. for three hours without apparent injury, although the wool will show a faint change in colour, especially when it is new. Perhaps this change is not more than the change which new white flannel undergoes when it is washed. The same may be said of dyed wools and printed cottons, and of most dyed silks; but there is one kind of white silk which easily turns brown by this heat, and pink silks of some kinds are also faded by it. The same or even slightly lowered temperature will, if continued for a longer period—seven or eight hours—slightly change the colour of, but not injure, white wool, cotton, silk, paper, and grey linen. A heat of 295° F., continued for about three hours, more decidedly singes white wool, and less so grey and white cotton and white silk, white paper, and linen, both grey and white; but does not, I think, injure their appearance materially. The same heat continued for about five hours, singes and injures the appearance of white wool, and cotton, grey linen, white silk and paper, some coloured fabrics of wool, or mixed wool and cotton, or mixed wool and silk.

These observations confirm the conclusion drawn from the previous one—that 250° F. was the best and most safe maximum heat to use. It is interesting to observe here that Dr. Henry (see foot-note in *Phil. Mag.*, vol. xi., p. 22) had ascertained that cotton would resist this temperature. I was not aware, however, of this until the spring of this year.

It is noteworthy that the singeing of any fabric depends not alone upon the heat used, but also on the time during which it is exposed; and is influenced by the presence of other articles in the stove capable of giving up moisture. The maximum temperature, which I find best for general purposes,—viz., 250° Fahr.—does not weaken the strength of cotton, silk, wool, or linen threads, even when continued for about eight hours; neither does it, so far as my experiments go, lessen the strength of textile fabrics composed of these yarns. This statement, however, refers only to articles which have been left aside long enough to have reabsorbed their normal hygrometric moisture. A temperature of from 293° to 300° F., continued from three to five hours, weakens the strength of cotton-thread; probably also that of linen to a less degree—not silk, and not wool. But the fabrics composed of woollen yarn become dusty, and, I should think, would be weaker after washing. Neither they, nor yet linen fabrics, as in bed-ticking, are demonstrably weakened by this heat.

Turning now to the difficult question of securing the penetration of heat into the inside of beds, etc., I must again notice that Dr. Henry states that this is only a question of time; and so, in the main, I find it to be by observation. The accompanying table, abstracted from my notes, will show this. But the penetration of heat depends not only upon the time of exposure, but also upon the thickness of the bed, the amount of hygrometric moisture it contains, the nature of the materials of which it is composed, and perhaps also their degree of compression, as well as on the temperature used. These conditions have to be borne in mind in working any disinfecting chamber.

No	Name, thickness, and condition of sample.	Heat used. deg. F.	Time heated.	Results. Heat of inside deg. F.	Loss of weight.	Singed or not.
1	Horse hair pillow, 5 in. thick; normal moisture	251-262 2 operations	8 hours	247	1-10th	Not.
2	The same, nearly dry	247	2⅔ ,,	221	1-40th	Not.
3	White blanket folded in 24 layers, 4½ in. thick; moist	248	6⅔ ,,	214	1-12th	A little; not injured.
4	Feather pillow, 5 in. thick; moist	241	7⅔ ,,	232	1-10th	Not.
5	Flock pillow, 5 in. thick; moist	237-245 2 operations	23 ,,	252*	1-10th	Not.
6	Horse-hair pillow, very moist, 5½ in. thick.....	293	3⅛ ,,	178	1-8th	Singed; injured
7	The same, much dryer	296	4¾ ,,	296	1-17th	Ditto
8	Flock pillow, 5½ in. thick; moist	293-300 2 operations	10½ ,,	280	1-10th	Ditto

A SUMMER DAY'S DISCOURSE.†

BY THE REV. W. C. GANNETT.

What would the spring be without the flowers! And yet a spring with flowers is a modern improvement. For ages and ages, through far the greater part of its life thus far, a flowerless earth turned its sombre face up to the sun. It had not learned to smile. All winter we warm ourselves with the ancient sunshine of springs and summers in the far-off past that made the trees that make our coal-beds. But the spring-times of those carboniferous ages had no flowers, no fruit-blossoms, no grass, and of course no bees, and no song-birds, in them! All the plants, the wise men say, were like our ferns or our club mosses, or our meadow horse-tails, only they "were giants in those days," or else, like our cone-bearing trees, all reproducing in the secret way the ferns still know, or the quiet way the pine cones have. Not till long, long ages afterwards did the earth bear blossoms.

Thinking of that, we cannot say "The good old times!" We thank Heaven that the birds and flowers came before us. Indeed, the earth had to be ripe for them before it

* Perhaps an error in instrument. The inner and outer thermometers in this case may be taken as equal.

† Abstracted from a sermon preached at Boston, Massachusetts, and quoted in the *Gardeners' Chronicle*.

could be ripe for us. So here we are to-day, and the whole land is laughing for us—laughing in grass and flowers. Great tribes of beings have been already born, and others are on their way into existence, to people the planet again with colour and beauty.

What place on it shall have the fairest? Where will the Great Gardener walk and work most fondly? On the broad stretches of prairie-floor paved with gay mosaic? Or in the secret places of the woods? Or on the tiny farms that hardly seem to dot the New England landscape, although Massachusetts is the crowded corner of America? No, none of these; for Dr. Hayes says he never saw such beautiful wild flowers as he found in the Arctic zone, where the summer is almost counted by hours! And Ruskin, with his mountain-love, claims the noblest for the uplands. The grass grows nowhere softer and greener than on the alpine pastures; and set out of the glaciers, nestled by eternal snows, rise rocks whose bright tops are gardens of anemones and gentians; while the lovers of the ocean tell us that nowhere do the colours glow and deepen as they do where the sea winds feed them. The reddest wild roses I ever saw grew out of the graves of the old Puritan ministers of Marblehead—who lie ranged in a row among the rocks of the seaward burying-ground. Or what think you of the great central plain of California in flower time? For six months of the year it is a scorched and dust-swept desert. In April it becomes one flower-bed nearly 400 miles long and 30 wide, set there under the snow mountains. A traveller writes of it: "Go where I would, east, west, north, south, I still plashed and rippled in flower-gems. More than a hundred flowers touched my feet at every step, closing above them as if I were wading in water." To count the riches he gathered the harvest of one square yard of plain, taken at random like a cupful of water from a lake, and it gave more than 7000 distinct flower-heads, besides 1000 stems of silky grasses, these rising from an inch-deep velvet floor containing by estimate a million of the tiny cups and hoods that we call mosses. What barns God has!

Where, then, is the place of the fairest, seeing that all eyes claim it for their own? Nay, which one of all these children of the sun is fairest? Thoughts about beauty turn into poetry of themselves. And one can hardly think about flowers without twining his words with verse. Let me quote, at least, this one delicate answer to our question—Which one is the fairest?

"The Daffodil sang, 'Darling of the sun
Am I, am I that wear
His colour everywhere!'

'The Violet pleaded soft in undertone:
'Am I less perfect made,
Though hidden in the shade
So close and deep that heaven may not see
Its own fair hue in me?'

"The Rose stood up full-blown,
Right royal as a queen upon her throne:
'Nay, but I reign alone,'
She said, 'with all hearts for my own.'

"One whispered with faint flush not far away,
'I am the eye of day,
And all men love me;' and with drowsy sighs
A Lotus from the still pond where she lay
Breathed—'I am precious balm for weary eyes.'

"Only the fair field Lily, slim and tall,
Spake not for all—
Spake not, and did not stir,
Lapsed in some far and tender memory.
Softly I questioned her,
'And what of thee?'

"And winds were lulled about the bended head,
And the warm sunlight swathed her as in flame,
While the awed answer came—
'Hath He not said?'"

The flowers are children of the sun, I said. Literally so. The sun makes these as actually as it makes the clouds. It is sun-stir, that motion in the earth-atoms which continually unbuilds and builds them up anew. All things take part in the great circulations of the system. It is heat and light that organize the minerals into root and stem and leaf, and then green leaf still higher into flower organs. Emerson's verse holds simple fact:—

"Heat gives the reed and lily length,
Adds to oak and oxen strength."

Earth and sun—it takes them both to make a clover head! And the flowers show their kinship with the sun by waiting on it punctually. As he takes his station in the heavens above, they take theirs in the fields below. Spring is spring for each flower separately, and the gay procession of life marches on in order. We can predict the coming banners. We can date the passing weeks by flower arrivals and departures—can count the quick hours by flower-wakings and flower-closings.

But without thinking of these upper sympathies that possess the little souls of our dumb spring angels, what a marvel is each one in itself, in its own make and stature! Think what the mathematics of the leaf-arrangement imply—that every leaf on every budding tree in Massachusetts, in this whole spring, is set in place by law! that not one has stumbled to its twig, or to its station on the twig, by any accident! and that this same ordered stationing can be traced all through the close phalanx of the pine cone's scales, and determines where the limbs shall start on every tree, and the very spot within the blossom where each stamen shall droop or nod.

That last word touches the greatest flower secret that has thus far been discovered. The high-school boys all know it now, but the wisest men were just high enough a century ago to guess it; and its outcome, the thought involved in it, has rechristened all our modern science. It is the secret that the botanists call metamorphosis, but, in its grander name, transfiguration, evolution—the secret that every organ of the flower is but a transformed leaf; that bud-scale, bract, and sepal and petal and stamen and pistil, back to the new bud-scale, in spite of all the differences of their forms and all their various tintings, are but successive leaf-transfigurations. Economic Nature gets her new effects, not by selecting new themes, but by playing variations on the old themes; and when she makes a blossom on an apple tree or on a pasture weed she only shortens and alters what would else have been a common leafy branch. How do we know it? By tracing the cousinship of each pair of neighbour organs through graded series of transitional forms; by watching the conversion and the reconversion of these organs into each other in domesticated double flowers; by studying the cases of monstrosity that so often blab Nature's riddles, and reveal the latent tendencies of beings. On such full evidence as this we know it. But, not content with such transfiguration, the mother of all beauty takes up the separate organs and tenderly carries out her variations on each one. She bears fixed laws in mind, and never really forgets her arithmetic—the rules of twos and threes and fours and fives; but by multiplying parts, by dividing parts, by joining them at this place on their edges and then at that, by enlarging some and making others smaller, by their complete abortion sometimes, by moulding horns and cups, by unfurling wings, by hanging bells and ravelling fringes out, by all sorts of dainty devices of sculpture, she makes the myriad distinct species of miracles that men stare at untiringly as the flowers of spring. It is rare luck, in some old classic land, to turn up from the soil the fragment of a marble statue of old beauty. But Nature, she flings her carvings everywhere above the ground—each one complete and fresh and perfect in its niche, and such a joy that were it the lone one of its race it would draw the nations into pilgrimage for its worship.

(To be continued.)

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 13, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

MEDICAL DRAGOONING.

THE victorious vote which the *pharmaciens militaires* have recently secured in the French Academy of Medicine has an interest for every pharmacist whose professional sympathies extend beyond the threshold of his own pharmacy. Not only is it gratifying to the *esprit de corps*, but it shows that—at least in France—below the superficial literary fussiness which in some medical quarters seems to find its highest gratification in expatiating on the duties of pharmacists, there is a much larger—though quieter—substratum of medical gentlemen who think that pharmacists are not in need of this *quasi*-paternal government.

The circumstances of the dispute, which are referred to in greater detail at p. 212, are briefly as follows. The corps of *pharmaciens militaires* has existed in France for the last eighty years, and during that time has constituted a parallel but independent section of the health service of the French army. Its officers, from aides-majors of the second class up to inspectors, exactly correspond with the officers similarly named in the medical service, and like them they rank in the army from sub-lieutenants to generals of brigades. All fresh privileges accorded to one section have been equally given to the other. Until the year 1852 another section of the health service had also existed, namely, the surgeons, similarly constituted and equally independent. But in that year the medical and surgical sections were incorporated, their members without distinction being entrusted with the practice of medicine and surgery.

It will not be matter of surprise to hear that more than once during these eighty years members of the medical section of the health service have been dissatisfied with the independent position of the military pharmacists and have attempted to relegate pharmacy to a subordinate position in the service. The latest attempt was made in 1870, when the general impulse to retrieve the position of the country by a general reconstruction of existing organizations reached the health service of the army in such a form. The question was first sent to a mixed commission, and upon its failure to come to a decision the Minister of War, GENERAL DE CISSEY, applied for advice to the Academy of Medicine. The questions which he submitted for consideration were the following:—(1) Should the pharmaceutical service be incorporated with the medical? (2) Ought the pharmaceutical service to be subordinated to the medical? At first the conclusion appeared to be a foregone one, and such was the temper of the medical majority of the committee to which the Academy referred the matter, that the minority of pharmaceutical members thought its dignity would be best consulted by retiring before a report was made and appealing to the entire body. The reporters recommended that the two sections should not be fused together; that the health service should be placed under the direction of a chief chosen from its members; and that as the *logical consequence (!)* of the autonomy of the health service pharmacy should be subordinated to medicine.

Fortunately, the cause of the pharmacists fell into the able hands of Messrs. POGGIALE, BUSSY, DUMAS, and BOUDET; and equally fortunate was that it these were able to point to the past history of the service, so rich in names famous in pharmaceutical and other applications of science. Taking their stand upon the broad fact that medicine and pharmacy require different qualifications in their followers, they asserted that there was nothing in a medical education that would ensure qualification to practise pharmacy, except in a most perfunctory way, and certainly nought to enable a medical man to act as a superior pharmaceutical officer. The appeals were eloquent and forcible—we regret that we shall only be able to give an outline of them—and the Academy acknowledged their justice in rejecting the proposition for the subordination of pharmacy by a large majority.

So much for the position accorded to pharmacists by medical men in France! We enjoy the conviction that in this country the bulk of medical men look upon them in quite as favourable a light. But the fact cannot be disguised that too often there is an offensive assumption of superiority. Only recently a gentleman whose name is not unknown to pharmacists, asserted that "the chemist is bound by every rule of law and right to strictly obey the physician's orders," and that "it is not optional for him to say he is not bound by law to put up a prescription." And this in the face of every day experience, and the fact that the pharmacist is specially examined as to his capability for recognizing unusual doses. Surely such assertions may be classed with his widely advertised indignation that any one should presume to speculate concerning the composition of a certain proprietary medicine. Too frequently also, when it is intended to prescribe a dose that *ought* to raise the pharmacist's scruples, no intimation is given that it is not an oversight, and it is then held to be the pharmacist's duty, at any inconvenience, to discover the name of the—possibly obscure—prescriber, and communicate with him. Surely common courtesy would dictate some better arrangement than this, for it cannot be supposed that these doses are prescribed without some consideration. As to the spurious indignation that has been vented respecting the alleged censorship of pharmacists, M. POGGIALE refers to a very suggestive incident, where a patient

was poisoned *in spite of* the pharmacist's remonstrances.

The dignified assertion in France of the right of the pharmacist to be considered a scientific man, and one qualified to render independent service to his country by his special scientific training, has our heartiest sympathy. In this country, the circumstances attending the initiation of the Adulteration Act developed a similar spirit, and, so far, the result has amply justified the position taken. Then, as recently, there was a display of medico-literary assumption quite disproportionate to the real feeling of the profession upon the matters discussed; and it is our opinion that if the propositions so dogmatically propounded could have been submitted to the vote of a really representative body, they would, as in France, have been rejected by a large majority!

THE BRADFORD MEETING.

BRADFORD will hardly have recovered from the excitement attending the opening of the new town hall, before her scientific visitors will commence to arrive, in anticipation of the Annual Meetings of the British Association and the British Pharmaceutical Conference, which are to be held there next week.

The Conference meetings are first in order of date, and will commence on Tuesday morning, at 10 a.m., in the Lecture Hall of the Church of England Literary Institute. On Tuesday evening the members and their friends will dine at the Victoria Hotel. On Wednesday morning, the Conference will reassemble at 10 a.m., and the proceedings will terminate on Wednesday afternoon. After the reading of the Report, and other preliminary business, the President, Mr. H. B. BRADY, F.C.S., F.L.S., will deliver an address. This will be followed by the reading and discussion of papers, and among those promised are the following :—

1. Unusually Large Doses in Prescriptions : should they be distinguished by Signs, and by what Signs. Mr. R. HAMPSON, Mr. H. WHITFIELD.
2. Urinary Examinations in General, and the Tests for Albumen and Sugar in Particular. Mr. L. SIEBOLD.
3. Amount of Calcic Oxalate Excreted in Oxaluria. Professor ATTFIELD.
4. Composition of the Air of Sewers and Drains. J. J. NICHOLSON, F.C.S.
5. Commercial Sulphate of Copper. W. W. STODDART, F.C.S.
6. Ammoniacal Salts, and their Usual Impurities. ALFRED PAYNE, F.C.S.
7. Pharmaceutical Notes : The Preliminary Examinations.—The Medical Profession.—Pharmaceutical Titles. Mr. R. S. ATKINS.
8. Absence of Morphia in the Petals of *Papaver Rheas*. Professor ATTFIELD.
9. Further Experiments on Nepaul Aconite, and on the Characteristics of the Aconitines. THOMAS B. GROVES, F.C.S.
10. A New Test for Morphia. Mr. L. SIEBOLD.
11. New Derivatives from Morphine and Codeine. Professor C. R. A. WRIGHT, D.Sc.
12. On the Essential Oil of Orange. Professor C. R. A. WRIGHT, D.Sc.
13. On the Essential Oil of Nutmegs. Professor C. R. A. WRIGHT, D.Sc.
14. Report on the Purity of Commercial Specimens of Official Acids. Mr. L. SIEBOLD.
15. The Bearings of Alchemy on Pharmacy. Mr. W. D. SAVAGE.
16. Note on the Presence of Bromine, Iodine, and Silver, in Sea Water. Mr. G. A. KEYWORTH.
17. Detection of the Adulteration of Tea. ALFRED H. ALLEN, F.C.S.
18. Some Starches Microscopically and Polariscopically Considered. Mr. H. POCKLINGTON.

As probably the precedent will be followed of inviting the attendance of the local medical practitioners, and these might be expected to attend in the greatest number to hear the presidential address, it would perhaps be advisable to give precedence to subjects having special medical interest, such as the verification of unusually large doses, in order that the Conference might be assisted in their discussion by an expression of medical opinion.

A reception-room, a meeting-room, and a news-room will be open for members of the Conference, at the Institute, on Monday, September 15th, Tuesday, September 16th, and Wednesday, September 17th. We need only allude to the proposed excursion to Bolton Abbey and Woods, on Friday, the 19th.

The first general meeting of the British Association will be held on Wednesday, September 17th, at 8 p.m. precisely, when Dr. CARPENTER, LL.D., F.R.S., etc., will resign the chair, and the President-elect, Professor A. W. WILLIAMSON, Ph.D., F.R.S., F.C.S., will assume the presidency, and deliver an address. On Thursday evening, September 18th, at 8 p.m., there will be a *soirée*; on Friday evening, September 19th, at 8.30 p.m., a discourse by Professor WILLIAMSON, F.R.S., on "Coal and Coal Plants;" on Monday evening, September 22nd, at 8.30 p.m., a discourse by Professor CLERK MAXWELL, F.R.S., on "Molecules;" on Tuesday evening, September 23rd, at 8 p.m., a *soirée*; and on Wednesday, September 24th, the concluding general meeting will be held at 2.30 p.m.

The different sections will assemble in the rooms appointed for them, for the reading and discussion of reports and other communications, on Thursday, September 18th; Friday, September 19th; Saturday, September 20th; Monday, September 22nd; and Tuesday, September 23rd, at 11 a.m. precisely.

Excursions to places of interest in the neighbourhood of Bradford will be made on Thursday, September 25th.

IN consequence of considerable difference of opinion having been manifested respecting the comparative value of the various methods of estimating cinchona barks, a Commission consisting of MM. BAUDRIMONT, MARAIS, JUNGFLEISCH, P. WURTZ, STANISLAS-MARTIN, and P. BLONDEAU, has been appointed to report upon the subject. The methods proposed by M. GUILLIERMOND, Dr. DE VRIJ, and M. CARLES, are to be specially considered

Provincial Transactions.

BRIGHTON ASSOCIATION OF PHARMACY.

The first annual meeting of the Association was held at 150, North Street, on the evening of Tuesday, the 2nd September, Mr. W. D. Savage (President) in the chair.

The minutes of the previous meeting having been read and adopted, the Secretary read the following report, after which the Treasurer presented his financial statement.

Report.

"In presenting this, the first annual report of the proceedings of the Association, your Committee have much pleasure in congratulating its members on the very cordial support given by so large a proportion of the chemists and druggists and their assistants at its commencement, 35 principals and 24 assistants having enrolled themselves. They naturally expected from a beginning so satisfactory a corresponding interest in the monthly meetings, which it was thought might prove a bond of union, and conduce to the general interests and improvement of the members at large. In this they have been greatly disappointed, for the number of members attending the meetings has been comparatively small, and it is therefore hoped that for the future greater efforts will be made to be present, otherwise the meetings of the Association will effect but little benefit.

"Some excellent papers have been read on subjects of interest to pharmaceutists, and your Committee feel that their best thanks are due to those members who have, in this way, so kindly assisted them in furthering the objects of the Association. The Lectures on Chemistry, arranged by your Committee, and delivered by Mr. Pankhurst, were well attended, considering the whole of the junior members were unable to absent themselves from business at the time of their delivery.

"Your Committee take this opportunity of acknowledging the kindness of Mr. W. H. Smith in undertaking to deliver a course of six or more lectures introductory to botany, should the attendance be satisfactory; but at the end of the seventh lecture, from various causes, the attendance was so small that it was thought advisable to discontinue them. This is to be regretted, as it is felt much good might have been obtained by those attending.

"One of the chief objects yuor Committee have had in view since the establishment of the Association has been the formation of a library of reference for the use of the members, and they have now much pleasure in announcing that, in addition to the books received from the old Association and those presented to the Association from the "Bell and Hills Fund," they have recently added ten volumes of valuable works on chemistry and pharmacy. The Committee are anxious that these standard works may not remain on the shelves idle, but that the members will make use of them freely.

"Your Committee congratulate the members on the very satisfactory state of the finances, for after expending the sum of £27 11*s.* 8*d.* in conducting the affairs of the Association for the past year, there still remains £4 0*s.* 10*d.* to the credit of the Association."

The Treasurer's statement showed the receipts during the year to have amounted to £31 12*s.* 6*d.* and the expenditure to £27 11*s.* 8*d.*, leaving a balance in hand of £4 0*s.* 10*d.* An extra sum of £9 17*s.* 2*d.* received by Secretary of Mr. Glaisyer, part sum of the Conference Fund, had been expended by Secretary in books for additions to library.

The Secretary's and Treasurer's reports having been adopted, and ordered to be printed and circulated amongst the members of the Association, some proposed alterations in the rules were discussed and agreed to, after which it was unanimously resolved: "That the best thanks of the Association be given to the President, Vice-President, and Secretary for their services during the past year." The following were elected to constitute the Committee for the ensuing year:—Messrs. Barton, Brew, Cornish, Ettles, Glaisyer, Gwatkin, jun., Haffenden, Higham, Mathews, Padwick, Savage, and Smith.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.—SCHOOL OF PHARMACY.

The Council of the Manchester Chemists and Druggists' Association announce that they have made arrangements with Mr. Louis Siebold for the delivery of the following lectures during the winter session, at the Manchester School of Pharmacy, 37, Blackfriars Street, and they trust that the advantages presented to apprentices and assistants in this extended and comprehensive scheme of pharmaceutical education may be widely appreciated. The fees have been fixed on a moderate scale in contemplation of large classes for each subject.

The lectures will be fully illustrated by experiments and specimens, and whilst they will afford the best possible aid to students preparing for examinations of the Pharmaceutical Society, the higher object in view will be to impart that thoroughly sound and practical acquaintance with the various subjects which can alone be of lasting service to the pharmacist or chemist and druggist.

Examinations will be held and prizes awarded in each of the classes at the end of the session.

The Council appeal earnestly to members of the trade to aid their efforts by giving time to apprentices and assistants to attend one or more of the lecture courses, and also to join the Association, which, by its monthly and other meetings, affords valuable opportunities for friendly intercourse and co-operation.

The lecture arrangements are as follows:—

Chemistry.—Twenty-five lectures on Tuesdays, from 8 to 9.30 p.m. Commencing October 7th, 1873. Fee, 25*s.*

Materia Medica and Pharmacy.—Twenty-five lectures on Fridays, from 8 to 9 p.m. Commencing October 10th, 1873. Fee, 21*s.*

Botany.—Fifteen lectures on Fridays, from 9 to 10 p.m. Commencing October 10th, 1873. Fee, 12*s.* 6*d.*

Students willing to attend all three courses may do so on payment of a reduced composition fee of £2 10*s.* Tickets and further information may be obtained of Mr. F. Baden Benger, 1, Market Place; or Mr. Louis Siebold, Oxford street, Manchester.

Proceedings of Scientific Societies.

PARIS SOCIÉTÉ DE PHARMACIE.

This Society met on Wednesday, August 6th, under the presidency of M. Grassi.

Estimation of Cinchona Barks.

It was reported that a note had been received from Dr. De Vrij upon the estimation of cinchonas. It was accompanied by a specimen of *Cinchona officinalis* and a sealed packet, in which its composition was indicated. Dr. De Vrij also made a reclamation for M. Delondre as the discoverer of quinium.

M. Boudet said that he had received from M. Guilliermond, jun., a memoir relative to the analysis of cinchonas, in which he recalled the labours of his father upon the subject.

It was therefore unanimously resolved to appoint a commission—consisting of MM. Baudrimont, Marais, Jungfleisch, P. Wurtz, Stanislas-Martin, and P. Blondeau—to examine and report upon the comparative value of the different methods of analysis, especially those of MM. Guilliermond, De Vrij, and Carles.

M. Buignet presented a paper by M. Yvon upon crystallized protoiodide of mercury.* A specimen of the product was also exhibited to the Society.

M. Marais exhibited a well-preserved specimen of *Amomum racemosum*, received from Cochin China.

Relations of the Medical and Pharmaceutical Services in the French Army.

Upon the invitation of the President, M. Boudet gave

* See *ante*, p. 43.

a summary of the discussions at the Academy of Medicine upon the questions submitted to it by the Minister of War,—Should the military medical and pharmaceutical services be fused? Ought the pharmaceutical service to be subordinated to the medical? or, Is it necessary to preserve the *statu quo*? He explained that the commission appointed by the Academy to report upon the subject consisted originally of nine members, but these were reduced to six by the resignation of Messrs. Bussy. Poggiale, and Gobley, who were the only representatives of pharmacy upon the commission. In the name of the commission so reduced, M. Broca had reported to the Academy for its adoption the following conclusions :—

(1) That the proposal to fuse medicine and pharmacy ought to be rejected as prejudicial to the interests of the army.

(2) That the actual organization of the military health service does not respond to the wants and true interests of the army. It is necessary that the service should be placed under the direction of a competent chief, taken from its members.

(3) That the subordination of pharmacy to medicine in the army is the logical consequence of the autonomy of the service of health.

M. Boudet said that upon the consideration of the report by the Academy, the first and second conclusions had been adopted without difficulty, but that the third, recommending the subordination of pharmacy to medicine, had been *rejected by a large majority*.

In referring to this vote as a fortunate result for pharmacy, M. Boudet proposed that the thanks of the Society should be tendered to M. Poggiale, for the remarkable talent with which he had defended the cause of the military pharmaciens.

This proposition was carried with acclamation, and M. Poggiale, who was present, in returning thanks, said that they were no less due to MM. Bussy, Dumas, Boudet, and Gobley, who had joined in resisting this unfair attack upon pharmacy.

It being the general feeling that it was desirable the speeches delivered at the Academy upon the subject should have the greatest possible publicity, it was resolved to make a grant of 300 francs towards the expense of printing them.

[It will be seen that under the head of the Academy of Medicine we have availed ourselves of these reports as far as published.]

ACADÉMIE DE MÉDECINE.

A discussion took place at the Academy of Medicine, on the 15th July, upon the report of a commission recommending the subordination of pharmacy to medicine in the French military health service. (See above.)

M. Bussy, in opposing the adoption of the report, first detailed the considerations which led him and two other of his colleagues to retire from the commission. He said the commission originally comprised nine members, of whom three were physicians, three surgeons, and three pharmacists. It was to a commission thus composed that the question whether pharmacy should be subordinated to medicine had been submitted. Without any reflection upon any of the members of the commission it might have been expected that the conclusions would not be favourable to pharmacy. When these probabilities appeared to increase in the progress of the discussion, he and his colleagues had thought it due to themselves to retire, so that their signatures might not appear at the foot of a document that would deprive pharmacy of the rank it occupied in the military service and thus inflict upon it an unmerited degradation. Leaving to M. Poggiale to deal with the proposition to abolish the organization of the service of health that had existed since 1793, in order to replace it by one borrowed from the Prussians, the speaker passed on to consider what must be understood as meant by this subordination of pharmacy to medicine. The letter of the Minister of War threw some light upon this question. In it he said—"In fact, the *corps* of military officers of health is divided in two sections, medical men and pharmacists, each with a separate recruitment and set of officials; two professions independent of each other whose incompatibility is consecrated by law, since no one can practise medicine without the doctor's diploma or pharmacy without that of the pharmacist. Although up to the present time this independence has not been any hindrance to the hospital service of our army, I have observed that in certain quarters, and especially with military medical men, it has been the subject of numerous criticisms. Indeed the military doctors called upon to treat our sick soldiers have manifested a tendency increasingly marked to act the part of superior to subordinate towards the pharmaciens charged with the execution of their prescriptions. Besides this the doctors see with reluctance that the pharmaciens of our military hospitals possess an official organization peculiar to themselves and enabling them to acquire a rank identical with theirs; and in order to do away with what they call a regrettable anomaly they demand either the suppression of the pharmacists, under the name of fusion, or their complet subordination to the medical department, a subordination which should lead, according to them, to a diminution of one degree in the official ranks at present attributed to military pharmacists." Here, said M. Bussy, is the true origin of the demand for change, an origin to be regretted, but indispensable to be known. The subordination proposed has nothing in common with the subordination that exists in the general military ranks, where a man may pass step by step to the highest grades. There there exists no subordination of one service to another; there the word applies to the superiority of one grade to another, but it can have no application as between scientific men of different professions. Chemistry cannot be subordinated to medicine, at least in the sense laid down in the letter of the Minister of War, that the pharmacist should remain in all its grades inferior to the medical man and that he should never attain the rank of inspector-general, that grade being exclusively reserved to a functionary belonging to the collateral service. Under such a system, neither Bayen, or Parmentier, or Serullas, or Millon would have been able to aspire to the rank of inspector-general. After alluding to the advantages resulting from a division of labour and pointing out that it was desirable that the sick should have the undivided attention of the medical man, he referred to the effect the proposed subordination would have in destroying the spirit of emulation and reducing the service to a dead level of mediocrity. In the past the military pharmacists had not confined themselves to the proper preparation of medicaments and their distribution according to prescribed rules, but from the nature of their studies they had naturally been called in to enlighten the ministry of war upon many important questions, and particularly upon those which require the application of chemistry and of the natural sciences. The splendid researches of one of their colleagues, a *pharmacien militaire*, upon the nutritive value of the principal alimentary substances that enter into the rations of the soldier, and also his memoirs upon potable waters, were well known to all chemists and a long list might be made of services rendered to science by members of the body. In conclusion, M. Bussy expressed his opinion that the two services should not be fused into one, that pharmacy in the army should not be subordinated to medicine, but that the system which for eighty years had undergone so gloriously the test of good as well as bad fortune in the field should remain unaltered.

M. Poggiale commenced his address by referring to the circumstances that led him and his colleagues to withdraw from the commission. Notwithstanding the importance of the question, and the fact that the control of the whole army was in a transitory state of reorganization, the commission, after hearing the evidence of two *médecins militaires*, had precipitately decided upon this vital question

before even the bases of the special law upon the administration of the army were known. He expressed his regret at the polemic ardour shown by some military medical men in the dispute. In that corps he counted many friends; he had often vaunted their knowledge, services, and devotion. It appeared to him that the interests and aspirations of both bodies were in some senses identical, and he had never ceased to recommend the respect and esteem of one for the other. It was therefore extremely painful for him to take part in such a debate, where both medical men and pharmacists had something to lose. But he felt it to be his duty to defend the services of a body unjustly attacked, of which he had been a member forty-four years and the chief for fourteen years. He rapidly traced the history of the laws, ordinances, and decrees of 1792, 1793, 1794, 1795, 1824, 1831, 1836, 1865, and 1870 which established the distinction, independence and absolute equality of the medical, surgical and pharmaceutical professions in the army. Arago, who was minister of war in 1848, in reconstituting the corps of officers of health in the army, decreed that each of these three branches of the service should comprise equally the ranks of *élève sous-aide*, *sous-aide*, *aide-major*, (two classes), *principal*, *principal inspecteur* and *inspecteur-général*, and that these should be assimilated to the grades of the officers of other corps in the army, from that of sub-lieutenant to general of brigade. This decree was discussed in the legislative assembly by whom it was remitted to a commission under the presidency of Marshal Vaillant. Here amongst other objections it was met with the proposition to incorporate the two branches; but the commission unanimously reported that the two sections of the new service of health, medicine and pharmacy, as well as being distinct, should receive the same hierarchic constitution and participate in the same advantages of every kind. In accordance with this report the President of the Republic, in 1852, issued a decree instituting a corps of military officers of health, comprising medical men and pharmacists, the first charged without distinction of profession with the practice of medicine and surgery, the latter with the practice of pharmacy. These were to form two sections parallel to and independent of each other, but under the authority of the military administration. In 1859 an augmentation of pay and rank was applied in strictly the same manner to both sections. The following represents the effective force of each according to this decree :—

	Médecins.	Pharmaciens.
Inspectors.	7	1
Principals (1st class) . . .	40	5
,, (2nd class) . . .	40	5
Majors (1st class)	260	36
,, (2nd class)	300	42
Aides-majors (1st class) . .	400	55
,, (2nd class) . .	100	15
	1147	159

The revolution of 1870 again brought the subject up, and it was entrusted by General Cissey to a mixed commission, which, after much disputing, and the consideration of many projects, in all of which the medical section demanded fusion or subordination, failed to come to a decision, and now the question had been sent to the Academy of Medicine. In dealing with the first question asked by the Minister of War, whether military pharmacy should be fused with military medicine, he maintained that it was not practicable; it would suppress the sole representatives in the army of the physical and natural sciences, and would replace competent and tried men with medical incapables. The medical man who was unable to devote himself to the study of chemistry, natural history, and pharmacy, would be unable to bring to the preparation of medicines and chemical analyses the scrupulous care and knowledge required. How many mishaps there would be to deplore if pharmacists did not supervise scientifically the medical prescriptions of the junior ranks of the medical service! He did not want to excite an angry debate by citing examples, but he could not forget that, in an important hospital, a man had died, poisoned by hydrochlorate of morphia, in spite of the remonstrances of the pharmacist. A demand had been made for a gram of that poisonous substance to dress a blister. The pharmacist refused it; but the demand had been insisted upon with so much energy, that he was compelled to deliver three decigrams of the poison, and the patient died the same day. He himself believed that it was necessary that the army should have tried physicians, skilful surgeons, and educated and practised pharmacists, and he regretted the fusion of medicine and surgery that had already taken place. If the proposed fusion of pharmacy with medicine were accomplished, it was easy to foresee that the preparation of medicines would be left to the nurses. It was unreasonable to suppose that the young medical man, after consecrating several years to the study of medical science, should undertake new studies to fit him for a position that would always be subordinate. Only mediocre men, idle and without character, the dry fruits of medicine, would accept such a position, and the results would be disastrous to the welfare of the army. In fact, it would enable the Minister of War to confer the right to practise pharmacy in the army without the safeguards,—represented by years of study certified by a diploma,—which have hitherto been demanded by the state in the interests of civilians. To the proposition that pharmacy should be subordinated to medicine, M. Poggiale gave a decided negative. For eighty years the military pharmacists had enjoyed the same rank as military doctors, and during that time they had never ceased to deserve it by their services. And yet at the moment it was proposed to suppress the rank of pharmaceutical inspector it was also proposed to largely increase the staff of army medical inspectors. The seats on the council of health that had been occupied by Bayen and Parmentier would be given up to men without any prestige, and not even having the authority of rank. No argument could justify this suppression, and the true motive for it was the unavowed spirit of domination. Medical inspectors would be quite unfitted for the inspection of the central and military pharmacies, and to perform many other important duties. Indignantly resenting the proposition to abolish the highest grade in the military pharmaceutical service, by which means the supremacy of the medical service would be secured, M. Poggiale mentioned several recent instances in which *pharmaciens militaires* had rendered valuable services to the state. He also quoted several instances where the value of their services had been acknowledged by medical men of high authority, amongst others the testimony of Larrey, after the battle of Moscow, that he owed to the *pharmacien-en-chef* of that day, and to many of his junior pharmaciens, praises and thanks for the zeal with which they had seconded him under the trying ordeal. "Larrey," said M. Poggiale, "never formulated a complaint against the *pharmaciens militaires*, and I am certain that if he were still living he would not agree with the sentiments, so wanting in friendliness, of a great number of *médecins militaires*."

(*To be continued.*)

BRITISH MEDICAL ASSOCIATION.

Disinfectants and Disinfection.

The reading of a paper by Mr. J. A. Wanklyn on the "Action and Relative Value of Disinfectants" (printed at p. 205), and another by Dr. Ransom on the "Mode of Disinfection by Heat" (printed at p. 206), before the Public Medicine Section of the British Medical Association during its recent meeting in London, gave rise to a very interesting discussion upon the subject, which is epitomized as follows in the *British Medical Journal* :—

Dr. Tripe (Hackney) said that he entirely agreed with Mr. Wanklyn that it was not necessary to use the host of disinfectants that had been lately introduced to the

public. There was one point with which the officers of health would have to deal, viz. the sewers. In order to use disinfectants properly, such as chlorine, they must not be used so strong as to be rendered dangerous. The first time that he used some chlorine he almost poisoned one or two persons. In using carbolic acid of the strength recommended, if something were got which was not carbolic acid, it would produce injury of the lungs. Care must be taken to get true carbolic acid. As to chloride of lime, so far from removing the smell from sewers, it very frequently aggravated it. Disinfection by heat was most important; but special regard must be paid to the amount of moisture. To disinfect clothes, beddings, etc., the heated air must be made to pass entirely through them. If they were put in in a mass, the inside was often found not to be dried. Flock he found to be very difficult to disinfect; it was often burnt, and new was given in the place of it. In his district, a brick building lined with iron was used, in which also disinfectants were used; for he never trusted to heat alone, but always used sulphur. In using sulphur in rooms, the bed should be taken down and put upon chairs, and the blankets and mattresses placed upon end, so that the whole might be as fully as possible exposed to the disinfectants. Care must be taken in setting fire to the sulphur that it did not burn the things. The sulphur to be burnt should be put into a pan, and this in a vessel of water, so that if the sulphur did happen to overturn it went into the water. He agreed with Mr. Wanklyn that if they used common salt and sulphate of iron they would not have to go further for disinfectants.

Dr. Bond (Gloucester) said he had considered how to provide an apparatus for disinfection. Being anxious not to put the authorities to much expense, he had made an apparatus which very closely resembled Dr. Ransom's. He was glad to see that Dr. Ransom had had his in operation for some time. It struck him that wherever gas was available it provided all that was necessary; and he should be glad to know whether there was any objection to make a disinfecting apparatus portable, because it was exceedingly desirable that it should be taken to the house where the clothes were to be disinfected. He had roughly designed a form of portable apparatus, which would answer certain other purposes. It was very important, in order to save expense, to combine several objects. It struck him whether it was not necessary to have an ambulance for removing the sick, a means of disinfecting clothes, and carrying disinfectants. He did not understand how common salt was to be used for the disinfection of clothes.

Mr. Wanklyn said that the only way of disinfecting clothes effectually was by burning them. Something might be done by exposing them to the weather, and to water and heat. He did not believe that liquids could be disinfected.

Dr. Ransom said that the cost of his apparatus, of which only one had been erected, and the drawings of another were prepared, was £50. If it came into general use, it would cost about half this sum. He thought that heat was the best disinfectant for clothes; but still he was inclined to think, with Mr. Wanklyn, that they could hardly be disinfected. As to the sulphurous acid, it destroyed the paper and bed-hangings.

Dr. Tripe said that he did not use the word disinfectant in its strictly chemical sense. He used it to mean the prevention of the reciprocal action between the virus and the body upon which it might have acted.

Dr. Syson said that his opinion was, that the best thing to do was to destroy the article. By disinfecting with water money and time would be wasted, and certainly the disease would be driven elsewhere; it was merely pickling the germs to be unpickled for the use of some one else. Sulphate of iron could only exercise a certain influence. His practice had always been to do a thing well, or not do it at all, rather than get into a feeling of false security by only half doing it. He should be happy to hear of Dr. Ransom's apparatus being thoroughly effective. As to the cost, it should not be reckoned against human life.

Mr. Grieve (Hampstead) had had practical experience of disinfection at Hampstead. They had received 12,000 cases of small-pox, and they disinfected the patients, and gave them on leaving the same clothing they had on when they entered the hospital. These patients had been traced, and there were no signs of their having carried the infection with them. The mode was to use heat combined with sulphur and sulphurous acid. It was found that they could be used in a chamber at a temperature of 230° F., without damaging the clothes. The buildings, which were of iron, were now occupied by pauper imbeciles. The plan recommended by Dr. Tripe was followed. Sulphur was burnt in the buildings; and, to make assurance doubly sure, every inch of the surface was washed with carbolic acid and well watered with the fire hose. The buildings were thus prepared, and there were now between 300 and 400 inmates, and not a single case of small-pox had arisen. Disinfection could not have been put to a more crucial test.

Dr. Farr (London) said that what was wanted to be known was whether disinfection was effectual against other diseases as well as small-pox.

Dr. Tripe said that he never knew of an infectious disease spreading after the application of sulphur at a temperature of 230°.

Mr. Hastings said that at the meeting of the Social Science Association, to be held at Norwich in the beginning of October, there was to be an exhibition of sanitary appliances; and he would suggest to Dr. Ransom to exhibit there the actual model, so that it might be seen, if necessary, in operation. Thus a more accurate idea would be arrived at as to how far it would be desirable to erect it in other places.

Dr. Ransom said that he was obliged to dissent from the sweeping proposition of Mr. Wanklyn. He had the evidence of Dr. Henry, of Manchester, who proved the easy destruction of the activity of vaccine by exposure to a temperature of 140° F., for an hour. The close analogy between that and small-pox made it exceedingly probable that the virus was destroyed by heat at a moderate temperature. With regard to scarlet fever, the object had been attained; for the clothes worn by those suffering from the disease had been subjected to the treatment, and were afterwards worn by others, and no harm had arisen from it. That was recorded in the *Philosophical Magazine*, volumes x. to xi. With regard to the destruction of clothes, that was practically impossible. Nothing would persuade people of a certain class to destroy their bedding and furniture (which, relatively to their income, were very valuable), and nothing would induce the ratepayers to pay for them. If it could be shown that clothing could be disinfected tolerably safely for a small sum, many people would take advantage of it. His object had been to remove the difficulty in the way of applying heat; and he trusted that in the course of time his suggestion would remove some of these evils.

Mr. Wanklyn said there were two ways of getting rid of infectious material. All organic matter was destroyed by a red heat, or by powerful chemicals. Many infectious materials were comparatively easily destroyed; he believed that the matter of small-pox perished as infectious material below even the boiling point of water. There was another way, and that was by extreme dilution. The material was a chemical substance, and at a certain point it ceased to be poisonous. By extreme dilution germ-poison could be destroyed. A certain quantity of water destroyed these germs, as far as development was concerned. With regard to the disinfection of clothes by heat, he thought that Dr. Ransom had furnished the answer. Flock must be heated twenty-four hours before the whole mass got the temperature. He did not think that it would be practical to disinfect the ditches, but he believed that something might be done to the drains and

sewers. If there were an abundant supply of water, he did not believe that any disinfectant was needed. It was only when the surface was getting dry that he believed that sulphate of iron and other things were necessary. He utterly disbelieved in the use of carbolic acid for this purpose.

Mr. Huntley (Jarrow) said that he came from a town where the atmosphere was pervaded with chlorine. They could not walk through the streets without having their noses tickled with it, and their eyes filled with it. If this chlorine were disinfectant, epidemic diseases ought to be altogether absent; but he was sorry to say this was not so. Jarrow had suffered from small-pox as severely as most places, and from time to time it was visited by various diseases.

SOCIETY OF ARTS.

On the Energies of the Imponderables, with especial reference to the Measurement and Utilization of them.*

BY THE REV. ARTHUR RIGG, M.A.

Lecture V.

On the Energy of Electricity, with especial reference to the Measurement and Utilization of it.

The energy of electricity is being manifested in phases new to men day by day. That which in the early part of the present century was unknown, is now so well known as to win neither surprise nor notice. The telegraph which girdles the earth—the electro-deposition of metals—the light which pales our brightest—the power which melts the most refractory metals (for I have seen a square bar of iron a foot in length, and about three-eighths of an inch on the side, fused into drops by a current of electricity in less time than this narrative has occupied)—these have been handed down by science to promote the commercial and social welfare of mankind.

What remains to be done by this energy, so recently harnessed, and as yet only partially trained, is beyond our present ken; but that it will—or, at least, that it can—be developed in a sufficiency to supply our coal-fields when exhausted, and take upon itself all that coal, and wind, and water now give of kinetic energy, no one who has watched the progress of the past need doubt; this, too, quite irrespective of the view that owing to the quantity of zinc consumed, electricity can never compete with coal in producing the same results. There is every reason to expect that long ere the coal-fields are exhausted, the tidal waves on our coasts will be supplying light enough and heat enough, and, therefore, power enough, for the requirements of Great Britain and Ireland.

Propositions better established than that which asserts electricity to be non-producible from sufficiently economical sources have faded into oblivion.

The energies of electricity are manifested whenever there is a molecular disturbance within or amongst bodies. Whenever any change takes place in anything whatever, and amongst any molecules whatever, an electric current is produced, and if not necessarily manifested to us, still it always is present. Probably there is not a single act of our lives, and it may be not even a thought in our heads, which is not associated with an electric current.

Kindly understand that the lecture is on the energy of electricity, and, therefore, time must not be occupied in describing instruments. Galvanometers are now-a-days made so delicate that if you lay one fingure in one trough of salt water, and another in another, and simply tighten the muscles of one arm, a current of electricity passes through the galvanometer and deflects the needle. We cannot raise our hands to our head without setting free a current of electricity, and in that current is energy. Its energy is manifested in the moving of the galvanometer needle. How much of that energy is merely the balance between two energies of large amount—how much is not manifested, owing to the sluggishness of the instrument and from other defects, we know not, but that some is thus interfered with there is very little doubt. We usually speak of a galvanic battery as being formed of zinc and copper, or of metals in chemically different relations to a liquid; if, however, you take a piece of ordinary copper bell wire, and connect the two ends of it with the galvanometer, then cut it in two with a pair of scissors, and dip each cut end into salt and water, or put them into your mouth, an electric current passes, and the galvanometer shows that there has been some species or other of molecular disturbance which has caused a manifestation of electrical energy.

This energy of electricity becomes kinetic when it is allowed to pass freely. For example, in any bodies which are quiescent, it is kinetic, but it is potential when resisted. If, for instance, a current of electricity passes along a wire and the action is resisted, the wire becomes hot. If it passes through any compound body, as, for instance, water, then it is resisted, and the water is immediately decomposed. Consequently we are dealing to-night with an energy manifested in molecular disturbance, and having both a potential or stored-up power, and a kinetic power in motion. The question now is, how is this energy to be measured, for the subject of the lecture this evening is a mode of measuring the energy of electricity.

Towards the middle of the last century (1746) the first electrical machine was made. In 1650, Otto Guericke, to whom we are indebted for the air-pump, suggested the scheme, but Hawksbee was the first to make one. His machine consisted of a ball of sulphur, afterwards altered to a ball of glass. The hands were employed to rub it, and a large fly-wheel, about six feet high, was employed to turn it. Silk threads from the ceiling held what we now call the conductor; and by the exercise of a very large amount of mechanical power they were enabled to get a small spark, to the surprise of all, to the curiosity of many, and the dread of not a few. After that we come to the plate machine, which is arranged, as you are aware, with cushions; still we have those sparks which were supposed to have much energy in them. We then pass on from the glass plate machine to the vulcanite plate machine. Here is a vulcanite-plate, and, as you are aware, by rotating it between cushions, the electricity is gathered upon this conductor. You see this large wooden ring—that was suggested by Winter; the object of it was, somehow or other, we do not know how, to condense the electricity, and to convert what might be a fine line spark, into a solid whitish spark. How this ring acts, and the whole history of this machine, would be quite sufficient matter for one lecture; but that with which we are now concerned is not how to produce such phenomena, but how to attempt to measure the energy of the electricity which these machines, and other means, can develop. I scarcely need tell you that it is not, in any sense of the word, an electrical lecture in which we are to be engaged this evening, and these apparatus are only here as illustrations of the operations. Sparks pass from the conductor, and are usually charged into a jar of this kind—a Leyden jar. That was first done in the year 1746. The jars were charged and discharged, and although great shocks were felt, yet no measure was taken, and it was supposed that in the shock consisted the energy of electricity.

Now, the mode in which electricity thus presenting itself was ultimately measured was by a small jar of this kind, called a unit jar. This unit jar is in all respects the counterpart of the Leyden jar, only made smaller, and one is here mounted on glass and brass rods. There are two brass balls, one connected with the inside of the jar and one with the outside, which balls can be set at any distance apart. The inside of the jar is charged from the electrical machine, and as soon as it is sufficiently charged, according to the distance of the balls from one another, a spark passes. So passing, spark after spark enters the

* Cantor Lecture, delivered February 21, 1873; reprinted from the *Journal of the Society of Arts*.

larger jar, and if we count the number of such entering, we have settled what was supposed to be the measure of energy contained in the large jar. We may put in 10, 20, 30, or 40 charges. It will be very obvious to you, however, that these unit jars vary. The same jar is always alike, but you cannot make two exactly alike. Even if this could be done, the state of the atmosphere and other surroundings would so influence the passing electricity that accurate comparisons and conclusions could not be made. Moreover, these jars vary on the surface, and in the character of the glass, and in other ways ; consequently, this mode of measuring energy must necessarly be a failure. The unit jar, therefore, has fallen into a complete disuse.

Hitherto the mode of producing the electricity to be measured has been by friction. Now, here is a machine, consisting of a thin circular vulcanite disc, capable of being put in rapid rotation, but there are no rubbers or other articles in contact with the plate. It is called a Bertsch machine. Here are three segments of thin vulcanite; one of these is rubbed with a piece of dry silk or fur, and, being slid in prepared grooves, the faces of the segment and rotating vulcanite are about one quarter of an inch apart. These two other segmental pieces can be slid behind the first one ; if the room and the atmosphere were not so damp we should probably get a four-inch spark from this machine. One segment is rubbed, and placed about a quarter of an inch from the disc, and by a process of induction, when it is rotated, there is a noise as of much electricity being brought forward and gathered by the conductor. Again, we have it here no quantity of electricity—we have no kinetic energy. The difference between energy as it is used, speaking electrically, and intensity, as it is also used, speaking electrically, is this, there may be great intensity and little or no quantity—no power, in the proper sense of the word. For example, if a piece of iron were taken and formed into needles, and if those needles were placed points downward upon the hand, and a small weight upon them, we should find that piece of iron possessed of great intensity ; but if this iron in rough block form, with any weight upon it, be placed upon the hand, although there be a very much larger quantity of iron, yet there is little intensity. In such a sense the distinction is drawn in electricity between quantity and intensity. There is great penetrative power in electricity obtained from this machine, but there is no quantity of electricity moving, and upon the quantity in motion depends our ability to get energy. If all our iron appeared in the form of needle-points we should do very little with it.

There is another matter, also peculiar to electricity of this character, compared with the uses to which iron is now applied. Here is a small glass flask with crumpled pieces of tinfoil in it. If this flask were coated on the outside, as a jar is, the amount of intensity and the shock that would be given by it, would be equal to what might be obtained from that large jar, for this reason, the electrical balances between the inner superficial metal surface and the outer coating of the jar depends upon the intensity of these two. Electricity of this character rests upon surfaces only ; electricity of that other character, with which we are more concerned, enters below the surface, and may be said to reside and travel within the body. Whatever, therefore, may be the number of, say, square inches of surface within the jar, the electricity upon the whole of them would be balanced by electricity of equal intensity upon an outer surface covering the jar only. This may be illustrated by reference to the large quantity of water contained in a dock for ships. It is supported or kept at its level by a gate which in no respect is stronger than would be required for a dock of the same depth containing not one-tenth of the quantity of water. So what is called the hydrostatic paradox, also so with Bramah's hydraulic press, and so with this little jar. There may be a large quantity of electricity within this jar if it have a large surface on which to distribute itself, and then it will be balanced or kept in equilibrium by a smaller surface on the outside charged to the same intensity.

The electricity here has been produced through physical exertion. We found, however, the other night that there is no physical exertion so great as that which takes place between the molecules of different bodies when chemical affinity is allowed to operate. If therefore, instead of getting molecular disturbance in the muscles of our arms by turning these handles, we produce molecular disturbance between the ultimate atoms, or molecules of matter, forces are called into play as far beyond the power of our arms as those of the most colossal steam-engine are beyond the power of a mouse. By chemical arrangements we are enabled to obtain electricity of a totally different character from that hitherto noticed—so different that there is little similarity between them, excepting a common name. In fact, the earlier attempts at telegraphy failed in consequence of the promoters using electricity produced by machinery such as this—an electricity which is possessed only of intensity and not of that energy consequent upon quantity.

Let us now pass on to the mode of obtaining electricity from chemical action. Before doing so a phenomenon should be noticed, which disturbs results very seriously, and which is, at present, not understood. Here is some copper wire, covered with cotton, coiled from end to end, say five or six times along this large bobbin of wood. Within the bobbin is a larger hole than usual. The two ends of this wire so coiled are connected with the reflecting galvanometer. The reflected light from this lamp is now visible and stationary upon the screen. You are aware that motion of that reflected speck of light will be the consequence of electricity passing through the coils of the galvanometer. Now, observe that, without either chemical or physical agency acting upon or in contact with the wire, we shall obtain a manifestation of electrical disturbance within the copper wire. Let the end of this steel magnet be introduced within the bobbin, you see that the speck of light immediately moves. Except in this manner, copper does not manifest electrical properties. Again, if the other end of the steel magnet be brought within the bobbin, you see the speck of the galvanometer moves in an opposite direction. Thus may be shown one form of electrical induction.

Now, with that phenomenon we are perplexed. This property of induction manifests itself at times and in ways of which we know nothing. For example, if a copper wire were laid upon this floor, and another copper wire were laid parallel to it on the floor below ; and if any current of electricity passed through the wire on this floor, the one below would answer to it, although there was not any apparent contact or communication between them.

The laws which govern such electrical manifestations as these are very partially understood, and therefore the measurements of the results of these laws are for general use almost valueless. We must, however, for the present assume that the nature of the phenomena of electrical induction is clear.

The next stage in obtaining electricity is by means of what is called agalvanic cell. Such a cell usually consists of two different metals, and one or two liquids. Whatever may be the arrangement, the electricity developed may be estimated by the intensity of chemical affinity during the process, and at the time of the measurement. But the whole of this question of chemical affinity must now be assumed, and some of the affinities explained in the last lecture are probably the chemical affinities operating in this cell. A chemical action takes place upon a square inch of one plate, and it is met by an action upon a square inch of the other, therefore on every square inch an action is produced. Between the two plates there is something (say the liquid) which causes the action. It is in fact the presence of this liquid which calls the chemical affinities into play.

A word must now be introduced which will often occur during the evening, and it is one which performs an important part in the measurement of electricity of the character which men utilise, *i.e.*, resistance. Indeed, this resistance to the free passage of an electric current is our

during the evening, and it is one which performs an important part in the measurement of electricity of the character which men utilise, *i.e.*, resistance. Indeed, this resistance to the free passage of an electric current is our chief business to-night. Whilst the size of the plates in these cells is increased, the resistance to the free course of the manifested electricity is not decreased. Thus, for instance, from a square inch of one plate there is a current of electricity meeting or co-operating with that developed from a square inch of the opposite plate. Whatever may be the energy of the chemical affinity upon one square inch, it is met by the energy of the chemical affinity upon the opposite square inch of the other, and that energy has to overcome the resistance of the liquid between them. Now, then, assume that each of these plates is enlarged by the addition of another square inch. This introduces an additional quantity of liquid, and we have to overcome the resistance of this liquid. The difficulty of overcoming the resistance of the intervening liquid is such that, however much we multiply the number of square inches, we also introduce more liquid, and by so doing add further electrical resistance. Hence, however large may be the plates, we do not overcome the resistance more easily. That led to the contrivance of thus coupling up in what is called "a series" in the form you see here, that which is familiar under the name of a cell-battery.

It may perhaps make clear what is a difficulty to many minds if an attempt be made to explain how it is that an electrical current which passes when cells are coupled up "in series," that is, one after the other, is more intense than when they are combined as one large single cell.

Supposing these two plates, each one square inch in area, were the only two concerned, therefore there would be a certain resistance to be overcome. The chemical affinity of one such combination not only overcomes that resistance but leaves a surplus of electricity, which surplus is said to run along the outside wire, and may produce what we call a telegraphic despatch. Now, suppose that in addition to those two plates, there are two others of the same size and material in a cell behind them. Between these second plates there is also a resistance similar to that between the first two. Those two second plates, however, also produce a surplus. Now as that surplus passes over it continues its way through the previous plates and wire, and the consequence is that when once the resistance of its own cell has been overcome, the surplus electricity can pass through the other cells without any resistance, and, therefore, we are enabled to add the surplus of one cell to the surplus of the next, and so on. Hence, when combined in the form in which they are combined in this battery, we are manifestly enabled to pass along the connecting wire successive equal amounts of electricities, and these flowing so very closely behind each other, produce an effect upon any resistance similar to that produced upon a slab of marble or of glass by the forcible driving against it of small grains of sand in a continuous stream. These grains penetrate, and, as it were, bore holes even in hardened steel; so these successive electricities are, as it were, continuous, and thereby overcome great resistance, It may, in connection with this, be remarked that, perhaps, in some such way as now described, the mighty energies of affinity may be accomplished by this clashing of millions upon millions of atoms and molecules. This may explain how and why it is that these cells thus arranged "in series" are under certain circumstances more effective than when the same amount of liquid and metallic elements operate as one cell only.

Electricity thus, or by other means at our disposal, is now to be measured. Two things are especially before us to-night. One to make clear how this measurement is made; the other to endeavour to make clear how the resistance of various bodies, be they wires or liquids, is also measured.

This electricity is measured in a very simple way. All the apparatus is here, but as it would take too long to show experiments in detail, perhaps you will kindly accept a statement of facts instead of a visible reproduction of them. In these cells is being produced a quantity of electricity which is to be measured, much as sugar is measured by the pound or liquids by the quart. The way it is measured is either by the chemical decompositions that it can produce, or by the amount of heat it can develop, or by other means, as for instance its effect upon the magnet in a given time.

This seems a convenient opportunity for directing attention to a galvanometer, which is arranged upon a plan by which is shown the amount of decomposition effected by the current indicated by the place of a needle on the dial. The gentleman who designed it had in view only a manufacturer's requirements. The measurement effected by such a galvanometer is not of that character with which this lecture is to be concerned, and therefore further reference to this particular one is not requisite.

To consider a mode of measurement we must recur to those elements—mass, space, and time. The apparatus on which my hand now rests consists of a wooden ring, about ten inches in diameter, having coils of copper wire around it. Within this circular box with a glass top is a small magnetized steel needle. Now, the small steel needle assumes a certain position in consequence of the influence of terrestrial magnetism. Such an influence as this is not unlike a stream of water in a brook upon a short stick, one end of which is tied to a stake by a string. So long as the stream flows steadily past the stick it is retained in the same position. Let a disturbance take place in the evenly flowing water, and the stick will no longer retain either steadiness or direction. Suppose, now, that this needle is retained in a certain direction by the influence of what we may call the stream of terrestrial electricity flowing through the atmosphere of this room. (That such a stream is so flowing through the atmosphere shall be made apparent presently.) From these four cells of a galvanic battery a current of electricity may be caused to pass along the wire which surrounds this wooden ring. The arrangements are made, and such a current is now passing. What is the consequence? The even flow of that which retained the needle is disturbed, and the needle answers as the stick in the water would have done to the disturbing causes. Clearly the nature and extent of the invisible disturbance may be estimated—indeed measured—by the motions of the visible needle, just as a new position assumed by the stick would measure the disturbing influence on the stream.

(*To be continued.*)

Parliamentary and Law Proceedings.

Attempted Murder and Suicide by Poisoning.

At the Lambeth Police Court on Saturday, September 6, Ann Dickson, 20, boot closer, was charged before Mr. Ellison with attempting to cause the death of Rose Alice Catheron, aged six years, by giving her a quantity of precipitate powder. She was also charged with attempting to commit suicide by taking a quantity of oxalic acid. A police constable said that at about a quarter past eleven o'clock on Friday night he was called to a house in Wood Street, Lambeth Walk. He found the prisoner lying on a bed in the back parlour. She was evidently suffering great pain. In the room there was also the child, Rose Alice Catheron, who was vomiting very much. He took them at once to Lambeth workhouse, and they were attended by the doctor, who found them suffering from the effects of poison. The prisoner, upon recovering, said, "I have done this through revenge. I have left my apartments this morning. What things I had I have sold, and I intended to do this when I left home this morning. I bought precipitate powder for the child, and oxalic acid for myself. The child's father has ruined me, and this was my revenge." Witness afterwards found some pieces of paper, one marked oxalic acid and the other precipitate powder. The child was still under medical care. The prisoner, who declined to say anything at present, was remanded.—*Standard.*

Suicide of an Apothecary by Aconite.

An inquest was held at Cork on Friday, September 5, upon the body of Mr. H. Haines, an apothecary. From the evidence of a brother of the deceased it appeared that he had been labouring under various delusions, and in a very desponding state of mind, which witness attributed to the recent loss of his wife and two daughters. His assistant also gave similar evidence, and deposed that he had at deceased's request prepared a sedative draught on two occasions just before his death. On the Thursday deceased left the shop and went into the laboratory, and witness feeling uneasy at his long stay went after him. Upon entering witness saw deceased finish drinking out of a tumbler something which at first he thought was wine, but upon asking him where he had taken it from, deceased pointed to the "aconite" bottle. Witness immediately called for assistance and administered sulphate of zinc and hot water, and similar treatment was continued by the medical man who attended, but deceased gradually sank and died in about half-an-hour. The bottle from which deceased took the "aconite" was a fresh one, and he drank more than an ounce from it. A verdict was returned that deceased committed suicide while in an unsound state of mind.—*From the Cork Advertiser.*

Prosecutions under the Adulteration Act.

THE SALE OF MILK.

At Worship Street Police Court on Thursday, Sept. 4, William Walker and Samuel Quint, of Heneage Street, Mile End, were summoned under the Adulteration of Food Act, 35 and 36 Vict., cap. 74, sec. 2, for selling milk and water as genuine milk. The sanitary inspector proved that on the 9th of July he purchased at the premises of the defendants a pint of milk, placed it in a bottle, and sent it to Dr. Meymott Tidy for analysis. Dr. Tidy, Professor of Chemistry at the London Hospital, then deposed that at least one-half of the "milk" was water. Mr. Hannay said the evidence was conclusive. The milk, however, had not been mixed with any deleterious matter, otherwise he would have imposed the full penalty. He now ordered the defendants to pay £5 and costs. The money was paid. Henry Foster, of Pelham Street, Mile End, was summoned for a similar offence, and was ordered to pay a like penalty and costs.—*Times.*

THE SALE OF TEA.

At the Birmingham Police Court, on the 3rd inst., Mr. Bakers, was summoned for having sold a quarter of a pound of black tea, and a quarter of a pound of green tea, both of which were alleged to be adulterated. Evidence was given as to the purchase, and two certificates from Dr. Alfred Hill, the borough analyst, stating that the black tea was adulterated with sandy matter, talc, and iron filings, to the extent of 4·7 per cent., and the green tea with similar foreign substances to the extent of 6·9 per cent. For the defence it was urged that the defendant had said that he could not guarantee the quality of the tea sold at the price paid for the samples, and that it was not necessary to state what the mixture was composed of; he had sold the tea as he received it. The Bench considered the offence proved, and inflicted a fine of 20*s.* and 8*s.* 6*d.* costs.—*Grocer.*

Action against a Wholesale House for Alleged Supply of Adulterated Jam.

An action has been brought in the Bath County Court, in which the plaintiff, Mr. Cox, a grocer, sued the defendants who are large wholesale confectioners, carrying on business in Botolph Lane, London, and having a factory at Ratcliff, to recover damages for the loss occasioned by a purchase of jam, which was made on the faith of the representations of the defendants' traveller. The plaintiff said that in August, 1872, the defendants' traveller came to him and urged him to purchase some of their jams. He ordered three gross of the best jams, at 7*s.* 3*d.* per dozen, to be delivered to him when he demanded them. The traveller guaranteed that the jams should consist only of the finest fruit and the best sugar, and that the fruit should be so labelled—strawberry should contain strawberry, and raspberry raspberry. The jams were delivered about April 15, and immediately plaintiff began to receive complaints about them. At length he had them analysed by Mr. Ekin, and, in consequence of his report, wrote to the defendants on June 6, and said he found their jams "highly adulterated," and requested them to take them back. Repelling the assertion that they were adulterated, the defendants declined to do so, and said their contract to make the jam only of the finest fruit and best sugar had been strictly fulfilled. Some further correspondence passed, and Mr. Cox sold the remainder by auction: what cost him £12 17*s.* 10*d.* realized net £6 3*s.* 10*d.*, and he therefore claimed the difference, £6 14*s.*

Mr. Ekin, F.C.S., described the analysis he had made of the sample jam; he considered it was not genuine jam, because when filtered and reduced to an extract it was deficient in flavour; there was a remarkable absence of pips, and artificial colouring matter was present. This he had proved by the application of caustic alkali, which discharged the colouring, while it would not natural colour. The colour, too, was too much of a pinkish tinge. He counted the pips in a quarter of a pound of the jam and found there were forty-five, or about enough for two strawberries. He was sharply cross-examined by the defendants' counsel. He said the number of pips in a strawberry varied, but not to the extent of 1000 per cent.

It was submitted, that the traveller collected accounts and received orders, but had no authority to give guarantee or to make a contract. He merely received Mr. Cox's order and presumably communicated to the firm, who, it was admitted, sent down a contract note. On that, it was stated, the house guaranteed to make their jams of the finest fruit and the best sugar. In the second place it was contended that that contract had been fulfilled. In the course of manufacture it was found necessary to add a little juicy fruit to the dry fruit, and *vice versâ*, to prevent deterioration, but that was all. The fact was that Mr. Cox found himself at the beginning of a cheap season with jams deficient in flavour and high in price, and he desired to get rid of them. But on account of the imputation made in his first letter the house declined to receive them. The traveller could not be called, as he was in California for the benefit of his health. If he had guaranteed the jams he did it in the teeth of his instructions. Evidence was then given as to the purity of the jams.

Judgment reserved.—*Grocer.*

Reviews.

Chemistry: General, Medical, and Pharmaceutical, including the Chemistry of the U. S. Pharmacopœia. A Manual on the General Principles of the Science and their Applications to Medicine and Pharmacy. By John Attfield, Ph.D., F.C.S., etc. Fifth Edition. Philadelphia: Henry C. Lea. 1873.

The difficulty of writing a good manual is generally acknowledged, but students, as a rule, are shrewd enough to avail themselves of one when it is produced. The fact that in a few years Professor Attfield's manual has reached its fifth edition—three in England and two in the United States—bears more eloquent testimony to its merits than any that we can express. The simple manner in which the student is led on step by step to comprehend the general principles of chemical philosophy, the analytical and synthetical reactions of the metallic and acidulous radicals, and to become initiated into the more recondite subjects of pharmaceutical chemistry, together with the inexpensive experiments by which each subject is illustrated, have combined to make his book a favourite both in this country and the United States.

The present edition is based upon the fourth (English)

edition, and is adapted to the chemistry of the new edition of the United States' Pharmacopœia. Amongst the fresh matter introduced, however, there is one statement to which exception may be taken. The formula for cantharidin is given on p. 409 as $C_5H_6O_2$ (?), and it is stated that Massing and Dragendorf consider it "to be an anhydride ($C_5H_6O_2$), and that with the elements of water it forms cantharidic acid ($H_2C_5H_6O_2$). These formulæ evidently contain a mistake. The fact is, that Dragendorf represents the metallic derivatives of cantharidin by $C_5H_7O_3M$ or $(C_5H_7O_3)_2M_{11}$. But this is a small matter, and we hope that the author will have many opportunities of setting it right.

WORKSHOP APPLIANCES. By C. P. B. SHELLEY. Longmans, Green, and Co. 1873.

It might possibly amuse a person "unaccustomed to private thinking" if he were told that a work such as the above would be really valuable to the students of surgery and medicine. He might possibly imagine that the light cast by the star of mechanics would be out of place in a chemical or pharmaceutical laboratory, and smile at the idea of a professor surrounded by a lathe, a press, a drilling machine, a circular shears and a grinding stone, and the possessor of a tool chest, where chisels, gouges, and files lay in ready contiguity. But any one who considered even for a moment the countless contrivances necessary in a hospital, and the endless inventions used in the workshop of a chemist, would at once perceive that unless the operators in either place were at least cognizant of the elements of machine designing and tool constructing, it might frequently happen that wise opportunities of improving their familiar appliances would be utterly lost; and it might even be at once conceded that had mechanics in past times intruded more into the curriculum of the school, college, or university, we should have seen a greater progress in surgical instruments and in the appliances for the relief of deformity, than a stroll through Class X., Div. II. of the International Exhibition of 1873 will afford us. It frequently happens that a something is wanted to perform a certain function, and no other, and unless it is handed over to the professional tool or instrument maker, at very often a prohibitive tariff, the idea of using that suitable article is dispensed with and a makeshift adopted. The dentist is almost entirely dependent upon his workshop, and if we could only know the thousands of instruments outside of odontology which have been originally invented by our physicians and surgeons, and could estimate rightly the advantage which would follow even the partial training of our students in applied and practical mechanics, so as to enable them to model and work in metal for themselves during their leisure hours, we should hail text-books like these with even superlative pleasure.

Professor Shelley's book is one of the series of 'Text-Books of Science' adapted for the use of all kinds of students, and of which series some excellent works upon mathematics, metals, mechanism, materials, manufactures, mensuration, magnetism, and other subjects boasting a greater variation of initial letters, have already appeared. We can safely say that if the *remaining* text-books are equally practical—and, as far as we can see from our experience, reliable—very forward strides will continue to be made in the right direction. The chief intention of this particular work is to stereotype a concise description of the varied tools used in the conversion of wood and iron, etc., into useful articles in the engineer's or amateur's workshop, and to enable even the youthful inhabitant of a remote village to compete as bravely for the Whitworth Scholarships as the junior or even senior residents of London, Leeds, or Birmingham.

In the preface, the author says—and it chimes in exactly with the views which we have heard expressed by some of our leading men—"the student, in making himself familiar with the appliances described, will but be following in the steps of many of our most eminent civil engineers, some of whom have made improvements in mechanism, upon which, however trivial they may appear in themselves, has depended the success of the most brilliant of their achievements." One might say the same of some of the wonderful instruments described in the reports of the Medical Officer of the Privy Council, or which are to be seen in the studios of our chief pathological men.

One might also almost admit that the students of to-day—whose patron in the olden times would have been the *healing* god—Æsculapius of Cos—have quite enough to do to master all the essentials of their own immediate profession without learning the mysteries of the drill-chuck or the machine for measuring to the 10,000th part of an inch. Even the *pharmaceutist* has sufficient to do. Botany must be his handmaiden, and he must be well acquainted with every flower and shrub pictured upon her ample robe; philology must be his, to lay bare the printed treasures of other lands; mineralogy must be his slave, and prompt him as to the properties of countless things obtained even far below in the Plutonic kingdom; chemistry must also be at his beck and call, with all her hieroglyphical-looking formulæ; and as for the classics, these must perforce be added to his repertory of powers, or he can never hope to weigh in the mental balances, properly, the strange things (he will perhaps never see) represented by the long-winded syllables of Greece and Rome, or venture to name for the future any discovery of his own. What use, therefore, of adding to his *répertoire*, or to that the student of medicine or surgery, any more of the 'onomies, 'ographies, 'ologies, or 'ognomies?

We cannot expect every one, or indeed *any one*, now-a-days to be an "Admirable Crichton." Nevertheless, the reviewer will have the last word, and humbly promulgate the idea that if our young men are wise they will, to the before-mentioned *extras*, add artistic and mechanical knowledge, and at least accord an hebdomadal hour or two to the ever-so-humble private workshop. Better a studio, dilapidated with earnest work, than a sumptuous billiard room, and yet nevertheless, of course, both in their place.

Notes and Queries.

[354.] SHEEP DIPPING COMPOSITION.—Will any reader favour me with a recipe for a Sheep Dipping Composition, free from arsenic, which could be put up in cans similar to the Dougall's or the "Glycerine Dip?"—E.W.

[355.] LIME JUICE AND GLYCERINE.—*X. Y. Z.* wishes for directions for making "Lime Juice and Glycerine" that will not separate upon standing.

[356.] MARKING INK.—We should be much obliged if some reader would favour us with a really good recipe for Marking Ink.—YOUNG and POSTANS.

[357.] FLUID EXTRACT OF MILLEFOLIUM.—I should esteem it a favour if you would inform me of a method of preparing Ext Millefol. Fluid.—J. A. MAXWELL.

[*** We do not know the Fluid Extract of Millefolium, but should imagine that a process similar to that given in the B. P. for the preparation of Ext. Pareiræ Liquid. would answer very well: strength—fℨj = ℨj of the dried plant. Perhaps some of our readers can give a formula.—ED. PH. J.]

[358.] RED HAIR.—Will some correspondent give me a recipe for making red hair lighter in colour?

[359.] STEEL OF ANTIMONY.—"*Nescius*" having been asked for "Steel of Antimony," would thank any student of abstruse pharmaceutical nomenclature to explain what it is.

[360.] DELECTABLE LOZENGES.—Can any one give me a good formula for delectable lozenges?—H. WONFOR, *Wincanton.*

Prescribers and Dispensers.

Sir,—I am very pleased to see that Mr. Hampson intends to bring forward the subject of doses in prescriptions at the Conference, and think some rule is necessary for alterations and additions in old prescriptions as well.

Alterations in quantities are frequently made in prescriptions that have been previously copied and numbered, and sometimes there is another ingredient added. When there is no erasure, there is nothing to attract the dispenser's attention to it, or to enable him to make the alteration in the prescription book, in order that future supplies may be dispensed accurately without the prescription. It is of no use leaving it to the patient to tell the chemist of the alteration made, for we all know how uncertain a method that is, and one throws the blame on the other if there is any mistake.

If by the side of any alteration or addition the medical man were to put his initials and the date, it would make everything quite clear, and facilitate business very much. If medical men only knew how many patients take their medicine without even unwrapping the bottle (just tearing the top of the paper off to get the cork out), they would be more particular in noting any alterations in medicines or doses, or times of taking them.

I have known several prescriptions lost through being cast away with the empty bottles (tied on to the wrapper); also bottles sent to be refilled with the old wrapper on, only just torn off at the neck.

It is very desirable that prescribers and dispensers should come to a good understanding on such matters, and have some recognized rules to guide them.

George Brown.

Sandown, I.W., Sept. 8th, 1873.

The Unjust Censure of a Chemist.

Sir,—It appears to me to be the duty of one and all the members of our Society to endeavour to remove the effect of the unjust stigma passed upon our professional brother, Mr. Fisher, of Ramsgate, in the late fatal case of *delirium tremens*. Allow me, therefore, to give experience of miswritten prescriptions.

Twenty years back I was living senior assistant at a well-to-do City pharmacy: among our customers was one of the operating surgeons of an East End hospital: his coachman called with a prescription written for himself by his employer, adding that his master wished us to book it to his own private account.

℞ Quinæ Sulph. . . . ℥ ss
Inf. Rosæ Co. ad . . ℥ vj
M. ft. mist. sumend. ¼ part. 6tis horis.

I told the coachman it would be ready in an hour. Meanwhile I called upon the surgeon in Broad Street: his footman stated that his master was at dinner and that I could not then have an interview. I said that it was matter of importance to the surgeon himself; so most unwillingly the latter left his meal, stood at the top of the first-floor staircase,—myself remaining in the hall—and then called out in the roughest manner,

"Well, what is it?"

"Sir, you have written a prescription for your coachman in which I fear there is some error,"

"I have made no error."

"Very well, Sir; I will return and dispense it, at your absolute order, thus relieving myself of all responsibility."

"Here, let me see it."

I then hand in prescription.

"Dear me; dear me;" laughingly, and casting aside his brusqueness. "I meant *magnes.* sulph. ℥ ss. I am glad you called."

I then withdrew, suggesting that he should not be so curt, as Pius IX. was the only man that had the reputation of being infallible.

Another prescription, No. 2662 in my journal, is this:—

℞ Liq. Morph. Acet. . . . ℥ j
Antimon. Sulph. . . . . gr. x.
Sacch. . . . . ℥ j
Divide in Pulv. viij.
One powder at bed time.
7/3/72. A. R.

In this case I knew what was meant and put in place:—
Morph. Acet. . . . . gr. ss.

If Dr. Collis Browne's dictum is correct I ought to have used "Liq. Morph. Acet.," made an electuary, and sent it to the patient in eight pieces of tin foil.

Robert Owen Fitch.

200, *Well Street, South Hackney.*

The Remuneration of Assistants.

Sir,—Permit me to insert a few remarks respecting the pay of chemists' assistants, contrasted with their qualification.

We are every week seeing the amount offered to a qualified man, viz., £40 per annum; this is the average for which he is expected to work from eight a.m. until ten p.m., in the majority of cases, and be in attendance a portion of Sunday, for which he is allowed perhaps one aiternoon a week. Now I maintain there is not a parallel case to be found in any other trade. There is no class of men equally educated whose labours are so badly remunerated.

A deal has been said about the poor agricultural labourer, and to some purpose. Might not more be said about the poor chemists' assistants, when it is a fact farm labourers are getting £6 per month (four weeks), and all found them in many districts for harvest work? Of course, I need hardly contrast the qualifications of the two, or the responsibility of dispensing poisonous medicines.

Another great point is the labourer does not work so many hours, and has the Sundays to himself.

This latter being a great consideration, and I cannot help feeling the majority of chemists who are in favour of Sunday work have not the interests of the public at heart, but their own pockets, and scruple not at selling many things which could well be done without. I speak from experience.

Such Sunday trading, I should have thought, would be looked upon as decidedly wrong by the most respectable amongst us, but I was sorry to see in the Journal, a few weeks back, it was thought a great convenience to the public.

I am inclined to think apprentices will be rather shy in entering the trade with its present prospects, and I am at a loss to know what inducements masters can hold out.

Richard Cattell.

PHARMACEUTICAL RESULTS OF THE CALCUTTA BOTANIC GARDENS.

Acclimatization of Jalap and Ipecacuanha.

Dr. Henderson, the superintendent in charge of the Calcutta Botanic Gardens during Dr. King's absence in England on sick leave, has produced a very interesting annual report on the work done and the requirements still needed in the garden, to which is added an elaborate appendix on the cultivation of the ipecacuanha.

First, with regard to an economic garden, Dr. Henderson says an Indian botanic garden ought to have some space devoted to plants of economic importance, which are grown in the country, as well as such plants from other countries as can be got to grow there. A commencement has been made to form such a garden, but the difficulty is, with native agency, to keep it up, for most of the plants have to be renewed every year, just as in the case of the herbaceous garden. A great variety of seed of fibre-yielding plants has lately been received from the commission appointed to inquire into the jute trade. This seed has all germinated, and when the plants flower, and can be identified, they may yield some interesting information. Dr. Henderson took with him to Calcutta in December last some jalap plants (*Exogonium purga*), which, he says, have, as yet, hardly had a fair trial, but the plant does not appear to thrive in Calcutta, and it will be tried in Sikkim. With regard to this hill garden in Sikkim Dr. Henderson says, "The climate and soil of the Calcutta gardens are unsuitable for so many plants which it is desirable to introduce into the Himalayas that for some years a small branch nursery garden has been kept up in Sikkim, at the cinchona plantations. I should like to see these nurseries very much extended, as there is now a large European population of tea-planters in Sikkim, and, as a rule, all are anxious to try new plants. A number of plants (250) of the European sweet-chesnut have been raised, and it is expected before the end of this year a very large number of plants will be got up for distribution, Dr. Oldham, on his way home on leave, having kindly undertaken to get seed for me in Italy. Coffee is also being tried, and succeeds very well. Many tea-planters now grow coffee for home use, but it will not pay so well as tea, I fear."

To the report, which concludes by drawing attention to the necessity of a building for a museum, and the propriety of making the gardens the head-quarters of a botanical survey of India, is added a lengthy appendix on ipecacuanha, which contains so much of interest that we give it entire :—

"As the experiments being made to introduce this plant into India are perhaps the most interesting attempts at acclimatization now being made, I think it as well to give a concise history of what has been already done, and the latest results of our experience regarding the plant. The history is a very instructive one, and shows how difficult it is to carry out such an experiment rapidly, nearly eight years having now been occupied in getting up a lot of stock plants, and as yet we have only about 7000 altogether, half of them minute cuttings. If ipecacuanha is ever to succeed in India, I think another year will see a small plantation fairly started.

"There are evidently several varieties, if not species, of ipecacuanha amongst the plants now in the Rungbee nurseries, and I think this gives us additional encouragement to persevere, for it is possible that these varieties may require just as different treatment as the different species of cinchona do, and that although one variety may not answer here, some of the others may. Besides this, plants grown from minute cuttings and reared under glass are much more delicate than those grown from larger cuttings and kept in the open air ; and I do not consider that the experiments hitherto made are of much value as showing whether or not the plant will thrive in the Bengal Presidency. It is one of the slowest growing plants I know, and one of the most difficult to propagate by cuttings. I have seen some cuttings of the stem remain quite fresh for over two months without an attempt at making roots. Root cuttings strike much more readily, but even they sometimes become quite stagnant, and will not put out shoots unless they are of pretty large size and get a brisk bottom heat. From all I hear of the soil and climate of the Andaman Islands, I believe the plant will thrive there, and I have offered to send General Stewart some plants for trial.

"But to return to the history of its introduction. In 1866 Dr. King brought a plant from Kew which had been originally got from Brazil ; two years later, namely, in 1868, this plant had been increased by cuttings to nine.

"1869.—Only nine plants, but Dr. Anderson, who had gone to England, was endeavouring to get more, and succeeded in obtaining a number in Edinburgh.

"1870.—Mr. Clarke reported that the plants were as at last report ; everything had been done for them, but they continued unhealthy and would not grow. Some sent to Sikkim were doing better.

"1871.—The plants in Calcutta are reported just as before.

"1872.—At the beginning of the official year there were five plants in Sikkim and seven in Calcutta, and those in Sikkim were multiplied by root cuttings to about 300 by the end of August."

"In a memorandum by Mr. Gammie, on the introduction of ipecacuanha to the Sikkim Himalayas, he says :—

"'Three plants of ipecacuanha were received at Rungbee from the Calcutta Botanical Gardens in 1868. These formed part of the produce of the single plant brought out by Dr. King from the Royal Gardens, Kew, in the early part of 1866. One of the three died soon after arrival at Rungbee, and on the 31st of March, 1869, the remaining two had been increased to five rooted plants and one cutting. The cutting afterwards died. On the same date in 1870 there were five rooted plants and seven cuttings, and again the cuttings were unfortunate, for a drunken washerman (dhobie) fell through the glass frame in which they were placed and completely destroyed them. We then determined not to cut the tops of the plants again, as we found that after cutting the plants were a very long time in throwing out fresh shoots, and even then most sparingly. We waited patiently to allow the plants to form a good supply of roots, and in consequence of this determination, and the dhobie accident, we had five plants only on the 31st March, 1871. In the summer of that year we partially stripped the plants of their roots, which we cut into very small pieces and treated as ordinary cuttings. By this method our stock of plants and cuttings was increased to about 300 by the end of August, 1871. Since then the following four consignments of plants

have been received at Rungbee from the Edinburgh Botanical Gardens and Messrs. Lawson and Sons, the Edinburgh nurserymen :—

September, 1871	11
March, 1872	247
December, 1872	112
January, 1873	10
Total	380

—the number that reached Rungee alive. On the 1st January, 1873, the total number of plants and cuttings was 3066.

"On 31st March last they mounted to no less than 6719 in Sikkim, and about 500 in Calcutta. In December last I brought out 128 plants from Kew and Edinburgh, and as the weather was then too cold to send them to Sikkim, I decided to see if they could be multiplied in Calcutta, notwithstanding that all former attempts made there had failed, as stated in the Annual Report for 1871-72.

"Mr. Lister, the second gardener, just arrived from the Edinburgh gardens, where he had seen the plant propagated, set to work and made cuttings both of the root and stem, and by the end of March about 500 new plants had been produced ; and most of the 128 original ones were sent by post to Sikkim, where they arrived as fresh and healthy as the day they left Calcutta. The roots, when packed in slightly moist earth, stand carriage remarkably well. I brought out some root plants from England packed in this way, and most of them arrived in good order. I do not like Mr. McNab's method of packing in sphagnum moss ; I think moist earth preferable.

"Besides trying to multiply them, I planted out a number in Calcutta under every variety of conditions—some in the open, some under moderate shade, and others under dense shade. Two plants fully exposed were killed by the sun ; all those under shade appear to thrive, but have met with many accidents. Single plants have been placed out at five different points along the bottom of the Rungbee valley, but with the exception of one plant under shade of cinchona, near Mr. Biermann's house, none seem to thrive, and even the successful one is no better than those planted under shade in Calcutta. At Bamunpokree, in the Terai, they are no better, with one exception. An experiment in planting out is now, at my suggestion, being tried on a much larger scale at Rungbee with several hundred plants, in beds of leaf mould very carefully prepared. Until the rains, these are being shaded with grass matting ; but as soon as the rains set the shades will be gradually removed. Mr. Jaffrey has not only succeeded in getting leaves planted as cuttings to make roots, but in ten months he has got these rooted leaves to produce as many as four shoots from half an inch to an inch-and-a-half long."

(To be continued.)

ANNUAL DINNER OF THE PHARMACEUTICAL CONFERENCE.

The annual dinner of the British Pharmaceutical Conference took place at the Victoria Hotel, on Tuesday, September 16th, at eight o'clock, Mr. F. M. Rimmington, of Bradford, one of the Vice-Presidents of the Conference, in the chair. About seventy sat down to dinner.

The cloth having been drawn,

The CHAIRMAN, in proposing "The Health of Her Majesty the Queen," said: Gentlemen, I believe that as a body we are essentially a Conservative confraternity, and therefore I have the greatest pleasure in proposing "The Health of the Queen."

The toast was drunk amid loud cheers, and was followed by "God Save the Queen."

The CHAIRMAN, in proposing "The Health of the Prince and Princess of Wales and the rest of the Royal Family," said : I have great pleasure in proposing "The Health of the Prince and Princess of Wales and the rest of the Royal Family." It is quite certain that every person here must feel the greatest interest in the succession to the Crown in this country. We see with pleasure that the spirit of republicanism and of anarchy which at one time did threaten the constitution of this country is fast falling into decay. I have the greatest pleasure in asking you to drink the toast which I have proposed.

The toast was warmly received, and was followed by "God Bless the Prince of Wales."

The CHAIRMAN, in proposing the toast of "The President and Officers of the Pharmaceutical Conference," said : Gentlemen, I really feel a great satisfaction—something, in fact, akin to pride—in presiding over this meeting, when I consider that, ten years ago, I was one of the twenty apostles who went to Newcastle with the view of establishing this now important Society. We assembled there in a small upper chamber, and from thence we promulgated the principle which has been perpetuated by this now highly respectable and influential Society. I have always felt an interest in the progress of this Association, and I have supported it as far as my abilities, time, and opportunities would allow me. I cannot pretend to have been a very active supporter of the Society, but I have done the best I could for it, and that is as much as most people can do. I can only say that I am glad to see that it is progressing, and that I am quite satisfied that the influence of the Pharmaceutical Conference both upon the ethics and the *esprit de corps* of the pharmaceutical world has been most beneficial, and that if the Society survives another decade, we shall see pharmacy occupying a very different position to that which it held before this Association was established. Of course, this Association may be said to have sprung out of the Pharmaceutical Society, because it was started, in the first instance, by eminent pharmacists who were members of that Society, who, actuated by high principles, and strong motives for raising the *status*, both socially and materially, of the profession, with no little labour and self-sacrifice, founded this Association. This Conference, however, is an itinerant society, which, by changing its locality, transfers its influence from place to place. It has hitherto been associated, as a rule, with the British Association, because it derives some advantage from connecting itself with that body ; but at the same time, the British Association may sometimes take flights in which this Society does not feel itself competent to take part. The Conference has hitherto confined its visits to England and Scotland, and if Ireland does not appear to wish for its interference,—and indeed somewhat repudiates such interference,—however much we may regret that determination, I think that the pharmacists of Ireland will have more reason to regret it eventually. I am sure that, at all events, we should have done no harm if we had gone there, and I think that it is very likely that we should have done them a great deal of good. We can, at all events, enjoy ourselves at home quite as much as we could in Ireland. In conclusion, I have great pleasure in proposing "The Health of the President and Officers of the Pharmaceutical Conference," coupled with the names of the President, Mr. Brady, and the Secretaries, Professor Attfield and Mr. Benger.

The toast was drunk with loud cheers.

Mr. BRADY (the President) in responding said : Mr. Chairman and gentlemen,—One of the most remarkable speeches I ever had the pleasure of listening to began with the words, "I had hoped that I might have been spared," and I confess that when the Chairman was concluding his speech that I too had begun to hope that on

the present occasion I might have been spared. It seems to me that the President of the Conference has a very wide duty to discharge, something after the nature of that of those farms in New England whose energetic owners set them up on end in order to grow corn on both sides of them. It seems to me that the President of the Conference has to deliver addresses all the morning and to make speeches all the evening. The duty of the President of the British Pharmaceutical Conference has become a very weighty and a very onerous one. In relinquishing that position however I feel that I ought to say a very few words not merely of congratulation to the Conference as to the position it now enjoys, but in reference to my own personal indebtedness to its members for the very kindly feeling they have always shown to me in whatever relation I have been placed towards them. The British Pharmaceutical Conference was born, as one may say, in Newcastle-upon-Tyne, my native town. The mere locality however was a matter of accident. The circumstance was brought about by but little real action on the part of the pharmacists of that town. It happened that I was the local secretary of the Pharmaceutical Society at the time, and as such I was called upon to make provision for those who assembled on that occasion. When the first staff of officers was discussed there was some difficulty in obtaining officers for the new and untried body, and I was asked to undertake the office of Treasurer. I had but little to do in that capacity; it was Professor Attfield and Mr. Reynolds who had the labour,—they kept the show and did all the work within, whilst I merely held the hat and took the money at the door. It was a very easy post, and to the mere moneytaker pertains very little of the credit of raising up an association of this kind. There is, however, a matter in connection with the present meeting to which I should wish to allude. I have felt that in coming to this part of Yorkshire I was returning to old familiar ground, because although my early life was spent in Newcastle my pharmaceutical education was obtained in Leeds, where I first formed a friendship with Mr. Reynolds, and where I first became acquainted with our chairman, Mr. Rimmington. Anything that I may have done in pharmaceutical science since then is due to the training which I received in your neighbouring town. I don't know that I can say anything more—I ought perhaps to have said less; but I feel that there is a debt of gratitude due from me to the Conference for the kindness which I have always experienced at the hands of its members, for the friendships I have made by attendance at its meetings, and for the very delightful evenings such as the present which I have spent in past years. In conclusion I can only express hearty thanks to you, gentlemen, officially on behalf of the Conference, and personally on my own account, for the kind manner in which you accepted the toast.

Professor ATTFIELD: I had hoped that after having heard the toast so ably acknowledged by your President, the chief of the officers and the Conference, you would have allowed me at once to have resumed my seat, but since you have been so kind as to call me forward I feel bound to express my acknowledgments for the kindness with which you have recognized my labours as one of your officers. When my friend, Mr. Reynolds, ten years ago, first drew my attention to the subject which had been suggested some time before by Mr. Schacht, respecting the importance of organizing such a body as this has become; and when Mr. Reynolds added that in his opinion the time had arrived for starting such a Society, I could but give in my adhesion to the proposal, and consented to devote what ability and energy I possessed to carry out successfully the idea originated by Mr. Schacht, and matured by Mr. Reynolds and Mr. Brady. If my efforts have apparently been successful, I therefore feel abundantly rewarded for my labours, and I can assure you that I shall continue to do my best to serve the Conference. I laboured heartily for it, because I saw from the commencement that it would promote pharmaceutical research, and tend to produce that unity amongst the whole body of pharmacists which was so much wanted. That it has produced an increase of pharmaceutical research nobody can deny. We may not have in this country a sufficient number of high class pharmacists to produce severe original researches every week, but you have at least more research than you had before this Conference was started. Any one who will take the trouble to count up the number of English pharmaceutical researches published before and since the establishment of this Association will find that what I say is correct. If I were to allude to the promotion of unity amongst us, I should only be reiterating what was so well said this morning by your President. With regard to the recent alterations in our financial arrangements, I must confess that I at first felt some misgiving that in attempting to raise the amount of our subscriptions, which it was imperative to do, we should probably frighten away a considerable number of our members, and I expected some six weeks ago when the annual circular to members was issued, that the post would bring me numerous resignations. Well, on the first day of receiving answers to the circular, forty letters came to hand. How many of them do you think contained post-office orders, and how many resignations? There were thirty-nine orders, and only one resignation. The next day I had sixty letters handed to me, and they all contained post-office orders for 7*s.* 6*d.* each. The following day I had 108 letters, and only two out of the 108 contained the remark by their writers that because the Year-book had only cost 5*s.* the year before, they did not see why it should cost 7*s.* 6*d.* for the following year. You will doubtless be glad to hear that from the 1st of August until yesterday, the number of subscriptions sent in to me has been three times as large as I have ever had at the corresponding period of the year, and that I have had during that time 800 subscriptions handed to me, while only three gentlemen have withdrawn from the Conference. In such a state of things as this, I need scarcely say that I feel that my labours in behalf of the Conference have been abundantly rewarded.

Mr. BENGER: I feel it a very great honour to have my name associated with such distinguished ones as those of Mr. Brady and Professor Attfield, although I cannot affect to regard my labours on behalf of the Conference as in any way equalling theirs in importance. Professor Attfield takes the greatest pleasure in discharging the duties of Secretary, and performs them so well that it would be a thousand pities to relieve him from them. The success that has attended the Conference hitherto makes me look forward with equal confidence to the future as pleasure to the past. I feel certain that an Association of two thousand English pharmaceutists must possess great intellectual energy, and that we shall not look in vain for great results from this Conference. It is to the local committees of the towns we visit that we owe much of our success in a social point of view, but it is to the general body of members that we must look to promote the other important object we have in view—that of increasing the common stock of pharmaceutical knowledge. I hope that in the future we shall produce some successful results by the formation of committees, or, if the word be preferred, of commissions, to examine into and report upon some special subject.

Mr. BELL: I have been requested to propose the toast of "The Pharmaceutical Press," and with it I beg to couple the names of Dr. Paul, of the PHARMACEUTICAL JOURNAL, and Mr. A. C. Wootton, of the *Chemist and Druggist*, to whom as representative of the local committee I offer a hearty welcome.

Dr. PAUL having expressed his thanks for the honour conferred upon him,

Mr. WOOTTON said: I should scarcely like to allow this opportunity, when the Conference is visiting for the first time a town in Yorkshire, to pass without my offering you, in the name of the *Chemist and Druggist* and of the

pharmaceutical press, my sincere thanks for the continued and very effective support which that press has received in this county. We always look upon Yorkshire as being our favourite county—as being, in fact, one of our best preserves for obtaining subscribers and the other advantages by which the pharmaceutical press lives. During this visit I have met with the utmost kindness from the pharmaceutists of Yorkshire, for which I beg to return my most sincere thanks. I adopt in full the words of Dr. Paul in responding to this toast, as I merely rose in order to avail myself of the opportunity to acknowledge my sense of the generous support the pharmaceutical press receives from this county.

The VICE-CHAIRMAN (Mr. Rogerson): The toast I have to propose is "The Health of the Visitors." We are all enlisted under the banners of the Pharmaceutical Society, in which we are all interested, and of which I had the privilege of being one of the founders. I am exceedingly happy to see so large a body of pharmaceutists gathered together in this room. Many have distinguished themselves in chemistry and pharmacy, but I believe that we were never so well represented in an intellectual point of view on any previous occasion as we are to-night sitting round this table. We look upon it as a great honour to have so many of the most distinguished chemists and pharmaceutists of this kingdom gathered together in Bradford. As, however, our time is short, I shall confine my remarks to one distinguished individual, Dr. Edwards, who I believe was one of the first who passed in the School of Pharmacy of Great Britain. Having been engaged in business for many years in Oxford Street, he has since been for some time in Canada, where he has greatly distinguished himself. I am sure that you will heartily join with me in offering him our congratulations, and in wishing him a safe return to Canada.

Dr. EDWARDS: Mr. Vice-President, your kindness, which reaches from one end of the room to the other, may perhaps be rather exhausting to yourself, but is by no means depressing to those who have listened to you. I do not feel like a stranger or a guest, but rather like a child at home. I was one of the original members of the Pharmaceutical Conference, and I have always regarded it as being one of those excellent institutions which is bound to go a-head. It is not an association that is calculated to interfere in any way with the Pharmaceutical Society, which may very properly be considered as the parent institution, and I trust that we shall always look upon that society with affection and friendship. I have made an effort to be present on this occasion, and in a short time I hope to be again at home in Canada, for although my native shore, this country is not now my home. I have spent many pleasant evenings, such as that I am now enjoying, with the members of the American Pharmaceutical Association, at their meetings at Chicago, Philadelphia, Boston, and other places, and I hope some day again to be present at such friendly gatherings on the other side of the Atlantic. Regretting that there were not present some more distinguished visitors than myself to respond to the toast, I beg to thank you for the honour you have done me in coupling my name with the toast you have so warmly received. I wish the Conference ten times more success in the future than it has had in the past.

Mr. SAVAGE: The toast I have been requested to propose is one which I feel sure you will receive most cordially. It is that of "The Health of our Chairman." It affords me the greatest possible satisfaction to meet him here on this occasion. Twelve months ago I had much pleasure in meeting him at Brighton, and I now come here relieved from all the cares which are undergone by those who are on local committees. Although for forty-one years I have lived in one of the most southern towns of England, yet I am a native of Yorkshire. We derive much advantage from our itinerant habits as a Conference, because, by mingling with those who live in different parts of the country, we rub off the angles that are the fruits of living in towns, and with them get rid of many prejudices which are engendered by constantly associating with the same persons. I have much pleasure in proposing the health of our Chairman, Mr. Rimmington, and thank him for the very efficient way in which he has performed the duties of the evening.

The CHAIRMAN: Your hearty cheers and expressions in my favour would quite overwhelm a stronger man than myself. I feel exceedingly glad—a sort of high satisfaction—in seeing you here enjoying yourselves this evening, and I cannot help expressing considerable regret that it may be a long time before we shall meet in Bradford again round such a table as this. One of the benefits of this Association is that it brings together heterogeneous elements into one body, and I heartily hope that we shall often meet again elsewhere if not here. I, again, beg to thank you for the honour you have done me in drinking my health.

Mr. BRADY: Gentlemen, for once we have beaten the Americans. When we telegraphed on a former occasion from Liverpool to the American Pharmaceutical Society, then sitting at Baltimore, we found that the Americans had been beforehand with us. But to-day we have forestalled them. We despatched a greeting to them at Richmond by telegraph at eleven o'clock this morning, and I have received a telegram in reply dated half-past five o'clock this afternoon, which is as follows:—

From the President of the American Pharmaceutical Association,
To the President of the British Pharmaceutical Conference at Bradford, England.

We return your hearty fraternal greetings.

(Loud cheers.)

Mr. WILLIAMS: I beg to propose the health of our Vice-Chairman, Mr. Rogerson. The Conference has received on this occasion such a reception as it never has had before, but we hope to do our best when we see the members in London, where I believe the next meeting of the Conference will be held.

The VICE-CHAIRMAN (Mr. M. Rogerson) said: We may congratulate ourselves that the Pharmaceutical Conference is not now, as it might have been some years ago, a thing to be hoped for, but hardly to be expected. It has become in a great degree, and it is becoming in a still greater degree, an accomplished fact. The Society has passed through troubles and undergone difficulties, as most of us do in the course of our days, but we now see that it is a success. I feel it to be a great honour to have the meeting of the Pharmaceutical Conference in our smoky town, where we are all busily engaged in trade and manufacturing pursuits, with a dense population surrounding us. The local committee have done their best for the accommodation and comfort of their distinguished visitors, but have fallen far short of what they would have wished to accomplish. It was quite new to us, and if we had to do it again, I am certain we could do it much better. We are under a great amount of indebtedness to those gentlemen who take an active part in the Conference, not only for scientific purposes, but to raise the standard of our avocation, which is so much needed. In this marvellously prosperous town, which I have known and lived in for forty-five years, we see a many who are engaged in the staple trade of the town amass large fortunes. In our avocation we cannot do this, but we ought not to feel discouraged when, if blest with good health, we can at least earn a comfortable and respectable livelihood.

Mr. COTTERELL proposed "The Health of the Local Secretary of the Conference (Dr. Parkinson) and of the Committee," coupling with the toast the name of Mr. Alderman Hicks.

Mr. Alderman HICKS, in responding, reminded those present that the usual hour for closing the hotel had arrived, and contented himself with heartily thanking them for drinking his health. He concluded by asking them to drink "To our next merry meeting."

The company then separated.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 20, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

BRADFORD.

THE attendance at this year's meeting of the British Pharmaceutical Conference has hardly been so numerous as on some former occasions, and it would seem that this has been in a great measure due to the circumstance that the ordinary charges for hotel accommodation have been very largely increased for the period of the British Association Meeting. We think this system an eminently vicious one, and that whatever arguments may be advanced in support of it, the legitimate interests of the hotel keepers could be at least quite as effectually guarded by other means less objectionable in their character. Surely it would be desirable if the representatives of a town inviting a visit from the British Association were to exercise their influence in regard to this point, by endeavouring to prevent a state of things not unfrequently denounced as extortion, and at least inappropriate under the circumstances.

However, in spite of such difficulties the meeting just terminated has been decidedly successful generally, and in some respects above the average. The Presidential address dealt with a variety of subjects important to the pharmacist, and a perusal of the report of this address, which we publish at p. 229, will convince our readers that it was justly listened to with attentive interest by the meeting. We may here refer to the admirable *résumé* given of cinchona cultivation in India and elsewhere as furnishing the best accessible account of the progress in that enterprise. Equally interesting was the narrative of the several steps recently taken towards the realization of the "dream of the dispenser," a cosmopolitan pharmacopœia. But it was when the speaker entered upon the subject of pharmaceutical education, and the influence exercised by the standard of the Society's examinations, that the chief effect was produced. Mr. BRADY'S remarks on this subject are deserving of thoughtful consideration, and their reception by the audience showed how desirable it is that there should not be any relaxation of the influence hitherto exercised by the Pharmaceutical Society towards the establishment of such a general high standard of technical qualification among the pharmacists of this country as shall place them collectively on a level with the same bodies in Germany and France. It is not fitting to enter on a discussion of this subject here at present, even if there were time to do so, for the opinions of the PRESIDENT of the Pharmaceutical Conference claim consideration first of all. We therefore limit ourselves to directing attention to them and to the expression of our earnest hopes that the action of the Pharmaceutical Society as regards education will still continue in its main results satisfactorily conducive to the attainment of that object which is desired by all, though it may be sought under the influence of different views.

In the proceedings immediately following the address of the PRESIDENT, attention was first directed to the very important subject of unusual doses in prescriptions, and the thanks of the pharmaceutical body at large are due to Mr. HAMPSON for having brought it forward in a manner calculated to enlist the co-operation of the medical profession in the endeavour to establish some recognized system by which the due fulfilment of the prescriber's intentions may be ensured in such cases, while, at the same time, security is afforded to dispensers that the responsibility falling upon them shall not be too onerous. The discussion that took place on this subject was in the best possible spirit, and the unanimous feeling of the meeting was in favour of some means to secure joint action on the part of medical men and pharmacists. Several suggestions were offered as the result of varied experiences, and a committee was appointed to take such steps as were advisable for arriving at the desired result. A report was afterwards presented and adopted, which the general secretaries were empowered to communicate to the medical profession in such a way as may be most suitable. We look forward to the issue of these deliberations with confidence that it will afford an illustration of the practical utility of such an association as the Pharmaceutical Conference.

Among other points of interest characterizing the meeting, it is pleasant to record the interchange of expressions of friendly greeting and sympathy between the British Pharmaceutical Conference and the American Pharmaceutical Association, now holding its meeting at Richmond, Virginia.

The papers read at the Conference were decidedly in advance of previous meetings, and showed evidence of increased scientific activity on the part of its members, which we trust will still continue to grow in extent and usefulness. One of the most important contributions was that on Nepaul aconite and aconitines by Mr. GROVES. Another on sewer gases by Mr. NICHOLSON, of Sunderland, and one on the detection of adulteration in tea by Mr. ALLEN, of Sheffield, may be mentioned as useful contributions to our knowledge of subjects apart from pharmacy, though of a nature to admit of the pharmacist's practical acquaintance with chemistry being applied to them with advantage. Among the more purely pharmaceutical papers we may also refer to those on the purity of commercial specimens of official acids, and on a new test for morphia by Mr. SIEBOLD, of Manchester, whose growing popularity as a teacher was evidenced by the hearty applause

with which he was welcomed. While speaking of the papers read, however, we must express our opinion that in some few instances they were overloaded with minute technical details in such a way as to detract from the interest they might be entitled to excite. It seems worthy of consideration whether in such cases much tedium might not be avoided and the ends of the authors and of the Conference equally well served by the preparation of abstracts giving the chief results obtained, afterwards publishing the papers *in extenso*, as at present, especially since the whole time at the disposal of the Conference is so short.

Of the cordial hospitality manifested towards the members of the Conference at Bradford and in the neighbourhood it would be impossible to speak too highly. Suffice it to say that it in no respect fell short of the reputation which Yorkshire enjoys in this respect ; that it was even more than could have been expected, so ample, hearty, and unostentatious in every way that we feel sure those who had the pleasure of participating in it will long retain a warm remembrance of their Yorkshire *confrères*.

The dinner organized by the Local Committee (a report of which appears on a preceding page) was a success certainly not inferior to that of any previous year. The same gentlemen also invited the members to accompany them on Friday in an excursion to Bolton Abbey and Woods.

The decision of the British Pharmaceutical Conference at its closing session, to take advantage of the opportunity afforded by the visit of the British Association to Belfast for holding a meeting in London in 1874 will undoubtedly meet with general approval. The offer of assistance made by the Council in the name of the Pharmaceutical Society, and the good fortune of the Conference in securing the services of so energetic a Local Secretary for the occasion as Mr. M. CARTEIGHE, may fairly raise the hope that next year's meeting will inaugurate the second decade of the history of the Conference with a fresh advance in its prosperity. In the President-Elect, Mr. T. B. GROVES, of Weymouth, a worthy successor to Mr. BRADY, has been chosen. Mr. GROVES' researches on the aconite alkaloid have now become part of the history of the plant, and his fresh memoir upon the subject will be read with interest by scientific pharmacists throughout Europe and America.

Another instance of the community of thought and feeling which, chiefly owing to the spread of pharmaceutical literature, now exists between pharmacists of different nations was afforded in the beautiful album presented to the Conference on behalf of the American Pharmaceutical Association. Among the portraits of leading American pharmacists which it contains, are those of many whose names are familiar to the readers of this Journal.

Thus another meeting of the Conference has been conducted to a successful termination. But busy, prosperous, money-making Bradford is still full of visitors. Up and down her crooked streets, where splendid new buildings tread on each other in curiously irregular succession, the members of the British Association will yet wander for some days. And we venture to say that when all is over, more pleasant memories will remain than would have been thought possible of a locality where man by the aid of smoke and stone and bricks has done so much to deface the beauties of nature as in the district of Bradford

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The tenth annual meeting of the British Pharmaceutical Conference was commenced on Tuesday, September 16, 1873, at the Church Institute, Bradford, under the presidency of Mr. H. B. Brady, F.L.S., F.C.S., of Newcastle-on-Tyne.

The Secretary (Professor ATTFIELD) read letters of apology from several members who were unable, from various reasons, to attend the Conference.

RECEPTION OF DELEGATES.

It was announced that the following gentleman were present as Delegates from the respective societies of which they were members :—

Brighton Association of Pharmacy.—Mr. W. D. Savage (President).

Bristol Pharmaceutical Association.—Messrs. G. F. Schacht, F.C.S. (President).

Edinburgh—North British Branch of the Pharmaceutical Society.– Dr. S. Macadam.

Glasgow Chemists and Druggists' Association.—Messrs. Thomas Davison Black and E. C. C. Stanford.

Halifax Chemists' Association.—Messrs. W. Dyer and W. Stott.

Hull Chemists' Association.—Mr. James Baynes.

Leeds Chemists' Association.—Messrs. Edward Brown, John Day, J. W. Longley, and Wm. Smeeton.

Liverpool Chemists' Association.—Messrs. Joseph Hallawell (Hon. Sec.), A. H. Mason, F.C.S., John Shaw, and Robert Sumner.

Northampton Chemists' Assistants and Apprentices' Association.—Mr. J. Berry.

Nottingham and Notts. Chemists' Association.—Messrs. J. H. Atherton and J. Rayner.

Manchester Chemists' and Druggists' Association.—Mr. F. Baden Benger (Hon. Sec.) and Mr. Louis Siebold.

Sunderland Chemists' Association.—Messrs. J. Harrison, J. J. Nicholson (Hon. Sec.), R. Robinson (Treasurer), and D. B. Sharp.

The Secretary stated that the number of Delegates present on this occasion was larger than had attended any former Conference.

PHARMACEUTICAL PHOTOGRAPHIC ALBUM.

The following letter from the representatives of the American Pharmaceutical Association was read by the Secretary :—

To the British Pharmaceutical Conference.

HENRY B. BRADY, Esq., President.

The undersigned, on behalf of the American Pharmaceutical Association, take great pleasure in presenting to the British Pharmaceutical Conference an album containing the "shadows" of some of the officers and members of our Association. May the fraternal feeling which has heretofore existed between these Associations ever continue, and the good work which has been accomplished for the advancement of the true interests of Pharmacy and its collateral sciences be an earnest of what the future shall show.

With great respect,

Committee on Photographic Album.
H. W. LINCOLN,
P. W. BEDFORD,
JAMES T. SHINN,
LOUIS STREHL,
MAURICE W. ALEXANDER.

By P. W. BEDFORD.

Professor ATTFIELD said: You are aware that our President (Mr. Brady) visited America a short time since. After his return he collected a large number of photographs of the leading members of the Pharmaceutical Society of Great Britain, and of this Conference, which

he sent in an album to the American Pharmaceutical Association. Since then, the gentlemen connected with the American Pharmaceutical Association have returned the compliment by sending us an album containing the photographs of the most eminent American Pharmaceutists. The album, which is now being brought over by a gentleman who is crosssing the Atlantic, has, however, not reached us at present.

Mr. J. WILLIAMS moved the following resolution :—

"That the thanks of the British Pharmaceutical Conference be presented to the President and members of the American Pharmaceutical Association for the album which has been sent to the British Pharmaceutical Conference containing the portraits of the leading members of the American Pharmaceutical Association."

The resolution having been seconded by Mr. GREENISH, was carried unanimously.

MESSAGE OF GREETING TO THE MEETING OF THE AMERICAN PHARMACEUTICAL ASSOCIATION AT RICHMOND, VA.

The PRESIDENT : It may be known to some present that at this moment the American Pharmaceutical Association is holding its meeting in Richmond, Virginia. On a former occasion, when we were holding our meeting at Liverpool and the American Association were holding theirs at the same time at Baltimore, we forwarded per telegram a greeting to our fellow pharmaceutists across the Atlantic. Is it your pleasure therefore that a similar message should be forwarded to-day to Richmond? It happened oddly enough on the last occasion that the same idea had occurred to the American Association, and that thus our messages of mutual greeting crossed each other on the way.

Mr. RIMMINGTON moved, and Mr. HAMPSON seconded a resolution to the effect that a message of greeting should be forwarded from the Conference to the meeting of American pharmaceutists at Richmond, and the following telegram was subsequently drawn up by the Secretary and approved by the meeting :—

From the President of the British Pharmaceutical Conference, Bradford, England,

To the President of the American Pharmaceutical Association, Richmond, Virginia.

Our members send to your members hearty fraternal greetings.

THE ELECTION OF NEW MEMBERS.

The following gentlemen were duly elected members of the Conference :—Mr. James L. Alexander, of Bathurst, N.S.W. ; Mr. Richard Appleyard, of Bradford ; Mr. John Townsend Bailey, of Bradford ; Mr. J. L. Benson, Ph.D., of Leeds ; Mr. Montague Browne, of Melbourne, Australia ; Mr. Henry Butterworth, of Bathurst, N.S.W., Mr. Alexander Courtenay, of London ; Mr. A. H. Crundall, of Bath ; Mr. S. H. Darwin, of Liverpool ; Mr. Joseph Farnell, of Bradford ; Mr. H. E. Firman, of Alton ; Mr. A. W. Gerrard, of London ; Mr. F. Grason, of Milan ; Mr. Robert Hitchin, of Burnley ; Mr. William Holloway, of Bradford ; Mr. W. Howie, of Edinburgh ; Mr. J. T. James, of London ; Mr. J. W. Longley, of Leeds ; Mr. Frank Midgeley, of Padiham : Mr. Freshfield Reynolds, of Leeds ; Mr. W. H. Rhodes, of Leeds ; Mr. Samuel Lloyd Stacey, of London ; Mr. Sutcliffe, L.D.S., of Bradford ; Mr. H. Swingbourne, of South Molton ; Mr. Richard Thomas, of Burnley ; Mr. Hezekiah Thornton, of Bradford ; Mr. W. F. Tomlinson, of Leeds ; Mr. William Veitch, of London ; Mr. Joseph Henry Watson, of Leeds ; Mr. E. T. Webster, of Newcastle-on-Tyne.

THE REPORT OF THE EXECUTIVE COMMITTEE.

Mr. F. BADEN BENGER then read the following report:—

Your Committee have met three times during the past year.

On May, 7th 1873, the Senior Secretary, Professor Attfield, reported that in the previous September, on endeavouring to renew the arrangements for the issue of the annual volume, he found that the printers required an advance on former prices of $7\frac{1}{2}$ per cent. for the greater part of the printing, paper, etc., and 8 per cent. on the binding. He had convinced himself that this demand was a reasonable one and had granted it ; and the Year-book had been published in December. It contained besides the 400 pages of abstracts of papers on pharmaceutical subjects collected by the editor, the names and addresses of the 2000 members of the Conference, an alphabetical list of towns with the resident members, and a complete report of the transactions of the Conference at the ninth annual meeting at Brighton. He further reported that, in December, circulars had been issued requesting members to forward their subscriptions ; a second and third application had in some cases been made in vain, and at the suggestion of the Secretary it was resolved that the fifty-seven members whose subscriptions were three years in arrear should have a final application addressed to them, directing attention to the rule respecting defaulters and stating that if no answer were received within ten days, the name of the member applied to would be struck off the roll by the Executive Committee.

The Junior Secretary (Mr. Benger) reported the steps he had taken to ascertain the opinions of leading members of the Conference respecting the most desirable method of appropriating the money placed at the disposal of the Executive Committee by Thomas Hyde Hills, Esq. Many valuable suggestions had been received, a summary of which he laid before the Committee, with a draft of a circular including rules relating to the application of the fund. The plan proposed was similar to that adopted by the British Association which has for many years granted money in aid of original research. After some slight alteration, it was resolved "That the statement and rules now read be printed and circulated in the manner suggested." The following is a copy of the circular referred to :—

"At the annual meeting held at Exeter in 1869, Mr. T. H. Hills presented the Conference with the sum of 50 guineas, half in his own name and half in memory of Jacob Bell, suggesting that 10 guineas should be applied for the purchase of books for the Chemists' library in that town. In subsequent years the Executive Committee gave further effect to Mr. Hills' desire to promote pharmaceutical education, by presenting the same value of books to the Chemists' library in the town visited. These books have been appropriately bound, and stamped with the device shown above.

"Shortly before the meeting at Brighton last year, when the fund was nearly exhausted, Mr. Hills, with characteristic generosity, added to his original gift the munificent sum of £200 (4 Russian bonds of £50 each). The Executive Committee, after consultation with Mr. Hills, drew up a resolution to the effect that the discretionary power of granting a sum of £10 for books to any local association in towns where the Conference had met be continued ; that the principal sum of £200 be retained until the Executive Committee decide that one Bond of £50 be sold out, such sale not to be repeated oftener than once in three years ; the Executive Committee for the current year to decide upon the appropriation of such income from principal and interest, by granting sums in aid of original research, or for the cultivation of pharmaceutical science. This resolution was carried unanimously at the Brighton meeting.

"The British Association for the Advancement of Science has for many years expended considerable sums in grants to individuals or committees willing to undertake special work, and this plan has resulted in the accomplishment of much valuable investigation. The Executive Committee of the Conference believe that they will do well to follow such a successful example in the appropriation of the fund placed at their disposal. The sum available during the next three years will be about £80 ; they are therefore prepared to receive applications for grants in aid of any

original research members may desire to initiate or elaborate on subjects of permanent interest and value in connection with pharmaceutical science. It is also thought that many published statements in reference to pharmacy and meteria medica need verification, and that some part of the fund may be applied to cover the expense of repeating experimental work, where corroboration may seem desirable.

"The Executive Committee will meet on the 20th of the present month, and again, if necessary, in June, to consider any applications, for grants which may in the meantime have been addressed to the Secretaries of the Conference (at 17, Bloomsbury Square, London). The Committee will also be glad to receive suggestions which may assist them in selecting either appropriate subjects for research, or a member, or two or more associated members, or sub-committee, to whom such investigations might be entrusted.

"*Rules.*

"Applications for grants in aid of original research, or to defray the cost of repeating or corroborating important experiments must be addressed to the Executive Committee of the Pharmaceutical Conference through the general Secretaries, such applications will then be considered, and grants made as far as the fund will allow.

"Applicants must give full particulars of the investigation they are willing to undertake, and state their estimate of the cost.

"Members or Secretaries of Committees to whom grants of money have been entrusted are required to present to the next annual meeting of the Conference a report of the progress which has been made, and before such annual meeting to forward to the general Secretaries or Treasurer a statement of the sums which have been expended, and the balance which remains disposable on each grant.

"In grants of money to members the Conference does not contemplate the payment of personal expenses. Grants of money sanctioned by the Executive Committee expire one week before the Annual General Meeting, and the Treasurer is not authorized after that date to allow any claims on account of such grants, unless they be renewed in the original or a modified form by the Executive Committee.

"In all cases where additional grants of money are made for the continuation of researches, the sum named is deemed to include, as a part of the amount, whatever balance may remain unpaid on the former grant for the same object.

"When Committees are appointed, the first member named is regarded as the Secretary, except there is a specific nomination, and he is the only person entitled to call on the Treasurer for such portion of the sums granted as may from time to time be required.

"Professor ATTFIELD, 17, Bloomsbury Square, W.C.
"Mr. F. BADEN BENGER, 1, Market Place, Manchester.
"*Hon. Gen. Secs.*"

Ten guineas from the Bell and Hills Fund had been devoted to the purchase of books for the Brighton Chemists' Association; the volumes, suitably bound, had been forwarded in the name of the Committee.

On May 21st, 1873, the Senior Secretary reported that the Bell and Hills Fund circular had been sent, accompanied by a private letter on the subject, to each member of the Executive Committee, to every member who had contributed an original paper to the Conference, and to the respective editors of the PHARMACEUTICAL JOURNAL and the *Chemist and Druggist*, who had kindly given considerable prominence to the matter. In answer, no actual applications for grants had been made, but many suggestions of subjects for investigation had been offered; amongst others, Mr. Martindale suggested a thorough investigation of the plasters of the Pharmacopœia; Dr. Wright, that sums might be offered to members who would aid in clearing up questions about doubtful alkaloids; Mr. A. H. Allen, for improved methods of detecting adulterations or admixtures of fixed oils; Mr. Tichborne, for researches having for their object the improvement of many of the official formulæ and the exclusion of others; contributions to the natural history of drugs; modes of economising alcohol in making spirituous preparations; investigations on disinfectants; and papers on the application of physical instruments in pharmacy; Mr. Savage for an improved pill-machine for dispensing purposes, and for machines for rapidly and perfectly commingling ingredients for large and small pill masses; and Mr. Greenish, for a model compact pharmaceutical laboratory. These, with the 200 subjects for research, given in the "blue list," a copy of which had recently been sent to every member of the Conference, afforded ample variety, and if the cost of working out researches deterred members from undertaking them, such members should at once apply to the Committee for grants.

The question of increasing the annual subscription to the Conference was discussed at this meeting. Professor Attfield pointed out that when the Conference was established, the founders did not entertain any idea of publishing that large and important volume 'The Year-book of Pharmacy.' After its publication, finding that their small annual subscription left them, year after year, with an increasing balance in hand, a decision was arrived at to use up the accumulated funds before making any charge whatever for the book. These funds had now been expended, the cost of producing the Year-book had recently increased, and the expenditure of the Conference was, in consequence, somewhat in excess of its income. It had become necessary for the Committee to devise and recommend a scheme which would place the Conference on a sound financial basis.

The Committee were of opinion that the money value of the book was double that paid for it by members, and that an increase in the subscription would not alienate any important number of their supporters. It was recommended that the annual meeting should pass the following resolution:—"That the annual subscription to the Conference be in future 7*s.* 6*d.* per annum."

It was announced that in consequence of the appointment of Mr. C. H. Wood, as Quinologist to the Indian Government, that gentleman had intimated the necessity of shortly placing his resignation in the hands of the Committee, and the Secretary was instructed to issue an advertisement, stating that the editorship of the "Year-book" for 1874 would be vacant, and inviting applications from candidates for the appointment.

A discussion took place on the question whether or not it was desirable, in accordance with the custom hitherto adopted, of assembling at the time and place of meeting of the British Association, to go to Belfast in the autumn of 1874. Letters addressed to the Secretary, from prominent members of the Conference resident in Ireland were read, adducing reasons against the visit. Further consideration of the subject was adjourned.

At this meeting sixty-one gentlemen were elected to membership.

On May, 29th 1873, a deputation, consisting of Dr. Whittaker and Mr. Pring, from the Protective Association of Licentiate Apothecaries of Ireland met the Committee. These gentlemen explained at length the relative position of apothecaries and druggists in Ireland, the latter class only dealt in drugs among other things, and did not dispense precriptions; and the apothecaries, whose position was identical with that of English pharmacists (and not with the English "apothecary") would object to meet men who knew little or nothing of the subjects likely to be discussed at a meeting of the British Pharmaceutical Conference. The deputation having retired, it was unanimously resolved—"That the Committee having heard the statement of Dr. Whittaker and Mr. Pring, apothecaries, of Belfast, regarding the present unsettled condition of pharmacy in Ireland, are of opinion that it would not be expedient for the Conference to meet in Belfast in 1874."

Some discussion ensued respecting the class of town in

which to meet in 1874, and a very general opinion was expressed in favour of London.

Little need be added as to the prospects and capabilities of our Association. Its continued success and usefulness depend no less on the activity of individual members than on the energy of its officers. A very wide field of research is suggested, and your Committee earnestly hope that during the present year the progress of pharmacy in England may receive a renewed impetus by the exertions of some of the 2000 members of the Conference.

The TREASURER (Mr. J. F. Schacht) read the financial statement of the Association as follows :—

Examined and found correct—
THOMAS A. BREW, JOSEPH HICK, } Auditors.

Having read the report, Mr. SCHACHT said : The result of the report shows that the expenses of the Association are in excess of its income, and in order to meet the deficiency I beg to move that the resolution recommended in the report to the effect that the subscription to the Conference in future be 7*s.* 6*d.* be adopted.

Mr. HAMPSON seconded the resolution, which was carried unanimously.

Mr. M. ROGERSON, in moving that the report of the Treasurer be received and adopted, said : The report seems generally to be very satisfactory, but I am sorry to hear that the financial position of the Association is not so good as it deserves to be. I have no doubt, however, that as the Association advances in usefulness any deficiency in its income will be soon made good.

Mr. BELL having seconded the resolution, it was carried unanimously.

THE PRESIDENT'S INAUGURAL ADDRESS.

The PRESIDENT then proceeded to deliver his inaugural address, as follows :—

Gentlemen,—The duty which devolves upon your President to open the proceedings of the Conference by a few introductory remarks, an "address" as your Secretaries are accustomed to say, need not, on the present occasion, detain you long from the more important business which you are assembled to transact. At the same time, we may remember that our present meeting in Bradford completes the first decade in the history of the Conference, and this fact suggests retrospective thoughts which may well for a moment occupy our consideration, and important questions which may rightly claim some preliminary attention — thoughts as to the progress of pharmacy during the ten years' interval, questions as to the objects sought by the founders of the Conference and the success or failure which has attended its labours. It is fortunate that we can look back with few regrets and that the record of our past is one which has no dark chapter.

It is now many years since our worthy Treasurer urged the desirability of a periodical gathering of pharmaceutists out of London, and though the precise course he proposed for effecting the object failed to evoke a practical response, it was founded on that principle of decentralization which is the almost essential basis of any scheme for the spread and advancement of knowledge and for the encouragement of united action amongst the members of a scattered body. His idea was allowed to slumber, but was too good to perish, and ere long it reappeared in a new form, recast and rehabilitated, at the hands of your late Secretary. Early in 1863 a suggestion appeared, bearing Mr. Reynolds' name, that the pharmaceutists who were accustomed to attend the meetings of the British Association should assemble at the then forthcoming meeting in Newcastle-upon-Tyne, with all others who inclined to join them, to consider the desirability of an annual conference to discuss subjects connected with pharmacy.

The energetic co-operation of Dr. Attfield from the very first and the hearty concurrence of a number of our present members, notably of Mr. Deane and Professor Bentley, ensured even at the commencement a modicum of success. It never occurred to the one-and-twenty gentlemen who met as proposed on the 2nd of September in that year that the number who had responded to the invitation was a small one, if taken to represent British pharmacy, nor did it prevent them from adopting a constitution founded on the very widest basis. When, a year later, the new society held its first meeting in Bath, and the twenty had become two hundred, a success unthought of was reached. Already political differences were dividing pharmacists into two sections, and the value of a common meeting-ground, undisturbed by party strife, was apparent to all, and in the years that followed, the association and friendly intercourse of men of every shade of opinion at our annual gatherings was one of the most potent agencies in removing the jealousies which ob-

structed pharmaceutical legislation ; nor is it too much to say that to the good offices of the Conference in this respect we owe the conditions under which alone the passing of the Pharmacy Act of 1868 was possible.

In 1865 Birmingham welcomed us, a still advancing body, and our meeting in the following summer at Nottingham is still fresh in remembrance, partly on account of the exhibition of objects of pharmaceutical and general scientific interest held in connection with it, the organization of which was due to the energy of Mr. Atherton and his colleagues, but not less from the admirable exposition of pharmaceutical ethics which was presented on that occasion by our able colleague Mr. Ince—the first recognition that to pharmaceutists, in their relation to each other or to society at large, pertained any specialized system of morality that could be appealed to as a standard of right.

In 1867 Dundee asserted that Scotland shared with England a zeal for scientific advancement which only needed an opportunity to display itself, and the subsequent success of the meetings at Norwich in the east and Exeter in the west, brought fresh proof that distance from populous centres scarcely affected the spirit of the meetings or the fulness of their attendance. These gatherings, indeed, were remarkable for nothing so much as their uniformly satisfactory character. Liverpool followed with a yet larger assemblage of members, and the proceedings of 1870 were chronicled in our first 'Year-book of Pharmacy.' Edinburgh then confirmed all the favourable opinions of Scottish interest and welcome, the foundation of which had been laid at Dundee.

Our meeting at Brighton last year is still fresh in your minds. Science for once scarcely had its fair share of attention, but gave way, perforce, to the pressing and at the time irrepressible question of "provincial education." Though it cannot be said that any definite solution of the much-vexed problem was the result, it is hardly possible to regret the time spent over a discussion that did such good service in ripening opinion on a new and many-sided subject.

Such, then, has been the course of our Association, and if you ask me what there is to show of results, I may point to the organization which renders possible such a meeting as we have here to-day as of itself no unworthy object to have worked for—to the scientific and ethical value of the papers which have been presented in past years, and the discussions which have taken place upon them—or to the 'Year-book of Pharmacy,' of which the fourth volume will ere long be in your possession, and I say that any of these would by itself be reason enough for the past, and promise for the future, of the Conference.

The ten years of its lifetime have been fruitful in external changes, modifying in many respects the relation of the Conference to general pharmacy. By far the most important of these have arisen out of the Pharmacy Act of 1868, the gathering thereby into one compact body of all who had any claim to be called pharmacists, and their separation by the hard line of registration from that large class of general dealers who, to the detriment of pharmacy and to the danger of the public, added a trade in medicines to their more miscellaneous calling. That the full effect of so radical a change is not yet apparent we all know, but every year gives fresh evidence of its salutary working.

There are few topics that have claimed so large a share of attention, or that have been discussed with the same earnestness, as the possibility of a general fusion of pharmacopœias, and there can hardly be one of greater importance to those who are liable at all times to be called upon to prepare the compounds of any of the very numerous existing codes. The spread of commercial enterprize and the yearly increasing disposition to travel in foreign countries for pleasure or gain are rapidly softening national boundaries, and some recognized system in medical formulæ must become more and more an international question of the same sort as the simplification of coinage or the adoption of common standards of weight and measurement. It is not to be expected that the dream of the dispenser—a universal pharmacopœia—can be brought about *per saltum*, the matter is too complicated to be settled in such a way, but it is no small thing to be able to record that in the short lifetime of the Conference two great steps have been taken towards the desired end.

In 1864, the three pharmacopœias of the United Kingdom, namely, those of London, Edinburgh, and Dublin, were merged into one volume under the authority vested in the General Medical Council. The representatives of each of the colleges had to surrender a good deal, but concessions which looked serious at first have caused comparatively little inconvenience in practice ; so little, that it seems wonderful in looking back that the same work was not accomplished many years earlier. The resulting volume was in many ways faulty, as indeed, it could hardly fail to be, but the principle was adopted, and the issue of a new edition three years later was a matter of routine not one of debate. The co-operation of two gentlemen distinguished in pharmacy, Professor Redwood and the late Mr. Warington, in the compilation of the edition of 1867, led to the production of a volume which might be compared without disadvantage with any pharmacopœia then existing.

Another step, at least as great, in the same direction has been more recently taken in the issue of the Pharmacopœa Germanica. Until a comparatively recent period not less than nine pharmacopœias were in force in the area comprised in the present German Empire, namely, those of Prussia, Hanover, Saxony, Hesse, Hamburg, Sleswick-Holstein, Baden, Würtemburg, and Bavaria. In the year 1861, a joint voluntary commission was appointed, at the instance of the pharmaceutical associations of Northern Germany, Southern Germany, and Austria, to consider the questions arising out of this complicated state of things, and if possible to compile a general pharmacopœia for German-speaking nations. The commission was composed of men of highest standing in the pharmaceutical sciences, and it succeeded in producing in 1865 the first "Pharmacopœa Germaniæ." In its original form this was not accepted by any of the German States, but in 1867 an amended edition was published, which was eventually adopted by the kingdom of Saxony, and, what is much more important, served as a basis for the "Pharmacopœa Germanica" of 1872, which is now the authorized codex for the whole German Empire. The only regret is that Austria was not concerned in the latter work, and is thereby shut out for the present from the benefit of uniformity.

Differences in climate, in national habits, in natural productions, and many other external circumstances, make it almost hopeless to look for one code of universal application, but that the British and German Pharmacopœias now cover the ground that nine years ago was occupied by at least a dozen dissimilar works, is a fair subject for congratulation. What the next advance may be it is not easy to guess. There are a large number of substances in general use as medicines in almost every civilized country, and officinal in almost every pharmacopœia ; and if the strengths of the preparations of such as are common to all were rendered uniform, one of the greatest causes of discrepancy in dispensing would be provided against. There would probably be no insuperable difficulty even now in unifying the recognized medicinal formulæ of Great Britain and the United States, and it would be worth a strong effort and some mutual concession to reduce to one standard the pharmacopœias of two great nations speaking the same language and otherwise closely connected.

The same period of about ten years—we will not draw the line very strictly—has been fruitful in the introduction of new remedial agents. Some of them experience has shown to be valuable additions to the materia medica, a

larger number have been found to have a limited application and to present no general superiority to older and well-known medicines, whilst others again have proved to be altogether valueless, their recommendation having been based on supposed properties to which they had no claim.

Of the first series, hydrate of chloral is a prominent example, a substance first introduced to us by Mr. Hanbury, who presented to the Exeter meeting of the Conference an abstract of the original paper read by Dr. Liebreich before the Berlin Chemical Society. The specimen of chloral hydrate exhibited on that occasion was regarded as a chemical curiosity, and there could be little idea that within so short a time it was to become an article of commerce on so enormous a scale. To dwell upon a substance now so familiar to all would be waste of time.

The modern germ theory and the views of advanced biologists as to the invariable presence in the air and in water of bodies, capable under favourable conditions of infinite reproduction, becoming thereby a fertile source of disease, has in the hands of Professor Lister caused a revolution in surgery, and carbolic acid, which a little time ago was scarcely thought of except perhaps as a substitute for creasote, has in consequence become one of the most important bodies with which the pharmaceutist has to do. Solutions of other substances such as chloride of zinc and boracic acid have been employed with more or less success for the same purposes, but it is with carbolic acid, or the mixed carbolic and cresylic products of the distillation of coal-tar, that antiseptic treatment in medicine and surgery is more especially connected. It may possibly still be deemed an open question how far the preference for the crystalline carbolic acid over the fluid product containing the cresyl derivative has any solid basis. We, as pharmaceutists, are too apt to forget that the term "acid," as applied to this substance, is to some extent a misnomer, that, chemically speaking, carbolic acid is the alcohol of the phenyl series,—its solvent, or as we say its corrosive properties, rather than its strict chemical relation, having given rise to its name. On this fact, the somewhat uncertain nature and instability of many of its so-called salts in great measure depend.

In the same category, in point of importance, may be placed the extended employment of phosphates in medicine in place of salts containing vegetable or mineral acids. This has given rise to the introduction of a long series of syrups prepared from various phosphates dissolved in excess of phosphoric acid. In most of them, iron is a prominent ingredient, but we have also calcium, sodium, potassium, nickel, and manganese amongst metallic bases, and in addition certain alkaloids, notably quinia and strychnia, presenting altogether an almost endless diversity of combination. Other phosphorus oxides, such as pyrophosphoric and hypophosphorous acid, have shared with phosphoric the favour of the medical profession, and recently, the direct combinations of phosphorus with metals, *e.g.*, phosphides of zinc or iron, have been called into vogue, and the dispenser has had his wits further perplexed with fancy modes of administration of phosphorus itself in pills, capsules, oil, or ethereal tincture.

Whilst the introduction of chloral, the employment of carbolic acid in the antiseptic treatment of disease, and the development of the use of salts with one or other of the phosphorus oxides as an acid, mark the most salient changes in medical practice as affecting the duties of the pharmaceutist, during the past decade, many other new remedies have established themselves more or less securely in public favour. A considerable proportion of them we owe to America, for example, Podophyllin, Leptandrin, Prunus Virginiana, Actæa racemosa, and Veratrum viride.

But we are possibly too apt to search at a distance for medicaments, to the neglect of many within easy reach of our own doors. I suppose it was always so, for did not Gerarde write thus of the virtues of golden rod two or three centuries ago :—

"It hath in times past been had in greater estimation and regard than in these dayes: for in my remembrance I have knowne the dry herbe which came from beyond the sea sold in Bucklers Bury, in London, for halfe a crowne an ounce. But since it was found in Hampstead wood, euen as it were at our townes end, no man will give halfe a crowne for an hundredweight of it: which plainly setteth forth our inconstancie and sudden mutabilitie, esteeming no longer of anything, how pretious soeuer it be, than whilst it is strange and rare. This verifieth our English prouerbe, Far fetcht and deare bought is best for ladies."*

Professor Christison corrected this tendency in one remarkable instance by the re-introduction of our common male fern (*Aspidium Filix-mas*), in place of the foreign remedies for tape-worm which were so popular a few years ago, and it would be easy to point to many other indigenous plants that have more recently received the testimony of medical authority in their favour. For example, the rhizome of the bog-bean (*Menyanthes trifoliata*) has been stated to be in many respects superior to the root of its ally, the officinal gentian, and the dried leaves of the common raspberry (*Rubus Idæus*), used in some parts of the country in domestic practice in place of ergot, yield by no means the inert infusion that might be expected. The use of the expressed juice of the common periwinkle (*Vinca minor*) in uterine hæmorrhage, of the rhizome of the couch-grass (*Triticum repens*) in irritable bladder, of the red clover (*Trifolium pratense*) in hay fever, of one of our brown seaweeds (*Fucus vesiculosus*) in obesity, of a species of bedstraw (*Galium aparine*) in some cutaneous affections, of the rhizome of the burdock (*Lappa minor*) in syphilitic eruptions, have all given results that, if not sufficient to establish the claims made for them, at least show a *primâ facie* case in their favour. The last-named is but one instance out of several in which an indigenous British plant is officinal in the United States' Pharmacopœia and not in our own. A Russian physiologist recently observed that the alcoholic extract of our common hound's-tongue (*Cynoglossum officinale*) had all the properties of curarè, and though a series of experiments made a year or two ago, in conjunction with my friend Professor M. Foster, by no means confirmed the statement, they showed that the plant had nevertheless certain very peculiar effects on the nervous system, which further research might utilize. I name these but as examples of a large number that might be selected from our native flora.

Few subjects have been so frequently before pharmaceutical readers during the past ten or fifteen years as the efforts of the governments of Holland and Great Britain to introduce the various species of Cinchona into their respective colonies. It would be hardly possible to overrate the importance of the enterprise and it is one that interests alike the pharmaceutist, the botanist, and the votary of economic science. The records of progress which have been made public are so scattered and unconnected, the opinions and reports so conflicting, that it has been difficult for the general reader to retain the thread of the story or to arrive at any very clear estimate of the present position and prospects of the undertaking. The earliest steps in this great experiment in acclimatization date back to a period before that which we have had under review, but so far as results are concerned, the subject is one which pertains essentially to the past few years, and I propose to place before you, in as few words as may be, and unincumbered by the controversial matter with which its literature abounds, an outline of the beginning of the enterprise and of its present practical aspect.

The initiative in Cinchona cultivation was taken, as you well know, by the Dutch government, whose efforts were directed to its introduction into the Island of Java

* Gerarde, 1633 ed., p. 430.

The first Cinchona trees which were sent out to that colony were a few specimens of *C. Calisaya** raised from seeds collected by M. Weddell in Bolivia, and forwarded by a firm of nurserymen in Paris in exchange for rare Javan plants. In the same year, 1852, the Dutch government were induced to send M. Hasskarl, a gentleman previously attached to the Botanic Gardens at Buitzenorg, on a mission to South America, for the purpose of collecting plants and seeds. During the two years following M. Hasskarl pursued his labours and succeeded in forwarding consignments from some parts of Peru, the Cinchona districts of Bolivia being for the most part closed against him; and his efforts were supplemented as to the New Granada species by the assistance of Dr. Karsten. The resulting collections were sent in part direct to Java, and the remainder to Amsterdam for re-shipment. I need not dwell on the mishaps and disappointments inevitable in so new and difficult an enterprise,—it is sufficient to note that within three or four years, that is by the middle of 1856, upwards of 250 plants almost exclusively of two species, *C. Pahudiana* and *C. Calisaya*, were flourishing in the Java plantation as the outcome of the expedition. In the same year, with wise forethought, an accomplished chemist, Dr. De Vrij, was sent out to conduct chemical observations on the growing barks.

We may pass over the long series of troubles that attended the early efforts of those in charge of the trees —the ravages of insects, the destruction of young plants by rats, the devastation committed by wild cattle and rhinoceroses, and, above all, the difficulties dependant on climate, which eventually necessitated the transplantation of nearly the whole of the trees from the locality first chosen, on the north side of the mountain range, to one with a southern aspect. We will pass on, I say, to the year 1863, and we shall find that the total number of Cinchona trees in Java was then 1,151,810. Of these about 99 per cent. were of the species known as *C. Pahudiana*, the remainder comprising about 12,000 of *C. Calisaya* and trifling numbers of four other species. This proportion was unfortunate, for the bark of *C. Pahudiana* was found to be deficient in alkaloids, and therefore supposed to be valueless, and by decrees dated 1862 and 1864 its further culture was ordered to be forthwith stopped.

We may now turn to the steps taken by the British Government in the same direction.

Dr. Ainsley, in his work on Materia Medica, was perhaps the first to suggest the idea of the acclimatization of the Cinchona in India, and, as early as 1839, Dr. Forbes Royle especially indicated the Neilgherry and Silhet mountains as eligible for the experiment. Appeals were subsequently made to the East India Company by Mr. Grant and Dr. Falconar, with the object of inducing them to take up the matter, and in 1852 instructions were sent to the British consular agents in South America to endeavour to procure seeds of the various species, but without much real effect. Dr. Royle, as Reporter on the Products of India, continued to urge the subject on the attention of Government up to the time of his death, and eventually, in 1859, at the instance of his successor in office, Dr. Forbes Watson, the services of Mr. Clements R. Markham were called into request by the home authorities.

Mr. Markham proposed a four-fold expedition to South America, and his scheme was at last sanctioned by the Secretary of State for India, and ordered to be carried out. The first portion of the expedition was directed to Bolivia and Caravaya, the region of *Cinchona Calisaya* and *C. micrantha* (var. *Boliviana*). Secondly, Huanuco and Huamalies were to be searched for *C. nitida* and *C. glandulifera*. Thirdly, Cuenca and Loxa in the Republic of Ecuador for *C. Chahuarguera*, *C. Uritusinga*, and *C. Condaminea*; and lastly, New Granada as the habitat of *C. Pitayo* and *C. lancifolia*. Mr. Pritchett and Mr. Spruce were appointed coadjutors to Mr. Markham, and the expeditions set out in 1859, the latter gentleman proceeding to the northern part of Bolivia, the district of the yellow barks; Mr. Spruce to the mountain region of Chimborazo, in quest of red cinchonas; Mr. Pritchett taking the grey bark forests of Huanuco, in the north of Peru. The perils encountered by these travellers, the hardships they endured, the disappointments they suffered, form a chapter in the history of travel. But illness and privation, bad roads, and even native jealousies, left unaffected the general success of the expedition, and though, unfortunately, the plants collected at great risk by Mr. Markham, including many of the best species of Bolivia, perished in the Red Sea in their transit to India, leaving no survivors, it is to the work accomplished by these three enthusiastic labourers that we owe the basis of our present Cinchona plantations. In 1860, the Ootacamund station was established, and the following year the number of young Cinchona trees was reported to be 1128. Under the excellent care of Mr. McIvor these had been increased in 1863, the date to which I have brought my account of the Java plantations, to 248,166.

It is no part of my purpose to enter into minutiæ of history, nor to do more than associate with the first steps in Cinchona culture the names of Messrs. Hasskarl and Markham, Spruce, and Pritchett as travellers, those of Dr. De Vrij and Mr. John Eliot Howard as advisers in technical details, and more recently, Messrs. McIvor and Broughton, who have been conspicuous, so far as India is concerned, in the rapid development of the enterprise.

The efforts of our own Government have not been confined to India, but localities have been sought in other parts of the world where natural conditions seemed to favour the chance of success in the introduction of quinine-yielding trees, and at the time I speak of (1863), there were under the care of Mr. Thwaites in Ceylon upwards of 20,000 young Cinchona plants. Jamaica also had made a successful beginning, and the authorities of several European countries were considering how far their respective colonies might be utilized to the same end, though but little decided action beyond what I have stated had been taken.

The ten years that have intervened need not detain us, but having noticed the origin we will turn at once to the practical aspect of the subject at the present time.

The latest official return places the number of Cinchona trees in cultivation in the Island of Java at two millions.

I can find no published account of the exact extent of the British plantations at the present time. My latest information I owe to the kindness of C. R. Markham, F.R.S., of the India Office. It is contained in the Parliamentary Blue-book of August, 1870, and refers only to the Madras and Bengal Presidencies. This gives the total number of Cinchona plants growing on the Neilgherries in January of that year at 2,595,176, of which nearly one-half (1,143,844) were permanently planted out.* The number at Darjeeling in the Bengal

* My friend, J. E. Howard, F.L.S., to whose kind revision subsequent paragraphs owe any scientific value they possess, tells me that, accurately speaking, these were *C. Calisaya*, var. *Josephiana*.

* Since this was written I have received a copy of a return which is believed to represent the actual number of Cinchona trees in the Government plantations in the Neilgherries at the present time. It shows an increase of 12,330 "planted out," and is as follows:—

Crown barks (*C. officinalis*)	508,878
Red barks	579,938
Yellow barks	33,859
Grey barks	28,759
Other species	4,749
	1,156,174

In addition to these, i must be recollected that the Government had up to 1870 distributed upwards of 178,000 trees from the Neilgherry nurseries, as well as nearly three

Presidency in March, 1870, is stated at 2;262,210, of which a million and a half were in permanent plantations.

Of the extent of the plantations in Ceylon and Jamaica I know nothing, but reports from time to time state that they are prospering. It is needless to refer to the experiments in cultivation in the South of Europe, the Caucasus, Brazil, the Philippines, or Australia, as these are not yet sufficient in extent to have any practical significance.

The relative value of the bark produced by the various species and varieties of Cinchona is a question that has received close attention and perhaps cannot be considered settled until something more like uniformity in the subdivision and nomenclature of the genus prevails. Plants regarded as merely varieties of the same species yield widely differing proportions of alkaloids, and the subject is further complicated by considerations as to the possible effects of cultivation and of different climatal conditions.

The result of last year's sale of Java barks at Amsterdam, and the statement of Dr. De Vrij upon the alkaloids they contained did not favour the hope that a permanent source of quinine supply had been secured. The highest price given on that occasion (about four shillings per pound) was for a parcel of *C. officinalis*, whilst one lot of *C. succirubra* (?) brought only 9*d.* per lb. Happily, the report for the present year has been reassuring. In the words of Mr. Howard (PHARM. JOURNAL, July 12, 1873), the Dutch "plantations have just been distinguished by a great success, in having sent into the market bark which has been sold at prices equal to from 8*s.* to 9*s.* 5*d.* per lb., and this not simply from such accidental circumstances as will sometimes occur, but from the intrinsic goodness of the bark." One of these Javan samples of *C. Calisaya* yielded 7·25 per cent. of alkaloids, of which 5·53 was quinine. The different alkaloid value of the so-called varieties of *C. Calisaya* was strikingly shown in this consignment—the bark from three of them yielding 1·23 per cent., 2·32 per cent., and 5·53 per cent. of quinine (alkaloid) respectively. The rich and valuable bark was all from trees the seed of which had been collected in Bolivia by Mr. Ledger, and it is to be regretted that at present so small a proportion of the whole is the product of that importation.

The barks now being produced in the Dutch and British colonies are referrible to five species, viz.:—

C. Calisaya, of which, as I have said, only a small proportion realizes expectation in its yield of quinine;

C. Hasskarliana (called a hybrid), which appears to be of little value in respect of alkaloids;

C. Pahudiana, deficient in the same particulars, but producing a bark which finds a ready market for pharmaceutical purposes;

C. officinalis, which, in British India,* appears to be the most generally satisfactory; and

C. succirubra, which, notwithstanding certain exceptional samples, has not turned out altogether well.

I have already stated the high price that Calisaya bark from Ledger's seed will fetch. Mr. Howard informs me that for the bark of *C. officinalis* grown in the Neilgherries or Ceylon, the firm of which he is a member, is ready to give the same price as for ordinary Bolivian Calisaya. The produce of *C. succirubra* appears very variable, but I have before me, through the kindness of the same gentleman, the commercial analysis of a sample from Ceylon which gives 5·51 per cent. as the total of pure alkaloids.

The pet idea of the Indian government, to manufacture on the spot a preparation supposed to consist of the crude mixed cinchona alkaloids, to sell at a very low price, is one that cannot be regarded with much favour. Any such product, however carefully made, must be of very uncertain composition, and, as is well known, samples which have reached this country have even contained poisonous metallic impurities. If cheap alkaloids are required, red bark will yield cinchonidine, the value of which as an antiperiodic is now well ascertained, and many species give cinchonine cheaply enough. But surely it were better that government should confine its attention to providing the material, and leave it to makers who have larger technical knowledge and practical experience to supply the low-priced alkaloids they desire.

Time is an important element in commercial matters, and the question as to the age at which it will pay best to collect the barks must remain at present in abeyance, and it probably will be found to differ in the different kinds—but already the sales of bark from acclimatized trees are considerable, and of course a yearly increase may be expected. Last year at the sale alluded to 5800 kilos (12,787 lbs.) were offered at Amsterdam, and it has been recently stated that our Neilgherry plantations alone will this year furnish 75,000 lbs. of bark for the English market.

I can say little about the West Indian plantations as to extent, but the quality of the bark they produce is encouraging. Mr. Howard reports that the chemical examination of barks from Jamaica is "highly satisfactory as regards the prospects of Cinchona culture in that island."

Various questions are still pending:—the influence of manures on the chemical constituents of the trees, the various methods of removing the bark from the tree, and the encouragement of renewal by the processes of stripping and mossing, and many others of like importance, the solution of which must be left to time and need not occupy our consideration here. My allusions to the subject have already been somewhat lengthy, but the scale of the experiment is gigantic and its issues momentous. I could not in a retrospect have omitted to notice it, and to have courted brevity beyond what I have done would have been at the risk of intelligibility.

Turning from our wider general retrospect to circumstances of more recent date affecting pharmacy, I may allude to two or three substances whose employment in medicine possesses more than common scientific interest, primarily to the Hydrate of Croton-Chloral and Propylamine or Trimethylamine.

The name of Dr. Oscar Liebreich is so favourably known in connection with chloral hydrate that any remedy introduced under his recommendation necessarily commands attention. In his further researches on bodies more or less related to chloral he discovered that croton-chloral, that is the substance represented by the same term in the allyl (C_3H_5) series that chloral has in the Ethyl (C_2H_5) group, in other words, dichlorcrotonic aldehyd, possessed very singular physiological properties. We gather that it is a powerful sedative, but that its action instead of affecting the entire nervous system, and to some extent the circulation also (like chloral hydrate), is confined to the fifth pair of cerebral nerves. Experiment in this country has at any rate in part confirmed Dr. Liebreich's views, and it is needless to say how important an acquisition to the medical practitioner would be any agent with well ascertained specialized action such as that described. Hydrate of croton-chloral very much resembles in appearance the ordinary chloral. I do not know what process is followed for its preparation on a commercial scale, but chemical text-books tells us that it may be

---

hundred ounces of the seeds of various species, to private individuals disposed to plant on their estates. After all, when the experimental stage of such an undertaking is over, private enterprise would seem to be its safest basis. A Parliamentary paper on the progress of India in 1872, just issued, gives the total number of plants in the Neilgherry plantations as 2,639,285, but this probably includes the very young trees still in nurseries. I have no particulars beyond what appear in a paragraph in the *Times*.

* This limitation is at present necessary. Dr. De Vrij's late paper on Jamaica barks (PHARM JOURNAL, August 16th, 1873) shows the produce of *C. officinalis* in that island to be very deficient in quinine, inferior indeed to *C. Pahudiana*, whilst a still later communication confirms Mr. Howard's opinion as to the richness of Indian-grown specimens.

prepared by passing chlorine gas into allylene, or by acting upon dichlorallyl and formic acid with alkalies.

The use of propylamine in medicine originated in Russia, but until quite lately the reports of Professor Awenarius and others on the success which had attended its employment in acute and chronic articular rheumatism passed almost unnoticed. During the present year however its medicinal properties have been closely investigated in the Paris hospitals by M. Dujardin-Beaumetz and the results published from time to time. An elaborate memoir, summarizing the whole, has just appeared, entitled 'Nouvelles Recherches sur la Triméthylamine.' It may be necessary to advert to the isomerism which gives rise to three different names for substances with the same ultimate composition (C_3H_9N), namely, propylamine, ethylomethylamine, and trimethylamine, inasmuch as the last name is employed with some emphasis by the French author, who also dwells upon the different physical characters of the three isomers and notes especially their widely different boiling points.

Propylamine is produced in minute quantities in plants of several genera, *e.g.*, *Chenopodium*, *Stapelia*, *Huernia*, *Apteranthes*, etc., and its isomer trimethylamine in many of the Rosaceæ. A tincture of the fresh plant of *Chenopodium vulvaria* has been used medicinally, but practically it is to the animal kingdom we must look for the supply. Professor Awenarius employs exclusively propylamine prepared from cod liver oil, but the French author alluded to adopts that extracted from herring brine. The latter dwells on the uncertainty in composition of the samples he has met with in commerce, and advocates the use of the hydrochlorate as likely to lead to greater uniformity. The dose of propylamine is from a gramme to a gramme and a half, but nearly double the latter quantity has been given without ill effect. The odour and taste are abominable, and it is therefore given with peppermint or other adjuvant having a strong flavour, or, better still, in a capsule. With its therapeutic effects we have less to do. It is described as relieving if not entirely subduing the pains of acute rheumatism within twenty-four hours, increasing the appetite, reducing animal temperature and often producing insomnia.

The introduction of guarana, or rather the resuscitation of its use, by Dr. Wilks, and the employment of copaiba resin in dropsies by the same gentleman, and the proposal of Mr. John Marshall to substitute a definite oleate of mercury for the clumsy and wasteful mercurial ointment, are other noteworthy topics that have of late occupied space in the medical journals. Nor must I omit to call attention to the most interesting and exhaustive paper by Mr. Hanbury (*vide* PHARMACEUTICAL JOURNAL of August 2nd and 9th), on the history and botanical origin of Pareira Brava. Few of us, I suspect, were prepared to learn that this drug had been in more or less repute for a couple of centuries. Its usually accredited botanical source—that is, to *Cissampelos Pareira*—Mr. Hanbury had before shown to be erroneous, but its identification beyond question as the root of *Chondodendron tomentosum* is an important addition to knowledge, and the means of diagnosis of the genuine and spurious drug of great value to the pharmaceutist.

Three new Pharmacopœias are before us—the 'Pharmacopœa Germanica' before referred to, and the 'Pharmacopœa Helvetica,' both bearing date 1872, and the 'Pharmacopœia of the United States,' 1873. I can do little more than direct your attention to them as material for most profitable study. Though as widely diverse in character as the nations they represent, each has an excellence of its own.

Many German formulæ, for example, *Pulvis Glycyrrhizæ compositus*,* *Tinctura colocynthidis*, and *Tinctura Ferri acetici ætherea* have already found their way into English practice, and circumstances may easily increase the number, so that were there no other reason, the pharmaceutist would do well to acquaint himself somewhat with the first named work. The Swiss Pharmacopœia is a model of simplicity. The whole book is but a hundred and eighty pages, the first hundred and fifty-six being occupied with materia medica and formulæ, the remainder being taken up with a series of useful reference tables. Its brevity is partly owing to the curtailment of processes. Formulæ are seldom given for the preparation of chemicals which in practice are manufactured on a large scale and purchased by the pharmaceutist, but the characters of the preparations are detailed with much minuteness, and the tests for purity given with great exactness.

The newly-revised Pharmacopœia of the United States, long waited for, appears fully to satisfy expectation, and is in many ways an example of advanced pharmacy. The elaborate synopsis of its contents which has recently appeared in the pages of the PHARMACEUTICAL JOURNAL, will enable those who have not the work to form some idea of its general character. In some little matters at least the compilers of the new edition of our Pharmacopœia might take useful hints from the transatlantic work—amongst minor details, the accented index seems likely to serve a very good purpose in promoting uniformity of pronunciation in Latin names.

Such then are the events that appear to me to mark the recent progress of pharmacy, and I would that I might stop here, but, *per contra*, I find other occurrences fraught with discouragement. At our last meeting I had occasion to advert to the aspects of pharmacy in relation to that higher scientific training which must be kept in view if the members of our craft in this country desire to take the professional position that is open to them, or to stand on the same intellectual level with the same class in many parts of the continent.

The Pharmaceutical Society with its extended powers and large income, with the halo about it of good work accomplished in past years, seemed then to be the source whence some effort might be expected to remedy deficiences that are not only the object of remark of foreigners, but are generally acknowledged amongst ourselves. It is not for me to criticize from this chair the action of the Society, except in so far as it affects the objects the Conference was established to promote.

The standard of the examinations adopted by the Society on the passing of the Pharmacy Act was very naturally decided in a spirit of extreme consideration for the circumstances of those who were already engaged in business in one capacity or other. For the Preliminary examination of young men *now* entering our ranks there can be no such plea for indulgence, and the recent revision of the examination regulations gave the opportunity for exacting some less discreditable minimum of preliminary education than heretofore. It is surely not too much to expect that a youth proposing to enter a professional or semi-professional calling should have had at least a good grammar-school education. But do not the questions that we see in our present examination papers suggest rather a constituency composed of the idle scholars of a village charity school; and the standard of that better period which is to commence at the end of 1874 is in no respect an advance on that which has hitherto been enforced, save that it requires a little extra knowledge of the table-book. I will not detain you with any remarks on the rest of the revised code, indeed I could add little to what I endeavoured to place before you last year, except the confirmation and extension of the views then expressed, which have arisen from continued observation.

I am not presumptuous enough to undertake a review of the recent fundamental change in the relation of the Society to scientific teaching, because, in common with many others, I have sought in vain for the principle on which the step has been based. If it be an indefensible anomaly, as has been stated, that the Pharmaceutical

* *Pulvis Liquiritiæ compositus* of the New German Pharmacopœia.

Society should be both an educating and an examining body, there can be no doubt that its educational functions ought to cease, seeing that those pertaining to examination cannot. And if this principle were really acted upon some good might perhaps arise from the stimulus that would be given to extra-academical teaching. But the new arrangements are incomprehensible in this light for, *cæteris paribus*, how could any man hope to compete with a rival who was rent-free, and had an annual subsidy in addition to his fees? Looking at the matter in its relation to the advancement of pharmacy in England, it seems obvious that the recent change can only promote that dull, low mediocrity which above all things it should be our aim to avoid. I am far from granting that the union of educational and examining functions in one body is anomalous, for I believe that a closer examination of the subject would lead to the opposite conclusion; but even were it so in this particular case, the anomaly would refer firstly, if not solely, to the Minor or compulsory examination. Education for the Major examination, which is an honorary degree, would certainly involve no anomaly, still less would the provision, which at the present time is of pre-eminent importance, for subsequent and more extended study. The new arrangements point solely to increased facilities for obtaining the minimum amount of knowledge necessary to pass the Minor examination. We are to have our lectures served up in a concentrated form, a *five* months' course guaranteed equal to *ten* according to the old formula, the resulting compound I suppose to be diluted when required for use. Our old acquaintance "Cram" to the front once more, but this time by permission and under the especial patronage of the Society.

The proposal of an eminent pharmaceutist to make the Minor the matriculation examination for students entering the school in Bloomsbury Square may be open to objection, but it would have remedied any anomaly that might have been supposed to exist in the old arrangement, whereas the new regulations perpetuate its worst features. The adoption of two short elementary courses of lectures in each subject in place of one of much more exhaustive character is in reality a provision for smatterers at the expense of those who wish to pursue their studies beyond the mere legal minimum.

That the education of students for a *compulsory* examination at the expense of the body had become undesirable is true in so far as it is no longer necessary, but the Major examination is *not* compulsory, and on that account it would seem to be equally the duty and the interest of the Society to afford facilities to students to prepare themselves for it. For the same reason, it becomes more than ever incumbent upon the Society to offer inducements to young men to pursue a higher education than anything prescribed by mere examination tests. The Society hitherto has had many functions, but if one may judge by recent events, we may fairly look for the time when the Council will have nothing to do but to register the decrees of the Board of Examiners, and to place annually in the Three per Cents. two thousand pounds of the money subscribed by the members for the advancement of pharmacy. It would be well for those who regard the present condition of pharmacy and pharmaceutical education in England with satisfaction, if there be such, to give their attention for a moment to the standard of attainment demanded in other European countries similar in political importance and intellectual standing to our own. I need hardly allude to the regulations in force in France so soon after the interesting papers on the École de Pharmacie of Paris, by Mr. Walter Hills,* but a recent visit to our valued fellow-member, Dr. Flückiger, the newly appointed Professor of Pharmacy in the University of Strasburg, has given me the opportunity of gleaning some information concerning the educational curriculum and qualifications demanded of the pharmaceutist in the new German Empire. I will give the result of my inquiries as nearly as may be in the Professor's own words:—

In Germany the pharmaceutical student must begin his education in a classical school or gymnasium. The period at which he is considered fit to enter on his apprenticeship is controlled by a medical officer (*Kreis-Physicus*). His term of apprenticeship is three years, but it may be reduced to two years and a half if he is very zealous and intelligent, and this is determined by annual examination. When his apprenticeship is completed, the preliminary examination (oral and written) follows, which entitles him to be recognized as an assistant.

In this capacity he must devote three years to actual practice in a pharmacy, and his duties therein are regulated by law. The term of three years may be reduced to two and a half if he enters the voluntary military service, and is actually employed in a military dispensing office for one year. Lastly, he must devote a year and a half to study in a university. Afterwards he presents himself for final examination in the following subjects:—

1st. The translation of two articles in the Latin Pharmacopœia.

2nd. The dispensing of particularly difficult prescriptions.

3rd. The preparation of two chemicals.

4th. The analysis, both qualitative and quantitative of an artificial or natural mixture.

5th. Toxicological analysis, both qualitative and quantitative.

6th. Three notices (brief essays I suppose) on general and analytical chemistry, written without books or other extraneous aid.

7th. The recognition and description of ten or more officinal plants likely to be confounded.

8th. The recognition and description of at least ten officinal drugs.

9th. Relates to pharmaceutico-chemical preparations, their recognition by external characters, preparation, use, falsification, etc.

10th. Lastly comes the oral examination in which the candidate must prove that he is well acquainted with theoretical chemistry, physics, natural history, toxicology, and pharmaceutical legislation.

Professor Flückiger adds that, though he has not yet much practical experience in the working of these examinations, he is under the impression that they are very strictly carried out, as almost everything is in new Germany.

I am far from thinking that so elaborate a scheme as that set forth is desirable, even if it were possible, in England, but it ought to set us thinking whether results as good might not be attained by means which are already in our power. We are ready enough to urge the claims of our body for scientific appointments, such as those which have recently arisen out of the Adulteration Act, but it seems to me that if first attention were paid to raising a class of men who, *as a body*, were competent to undertake the responsible scientific duties involved in such offices, the public would see its own advantage in according them to us. At present, I confess, I cannot see that the mere diploma of the Society is of itself any guarantee of the necessary qualification.

Amongst the events of the past year are some of sorrowful import. The death of one who had identified himself with the Conference from its commencement, and who had served it with a whole heart, even in feeblest health, and that of another, eminent in pharmacy, whose sympathies were ever with us, though his sphere of active life lay in the other hemisphere, are still uppermost in our thoughts:—I need not say I allude to John Cargill Brough and Edward Parrish. Enough has been written concerning both as a memorial of their lives, but it were not fitting that their names should be unremembered here. The services of the late editor of our Year-book it is

* *Vide* PHARMACEUTICAL JOURNAL, 3rd series, vol ii., pp. 121 and 561.

scarcely possible to overrate. The scheme of the Conference was one which coincided exactly with the bent of his own mind. He came amongst us at our first meeting known only by name as the editor of the *Chemist and Druggist*, and from that moment, nay indeed before that, the objects of the Conference had the unswerving support of the journal which he directed. He was the consistent advocate, as indeed it was his nature to be, of the claims of those who seemed likely to suffer from the early proposals in the way of legislation, and in the opportunity for intercourse afforded by our annual meetings he saw the means of softening the differences that at first so grievously divided the general body of chemists to their common injury. Advocacy of high class pharmacy gave way before his sympathy with his fellow men. Trained as a literary man, his connection with pharmacy was so to speak accidental. He lived the up-hill life of a *littérateur*, —one of exhausting labour aggravated by ill-health, perplexed by the cares of a young family, and saddened by bereavements; yet, to the end he fought bravely and cheerfully on.

"And, oh! when Nature sinks, as oft she may,
Through long-lived pressure of obscure distress,
Still to be strenuous for the bright reward,
And in the soul admit of no decay,
Brook no continuance of weak-mindedness—
Great is the glory, for the strife is hard!"

At our meetings his voice was seldom heard; extreme diffidence seemed to prevent his taking much part in discussions. His contributions to our 'Proceedings' consist of three papers,—one in 1865 "On the proposed Introduction of two Systems of Chemical Notation in the British Pharmacopœia," one in 1868 "On Narcotine and the Products of its Decomposition" and another in the same year, "On an improved Differential Thermometer." When the Conference determined to publish a 'Year-book' his singular fitness for the post of editor was at once recognized, but before he had proceeded far with the preparation of the first volume he was compelled by failing health to relinquish the task. A few months before he had received the appointment of Chief Librarian to the London Institution, and there seemed for a time a hope that the unwonted quiet of his new sphere, the relief from care in pecuniary matters, and the congenial nature of his occupation, might have restored him to physical vigour—but it was not so to be. So gradual was his decline that he cherished almost to the last the idea of attending the Conference at Brighton last year.

To the outside world Mr. Brough was known as the editor of the *Laboratory*, and one or two trade journals; as the sub-editor of *Nature*, as the author of 'Fairy Tales of Science,' of some serious and many humorous essays, the latter especially, whether in prose or rhyme, models of felicitous handling. To his friends he seemed the reflex of every noble quality he sought in others; if they speak little of his published works 'tis but from the recollection of his inimitable letters; if they mourn in silence 'tis in the heavy sense of loss that time cannot replace.

Probably few of the present company were personally acquainted with Professor Parrish, yet he was well-known by name to all, and it was not merely from the position he held amongst our American brethren that he was amongst the first whom the Conference elected to its honorary membership. An able writer, a fluent speaker, and an accomplished pharmaceutist, he excelled perhaps more as a teacher than as an original investigator. Of his genial affectionate manner an evidence is seen in the terms by which his students of past years loved to speak of him. He had long intended to revisit England, and looked forward with pleasure to the probability of being able to attend the Conference at Brighton, and even in May last year he spoke of his visit as depending on the completion of a new edition of his book on pharmacy, which was then in the press. Before leaving Brighton I received a letter from him—a kindly message to the Conference, expressing his interest in the success of the meeting, but telling of other duties nearer home that claimed him for the time and prevented his being with us. He alluded to his appointment on a government commission to one of the hostile tribes of Indians in the South-western States, and it was whilst engaged upon this work of peace and reconciliation that he was struck down by fever. His loss, whether in a professional or in a social capacity, has been and must be widely felt; scarcely a society or periodical connected with pharmacy in America but has had some eloquent tribute to his memory.

And now, gentlemen, in conclusion, let me remind you that the Conference has but one object—the advancement of pharmacy—and by that means the material and intellectual advancement of pharmaceutists. There is much to be accomplished, both in scientific and ethical relations before pharmacy in this country can stand in the place that belongs to it of right—so much, that it needs a stout heart to face the future; and let no member think that the efforts of others absolve him from his share of the labour. Abilities, opportunities, inclinations differ, but in the body politic there is a sphere of active usefulness for each, a line of duty easily ascertained, from which no man may shrink and hold himself blameless.

Mr. Ekin (Bath) moved a vote of thanks to the President for his able and interesting address.

Mr. Rimmington (Bradford), in seconding the proposal, said: I have listened with very great pleasure to the able address of the President, and with the great majority of his observations I entirely concur. I cannot but feel that such an address as he has just delivered will tend to raise the *status* of pharmacy in this country, and to extend its sphere of usefulness; and to elevate us above the rank of mere traders by showing that pharmaceutists are men of intelligence and of education. And in my opinion that is one of the main objects which this Association is intended to accomplish. It cannot be disputed that one of the results of the establishment of this Association has been to raise our position, which is far different from what it was ten years ago. It is with much pleasure that I beg to second the vote of thanks to our President for his very able speech.

Mr. J. Williams (Vice-President) having put the question, the vote of thanks to the President was carried amid applause.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The forty-third Annual Meeting of the British Association for the Advancement of Science commenced at Bradford on Wednesday, September 17th. In the evening, at St. George's Hall, the President-Elect, Professor A. W. Williamson, F.R.S., delivered the following

Presidential Address.

Ladies and Gentlemen,—

Instead of rising to address you on this occasion I had hoped to sit quietly amongst you, and to enjoy the intellectual treat of listening to the words of a man of whom England may well be proud—a man whose life has been spent in reading the great book of nature, for the purpose of enriching his fellow men with a knowledge of its truths —a man whose name is known and honoured in every corner of this planet to which a knowledge of science has penetrated—and, let me add, a man whose name will live in the grateful memory of mankind as long as the records of such noble works are preserved.

At the last meeting of the Association I had the pleasure of proposing that Dr Joule be elected President for the Bradford Meeting, and our Council succeeded in overcoming his reluctance and in persuading him to accept that office.

Nobly would Joule have discharged the duties of President had his bodily health been equal to the task; but it became apparent after a while that he could not rely upon sufficient strength to justify him in performing the

duties of the chair, and, in obedience to the order of his physician, he placed his resignation in the hands of the Council about two months ago. When, under these circumstances, the Council did me the great honour of asking me to accept their nomination to the Presidentship, I felt that their request ought to have with me the weight of a command.

For a good many years past chemistry has been growing at a more and more rapid rate, growing in the number and variety of facts which are added to its domain, and not less remarkably in the clearness and consistency of the ideas by which these facts are explained and systematized. The current literature of chemical research extends each year to the dimensions of a small library; and mere brief abstracts of the original papers published annually by the Chemical Society, partly aided by a grant from this Association, take up the chief part of a very stout volume. I could not, if I would, give you to-night even an outline of the chief newly-discovered compounds and of the various changes which they undergo, describing each of them by its own name (often a very long one) and recording the specific properties which give to each substance its highest scientific interest. But I am sure that you would not wish me to do so if I could; for we do not meet here to study chemistry; I conceive that we meet here for the purpose of considering what this wondrous activity in our science means, what is the use of it, and, true to our object as embodied in the name of this Association, to consider what we can do to promote the advancement of science. I propose to lay before you some facts bearing on each of these questions, and submit to you some considerations respecting them.

In order to ascertain the meaning of the work which has been going on in chemistry, it will, I think, be desirable for us to consider the leading ideas which have been in the minds of chemists, and which guided their operations.

Now, since the father of modern chemistry, the great Dalton, gave to chemists a firm hold of the idea of atoms, their labours have been continually guided by that fundamental idea, and have confirmed it by a knowledge of more and more facts, while at the same time steadily adding to our knowledge of the properties of atoms. Every chemist who is investigating a new compound takes for granted that it must consist of a great number of atom-clusters (called by him molecules), all of them alike, and each molecule consisting of a certain number of atoms of at least two kinds. One of his first endeavours is to ascertain how many atoms of each kind there are in each molecule of the compound. I must not attempt to describe to you the various kinds of experiment which he performs for the purpose of getting this information, how each experiment is carried out with the aid of delicate instruments and ingenious contrivances found by long experience to enable him to obtain the most trustworthy and accurate results; but I want to draw your attention to the reasoning by which he judges of the value of such experiments when they agree among themselves, and to the meaning which he attaches to their results.

If the result of his experiments does not nearly agree with any atomic formula (that is, if no conceivable cluster of atoms of the kinds known to be in the compound would on analysis give such results as those obtained), the chemist feels sure that his experiments must have been faulty: either the sample of substance which he worked upon contained foreign matter, or his analyses were not made with due care. He sets to work again, and goes on till he arrives at a result which is consistent with his knowledge of the combining-properties of atoms. It is hardly necessary to say that even the best experiment is liable to error, and that even a result obtained with the utmost care cannot be expected to afford more than an approximation to the truth. Every good analysis of a pure compound leads to results which approximate to those required by the atomic theory; and chemists trust so thoroughly to the truth of that guide, that they correct the results of such analysis by the aid of it.

The chemical idea of atoms serves for two purposes:—

1. It gives a clear and consistent explanation of an immense number of facts discovered by experiment, and enables us to compare them with one another and to classify them.

2. It leads to the anticipation of new facts, by suggesting new compounds which may be made; at the same time, it teaches us that no compounds can exist with their constituents in any other than atomic proportions, and that experiments which imply the existence of any such compound are faulty.

We have the testimony of the great Berzelius to the flood of light which the idea of atoms at once threw on the facts respecting combining proportions which had been accumulated before it was made known; and from that time forward its value had rapidly increased as each succeeding year augmented the number of facts which it explained.

Allow me at this point of my narrative to pause for a moment, in order to pay a tribute of respect and gratitude to the memory of one who has recently passed from among us, and who in the time of his full activity was a leader of the discoveries of new facts in the most difficult part of our science. Liebig has been generally known in this country through his writings on agricultural chemistry, through his justly popular letters on chemistry, and other writings, by means of which his brilliant intellect and ardent imagination stimulated men to think and to work. Among chemists he was famed for his numerous discoveries of new organic compounds, and their investigation by the aid of improved methods; but I believe that the greatest service which his genius rendered to science was the establishment of the chemical school of Giessen, the prototype of the numerous chemical schools for which Germany is now so justly celebrated. I think it is not too much to say that the Giessen laboratory, as it existed some thirty years ago, was the most efficient organization for the promotion of chemistry which has ever existed.

Picture to yourselves a little community of which each member was fired with enthusiasm for learning by the genius of the great master, and of which the best energies were concentrated on the one object of experimental investigation.

The students were for the most part men who had gone through a full curriculum of ordinary studies at some other University, and who were attracted from various parts of the world by the fame of this school of research.

Most of the leading workers of the next generation were pupils of Liebig; and many of them have established similar schools of research.

We must not, however, overlook the fact that Liebig's genius and enthusiasm would have been powerless in doing this admirable work, had not the rulers of his Grand-Duchy been enlightened enough to know that it was their duty to supply him with the material aids requisite for its successful accomplishment.

Numberless new compounds have been discovered under the guidance of the idea of atoms; and in proportion as our knowledge of substances and of their properties became more extensive, and our view of their characteristics more accurate and general, were we able to perceive the outlines of their natural arrangement, and to recognize the distinctive characteristics of various classes of substances. I wish I could have the pleasure of describing to you the origin and nature of some of these admirable discoveries, such as homologous series, types, radicals, etc.; but it is more to our purpose to consider the effect which they have had upon the idea of atoms, an idea which, still in its infancy, was plunged into the intellectual turmoil arising from a variety of novel and original theories suggested respectively by independent workers as best suited for the explanation of the particular phenomena to which their attention was mainly directed.

Each of these workers was inclined to attach quite sufficient importance to his own new idea, and to sacrifice for its sake any other one capable of interfering with its due development.

The father of the atomic theory was no more; and the little infant had no chance of life, unless from its own sterling merits it were found useful in the work still going on.

What then was the result? Did it perish like an ephemeral creation of human fancy? or did it survive and gain strength by the inquiries of those who questioned Nature and knew how to read her answers?

Although anticipating my answer to these questions, you will probably be surprised to hear the actual result which I have to record, a result so wonderful that the more I think of it the more I marvel at it. Not only did these various theories contain nothing at variance with the atomic theory; they were found to be natural and necessary developments of it, and to serve for its application to a variety of phenomena which were unknown to its founder.

Among the improvements of our knowledge of atoms which have taken place, I ought to mention the better evaluations of the relative weight of atoms of different kinds, which have been made since Dalton's time. More accurate experiments than those which were then on record have shown us that certain atoms are a little heavier or lighter than was then believed, and the work of perfecting our observations is constantly going on with the aid of better instruments and methods of operation. But, apart from these special corrections, a more sweeping change has taken place, not in consequence of more accurate experiments interpreted in the usual way, but in consequence of a more comprehensive view of the best experimental results which had been obtained, and a more consistent interpretation of them. Thus the atomic weight of carbon had been fixed at 6 by Dumas's admirable experiments; and it was quite conceivable that a still more perfect determination might slightly increase or diminish this number. But those who introduced the more sweeping change asserted in substance that two of these supposed atoms, whatever may be the precise weight of each, always are together and never separate from one another; and they accordingly applied the term atom to that indivisible mass of carbon weighing twice as much as a carbon atom had been supposed to weigh. So also with regard to other elements, it has been shown that many atoms are really twice as heavy as had been supposed, according to the original interpretation of the best experiments. This change was brought about by what I may be permitted to call the operation of stock-taking. Dalton first took stock of our quantitative facts in a business-like manner; but the amount and variety of our chemical stock increased so enormously after his time, that the second stock-taking absorbed the labours of several men for a good many years. They were men of different countries and very various turns of mind; but, as I mentioned just now, they found no other fundamental idea to work with than Dalton's; and the result of their labours has been to confirm the truth of that idea, and to extend greatly its application.

One of the results of our endeavours to classify substances according to their natural resemblances has been the discovery of distinct family relationships among atoms, each family being distinguished by definite characteristics. Now, among the properties which thus characterize particular families of atoms, there is one of which the knowledge gradually worked out by the labours of an immense number of investigators must be admitted to constitute one of the most important additions ever made to our knowledge of these little masses.

I will endeavour to explain it to you by a simple example. An atom of chlorine is able to combine with one atom of hydrogen or one atom of potassium; but it cannot combine with two atoms. An atom of oxygen, on the other hand, can combine with two atoms of hydrogen or with two atoms of potassium, or with one atom of hydrogen and one of potassium; but we cannot get it in combination with one atom of hydrogen or of potassium solely.

Again, an atom of nitrogen is known in combination with three atoms of hydrogen; while an atom of carbon combines with four of hydrogen. Other atoms are classified, from their resemblance to these respectively, as monads, dyads, triads, tetrads, etc.

The combining value which we thus recognize in the atoms of these several classes has led us naturally to a consideration of the order in which atoms are arranged in a molecule. Thus, in the compound of oxygen with hydrogen and potassium, each of these latter atoms is directly combined with the oxygen, and the atom of oxygen serves as a connecting link between them. Hydrogen and potassium have never been found capable of uniting directly with one another, but when both combine with one atom of oxygen they are in what may be called indirect combination with one another through the medium of that oxygen.

One of the great difficulties of chemistry some few years ago was to explain the constitution of isomeric compounds, those compounds whose molecules contain atoms of like kinds and in equal numbers, but which differ from one another in their properties. Thus a molecule of common ether contains four atoms of carbon, ten atoms of hydrogen, and one of oxygen. Butylic alcohol, a very different substance, has precisely the same composition. We now know that in the former the atom of oxygen is in the middle of a chain of carbon atoms, whereas in the latter it is at one end of that chain. You might fancy it impossible to decide upon anything like consistent evidence such questions as this; but I can assure you that the atomic theory, as now used by chemists, leads frequently to conclusions of this kind, which are confirmed by independent observers, and command general assent. That these conclusions are, as far as they go, true descriptions of natural phenomena is shown by the fact that each of them serves in its turn as a stepping-stone to further discoveries.

One other extension of our knowledge of atoms I must briefly mention, one which has as yet received but little attention, yet which will, I venture to think, be found serviceable in the study of the forces which bring about chemical change.

The original view of the constitution of molecules was statical; and chemists only took cognizance of those changes of place among their atoms which result in the disappearance of the molecules employed, and the appearance of new molecules formed by their reaction on one another. Thus, when a solution of common salt (sodic chloride) is mixed with a solution of silver nitrate, it is well known that the metallic atoms in these respective compounds change places with one another, forming silver chloride and sodic nitrate; for the silver chloride soon settles to the bottom of the solution in the form of an insoluble powder, while the other product remains dissolved in the liquid. But as long as the solution of salt remained undecomposed, each little molecule in it was supposed to be chemically at rest. A particular atom of sodium which was combined with an atom of chlorine was supposed to remain steadily fixed to it. When this inactive solution was mixed with the similarly inactive solution of silver nitrate, the interchange of atoms known to take place between their respective molecules was nominally explained by the force of predisposing affinity. It was, in fact, supposed that the properties of the new compounds existed and produced effects before the compounds themselves had been formed.

I had occasion to point out, a good many years ago, that molecules which appear to be chemically at rest are reacting on one another when in suitable conditions, in the same kind of way as those which are manifestly in a state of chemical change—that, for instance, the molecules of liquid sodic chloride exchange sodium atoms with one another, forming new molecules of the same compound undistinguishable from the first, so that, in an aggregate of like molecules, the apparent atomic rest is the result of the interchange of like atoms between contiguous molecules.

Such exchanges of atoms take place not only between molecules of identical composition, but also between contiguous molecules containing different elements. For instance, in a mixture of sodic chloride and potassic iodide an interchange of metallic atoms takes place, forming potassic chloride and sodic iodide. The result of the exchange in such a case is to form a couple of new molecules different from the original couple. But these products are subject to the same general law of atomic exchanges, and their action on one another reproduces a couple of molecules of the materials.

Thus a liquid mixture formed from two compounds, contains molecules of four kinds, which we may describe as the two materials and the two products. The materials are reacting on one another, forming the products; and these products are, in their turn, reacting on one another, reproducing the materials.

If one of the products of atomic exchange between two molecules is a solid, while the other remains liquid (as when sodic chloride is mixed with silver nitrate), or if one is gaseous while the other remains liquid, so that the molecules of the one kind cannot react on those of the other kind and reproduce the materials, then the continued reaction of the materials on one another leads to their complete mutual decomposition. Such complete mutual decomposition of two salts takes place whenever they react on one another under such conditions that the products cannot react on one another and reproduce the materials; whereas partial decomposition takes place whenever the materials form a homogeneous mixture with the products.

Now, if in any such homogeneous mixture more exchanges of atoms take place between the materials than between the products, the number of molecules of the products is increased, because more of them are being made than unmade; and reciprocally, if more exchanges of atoms take place between the products than between the materials, the number of molecules of the materials is increased. The mixture remains of constant composition when there are in the unit of time as many decomposing changes as reproducing changes.

Suppose that we were to determine by experiment the proportion between the number of molecules of the materials, and the number of molecules of the products, in a mixture the composition of which remains constant, and that we found, for instance, twice as many of materials as of products; what would this mean? Why, if every two couples of materials only effect in the unit of time as many exchanges as every one couple of products, every couple of materials is only exchanging half as fast as every couple of products.

In fact you perceive that a determination of the proportion in which the substances are present in such a mixture will give us a measure of the relative velocities of those particular atomic motions; and we may thus express our result:—The force of chemical combination is inversely proportional to the number of atomic interchanges.

I cannot quit this part of our subject without alluding to the fact that some few chemists of such eminence as to be entitled to the most respectful attention have of late years expressed an opinion that the idea of atoms is not necessary for the explanation of the changes in the chemical constitution of matter, and have sought as far as possible to exclude from their language any allusion to atoms.

It would be out of place on this occasion to enter into any discussion of the questions thus raised; but I think it right to point out:—

1. That these objectors have not shown us any inconsistency in the atomic theory, nor in the conclusions to which it leads.

2. That neither these nor any other philosophers have been able to explain the facts of chemistry on the assumption that there are no atoms, but that matter is infinitely divisible.

3. That when they interpret their analyses, these chemists allow themselves neither more nor less latitude than the atomic theory allows; in fact, they are unconsciously guided by it.

These facts need no comment from me.

Our science grows by the acquisition of new facts which have an intelligible place among our ideas of the order of nature; but in proportion as more and more facts are arranged before us in their natural order, in proportion as our view of the order of nature becomes clearer and broader, we are able to observe and describe that order more fully and more accurately—in fact, to improve our ideas of the order of nature. These more extensive and more accurate ideas suggest new observations, and lead to the discovery of truths which would have found no place in the narrower and less accurate system. Take away from chemistry the ideas which connect and explain the multifarious facts observed, and it is no longer a science; it is nothing more than a confused and useless heap of materials.

The answer to our question respecting the meaning of the earnest work which is going on in our science must, I think, now be plain to you. Chemists are examining the combining properties of atoms, and getting clear ideas of the constitution of matter.

Admitting, then, for the present, that such is the meaning of chemical work, we have to consider the more important question of its use; and I think you will agree with me that, in order to judge soundly whether and in what manner such a pursuit is useful, we have to consider its effect upon man. What habits of mind does it engender? What powers does it develop? Does it develop good and noble qualities and aspirations, and tend to make men more able and more anxious to do good to their fellow men? Or is it a mere idle amusement, bearing no permanent fruits of improvement?

You will, I think, answer these questions yourselves if I can succeed in describing to you some of the chief qualities which experience has shown to be requisite for the successful pursuit of chemistry, and which are necessarily cultivated by those who qualify themselves for such a career.

One of the first requirements on the part of an investigator is accuracy in observing the phenomena with which he deals. He must not only see the precise particulars of a process as they present themselves to his observation; he must also observe the order in which these particular appearances present themselves under the conditions of each experiment. No less essential is accuracy of memory. An experimental inquirer must remember accurately a number of facts; and he needs to remember their mutual relations, so that one of them when present to his mind may recall those others which ought to be considered with it. In fact, he cultivates the habit of remembering facts mainly by their place in nature. Accuracy in manual operations is required in all experimental inquiries; and many of them afford scope for very considerable skill and dexterity.

These elementary qualities are well known to be requisite for success in experimental science, and to be developed by careful practice of its methods; but some higher qualities are quite as necessary as these in all but the most rudimentary manipulations, and are developed in a remarkable degree by the higher work of science.

Thus it is of importance to notice that a singularly good training in the accurate use of words is afforded by experimental chemistry. Every one who is about to enter on an inquiry, whether he be a first year's student who wants to find the constituents of a common salt, or whether he be the most skilled and experienced of chemists, seeks beforehand to get such information from the records of previous observations as may be most useful for his purpose. This information he obtains through the medium of words; and any failure on his part to understand the precise meaning of the words conveying the information requisite for his guidance is liable to lead him astray.

Those elementary exercises in analytical chemistry, in which brief directions to the students alternate with their experiments and their reports of experiments made and conclusions drawn, afford a singularly effective training in the habit of attending accurately to the meaning of words used by others, and of selecting words capable of conveying without ambiguity the precise meaning intended. Any inaccuracy in the student's apprehension of the directions given, or in the selection of words to describe his observations and conclusions, is at once detected, when the result to which he ought to have arrived is known beforehand to the teacher.

Accuracy of reasoning is no less effectively promoted by the work of experimental chemistry. It is no small facility to us that the meaning of the words which we use to denote properties of matter and operations can be learnt by actual observation. Moreover, each proposition comprised in chemical reasonings conveys some distinct statement susceptible of verification by similar means; and the validity of each conclusion can be tested, not only by examining whether or not it follows of necessity from true premisses, but also by subjecting it to the independent test of special experiment.

Chemists have frequent occasion to employ arguments which indicate a probability of some truth; and the anticipations based upon them serve as guides to experimental inquiry by suggesting crucial tests. But they distinguish most carefully such hypotheses from demonstrated facts.

Thus a pale green solution, stated to contain a pure metallic salt, is found to possess some properties which belong to salts of iron. Nothing else possesses these properties except salts of nickel; and they manifest a slight difference from iron salts in one of the properties observed.

The analyst could not see any appearance of that peculiarity which distinguishes nickel salts; so he concludes that he has probably got iron in his solution, but almost certainly either iron or nickel. He then makes an experiment which will, he knows, give an entirely different result with iron salts and nickel salts; and he gets very distinctly the result which indicates iron.

Having found in the green liquid properties which the presence of iron could alone impart, he considers it highly probable that iron is present. But he does not stop there; for, although the facts before him seem to admit of no other interpretation, he knows that, from insufficient knowledge or attention, mistakes are sometimes made in very simple matters. The analyst therefore tries as many other experiments as are known to distinguish iron salts from all others; and if any one of these leads distinctly to a result at variance with his provisional conclusion, he goes over the whole inquiry again, in order to find where his mistake was. Such inquiries are practised largely by students of chemistry, in order to fix in their minds, by frequent use, a knowledge of the fundamental properties of the common elements, in order to learn by practice the art of making experiments, and, above all, in order to acquire the habit of judging accurately of evidence in natural phenomena. Such a student is often surprised at being told that it is not enough for him to conduct his experiments to such a point that every conclusion except one is contrary to the evidence before him—that he must then try every confirmatory test which he can of the substance believed to be present, and ascertain that the sample in his hands agrees, as far as he can see, in all properties with the known substance of which he believes it to be a specimen.

Those who tread the path of original inquiry, and add to human knowledge by their experiments, are bound to practise this habit with the most scrupulous fidelity and care, or many and grave would be the mistakes they would make.

Thus a chemist thinks it probable that he might prepare some well-known organic body of the aromatic family by a new process. He sets to work and obtains a substance agreeing in appearance, in empirical composition, in molecular weight, and in many other properties with the compound which he had in view. He is, however, not satisfied that his product is a sample of that compound until he has examined carefully whether it possesses all the properties which are known to belong to the substance in question. And many a time is his caution rewarded by the discovery of some distinct difference of melting-point, or of crystalline form, etc., which proves that he has made a new compound isomeric with the one which he expected to make. It seemed probable, from the agreement of the two substances in many particulars, that they might be found to agree in all, and might be considered to be the same compound; but complete proof of that conclusion consists in showing that the new substance agrees with all that we know of the old one.

In the most various ways chemists seek to extend their knowledge of the uniformity of nature; and their reasonings by analogy from particulars to particulars suggest the working hypotheses which lead to new observations. Before, however, proceeding to test the truth of his hypothesis by experiment, the chemist passes in review, as well as he can, all the general knowledge which has any bearing on it, in order to find agreement or disagreement between his hypothesis and the ideas established by past experience. Sometimes he sees that his hypothesis is at variance with some general law in which he has full confidence, and he throws it aside as disproved by that law. On other occasions he finds that it follows of necessity from some known law; and he then proceeds to verify it by experiment, with a confident anticipation of the result. In many cases the hypothesis does not present sufficiently distinct agreement or disagreement with the ideas established by previous investigations to justify either the rejection of it or a confident belief in its truth; for it often happens that the results of experience of similar phenomena are not embodied in a sufficiently definite or trustworthy statement to have any other effect than that of giving probability or the contrary to the hypothesis.

Another habit of mind which is indispensable for success in experimental chemistry, and which is taught by the practice of its various operations, is that of truthfulness.

The very object of all our endeavours is to get true ideas of the natural processes of chemical action; for in proportion as our ideas are true do they give us the power of directing these processes. In fact our ideas are useful only so far as they are true; and he must indeed be blind to interest and to duty who could wish to swerve from the path of truth. But if any one were weak enough to make the attempt, he would find his way barred by innumerable obstacles.

Every addition to our science is a matter of immediate interest and importance to those who are working in the direction. They test in various ways the statements of the discoverer, and seldom fail to notice further particulars, and to correct any little errors of detail into which he may have fallen. They soon make it a stepping-stone to further discoveries. Anything like wilful misrepresentation is inevitably detected and made known.

(*To be continued.*)

In consequence of the great pressure upon our space this week, due to the reports of the scientific meetings at Bradford, we are compelled to defer the insertion of several communications.

C.—As you will see by reference to the acknowledgment of its receipt, Mr. B. S. Proctor's new work on Practical Pharmacy is published by Messrs. J. and A. Churchill, New Burlington Street.

"*Nummi.*"—We believe it is intended to publish an Appendix to the present British Pharmacopœia, but cannot say when nor what it will include.

W. J. Smith.—See Mr. Brady's remarks on croton-chloral hydrate on p. 233 of the present number.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. W. Ransom, Mr. J. Tully, Mr. J. Abraham, Mr. H. Horncastle, Mr. Harper, Professor Attfield, Mr. E. Nicholson, Mr. J. Oakman, Mr. J. Burt, Dr. De Vrij, "Midland," "Granum," "Lotio," "Compositæ," "Scott," A. D. P., S. C., L. P. S.

THE SEPARATION OF THE MIXED ALKALOIDS FROM CINCHONA BARKS.

BY DR. J. E. DE VRIJ.

Recently a London firm of manufacturing chemists, who had read with interest my paper on cinchona alkaloids published in this Journal, applied to me to inform them "by what means I separate the mixed alkaloids from the dry bark." I therefore suppose it may perhaps be useful also for other readers of this Journal if I publish my actual method—which has been published in a Dutch periodical in 1871—also in this Journal. 20 grammes of powdered and sifted bark, dried at 100° C., are mixed with milk of lime, made of 5 grammes of dry slaked lime and 50 grammes of water. This mixture is slowly dried, and when entirely dry, heated in a flask with 200 cubic centimètres of very strong spirit (the strongest possible) till it boils. After cooling and subsiding, the clear liquid is poured on a filter large enough to contain all the bark, but not larger than is strictly necessary (a filter of 15 centimètres diameter is sufficient). The residue in the flask is now mixed again with 100 cubic centimètres of spirit, this mixture well shaken, and poured on the filter. When all the liquid has passed through the filter, the powder remaining on the filter is washed with 100 cubic centimètres of alcohol, so that in the whole 400 cubic centimètres of alcohol are used for 20 grammes of bark. The united liquors are now slightly acidulated with weak sulphuric acid, whereby a precipitate of sulphate of lime is formed. After this has subsided the greater part of the liquor can be poured off, the rest being filtered through a small filter. The clear liquid is now distilled to obtain the greater part of the spirit used, and the remaining liquid poured into a capsule, to which is added the spirit and the water by which the distilling apparatus is subsequently washed. The capsule is now heated on a water-bath till all the spirit has been expelled, and the remaining liquor which contains all the alkaloids in the form of acid sulphates, is, after cooling, filtered through a small filter. On the filter remains a mixture of quinovic acid and fatty substances, which must be washed repeatedly with water slightly acidulated by sulphuric acid till caustic soda no longer produces any turbidity in the passing liquid. The filtrate is now reduced to a small volume by heating on a water-bath, and while *still warm* precipitated by a slight excess of caustic soda. The benefit derived from this kind of precipitation is that the alkaloids precipitated from a warm solution are less voluminous, and can, therefore, more easily be washed. The drawback, however, is that the alkaloids from some barks melt under these circumstances, which drawback can, however, easily be rectified by powdering carefully the alkaloids after the cooling of the liquor, and collecting this powder on a small filter. After washing with the smallest possible quantity of distilled water, sufficient to remove the soda salt but not to dissolve quinine, the filter is laid upon blotting paper, and this so often renewed till the mixed alkaloids can easily be separated from the filter without adhering to it, which can be done before they are entirely dry, but requires some practice. They are then heated in a weighed capsule on the water-bath, till repeated weighings show that the weight remains constant. The observed weight multiplied by five gives the amount of mixed alkaloids in 100 parts of bark.

The amount of quinovic acid can be ascertained in the meantime, if the mixture of quinovic acid and fatty substances be treated with a weak solution of caustic soda, by which a great part of this mixture is dissolved. If to this turbid solution a slight excess of chloride of calcium is added, only the quinovate of lime remains in solution and can be obtained in the shape of a clear slightly-coloured liquid by simple filtration. If this clear liquid be acidulated by hydrochloric acid, the quinovic acid is precipitated in the shape of a voluminous jelly. As the amount of quinovic acid is generally very small, its quantity can rarely be ascertained with accuracy, unless the amount of bark be not under 40 grammes. As I generally make two analyses of 20 grammes of bark, I combine the mixture of quinovic acid, etc., of the two filters for the determination of the quinovic acid. If the two analyses are carefully performed under the *same* circumstances, the results differ only very slightly, as may be seen in my analysis of some Jamaica barks, published on p. 121 of this Journal.

The Hague, 17th September, 1873.

PHARMACEUTICAL RESULTS OF THE CALCUTTA BOTANIC GARDENS.

Acclimatization of Ipecacuanha.

(*Continued from p.* 222.)

"The plants in Sikkim are located about 3000 feet above the sea, in glass-covered frames, and planted in a mass of well-drained leaf-mould, but without bottom heat, which is only used when cuttings are being struck. Nothing could be more healthy in appearance than the young plants in the frames. Their leaves are of a dark green colour, and without a single spot or blemish; but the plant is a slow growing one, and we have evidently not yet discovered the conditions under which it will thrive in the open air. I believe it requires a moist, hot, equable climate, with a soil porous and well drained—in fact, resembling leaf-mould. Mr. Gammie thinks they will not do, as recommended by Mr. Kurz, in places subject to periodical inundations. I have asked Mr. Kurz how he came to recommend such situations, and he has given me the following note:—

Memorandum by Mr. Kurz.

"'It is right to state, in explanation to Mr. Gammie's remark about my statement regarding the ipecacuanha plant, that I have based my deductions regarding its requirements upon Professor Grisebach's recent work, and upon his review of Weddell's paper on the ipecacuanha.

"'Dr. Grisebach states therein (*Bericht über die Lerstungen in der Pflanzengeographie für* 1849, p. 57), that the ipecacuanha grows in the dense shade of certain palms and trees on marshy grounds (*quellichte gruende*), whereas on a perusal of Weddell's French original, I find it distinctly stated that the plant grows chiefly on firm grounds surrounding these little marshes (*surtout sur la terre ferme qui entoure ces petits marais*).

"'I think that Weddell's excellent paper (*Note sur le Cephaëlis Ipecacuanha, son mode de végétation, etc.*, in *Annales des Sciences Naturelles*, série 3, xi, 193-202), which I could not consult when I formed my views on the plant, should leave no doubt as to the real requirements of the ipecacuanha plant" (l. c., page 197-198).'

"I have read the excellent paper of Mr. Weddell's which Mr. Kurz refers to, and as it is one of the most important documents on the subject we have yet got, I give a translation of it. It is published in the *Annales des Sciences Naturelles*, troisième série (*Botanique*), page 193, and is entitled *Note sur le Cephaëlis Ipecacuanha, son mode de végétation, et son exploitation dans la Province de Matto Grosso, en Brazil.* One of the most important pieces of information contained in this paper is that in three or four years after ipecacuanha roots have been dug up, they are reproduced from the fragments of root left in the ground, so that a crop is got every three or four years without any replanting. There is another encouraging fact which Mr. Gammie has just brought to my notice, namely, that some of the plants which have very little foliage, and do not seem to be thriving, are found, on being dug up, to have made a large quantity of roots; and as what is generally called the root of ipecacuanha is in reality an underground stem, it probably performed, in part at least, the function of foliage, particularly where grown in loose leaf-mould, which is freely permeated by air, as all our plants have hitherto been grown."

The following is a translation of the paper above referred to by Dr. Henderson:—

The medicine called by the name of ipecacuanha is known to be the product of several species of plants. The same name is generally given to all emetic roots, whatever may be the natural family to which they belong. The product of this name, which is now commonly used in Europe, is derived from a plant of the rubiaceæ family (the *Cephaëlis Ipecacuanha;* M. A. Richard has given it the name of annulated (*annelé*) ipecacuanha. The striated (*strié*) ipecacuanha of the same author (very rare in pharmacy in our day) is produced by the *Psychotria emetica* of Mutis. The last is indigenous in New Granada; the *Cephaëlis*, on the contrary, is peculiar to Brazil. It is this last which I have had special means of observing, and of which I shall here endeavour to give some account.

Several points in the history of this plant are so generally known that it is useless for me to go over them, but I shall dwell on those which are only treated of in little-known works, and I shall endeavour principally to make known the geographical distribution of the plants, the manner of gathering the roots, and the means used by nature for favouring its reproduction. This part of the question has appeared to me so much the more interesting as its solution is a complete answer to the fears that have been entertained of this plant becoming extinct.

The word ipecacuanha appeared in Europe with the works of Pison and Marcgraff, and seems to be the name by which the *Cephaëlis* was known in that part of Brazil where the Portuguese first learnt to make use of it. Still it may be, as some accounts lead one to believe, that it has been with ipecacuanha as with Jesuit's bark, which has usurped a name which had been created for another plant. The term ipecacuanha is, in short, in no part of Brazil applied to the *Cephaëlis*, which is now known everywhere by the name of *poaya*, a term which, according to M. Auguste St. Hiliare, would be a corruption of the Indian words "*y cipo ayaca*," which means "*liane-à-panier.*" This etymology is so much the more probable, as the European Portuguese still often call ipecacuanha by the name of *cipo* or *liane.* One of the best emetic roots of Brazil is indeed the product of a little plant which is remarkable for the brilliancy of its flowers, and it is not at all impossible that the discovery of this plant may have preceded that of other species of poaya, and given its name to them.

The first knowledge of ipecacuanha appears, according to the general assent of authors, to go back to the Indians, who preceded the Portuguese in Brazil, and here, as in other circumstances, tradition has it that man was preceded by animals. There were wolves which having indigestion had the idea of curing themselves by chewing the roots of the *Cephaëlis*, and were afterwards imitated by the Indians. The tale will recall that of the falcon of New Granada drawing the attention of the aborigines of the country to the famous cure for poisoning, known as guaco, as well as that of the lions of Loxa curing themselves of fever with the water of the ponds where the stems of the cinchona had been macerated.

(*To be continued.*)

A SUMMER DAY'S DISCOURSE.*

BY THE REV. W. C. GANNETT.

(*Concluded from* p. 208.)

Nature paints flowers, too; she gives them colour. If any one seems ugly, as a whole, take a bit and put it under a microscope, and see what firmaments of colour, what mines of sparkling gems, you have burst into! Under the lens a quarter-inch of rosy petal flushes and spreads like a sunset sky! A mottled streak turns into a glorious sunrise! You can think of nothing else for fit comparison. And then, instead of speech, she gives them fragrance. They have no language, but in this way "their music goes forth through all the earth, and their word to the end of the world." Unless, indeed, Huxley's fancy be true, and by ears fine enough (possibly only insect-fine), a voice also could be heard, "a beauty born of murmuring sound" would pass into our face as we bent over them—sound such as streams have that run through secret channels. If so, what choruses rise through all our fields that some one hears!

But what is all this lavish sculpture and painting and fragrance for?—lavished on the waste where no eyes see as well as in the garden-bed; lavished on the inner slopes and curves where human eyes cannot detect it, as well as on the inch of outward surface. We used to say, God made it so! We used to say, see His delight in simple beauty by itself! We used to say—

"If eyes were made for seeing,
Then beauty is its own excuse for being;"

but to-day again steps forward with a new and better word, and hints—not that the beauty is not beauty—that use is the end, and that all this beauty and fragrance is but a path to that end. We can see plainly enough that all the energy of the plant goes to secure reproduction, that all the parts of the flower subserve the purpose of seed-making. Deep hidden within the flower's heart lies the little nursery where the seeds are to be born; most cunningly the pistil and the stamen watch each other like true lovers for a greeting; tenderly the petals close around them in the cool, and open through fit hours of sunlight. And when the stamens and the pistils cannot meet directly, but the message must be borne by insect rovers, then the complication of contrivance to secure the transport of the message almost exceeds belief. The pollen must be brought from one certain spot in one flower and left upon a certain spot upon another. Says one, speaking of Darwin's search into the fertilization of the orchids:

* Abstracted from a sermon preached at Boston, Massachusetts, and quoted in the *Gardeners' Chronicle.*

—"'Moth-traps and spring-guns set on these grounds' might well be the motto of these flowers. There are channels of approach along which the nectar-loving insects are surely guided so as to compel them to pass the given spots; there are adhesive plasters nicely adjusted to fit their proboscides or to catch their brows, and so unload their pollen burden; sometimes where they enter for the honey there are hair-triggers carefully set in their necessary path, communicating with explosive shells that project the pollen-stalks with unerring aim upon their bodies." And now Darwin adds to his explanations the thought (it is not yet wholly proved, but it is well advanced in proof) that the lustrous colours of the flowers and their rich odours are also contrivances to aid in the reproduction. He has found it "an invariable rule that flowers fertilized by the wind never have the gaily-coloured petals," and draws the inference that the beauty and the fragrance come upon the blossoms by long processes of natural selection, because attractive to the insects that are needed to assist in fertilizing them. The colours and the songs of birds and insects, he shows in part, are similarly brought about—and thus all that gives the life and motion and peculiar gladness to the fields in spring would be literally but the deep inbreathing of the spirit of love in Nature. How far down it goes! It touches the whole planet to grace and beauty! Or rather how it lifts the reins of our poor thought and gives our highest conception of love a glory of meaning we never guessed before! It seems to make real the thought of a Father's heart beating in all things.

And in this distinction of sex the plants lay hold of us. They come between the mineral and animal kingdoms as the connecting link. They not only exercise the primitive digestion, organizing minerals into the food on which we higher creatures live; they not only thrive while they prepare our respiration, draining clear the air of that which poisons us, and re-stocking it with that which we must breathe; but in this distinction of sex in flowers they rise to the height of their stature and foreshadow the third great function of the animal world—that of reproduction. So the flower is the plant-part nearest to the animal. Like us it breathes oxygen and gives out the other gas. Like us it therefore gives out heat; the flower is the hottest part of the plant. Like us, it has rest seasons; sleep, so-called; and for reproduction needs to hoard, and in the process exhausts vitality. And, like animals, plants have ancestry and kindred, and can only be arranged in a true system when we consider them physiologically as they truly exist in Nature. When we "consider" the flowers and find such thoughts as these all waiting for us, the words of Tennyson grow very real to us:—

> "Flower, in the crannied wall,
> I pluck you out of the crannies;
> Hold you here, root and all, in my hand,
> Little flower; but if I could understand
> What you are, root and all, and all in all,
> I should know what God and man is!"

But I must leave the flowers themselves to speak a word about flower-love.

The Arabs, passing a rich harvest-field or a tree in full bloom, will greet it with a "Barak-Allah!"—May God bless you! That hints the world-wide feeling. And the Arab beggars name their children Ruby and Diamond, Lily, Rose, and Jessamine. So still do we. Gems and flowers, each the highest product of its kingdom, for a gem is the exquisiteness of flint or clay, and a flower the transfiguration of the plant; instinctively and fitly we take them to name all other things precious and beautiful.

This flower-love declares itself in many ways. We set the pots like traps to catch the sunbeams at our windows, and like to have creation going on in our parlours. We make believe at "woods" in little ferneries. We concentrate the fields in our gardens and concentrate the climates in our greenhouses. The Horticultural Society in Boston holds its Saturday morning worship all through the summer, and it is better than cathedral joy to linger at their altars. In southern France there are flower-farms. In some parts of England the rich people have established working men's flower exhibitions. The little gardens that furnish the competitors are window-ledges in the back streets of London, or little plots six feet by ten before the country door. A boy will bring his solitary geranium, a girl her carnation, the father has one or two rare roses (perhaps the money that bought them was saved from the alehouse), roses whose every leaf-bud has made breakfast-talk and after-supper watchings for the family. Each competing pot must have its seal and knot of ribbon. And when the day arrives the lords and ladies come and look and praise; and then the 6*d.* admission lets in the eager, well-dressed crowd, and all get prizes, I believe; and the factory-hands go home deciding what flower they will train to enter at the next annual show. The factory-hand's life holds room for that! Once in Holland this flower-love drove the sober-headed Dutchmen crazy. They grew ecstatic over tulips, so crazily fond of tulips that 2000 dols. was cheap for a certain bulb. All ranks, high and low, were carried off their understandings into speculations; the towns had their tulip exchange; the public notary became almost the tulip notary. And when the bubble burst, and the general repudiation came, fortunes vanished, the panic was national, and the country did not get over the shock to its commerce for several years.

But in other deeper ways than this of cultivation the ancient world-wide love has shown itself. Art has always fed itself on flowers. Architecture tells the story earliest. The heavy Egyptian column imitates, it is supposed, the palm tree's trunk, and its capital the lotus bud of the Nile. The Corinthian capital is the acanthus leaf, and the stones of Gothic architecture conspire in a hundred forms to imitate the vegetable structure.

Poetry is full of flower-fields, because each flower seems so full of poetry to us. The very flower-names are often poems. Some come down to us impearled with old myth, and story, and tradition—like the hyacinth, narcissus, Solomon's seal, arethusa, and passion-flower. What sacred romances the lotus flower, the martyr's palm, the victor's laurel recall! Those long, uncouth Greek names we dread in botany hide nature meanings in them, only they are Greek to us. Heliotrope is "she who turns to the sun;" Mesambryanthemum is simply "flower of the mid-day;" nasturtium carries its meaning of "bent nose" in its face; geranium is "crane's bill" (let the seed vessel grow and it will tell the reason why); saxifrage is rock-cleaver (named so from its birth-place); anemone is "wind-flower." These were all but simple heart and eye names to the Greeks or Romans—each people has its own—just as we call the pets heartsease, day's-eye, morning-glory, honeysuckle, mignonette. And when the lovers want to tell the unutterable words they still betake themselves to the dumb messengers that have learned to say so much. There is probably no famous poet that has not sealed his fame into a song about some favourite of the fields. Wordsworth's celandines and daffodils are noted, and Burns' daisy, and Herbert's rose, and Emerson's rhodora, and Lowell's dandelion; while in Chaucer the whole spring buds and sings, and all along the lines of Tennyson flowers brush you with fine touches. Nay, every one plays poet with them, though he write no verses.

We use them to interpret all the tenderest things in life. When we want to remember a hill-top view, a meeting that has made a holiday, some spot holy with old history, we pluck a flower to hold the memory fast. If we want to send the home-presence tangibly in a letter, a flower from the window or the field close by will carry it best. Old books drop out the "faded yellow blossoms 'twixt page and page"—put there "to mark great places with due gratitude." The California miner saw the mountain heartsease where his pick was going to fall, and, before it fell, he was at home across the continent, quicker than telegrams can fly, and in his own pasture where he drove the cows a thousand times. Hollyhocks or lilacs—who thinks of them and does not see a quiet country

dooryard in the sunshine ! How the sick soldiers in army hospitals, longing for certain faces and certain tones and touches, greeted the spring flowers as the nearest substitute ! "Now, I've got something for you !" said a woman-nurse, holding the bunch behind her, to a very sick New England soldier—"something for you just like what grows in your front dooryard at home ! Guess !" "Lalocs !" he whispered ; and she laid them on his folded hands. "Oh, lalocs !—how did you know that !" The lilacs outlived him. And so the flower-love, mounting, comes to show itself in man's worship also ; and the thought never rises more naturally up to God, I think, than when it rises from bending over flowers. In Buddhist lands they have long been the choicest offering that man brings his Maker, and there are holy blossoms that have symbolized the sun, the world, and God's throne ! We bring them into church ; like visible music they fill the pauses ; and who comes here with purer face or life of sweeter obedience to the great laws of Nature !

So sweet, so pure, they are, that, like our holiest friends, they fit not joy and wedding moments only, but still more naturally they come in together with the tragedies, the silences, the heart-break. And why ? Is not this the reason ?—

"When heaven grows dim, and faith seeks to renew
The image of its everlasting dower,
I know no argument so sweet as through
The bosom of a flower—
A wicket-gate to heaven (of which death
Is the grand portal sealed to mortal eyes),
Between whose little bars there comes the breath
Of airs from Paradise."

When the "grand portal" has opened and shut close to us, and we are left with straining gaze outside, the "wicket-gate" seems to give comfort. It seems to grant some little vision into the hidden heart of things, suggesting that the darkness everywhere holds possibilities better than our brightest hopes. Save for the flower-fact here before us, who could have dreamed that such beauty lurked in the dark earth, was latent in the tiny seed ! So we place the flowers around the still, cold face ; we lay them on our soldiers' graves ; we bring them to the sick-room and the bedside of the dying ; and everywhere, after words fail and even music hushes, the presence abides—a voiceless, unconfuted argument that the power within all silences, and pains, and tragedies, is love, and that the possibilities of life are infinite.

Flowers and art. Flowers and poetry. Flowers and worship. But the flower-thought of all is that I spoke of—growth ; and so we add the flowers and science. For in the flower "a new name is written," and that name now is found to have been written in all things that are. The old name was revelation ; it is not false ; but the new name, evolution, widens out its meaning. All things grow—all. The flower is type of the universe, and the lily of the field is solving over again all problems.

THE CONFERENCE EXCURSION TO BOLTON ABBEY AND WOODS.

By the courtesy of the Local Committee, the members of the Conference were invited to form an excursion party, devoting Friday, September 19th, to the exploration of some of the beautiful scenery of Wharfedale, notably that of Bolton Abbey and its surrounding woods. At 9.45 a.m., the party, which included several ladies, left Bradford by train in a saloon carriage, its number, after some reinforcement from Leeds, being about thirty persons. An hour's ride led first along a part of Airedale, and afterwards through the elevated ground which separates that busy manufacturing valley from the more rural vale of Wharfe. Here our tourists noticed the commanding turrets of that famous health-resort, Ben Rhydding, where the water-treatment finds full play, and is supplemented by the compressed air-bath, and other adjuncts. The terminus of the railway is at Ilkley, a mile further, where four other hydropathic establishments open their doors to various ranks of invalids. The springs of this favourite watering-place offer no variety such as its neighbour Harrogate can boast of. Water so pure as to contain but two or three grains of solid matter per gallon, leaves little for the chemist to descant upon. Its gathering ground is the breezy plateau of Rombald's Moor upon the mill-stone grit formation. Ilkley nestles beneath this, and no longer rests content with its ancient fame as Olicana of the Romans. The last few years have seen its reconstruction—thatch and white-washed walls giving place to handsome stone buildings. The trepidation of some of its inhabitants and of more of its visitors, consequent upon a probability that a permanent military camp would be established in its vicinity, has just passed away. The rocks here have a strikingly bold character, and the elevated masses known as the "Cow and Calf" form a landmark to be seen from a long distance. In the churchyard are three Saxon stone crosses, covered with designs introducing animals.

The vehicle of the district is the waggonette, and into three of these commodious and sociability-promoting conveyances the company was distributed. A drive of five miles up the valley, passing through the quiet village of Addingham, brought the party to Bolton Bridge. Here the road enters the woods, and for two or three miles the road follows the narrowed and richly-wooded valley which forms the upper end of Wharfedale. Well might the Yorkshire members feel pride in pointing out new beauties at every turn, as the ruined abbey came in sight, followed in quick succession by ever-changing glimpses of the rapid and brilliant river—here to be crossed in drier weather by the long line of "stepping-stones ;" there broken by islets at a spot known as "the meeting of the waters ;" again, showing a long reach or a briefer peep through overhanging trees. The carriages halted, and a few paces brought the party to the most striking natural object of the valley. This was the Strid, immortalized by Wordsworth in the well-known lines—

"The pair have reached that fearful chasm ;
How tempting to bestride !
For lordly Wharfe is there pent in
With rocks on either side."

But the volume of surging, peat-stained water that poured through the Strid to-day was enough to check any venturesome spirits.

A short walk through the woods brought the party to more open country, overlooked by the grey front of Barden Tower, long the home of the Cliffords. The word was passed to return by a deviating path, and the walk finished with an inspection of the grand old abbey. A portion of the building has been roofed over and is used for Divine service, this restoration being the work of the noble owner, the Duke of Devonshire, whose shooting-box adjoins the ruins.

And now many seemed to agree in the opinion of Dr. Johnson, that "the finest landscape is much improved by a good hotel in the foreground." Such was found in the famed "Devonshire Arms," where ample preparation was made for appeasing any pangs of hunger. A cold collation was already spread and received full justice, until a satisfied, if not satiated, chemist declined further action upon the pastry, and was taunted with his unreasonable objection to *Bi-tart*rates ! The repast was all that need be desired, and if the necessities of an hostelry far removed from towns limited it to modest pretensions, there were some who thought this no fault, and that the Conference interests were then as well served as if greater display had been possible. But one toast was given—"Our next merry meeting," and it was received enthusiastically. Then the return journey began, and by seven o'clock the party reached Bradford, under the charge of the two gentlemen, Mr. Rimmington and Mr. Bell, to whose excellent arrangements and guidance this delightful excursion owed all success beyond that dependent upon most propitious weather.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 27, 1873.

Communications for this Journal, and books for review, etc. should be addressed to the EDITOR, 17, *Bloomsbury Square*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE BRITISH ASSOCIATION AT BRADFORD.

ON Wednesday last the forty-third meeting of the British Association for the Advancement of Science, so ably inaugurated on that day week by Professor A. W. WILLIAMSON, F.R.S., in the Address which appears in our columns, was brought to a close. One or two excursions remained to be enjoyed, but the business of the meeting was then concluded. The number of members and associates attending it, 1983, and the receipts, £2102, have been the lowest since the meeting at Exeter in 1869. This probably is due in great measure to the situation and characteristics of the town of Bradford, but also in no little degree to the exorbitant charges demanded by the hotel keepers, in regard to which the dissatisfaction has been general among members of the British Association, and the course adopted has been strongly condemned by the people of Bradford.

The multiplicity of the papers read prevents any attempt even to recapitulate them here. The Chemical Section was opened by the President, Dr. W. J. RUSSELL, F.R.S., with a valuable address, the principal topic of which was the history of the colouring matter found in madder, the steps leading up to the artificial production of alizarine, and how it is superseding for manufacturing purposes the long used natural product. Dr. SIEMENS has lectured to the working classes on the all important subject of "Fuel." Professor CLERK MAXWELL has discoursed to the members on "Molecules." Dr. CARPENTER and Professor W. C. WILLIAMSON, though not pledged teetotallers, have expatiated on the blessings of temperance. And although no "discoverer of LIVINGSTONE" was present, there was news from the LIVINGSTONE expedition, from Sir SAMUEL BAKER, and from the "Polaris;" while the Section for Economic Science and Statistics had a Cabinet minister for its president. Another Sewage report has been presented, and one on the Metric System, and during the discussion of the latter it transpired that while the Committee was unanimous in favour of the application of the metric system to weights and measures it was not agreed as to the principles of a decimal coinage.

At the meeting of the General Committee on Monday, it was decided to accept the invitation to hold the meeting for 1875 in Bristol. Upon a proposition being made that Professor TYNDALL should be appointed the President-Elect for the meeting at Belfast next year, there arose a warm discussion; the MAYOR OF BELFAST, who was present with a deputation, opposing the motion, on the ground that they possessed in Belfast, among themselves, a gentleman well fitted for the post in the person of Dr. ANDREWS, of Queen's College. The PRESIDENT, however, after a high eulogium upon Dr. ANDREWS as a cultivator of science, expressed his confidence that the effect of the work of the President's office upon one in his state of health might result in serious injury to him, and Dr. CARPENTER expressed a similar opinion, after which the opposition was withdrawn, and Professor TYNDALL was elected. Although election to preside over the British Association is often considered the highest honour that can be conferred on a scientific man in this country, there can be no doubt that the occupation of the presidential chair by Dr. ANDREWS would have been far more an honour to the Association than his election would have been an honour to him. However, as we find it pointedly stated in the *Times* that Dr. ANDREWS has declined to accept the office of President, the Council of the Association may have had better reason than is apparent for nominating Professor TYNDALL. It was announced that the sum of £1545 had been voted for scientific purposes during the ensuing year.

A deputation from Glasgow invited a visit from the Association in 1876, and there seemed to be a general impression that this would be accepted next year.

COCOA.

CONSEQUENT upon the passing of the recent Adulteration Act, the sale and manufacture of cocoa have received considerable attention of late, and have much puzzled certain metropolitan magistrates and analysts, who seem to be very uncertain in their opinion as to the best form in which cocoa should be sold to the public. On the one hand, it is asserted that, scientifically speaking, cocoa is at present sold and manufactured in a not altogether commendable manner. As our readers are aware, "admixture" is a great element in the manufacture, and the many soluble cocoas offered to the public all contain a greater or less amount of sugar and farina in their composition. There are certain scientific men who contend that this is unquestionably an adulteration of cocoa, that the article does not require these admixtures, that they debase it, and that the public ought to get the benefit of the cocoa-nib in its pure form. On the other hand, the manufacturers of the cheap, loose cocoa assert that these admixtures do not in any way depreciate the cocoa, that, in fact, they improve it, and render it saleable as a cheap commodity amongst consumers, and that, generally speaking, they repudiate the idea of adulteration in connection with these goods. Prosecutions have arisen with regard to cocoa under the Adulteration Act, and one of the most important (that heard before Mr. D'Eyncourt, the magistrate at Marylebone) was reported in the PHARMACEUTICAL JOURNAL at the time. In this case

the cocoa manufacturers got the best of it. They showed conclusively that there was nothing deleterious in the article as they made it, and that, as a practical fact, the admixture of sugar and farina was necessary, in order to popularize that article with the public, and make it a general and cheap article of sale. Mr. D'Eyncourt, after hearing lengthened arguments on each side, dismissed the summons, declaring his opinion that the soluble cocoa could not be regarded as an adulterated article.

It will not be uninteresting if we shortly point out how materially this branch of our commerce has developed. Going as far back as thirty years, or say to 1840, we find that the imports of cocoa into the United Kingdom then amounted to 3,499,746 lbs.; in 1850 this amount had increased to 4,478,252; in 1860 it was 9,009,860 lbs.; and in 1870 the total reached the vast amount of 14,793,950 lbs. This augmentation is a remarkable fact, and speaks volumes as to the increasing popularity of the article with the public. Most of this cocoa, as thus imported, is manufactured into the loose soluble cocoas which we see in the shops, and here we have convincing proof that the method of manufacture adopted of late years has been a great success, or our imports of cocoa would not have increased with such startling rapidity. It may be mentioned, too, as an interesting fact that the imports of cocoa for the first eight months of the present year amounted to no less than 15,372,502 lbs. against 13,284,369 lbs. in the same period of 1872, and 13,688,749 lbs. in the corresponding period of 1871.

The importance of the cocoa trade, as a distinct branch of the industry of the country, will be readily perceived from the statistics which we have just quoted. We thus see the amount which is imported, and which is manufactured into the various forms in which the article is generally sold to the British public. The greater portion—in fact, nearly all—finds its way into consumption in the shape of cocoa-powder, commonly and popularly known as soluble cocoa, and we are quite right in saying that very little of the pure nib is sold. The public much prefer the article as it is ordinarily sold, and do not seem to be partial to the theory that the pure nib is better for them. Considering the matter quite impartially, it is certain that as a beverage we get cocoa very good now-a-days, and we cannot conscientiously complain of our cocoa manufacturers. With regard to the prosecutions which have already resulted, it is satisfactory that they have nearly always ended in favour of the manufacturers, and corroborate the position they assume—viz., that they sell a perfectly pure and wholesome article of consumption, most useful and acceptable to the community at large.

On Wednesday evening next, October 1st, the Sessional Prizes and Certificates awarded to students in the School of Pharmacy will be distributed at 17, Bloomsbury Square; after which George Webb Sandford, Esq., will deliver an Address to the students. The Chair will be taken at 8.30 precisely. Ladies are invited to attend.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Tuesday, September 16th.

(*Continued from p.* 236.)

After the delivery of the President's address, the ordinary business of the meeting was proceeded with. The first paper read was—

A Proposition for a Sign to be Used by Medical Men to Mark Unusual Doses in Prescriptions.

by R. Hampson.

In proposing a sign, for the adoption of medical men, to denote with unerring significance the prescribing of unusual doses, I feel that I may almost be open to the charge of trespassing upon medical ground, and I must admit that a proposal of this kind would have come with greater propriety from medical men themselves. I believe, however, in the light of a recent painful event, that the time has arrived when the adoption of a distinctive sign will be welcomed both by the prescriber and the dispenser.

The interests of pharmaceutists are in a great measure so identical and so intimately bound up with the physician's interest in his patients' welfare, that the adoption of a sign, if recommended by this Conference, will, I have no doubt, be received by the medical profession with proper consideration and respect.

An unusual dose I define as a dose in excess of the maximum adult dose of the Pharmacopœia, or a dose exceeding that commonly administered.

Our experience as dispensers of medicines will have fully proved to us that the marking of unusual doses would be accepted as a long desired boon by all concerned.

The prescriber, in employing an accepted sign, of easy recognition, would be assured by its use that it would remove all hesitation and questioning doubt from the mind of the dispenser, and that it would ensure for his patients the receiving of the prescribed medicines without needless delay—which delay, in some cases, may mean loss of life or the suffering of unnecessary pain and watchfulness.

The pharmaceutist, whose occupation it would be to dispense the duly marked doses, would greet these unmistakeable signs with genuine pleasure and relief, and their use would save him considerable anxiety, as well as the loss of much time and the inconvenience so often caused in seeking out the prescriber's real intentions.

I shall not take up time in citing cases which have occurred to me individually, or in alluding to any brought under my notice, to prove that the use of a sign is imperatively demanded by the exigencies of the case. Everyone present whose vocation it is to dispense prescriptions will call to mind frequent instances when an indicating sign to mark the unusual doses would have saved considerable time, trouble, and vexation.

It is certainly very remarkable that, in this country of practical expedients, a rule of this kind should not years ago have been in use.

In Germany and Austria, where many things are arranged by the strong hands of the state, a clearly defined rule, of a too arbitrary character for adoption here, set forth in the pharmacopœias of those countries, has been employed for some time, and this fact is presumptive evidence that a rule, or rather a sign, of some kind is required in this country.

It is folly to suppose, as averred, that we can have any conceivable interest in "limiting medical practice," or in any way passing a shade of criticism upon it. Our interest is almost necessarily in a contrary direction, and our duty is obviously clear and well defined. It is simply to provide with perfect integrity the medicines prescribed; but I certainly think we are entitled to have them prescribed as plainly and as legibly as possible; and when an

unusual dose is required it is only reasonable to request that it shall be so described and signally marked that there shall be no room for doubt in the mind of the dispenser that the dose is really intended, and not *mis*-prescribed.

If doubt should exist as to whether a prescribed dose is intended, it is the dispenser's acknowledged duty to communicate speedily with the prescriber to ascertain his intentions.

We must not, however, let it be supposed that a pharmaceutist is *not* at liberty to decline to dispense a prescription in which an unusual dose of a remarkable character is prescribed.

My experience includes the dispensing of some very unusual doses, and I cannot forget the grave sense of personal responsibility dwelling in my mind whilst dispensing these particular prescriptions.

If we feel the responsibility too oppressive, we ought to consider ourselves fully at liberty to decline to dispense prescriptions of this exceptional character. I am sure we should never lightly exercise this undoubted right of refusal, or in any way forget to show, on such occasions a proper and due regard for the delicate professional position of the prescriber.

As the object we have in view is of more importance to medical men than to pharmaceutists, I trust the medical profession will give their willing and necessary aid in bringing about the general adoption of a sign to mark unusual doses. We may, I hope, also look with confidence to the medical journals to endorse our efforts to establish the use of that sign which may be considered to be best suited for the purpose intended.

In Germany and Austria a point of exclamation is used to denote an unusual dose ; thus—

Tincturæ Digitalis . . . . . ℥iv !

This is an excellent sign, and might answer the purpose in this country, but I am strongly disposed to think the use of the initial letters of the prescriber's name is the best and most appropriate sign to be employed.

It is a custom in England to use the initial letters of a signature when a deed is altered to denote agreement or acquiescence, and there would be a legal value attached to the initial letters written by the prescriber, and they would be useful to compare with the actual signature, if a dispute at any time arose concerning a prescription to which they were attached.

The sign I offer for your acceptance is therefore the prescriber's initials in brackets, written immediately after the unusual dose ; thus—

Tincturæ Digitalis . . . . ℥iv. [J.R.L.]

It would also be of inestimable advantage if the name and address of the prescriber were printed or written upon *every* prescription.

In the United States this is invariably done.

The loss of much valuable time would be obviated if the latter suggestion became the rule.

The prescriber's initials, which may be known only to a few pharmaceutists, are not sufficient to denote proper authenticity, and the full name and address would also afford protection to the prescriber and dispenser alike.

I hope this Conference will not only fully deliberate upon this important question, but will decide *unanimously* upon the sign to be suggested to the medical profession for their adoption, and it is equally desirable that a resolution embodying your decision be carried and duly published.

The Secretary then read the following note from Mr. Henry Whitfield, of Worcester, upon the same subject:—

To Professor Attfield.

Sir,—I enclose two prescriptions, which I should feel obliged by your showing at the forthcoming meeting of the Pharmaceutical Conference, if you think that they would prove interesting. The one shows a dose of tincture of digitalis identical with that ordered in the recent Ramsgate case, and the other a somewhat unusual dose of morphia. The patient, a very strong man, was suffering from a second attack of delirium tremens, but under the treatment recovered, and having taken (and kept) the pledge for about twelve months, is now in good health. The late Mr. Carden, of Worcester, who prescribed the above, himself called and explained the circumstances, so it was all plain sailing ; but in another case, where three draughts were ordered, each containing half an ounce of tincture of digitalis, and one to be taken every four hours, it was deemed advisable to consult the medical man before making up the prescription. The moral is, that if the prescriber, when ordering a very unusual dose, is unable or unwilling to call on the chemist, he need only underline the dose, or place his initials opposite to it, for the chemist to be sure that the large dose is really intended. Had this been the case in the recent case at Ramsgate, much ill-feeling and unpleasantness would have been spared to all parties.

I will thank you to hand over the prescriptions to the Pharmaceutical Society after the meeting, for insertion in the book at Bloomsbury Square.—I am, Sir, yours truly,

Worcester. Henry Whitfield.

The President : It will probably be thought fitting to take the discussion on this question now, and I will merely suggest that it is rather a wide subject, and may become unmanageably large unless the point is adhered to closely. We have not now to discuss the propriety of giving extraordinary doses, but merely whether it is our duty to recommend to the medical profession the adoption of some manner of writing prescriptions which will prevent accidents when unusually large doses are ordered unintentionally, and will ensure the dispensing of the prescription when it is intended that extreme quantities should be administered.

Mr. Martindale (London) : I quite agree with Mr. Hampson that the medical man's initials placed against the quantity would be the best mode of indicating when it is his intention that an unusual dose shall be given, and I know that that course is adopted by many physicians in London. There are one or two points in connection with this subject to which I should wish to draw attention. In the first place I think that for our general security prescriptions should be stamped with authority as much as a bank note, and for this purpose it has been suggested that they should bear the name and address of the physician prescribing. There might however be some little difficulty in getting physicians to write their names in full on account of professional delicacy. But if physicians would place their address on their prescriptions their names could be easily ascertained by reference to the medical directory. I have known cases in which the authenticity of hospital prescriptions has been open to doubt, and several of the hospitals require all their prescriptions to be written on hospital paper ; I think some similar plan might be adopted in reference to general prescriptions.

Mr. Hasselby (Goole) : Twelve years ago when I was an assistant a prescription prescribing an unusually large dose of digitalis was brought to me. After consultation we sent to the physician who had written the pre-

scription and ascertained that he had intended that the unusual dose should be given. In the case of Mr. Fisher, at Ramsgate, I should have made great effort to see the physician and should have taken no notice of the impertinence of the messenger, except to order him out of the shop. In country places however where the customer cannot wait and the physician may live miles away, it might be impossible to take the course I have suggested of seeing the physician in case of doubt. In all such cases therefore we ought to make a dead stand upon this point and insist that physicians should distinguish unusual doses which they desire to be given by some distinct mark. We have plenty of responsibility and little enough pay for what we do, and I think that the medical profession should relieve us from as much of the responsibility as they can.

Mr. COTTRILL (Shepton Mallet) : I wish to speak in favour of the physician's initials being used as the distinguishing marks of an unusual dose. We may be thoroughly up in the nature and the properties of drugs, but we cannot be expected always to divine the intention of the physician. Some years ago, when I was in the establishment of a firm doing an extensive business in Exeter, a physician with whom I had occasion to communicate on two occasions in connection with his prescriptions said to me, "Whenever I make a mistake, or you think I have done so, just do what you think I intended you should do, and let me know what you have done." That was all very well in its way as a compliment to me, but if Mr. Fisher's case had come before me I should have made an alteration in the prescription and the result would have been the same—the man would have died.

Mr. L. SIEBOLD (Manchester) : I think the initials would be preferable as a distinguishing mark to a note of exclamation, and that the chemist should decline to undertake the responsibility of dispensing an obviously fatal dose of a poison, notwithstanding its being distinguished by the initials of the medical man. Where unusual doses which are distinguished by the physician's initials are given, the chemist should be allowed to retain the original prescription, to be used if needed in his own defence. For if not retained by him, the prescription may be lost or destroyed and the dispenser thus deprived of the most valuable piece of evidence.

Mr. RIMMINGTON (Bradford) : I have taken considerable interest in this question for a long time, before the case occured to which reference has been made. Every dispenser must have felt the necessity for unusual doses being distinguished by some distinct mark, so as to relieve him from the anxiety he now undergoes. Under the present system it is often difficult to identify the physician who writes the prescription, and it is perfectly impossible to communicate with him. In such cases the chemist should simply exercise his own judgment as to the propriety of making up the prescription. In one instance we once received a prescription directing thirty-three grains of arsenic to be made up into four hundred pills, three of which were to be taken at dinner time. That prescription bore no signature whatever and we scarcely knew what to do in the matter. Having reckoned up the amount to each dose we found that it was in excess of the maximum dose, but we also found on inquiry that the patient had frequently taken the dose before, and we therefore came to the conclusion that he was suffering from some cutaneous disease which probably required this excessive dose to be administered. We therefore made up the pills according to the prescription, which was registered for reference in case of necessity. In another case where a grain of strychnine was prescribed, it turned out on reference to the physician that a grain of extract of *nux vomica* was intended. I think that the initials of the physician placed opposite to the unusual dose would be the best safeguard, and I have often wondered why we could not adopt some such plan in this country as is the custom on the continent. If such a course be adopted all doubt, to a great extent, will be removed. The question whether the physician's address should be put in full is probably open to some discussion, although I know some leading physicians in London who write their names in full on their prescriptions—and in fact it is difficult to recognize the writing of many physicians.

Mr. GREENISH (London) : Having been engaged for many years in dispensing medicine, I am prepared to say that the time has arrived when we may fairly call upon the medical men to attach some sign to unusual doses. It was my idea at first that the sign (!) would be better than the initials as a mark of distinction, the former mode having been adopted in Germany and Austria ; and it being desirable, if possible, that such signs should be universal. After consideration, however, I have come to the conclusion that the initials would be preferable. I am satisfied that if this matter were brought fairly before the medical profession, they would coincide with our views. The medical man expects us when we have any doubt about the strength of the doses to apply to him. It is very often difficult now to ascertain where he lives ; if, however, his address were placed on the prescription, it would be easy to find him, and the necessity of applying to the patient would be avoided. But I agree with Mr. Hampson in thinking that, even when the signature is attached, if we feel the responsibility too oppressive, we are quite at liberty to decline to dispense prescriptions of this exceptional character.

Mr. SAVAGE : I think that Mr. Hampson is quite right in the view he takes in his paper, and that we should not advert to any particular case, but deal with the question as a general one. I think, as a body, we ought to be in accord with the medical man. It seems to me that medical men and pharmacists and the medical and pharmaceutical press should all be in accord with one another on this matter. I should prefer the use of initials as a distinguishing mark for unusual doses. I have seen it suggested that the quantity should be written out in full when unusual doses are ordered, but I do not see what additional security that would give us, because it might be repudiated by the medical man ; whereas, if he puts his initials for the dose that would be a sufficient authority for us to dispense it. I think if we were to respectfully make this suggestion to the medical profession it would be adopted to our mutual advantage.

Mr. R. REYNOLDS (Leeds) : The unanimity of feeling on the part of the meeting on this subject may be easily gathered from the expressions of opinion which have fallen from the various speakers ; the only question therefore that remains is the form into which we shall put the suggestion. I feel sure the medical profession will regard with approval this proof of the vigilance of the pharmaceutical body, and that they will give their careful attention to any suggestion which this Conference may offer. It appears to me desirable that besides the main question of indicating extraordinary doses, other proposals made in the course of discussion should be sifted more closely than would be possible in this meeting. I beg, therefore, to move the appointment of a small committee, to whom shall be entrusted the drawing up of a resolution ; such committee to consist of Messrs. Hampson, Greenish, Rimmington, Benger, and Martindale.

Mr. M. ROGERSON (Bradford) : I think it very desirable that some definite resolution should be come to on this subject, and that a committee should be appointed, as suggested by Mr. Reynolds.

Mr. WILLIAMS (London) : As to retaining the prescription prescribing the unusual dose, I do not think there is any use in returning it to the patient, because such dose would only be given with some special object, and therefore it would be improper for the dose to be repeated without reference being made to the medical man. I think, therefore, the chemist ought to retain it in his own possession.

Mr. DYER (Halifax) : While agreeing with Mr. Williams that the chemist should be entitled to retain the unusual prescription, I think that he ought to send a copy of it to the

patient, so that the medical man might have an opportunity of seeing what he had written.

The resolution appointing the committee was then put and carried.

The next paper read was on—

Urinary Examinations in General, and the Tests for Albumen and Sugar in Particular.

BY LOUIS SIEBOLD.

As pharmacists are now fast advancing from the position of mere traders to the rank of scientific men, the testing of urine will be more frequently entrusted to them by the medical practitioners, who themselves—as a rule—have not the necessary practical experience for conducting such examinations. Pharmacists, I think, cannot be too strongly recommended to devote some of their time and energy to the acquisition of an intimate knowledge of urinary analysis, especially as we find that our professional analysts in general are but imperfectly acquainted with this branch of analytical chemistry. In bringing this subject before you, gentlemen, I shall, of course, not attempt to treat it in its entirety, for this would be impossible to do, even in a very superficial manner, in the short time at my disposal. I merely wish to draw your attention to the commonest and most important tests, and to point out some great errors in connection with urine-testing which are very generally committed by medical practitioners—errors which in many cases render the examination quite worthless. Let us at once pass on to instances of this kind. A medical man requests his patient to send him a sample of his urine, and a quantity varying from two to eight fluid ounces is supplied in due course and examined. Now if the question to be decided is simply the presence or absence of an abnormal substance, such as sugar, bile, or albumen, the sample of urine thus supplied will answer the purpose. But if the specific gravity be required, or if the percentage of urea, phosphates, chlorides, sulphates, or of any other constituent is to be ascertained, then this mode of examining a sample of urine which does not represent the chemical composition of the entire renal discharge of twenty-four hours is highly objectionable. If I say that portions of urine passed by the same man at different hours of the day or night vary very considerably in their composition, and that the quantitative analyses of any such single portion, whether passed in the morning, afternoon, or evening, affords no satisfactory insight into the patient's condition, I am merely uttering a truth which is known, or ought to be known, to every medical practitioner. Nevertheless, this truth is very generally ignored. Small samples of urine, which in no way represent the daily discharge, pass day after day from the medical man, or, by his orders, direct from the patient, into the hands of the analysts, and however correct the analyses may be, they will be useless in very many cases, and lead to erroneous conclusions. Instead of so doing the whole quantity of urine passed within twenty-four hours should be collected, mixed and measured, and a portion of this mixture submitted to an analysis. If medical men forget this fact, let chemists who are called upon to undertake urinary analyses remind them of it, and let them do so persistently as long as their efforts are not successful. Let us look at a few practical instances. The specific gravity of healthy urine collected during twenty-four hours usually ranges between 1·016 and 1·024, the normal quantity discharged within that time being from 1200 to 1600 cubic centimetres, or from 40 to 56 fluid ounces. The density of the various samples collected during that time, if estimated separately, may however vary far more considerably, so that the density of one portion may be below 1·016, and that of another portion may be above 1·030, although the whole mixture shows the average normal density of 1·020. If by copious water drinking the daily quantity of urine from a healthy person be increased to 2000 c.c. or beyond, or if it be decreased in another case by a scanty consumption of liquids to 800 c.c., or below, the specific gravity of the urines would be lower or higher accordingly, and although the percentage of solid constituents in such urines might appear abnormal, yet the total quantity of solid matter discharged within twenty-four hours would be about equal in both cases, and would indicate a healthy condition in either of the two persons. Thus it will be seen that if the precaution of collecting and measuring the entire quantity of twenty-four hours be neglected the density may vary enormously. It may be as low as 1·005 in one case, and it may be 1·035 in another case, and yet a medical man might commit a serious error were he to assume a hydraemic state in the former or a diabetic state in the latter case. No reliable conclusion of any kind can be drawn from the specific gravity in either instance, and it might therefore just as well be left undetermined. The only exceptional instance in which the mere density, regardless of the above precautions, affords a valuable diagnostic expedient is that of a pale-coloured urine of very high specific gravity. In many cases it is of great importance to ascertain the exact quantity of urea or that of phosphates or chlorides, but here again it is almost equally necessary, if not more so, to take the total daily volume of urine into account as the mere percentage of those substances contained in a small sample of the urine proves nothing whatever. Yet we are constantly called upon to carry out such examinations and the most unwarrantable inferences are often drawn from our results by members of the medical profession. Contrary to my clearly expressed desire as to the form in which the urine should be supplied to me for the purpose of a quantitative analysis, I have had to undertake many such analyses of samples of urine not representing the composition of the whole day's discharge, which had never been collected or measured; and whatever the value of the qualitative and the miscroscopic examinations may have been in such cases, the quantities per cent. of urea, phosphoric acid, etc., might as well have been left out from the report. On one occasion a large percentage of phosphates was found, and the medical gentleman, a physician of high repute, looked upon this as indicating an increased waste of nerve substance. A careful examination however showed that the phosphates discharged with the urine within twenty-four hours fell considerably short of their normal amount. A gentleman suffering from saccharine diabetes had his urine examined by a chemist on the continent who found 5·5 per cent. of sugar. Shortly afterwards he requested me to make an analysis of his urine and supplied me with the entire quantity collected in twenty-four hours, amounting to 2600 cubic centimetres. I found 5·3 per cent. of sugar, which represents a discharge of 138 grammes of sugar per day. He went again on a tour to the continent, and improved much in general health and strength. When he returned to England four months afterwards he seemed much alarmed by the result of an analysis of his urine made by a French chemist who had found six per cent. of sugar. I also examined his urine with the same result, but far from there being any cause for alarm, the patient was undoubtedly much better, for though the sugar amounted to six per cent. the quantity of urine passed within twenty-four hours was only 1550 cubic centimetres, showing that the daily discharge of sugar had fallen from 138 to 93 grammes. The percentage alone seemed to indicate a worse condition, but in combination with the measurement of the urine it showed a vast improvement. I may here mention that the percentage of sugar in the urine of a diabetic patient also varies exceedingly at different hours of the day and night and under the influence of diet.

Of course, there is not always a necessity for mixing the urines passed during the whole day and night, in order to make a useful quantitative analysis. In cases of acute inflammatory diseases and the like, where a careful and uniform diet is observed day and night, there is not much variation in the composition of the urines passed at different hours, so that any sample may be looked upon

as fairly representative, and fit for the determination of specific gravity, urea, phosphates, etc. But even then the quantity of urine passed in twenty-four hours should be at least approximately known and taken into consideration. In these cases a quantitative analysis will have more of a prognostic than a diagnostic importance, whilst my remarks refer chiefly to the numerous instances of chronic disorders in which a quantitative analysis is desired for the diagnosis.

From these general remarks on quantitative analyses of urine, I will now turn to the qualitative tests for albumen and sugar, the two abnormal substances most commonly sought for in urine.

The means generally employed for the detection of albumen are:—1. The application of heat; and 2. The addition of nitric acid. The manner in which these tests are performed and the precautions which must be observed to avoid mistakes are so generally known to chemists, that I will not trouble you with a description of them. Whichever of the two tests is used, the detection of an appreciable amount of albumen is always an easy matter. But when we have to search for exceedingly small traces of that substance, which no doubt occur in the urine of patients long before the chronic state of Bright's disease is suspected or recognized, then the question which of the tests should be preferred becomes undoubtedly one of great importance. Our modern authors have decided this question unhesitatingly in favour of the nitric acid test, which is to be so applied that the acid is poured very carefully into the urine, so that it does not mix with it, but forms a distinct layer at the bottom, above which the hazy zone of coagulated albumen shows with great precision. This is no doubt a delicate test, but, on the strength of very numerous experiments which I have made on the subject, I am justified in asserting that it is far surpassed in delicacy by a simple modification of the heat test, which I shall presently describe. You all know that albumen is not coagulated by heat in alkaline urines, and that it is not completely coagulated if the reaction of the urine be neutral, for which reasons alkaline or neutral urines are slightly acidified by acetic acid before the heat test is applied. It is also well known that an excess of acetic acid will greatly interfere with the test and completely prevent the coagulation of traces of albumen. Analysts who have devoted much attention to the tests for albumen will agree with me that even as little as a few drops of acetic acid, the quantity generally recommended to be added to about half a test-tubeful of neutral urine, may be sufficient to prevent the detection of very minute traces of albumen. If the urine be acid, there is of course no acetic acid added before heating, but in this case also small traces of albumen are often overlooked, as Bence Jones has pointed out to be the case, where large doses of nitric or hydrochloric acid are taken medicinally. In such cases it is recommended to neutralize the urine or almost to neutralize it by ammonia. There are however acid states of the urine in patients who have not taken any mineral acids, which also prevent the coagulation of very small traces of albumen, and numerous experiments which I have made have convinced me that in every instance in which a trace of albumen could be detected by the nitric acid test and not by heat, the failure in the latter test was attributable to the acid state of the urine. I therefore propose the following modification of the heat test which I have found to answer remarkably well. Add solution of ammonia to the urine until just perceptibly alkaline, filter and add diluted acetic acid very cautiously until the urine acquires a faint acid reaction, avoiding the use of a single drop more than required. Now place equal quantities of this mixture into two test tubes of equal size, heat one of them to ebullition and compare it with the cold sample contained in the other test tube. The least turbidity is thus distinctly observed and gives absolute proof of the presence of albumen, the error of confounding phosphates with albumen being out of the question, as they are precipitated by the ammonia and removed by filtration. Proceeding in this way we can find even such faint traces of albumen as will escape detection by the nitric acid test. This test can of course be used in every instance, whilst the nitric acid test is not suitable for urines containing deposits of urates. It surpasses the nitric acid test in general applicability and in delicacy.

How greatly the internal use of mineral acids may interfere with the detection of albumen by the ordinary mode of heating may be seen from the following case. A physician delivered to me a sample of blood-red coloured urine from a patient suffering from hæmatinuria, and requested me to estimate the quantity of urea. To do this it was of course necessary first to remove the albumen which as a matter of course was present. The urine was strongly acid and remained perfectly clear upon boiling, and also upon boiling with a drop of acetic acid, not a trace of albumen being coagulated. After treating it with solution of ammonia and then with dilute acetic acid in the manure described, a very considerable quantity of coagulum separated upon boiling, and the pale yellow filtrate was now perfectly fit for the determination of urea. I concluded that mineral acids had been administered, and the physician confirmed my supposition.

Permit me now to offer a few remarks on the detection of sugar in urine, or rather on the copper test, which is generally acknowledged to be the best and most reliable. This test is certainly a delicate and reliable one in the hands of an experienced manipulator, but it is altogether unsafe in the hands of medical men or of analytical chemists who have not made a close and special study of urinary examinations. Thus we find that in applying the copper test in the ordinary and well known way, sugar is very frequently found where there is none, and is not detected where it is present, and such mistakes are made, too, by analysts of scientific eminence. Not that there is any difficulty in detecting sugar in a decidedly diabetic urine, for such urine may be looked upon as almost a pure solution of grape sugar, containing the ordinary normal constituents of urine in such small quantities that they do not interfere with the test, but the detection of traces of sugar in non-diabetic urine is a very different and much more difficult task, yet it is one of very great importance indeed, as it may enable the physician to discover and perhaps to remove a tendency to diabetes before it develops into the actual disease. As a rule diabetes is not recognized or suspected until one or more of the peculiar symptoms manifest themselves, and the urine is then found on examination to be of a decidedly diabetic character. But it can hardly be supposed that this disease comes on suddenly, or that a man is quite healthy to-day, and discharges urine containing 5 per cent. of sugar to-morrow. There is most probably a time, long before the actual disease shows itself by outward symptoms, when the urine still contains the ordinary constituents in normal quantities, and in addition to them a minute trace of sugar, which may gradually increase until its quantity is such that the disease is confirmed and perhaps incurable. If this be so, it must appear important that we should be able to discover even very small traces of sugar in otherwise healthy urine. Numerous modifications of the copper test have been recommended, most of which still require experienced hands, and yet will fail to detect sugar if present in mere traces. There is one, however, which appears perfectly satisfactory, and which is so strikingly superior to all the others, that I think it ought to be universally adopted. I mean the modification of the copper test proposed by Dr. William Roberts, in his work on 'Urinary and Renal Diseases.' It enables an analyst, inexperienced in urine testing, to find $\frac{1}{20}$ of a per cent. of sugar, whilst with a little practice he will soon learn to detect as little as a $\frac{1}{40}$ of a per cent. without fear of an error. The test is best performed in the following way:—Heat in a test tube two fluid drachms of Fehling's standard solution of copper, and, when boiling, add five to ten drops of the

urine to be tested; if sugar be abundant, as in a decidedly diabetic urine, a yellowish or brick-red opacity and deposit will be produced. If no such reaction ensue, test for traces of sugar by adding one and a-half fluid drachms of the urine to the hot liquid, heat again to ebullition, and set aside for some time. If no milkiness is produced as the mixture cools, the urine is either quite free from sugar, or at any rate contains less than $\frac{1}{40}$ of a per cent. If the quantity of sugar is very small, viz., from $\frac{1}{2}$ of a per cent. to $\frac{1}{40}$ of a per cent., the precipitation of the yellow or red cuprous oxide does not take place immediately, but occurs after some time as the liquid cools, and the manner of the change is peculiar. First, the mixture loses its transparency, and passes from a clear bluish green to a light greenish opacity, looking just as if some drops of milk had fallen into the tube. This green milky appearance is quite characteristic of sugar. In performing this test for the first time, a difficulty may be experienced on account of the phosphates of the urine being precipitated by the alkali of the test solution. These phosphates, however, are thrown down in large flakes, which are seen floating in a clear bluish-green medium by holding the tube between the eye and the light. The presence of sugar does away with all transparency, which gives place to a milky greenish or yellowish opacity. This mode of applying the copper test is simple, very delicate, and thoroughly reliable. It is based upon the fact that urine which is free from sugar never discharges the colour from more than an equal bulk of Fehling's solution. For this reason, a little more of test solution is used than of the urine. Fehling's solution is apt to deteriorate by keeping, so that without any addition it may cause a precipitation of cuprous oxide upon boiling: and for this reason, Lehmann and others have condemned it as a test for sugar. Proceeding, however, in the manner described, the test solution is boiled first, and if it remains clear there is a proof that it is in good condition. If instead, it forms a deposit on boiling, it must be rejected and a fresh supply of it made.

I have dwelt at such length on this modification of Trömmer's copper test, because I believe it is not generally known amongst chemists, and because I am so thoroughly convinced of its practical utility and its superiority over all other sugar tests that I feel sure it need only be tried to be at once adopted. The other tests for sugar in urine, viz., fermentation, boiling with solution of potash, boiling with carbonate of sodium and subnitrate of bismuth, etc., are far less delicate, and very apt to lead to errors, whenever traces of sugar are sought for.

Professor ATTFIELD: I quite agree with all, or at all events, with nearly all that has fallen from Mr. Siebold on this question, and I should merely wish to add the remark that it is highly important that pharmaceutists and others in examining urine should remember that these small quantities of albumen and calcic oxalate may occur in urine temporarily and be of almost no significance. They should also not forget that small quantities of sugar really form part of the normal constituents of urine, as was demonstrated by Brücke and confirmed by Dr. Bence Jones. Not only should the chemist examine the whole of the urine passed in the twenty-four hours, and note the quantity, but he should, if possible, examine it from day to day for several days. I quite agree with Mr. Siebold that very delicate tests for albumen and sugar are important, but unless we find that sugar and albumen are present from day to day we cannot draw the conclusion that the presence of such very small quantities on one or two occasions is of any significance.

Mr. EKIN: I think it will be found that urines are often condemned as containing sugar in consequence of the impurity of the reagents employed.

The Conference then adjourned for luncheon. On reassembling a paper was read on—

THE AMOUNT OF CALCIC OXALATE EXCRETED IN OXALURIA.

BY PROFESSOR ATTFIELD.

The appearance of the minute octohedra of calcic oxalate must be familiar to every microscopist who has frequently examined urinary sediments, but I am not aware that the proportion of this deposit has ever been determined. Believing the matter to possess some pathological interest, I recently embraced an opportunity of estimating the total amount of calcic oxalate excreted in twenty-four hours by a gentleman in whose urine his medical attendant and I myself had frequently detected this substance. I communicate the result to the Pharmaceutical Conference, because I know that the aid of the educated pharmacist is frequently sought by the physician in cases involving the chemical characters of urine.

Two and a-half pints of urine were excreted by the patient between 10 p.m. on one day and 10 p.m. on the following day. The whole quantity contained 425 grains of urea, an amount beyond the average secreted by healthy adult males, but not more than that commonly given by patients suffering from oxaluria. The sediment, which was not unusually voluminous, consisted of urates and mucus, studded with octohedra of calcic oxalate. No trace of oxalate remained in solution in the urine. The specific gravity of the urine was 1027; in other respects it was normal. The sediment was collected on a Swedish filter, and every trace of oxalate was found to be thus secured. It was then treated with a little warm diluted hydrochloric acid, no particle of oxalate remaining undissolved. Ammonia, added to the filtered acid liquid, gave a precipitate of calcic oxalate which after some time was collected, slightly washed, dried, and weighed. The amount was two-thirds of a grain, or exactly 0·68 (or, in one litre, 0·031 of a gram).

Less than a grain, therefore, of calcic oxalate was excreted by this patient in twenty-four hours. Whether or not this small quantity represents the average amount in such cases I cannot state. Further analyses must be made before this point can be decided. If one may judge from one's memory of appearances under the microscope I should say that I have frequently met with instances in which the proportion of calcic oxalate was three or four times that just mentioned. But whatever be the amount, some effort should be made to determine it, for the occurrence of calcic oxalate in the urine is said to be highly significant, although its source and mode of action in the system is obscure. If the influence of the oxalic acid or other oxalic compound be toxic, the extent of its action will depend very greatly on its amount. If the oxalic radical occurs in the blood as oxalic acid, and its action, as held by some, is that of a solvent of calcic phosphate, then again the extent of its influence will turn upon its amount. A few quantitative analyses would scarcely fail to throw light on these points, and to possess chemical, pathological, and physiological interest. I should myself be quite willing to estimate the amount of calcic oxalate in the urine in well marked cases of oxaluria if the medical practitioner, or the microscopist, or pharmacist who may examine the urine will send portions to me at the laboratories of the Pharmaceutical Society, 17, Bloomsbury Square, London.

The PRESIDENT: I think there can only be one opinion amongst us, and it is that our best thanks are due to Professor Attfield for having brought forward this important question. The analysis of urine is daily becoming more and more important to the pharmaceutist in his character as the scientific adviser, on many points, of the medical man; and there can be no doubt that an accurate means of estimating oxalic acid in urine is very much needed.

Mr. SIEBOLD (Manchester): I have often been surprised to find that the authors of books on urinary analysis never allude to the quantity of oxalate of lime discharged, for I feel perfectly sure that that part of the question is of the highest importance. It may also be important to

ascertain the quantity of oxalic acid which is left in urine in a dissolved state. Cases have occurred, not unfrequently, where with great care oxalic acid in a dissolved state could be detected by mixing the clear urine with a small quantity of solution of calcium chloride, evaporating to about $\frac{1}{8}$th of its original volume, acidulating with a sufficient quantity of hydrochloric acid, filtering after some time, and adding to the clear filtrate strong solution of sodium acetate in excess. The precipitate formed contains all the oxalic acid in the shape of calcic oxalate. To ensure complete precipitation, the mixture should be allowed to stand for twelve hours.

Professor ATTFIELD: Mr. Siebold's remarks confirm those which Mr. Day has made in his 'Physiological Chemistry,' where he alludes to some experiments which seem to show that after the liquid has been set aside for twenty-four hours, urine apparently containing no oxalic acid at length deposits crystals. As regards the amount of calcic oxalate in urine, I brought the matter under the notice of Dr. Lionel Beale, who is an excellent authority on the question. He told me that he did not know of any paper where the amount was mentioned, and he was of opinion that the subject was one which called for the attention of microscopists. It is for that reason I have read this paper to the Conference to-day.

Mr. REYNOLDS (Leeds): Those who are in the habit of examining the deposits in urine are aware that, although no crystals of oxalate of lime may at first be detected, yet if the liquid be set at rest for a longer time, crystals may appear after all. The microscopist plays an important part, but I think the chemist is not less essential than he in the investigation.

Professor Attfield then read a paper on

AMMONIACAL SALTS AND THEIR USUAL IMPURITIES.

BY ALFRED PAYNE, F.C.S.

In this paper, in response to a query in the list of subjects for research issued by the British Pharmaceutical Conference, I beg to offer to pharmacists some of my experiences in ammonia manufacture gained during the past forty years.

Bones, tar liquor, and gas liquor are the only commercial sources of ammonia.

Up to about 1840 bones were the chief source of ammonia. They were burnt largely to produce animal charcoal and bone ash. The liquor which distils from them is rich in ammonia, twenty tons of bones yielding about one ton of rough ammoniacal salt.

The chief impurity in ammoniacal salts made from bones is the dipples oil. This oil is a complex body and contains, picolin, lutidin, collidin, and other compounds.

Although the elements of ammonia (nitrogen and hydrogen) occur largely in bones, the bones contain no trace of ammonia itself, nor any of the above named principles, nor are any of these principles formed when bones decompose spontaneously, but, on the other hand, are produced when bones are suddenly heated to redness. There is a definite temperature at which ammonia forms, and another at which the oil is produced; and if the ammonia-forming temperature could be uniformly applied to the burning bones we should increase that valuable product, and more or less avoid the formation of the offensive oils. There is also formed some phosphoretted hydrogen in bone burning, which oxidizes in the condensers, producing a little phosphate of ammonia. These two impurities, viz., dipples oil and phosphate of ammonia, we may expect in bone-ammonia.

Since 1840, about which time bones came largely into use for agricultural purposes, the price of them has more than doubled, and their ammoniacal value has been diminished by treatment for the extraction of glue, size, and fat, so that they are rarely used now for this purpose. The ammoniacal liquor produced at gas works is almost the only source from which commercial ammonia is now derived.

The elementary matters found in gas liquor are hydrogen, oxygen, nitrogen, carbon, sulphur, iron, phosphorus, arsenic, and sometimes traces of potassium and calcium. The proximate principles into which these group themselves are numerous, and vary much according to the temperature used in carbonizing the coals (or in gas making) and of course they affect the purity of the salts formed from the liquor which contains them.

Coals, also, contain neither ammonia nor oils, and the numerous principles derived from them by distillation are formed at the respective temperatures met with in the retorts from the moment the cold coals are thrown in till the vapours arising from them come into contact with the bright red sides of the retort.

Some of these principles have acid qualities and adhere with such tenacity to the volatile alkali of the gas liquor that they cannot be separated from it either by oxidation, distillation, or by detergent agents. For instance we may separate the sulphur by a hydrated metallic oxide, then treat the filtrate with permanganate, and distil it two or three times and we shall get a product sweet and brilliant; but after standing a month in a white glass bottle a deep indigo blue deposit forms on the glass.

Twenty years ago I formed the opinion that this deposit is a true indigo resulting from a rearrangement of the elements of the gas tar and the ammonia, and subsequent discoveries as to the constituents of gas tar confirm the impression. The tendency to form this blue deposit renders such liquor ammoniæ unfit for pharmaceutical and some other purposes.

Thus before we can produce even plain liquor ammoniæ pure enough for use, the ammonia must be reduced by saturation to a fixed salt, and the adhering impurities then got rid of. But here a new difficulty presents itself. Part of the carbon, nitrogen, and sulphur which the gas liquor contains are always found grouped together as sulpho-cyanogen, and this with the ammonia forms a fixed salt which remains as an impurity in the sulphate or chloride of ammonium, rendering those salts, if made by direct saturation, unfit for most purposes. At certain temperatures also, the elements assume a different arrangement and form bisulphide of carbon. Though in this decomposition a saving of ammonia is effected, the nitrogen of the cyanogen coming out as ammonia, still it does not compensate for the danger; for I have seen a strong wrought iron still eight feet long blown into pieces by the accidental ignition of gases liberated in this reaction: besides which the resulting ammonia is always tinted and impure.

For these reasons, the direct saturation of gas liquor by fixed acids is almost everywhere abandoned.

If, however, the gas liquor be first distilled, the sulphocyanides remain behind; whilst the distillate contains ammonia, sulphur, carbonic acid, sulphide of ammonium, and hydrocarbon oils. There is great liability to loss in conducting this process on a large scale, and the most careful attention to all the physical laws concerned in it is necessary to ensure a good economic result; but on saturating the distillate and filtering and boiling the liquor, a good white commercial salt (either sulphate or muriate) is obtained. Even this, however, will contain traces of the hydrocarbon oils and their colour-forming principles; also metallic impurities derived from the saturating acids, and from the wear and tear of the apparatus, and if absolutely pure products are desired, it is at this stage that these impurities must be eliminated.

Solution, filtering through animal charcoal, and repeated crystallizations, will separate the hydrocarbon oils.

Magnesia salt, carefully added, will separate the phosphates (provided the solution contains a slight excess of ammonia).

Arsenic (derived either from the coals used in gas-making or from pyrites acid) may be detected by Marsh's test, using magnesium, which will also manifest the presence of copper, lead, mercury, zinc, and other poisonous metals.

If chloride of ammonium contains arsenic it should be

boiled with excess of acid, when the arsenic will pass off in vapour as terchloride.

If sulphate contains arsenic it can be separated by boiling with zinc and excess of acid, when the arsenic passes off as arsenuretted hydrogen.

All other probable metallic impurities may be separated by first rendering the solution acid, treating with sulphuretted hydrogen, and filtering out the precipitate, then rendering the filtrate alkaline with ammonia, and precipitating with sulphide of ammonium, and again filtering bright and crystallizing.

It may be assumed that an ammoniacal salt which has been subjected to this treatment is pure, *i.e.*:—

1. Boiling with animal charcoal, filtering, and recrystallizing.
2. Precipitating its alkaline solution with magnesium salt, and filtering.
3. Boiling (if a chloride) with excess of hydrochloric acid, or (if a sulphate) with zinc and excess of acid.
4. Treating the *acid* solution with sulphuretted hydrogen and filtering.
5. Treating the *alkaline* solution with sulphuretted hydrogen and filtering.
6. And finally, recrystallizing from an accurately neutral solution, which has previously been cleansed from sulphuretted hydrogen by boiling with a slight excess of acid.

The above treatment ensures a pure salt, from which all the preparations of ammonia may be safely made when only the *legitimate* commercial raw materials have been used.

But unfortunately, the competition of trade and the struggle to produce cheap articles lead some manufacturers to utilize waste products as saturators, by which other classes of impurities are introduced. The commonest of these is the residuum (chiefly chloride of manganese) left in the stills after the generation of chlorine. When this is used the chlorine combines with its equivalent of ammonium, but the manganese does *not* subside; it attaches itself to the cyanogen of the crude gas liquor (for, of course, these crude saturators would not be used with the distilled liquor), and thus forms mangano-cyanogen, from which results a mangano-cyanide of ammonium, a salt which can scarcely be separated from the various preparations in which the ammonia is afterwards used.

To the sesquicarbonate it imparts a red tint, often exhibited in thin lines or layers on the fractured surface; all such ammonia should at once be rejected as unfit for use.

Gypsum, or sulphate of lime, is sometimes used as a saturator in districts where mineral acids are not made; portions of this, and sometimes of sulphide of calcium, often remain as impurities in the resulting salt, but these are easily separated by careful recrystallization.

In conclusion, the pharmacist has to do with only liquor ammoniæ, sesquicarbonate of ammonia, hydrochlorate of ammonia, nitrate of ammonia.

The liquid preparations he will himself prepare from the above.

Liq. ammoniæ should make a clear and colourless solution with either nitrate of bismuth or nitrate of silver, which shows the absence of hydrocarbon oils.

The nitrate of ammonia should be scrupulously neutral, or it will be unfit for making the anæsthetic gas. For further examination each of the preparations should be tested thus :—

For phosphates make the solution slightly alkaline, and try magnesia salt.

For arsenic try the acid solution in Marsh's apparatus with magnesium.

For other metals try an acid solution with sulphuretted hydrogen, and then an alkaline solution with sulphide of ammonium.

If the ammoniacal preparations will pass this ordeal, and meet these reagents, without cloud, tint, or other indication of impurity, they may be regarded as perfect, and fit for any purpose in pharmacy or the arts.

Professor ATTFIELD: There is one other commercial source of ammonia beside that mentioned by Mr. Payne, and, with reference to it, I think it is important we should have the experience of gentlemen who, like him, have been engaged for many years in the manufacture and examination of salts of ammonia. I refer to volcanic ammonia. This is a source of ammonia now introduced to pharmacists. It is only fair to say that pure salts are made from the ammoniacal liquor of gas works, as pointed out by Dr. Parkinson at our meeting held at Birmingham.

Mr. BOOTH (Heckmondwicke): There is another source of ammonia that has not been mentioned, namely, the waste product of woollen manufacture. Formerly all, and still a good deal of this waste product is sent down into Kent for the purpose of manuring the hop plants. The animal charcoal is used principally in iron manufacture for blackening models, so that they may be drawn away from the sand more easily. The ammoniacal liquor is used principally for scouring and washing purposes.

Mr. COUPLAND (Harrogate): Another salt is the benzoate of ammonia, which for some weeks I regularly compounded as a medicine, but owing to an interruption of supply I was obliged to make application to a local chemist. He opened a fresh bottle, and sent me some. Its odour was unmistakeably disagreeable, and rendered it unsuitable for the purpose for which I wanted it. I secured a portion of the sample, as I thought it desirable to have it submitted to analysis. It had a coal tar odour. I think it desirable the attention of the Conference should be directed to this matter, as no reference has been made to it in the paper, and chemists should recognize the fact that in the course of business other preparations of ammonia may be met with subject to contamination from similar sources of impurity.

Mr. WILLIAMS: It should not be forgotten that benzoic acid produced from gum, though properly used for medicinal purposes, is not entirely true benzoic acid, but contains a considerable quantity of cinnamic acid. For strictly chemical purposes, not for medical purposes, benzoic acid produced from urine is the pure body. However, the price of gum having materially decreased of late years, I believe the acid made from it has been quite as cheap as that made from the urine of horses and cows. The acid made from the urine of cows, I believe, comes principally from Germany, while that made from gum is principally prepared in England.

(*To be continued.*)

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE PRESIDENT'S ADDRESS.

(*Concluded from page* 240.)

It must not, however, be supposed that the investigator drifts unconsciously into the habit of truthfulness for want of temptation to be untruthful, or even that error presents itself to his mind in a grotesque and repulsive garb, so as to enlist from the first his feelings against it; for I can assure you that the precise contrary of these things happens. Error comes before him usually in the very garb of truth; and his utmost skill and attention are needed to decide whether or not it is entitled to retain that garb.

You will easily see how this happens if you reflect that each working hypothesis employed by an investigator is an unproven proposition, which bears such resemblance to truth as to give rise to hopes that it may really be true. The investigator trusts it provisionally to the extent of trying one or more experiments, of which it claims to predict the specific result. Even though it guide him correctly for a while, he considers it still on trial until it has been tested by every process which ingenuity can suggest for the purpose of detecting a fault.

Most errors which an experimentalist has to do with

are really imperfect truths, which have done good service in their time by guiding the course of discovery. The great object of scientific work is to replace these imperfect truths by more exact and comprehensive statements of the order of nature.

Whoever has once got knowledge from nature herself by truthful reasoning and experiment, must be dull indeed if he does not feel that he has acquired a new and noble power, and if he does not long to exercise it further, and make new conquests from the realm of darkness by the aid of known truths.

The habit of systematically searching for truth by the aid of known truths, and of testing the validity of each step by constant reference to nature, has now been practised for a sufficiently long time to enable us to judge of some of its results.

Every true idea of the order of nature is an instrument of thought. It can only be obtained by truthful investigation; and it can only be used effectively in obedience to the same laws. But the first idea which is formed of anything occurring in nature affords only a partial representation of the actual reality, by recording what is seen of it from a particular point of view. By examining a thing from different points of view we get different ideas of it; and when we compare these ideas accurately with one another, recollecting how each one was obtained, we find that they really supplement each other.

We try to form in our minds a distinct image of a thing capable of producing these various appearances; and when we have succeeded in doing so, we look at it from the different points of view from which the natural object had been examined, and find that the ideas so obtained meet at the central image. It usually happens that an accurate examination of the mutual bearings of these ideas on the central image suggests additions to them, and correction of some particulars in them.

Thus it is that true ideas of a natural phenomenon confirm and strengthen one another; and he who aids directly the development of one of them is sure to promote indirectly the consolidation of others.

Each onward step in the search for truth has made us stronger for the work; and when we look back upon what has been done by the efforts of so many workers simply but steadily directed by truth towards further truth, we see that they have achieved, for the benefit of the human race, the conquest of a systematic body of truths which encourages men to similar efforts while affording them the most effectual aid and guidance.

This lesson of the inherent vitality of truth, which is taught us so clearly by the history of our science, is well worthy the consideration of those who, seeing that iniquity and falsehood so frequently triumph for a while in the struggle for existence, are inclined to take a desponding view of human affairs, and almost to despair of the ultimate predominance of truth and goodness. I believe it would be impossible at the present time to form an adequate idea of the vast consequences which will follow from the national adoption of systematic measures for allowing our knowledge of truth to develop itself freely through the labours of those who are willing and able to devote themselves to its service, so as to strengthen more and more the belief and trust of mankind in its guidance, in small matters as well as in the highest and most important considerations.

I am desirous of describing briefly the more important of those measures; but first let me mention another habit of mind which naturally follows from the effective pursuit of truth—a habit which might be described in general terms as the application to other matters of the truthfulness imparted by science.

The words which the great German poet put into the mouth of Mephistopheles when describing himself to Faust afford perhaps the most concise and forcible statement of what we may call the anti-scientific spirit:—

> "Ich bin der Geist der stets verneint,
> Dem alles, was entsteht, zuwider ist."

The true spirit of science is certainly affirmative, not negative; for, as I mentioned just now, its history teaches us that the development of our knowledge usually takes place through two or more simultaneous ideas of the same phenomenon, quite different from one another, both of which ultimately prove to be parts of some more general truth; so that a confident belief in one of those ideas does not involve or justify a denial of the others.

I could give you many remarkable illustrations of this law from among ideas familiar to chemists. But I want you to consider with me its bearing on the habit of mind called toleration, of which the development in modern times is perhaps one of the most hopeful indications of moral improvement in man.

In working at our science we simply try to find out what is true; for although no usefulness is to be found at first in most of our results, we know well that every extension of our knowledge of truth is sure to prove useful in manifold ways. So regular an attendant is usefulness upon truth in our work, that we get accustomed to expect them always to go together, and to believe that there must be some amount of truth wherever there is manifest usefulness.

The history of human ideas, so far as it is written in the records of the progress of science, abounds with instances of men contributing powerfully to the development of important general ideas by their accurate and conscientious experiments, while at the same time professing an actual disbelief in those ideas. Those records must indeed have been a dead letter to any who could stand carping at the intellectual crotchets of a good and honest worker, instead of giving him all brotherly help in the furtherance of his work.

To one who knows the particulars of our science thoroughly, and who knows also what a variety of ideas have been resorted to in working out the whole body of truths of which the science is composed, there are few more impressive and elevating subjects of contemplation than the unity in the clear and bold outline of that noble structure.

I hope that you will not suppose, from my references to chemistry as promoting the development of these habits and powers of mind, that I wish to claim for that particular branch of science any exclusive merit of the kind; for I can assure you that nothing can be further from my intention.

I conceived that you would wish me to speak of that department of science which I have had occasion to study more particularly; but much that I have said of it might be said with equal truth of other studies, while some of its merits may be claimed in a higher degree by other branches of science. On the other hand, those highest lessons which I have illustrated by chemistry are best learnt by those whose intellectual horizon includes other provinces of knowledge.

Chemistry presents peculiar advantages for educational purposes in the combination of breadth and accuracy in the training which it affords; and I am inclined to think that in this respect it is at present unequalled. There is reason to believe that it will play an important part in general education, and render valuable services to it in conjunction with other scientific and with literary studies.

I trust that the facts which I have submitted to your consideration may suffice to show you how fallacious is that materialistic idea of physical science which represents it as leading away from the study of man's noblest faculties, and from a sympathy with his most elevated aspirations, towards mere inanimate matter. The material work of science is directed by ideas towards the attainment of further ideas. Each step in science is in addition to our ideas, or an improvement of them. A science is but a body of ideas respecting the order of nature.

Each idea which forms part of physical science has been derived from observation of nature, and has been tested again and again in the most various ways by reference to nature; but this very soundness of our materials

enables us to raise upon the rock of truth a loftier structure of ideas than could be erected on any other foundation by the aid of uncertain materials.

The study of science is the study of man's most accurate and perfect intellectual labours; and he who would know the powers of the human mind must go to science for his materials. Like other powers of the mind, the imagination is powerfully exercised, and at the same time disciplined, by scientific work. Every investigator has frequent occasion to call forth in his mind a distinct image of something in nature which could produce the appearances which he witnesses, or to frame a proposition embodying some observed relation; and in each case the image or the proposition is required to be true to the materials from which it is formed. There is perhaps no more perfect elementary illustration of the accurate and useful employment of the imagination than the process of forming in the language of symbols, from concrete data, one of those admirable general propositions called equations; on the other hand, the contemplation of the order and harmony of nature as disclosed to us by science supplies the imagination with materials of surpassing grandeur and brilliancy, while at the same time affording the widest scope for its efforts.

The foregoing considerations respecting the meaning and use of scientific work will, I trust, afford us aid in considering what measures ought to be taken in order to promote its advancement, and what we can do to further the adoption of such measures.

Like any other natural phenomenon, the growth of knowledge in the human mind is favoured and promoted by certain circumstances, impeded or arrested by others; and it is for us to ascertain from experience what those circumstances respectively are, and how the favourable ones can be best combined to the exclusion of the others.

The best and noblest things in this world are the result of gradual growth, by the free action of natural forces; and the proper function of legislation is to systematize the conditions most favourable to the free action which is desired.

I shall consider the words "Advancement of Science" as referring to the development and extension of our systematic knowledge of natural phenomena by investigation and research.

The first thing wanted for the work of advancing science is a supply of well-qualified workers. The second thing is to place and keep them under the conditions most favourable to their efficient activity. The most suitable men must be found while still young, and trained to the work. Now I know only one really effectual way of finding the youths who are best endowed by nature for the purpose; and that is to systematize and develop the natural conditions which accidentally concur in particular cases, and enable youths to rise from the crowd.

The first of these is that a young man gets a desire for knowledge by seeing the value and beauty of some which he has acquired. When he has got this desire he exerts himself to increase his store; and every difficulty surmounted increases his love of the pursuit, and strengthens his determination to go on. His exertions are seen by some more experienced man, who helps him to place himself under circumstances favourable to further progress. He then has opportunities of seeing original inquiries conducted, perhaps even of aiding in them; and he longs to prove that he also can work out new truths, and make some permanent addition to human knowledge. If his circumstances enable him to prosecute such work, and he succeeds in making some new observations worthy of publication, he is at once known by them to the community of scientific men, and employed among them.

We want, then, a system which shall give to the young favourable opportunities of acquiring a clear and, as far as it goes, a thorough knowledge of some few truths of nature such as they can understand and enjoy—which shall afford opportunity of further and further instruction to those who have best profited by that which has been given to them, and are anxious to obtain more—which shall enable the best students to see what original investigation is, and, if possible, to assist in carrying out some research—and, finally, which shall supply to each student who has the power and the will to conduct researches, all material conditions which are requisite for the purpose.

But investigators, once found, ought to be placed in the circumstances most favourable to their efficient activity.

The first and most fundamental condition for this is, that their desire for the acquisition of knowledge be kept alive and fostered. They must not merely retain the hold which they have acquired on the general body of their science; they ought to strengthen and extend that hold by acquiring a more complete and accurate knowledge of its doctrines and methods; in a word, they ought to be more thorough students than during their state of preliminary training.

They must be able to live by their work without diverting any of their energies to other pursuits; and they must feel security against want, in the event of illness or in their old age.

They must be supplied with intelligent and trained assistants to aid in the conduct of their researches, and whatever buildings, apparatus, and materials may be required for conducting those researches effectively.

The desired system must therefore provide arrangements favourable to the maintenance and development of the true student-spirit in investigators, while providing them with permanent means of subsistence, sufficient to enable them to feel secure and tranquil in working at science alone, yet not sufficient to neutralize their motives for exertion; and at the same time it must give them all external aids, in proportion to their wants and powers of making good use of them.

Now I propose to describe the outlines of such a system, framed for the sole purpose of promoting research, and then to consider what other results would follow from its working.

If it should appear possible to establish a system for the efficient advancement of science, which would be productive of direct good to the community in other important ways, I think you will agree with me that we ought to do all that we can to promote its adoption.

Let the most intelligent and studious children from every primary school be sent, free of expense, to the most accessible secondary school for one year; let the best of these be selected and allowed to continue for a second year, and so on, until the *élite* of them have learnt all that is to be there learnt to advantage. Let the best pupils from the secondary schools be sent to a college of their own selection, and there subjected to a similar process of annual weeding; and, finally, let those who get satisfactorily to the end of a college curriculum be supplied with an allowance sufficient for their maintenance for a year, on condition of their devoting their undivided energies to research, under the inspection of competent college authorities, while allowed such aids and facilities as the college can supply, with the addition of money-grants for special purposes. Let all who do well during this first year be allowed similar advantages for a second, and even a third year.

Each young investigator thus trained must exert himself to obtain some appointment which may enable him to do the most useful and creditable work of which he is capable, while combining the conditions most favourable to his own improvement.

Let there be in every college as many professorships and assistantships in each branch of science as are needed for the efficient conduct of the work there going on, and let every professor and assistant have such salary and such funds for apparatus, etc., as may enable him to devote all his powers to the duties of his post, under conditions favourable to those duties; but let each professor receive also a proportion of the fees paid by his pupils, so that it may be his direct interest to do his work with the utmost attainable efficiency, and attract more pupils.

Let every college and school be governed by an independent body of men, striving to increase its usefulness and reputation, by sympathy with the labours of the working staff, by material aid to them when needed, and by getting the very best man they can, from their own or any other college, to supply each vacancy as it arises.

In addition to colleges which are and always have been the chief institutions for the advancement of learning, establishments for the observation of special phenomena are frequently needed, and will doubtless be found desirable in aid of a general system for the advancement of science.

Now, if a system fulfilling the conditions which I have thus briefly sketched out were once properly established on a sufficient scale, it ought to develop and improve itself by the very process of its working; and it behoves us, in judging of the system, to consider how such development and improvement would come about.

The thing most needed at the present time for the advancement of science is a supply of teachers devoted to that object—men so earnestly striving for more knowledge and better knowledge as to be model students, stimulating and encouraging those around them by their example as much as by their teaching. Young men do not prepare themselves in any numbers for such a career :—

1. Because the chief influences which surround them at school and at college are not calculated to awaken in them a desire to obtain excellence of such kind.

2. Because they could not expect by means of such qualities to reach a position which would afford a competent subsistence.

Let these conditions be reversed, to the extent that existing teachers have powerful inducements to make their students love the study of science for its own sake, with just confidence that they will be able to earn a livelihood if they succeed in qualifying themselves to advance science, and the whole thing is changed. The first batch of young investigators will be dispersed among schools and colleges according to their powers and acquirements, and will at once improve their influence upon the pupils, and enable them to send up a second batch better trained than the first. This improvement will go on increasing, if the natural forces which promote it are allowed free play; and the youth of each successive generation will have better and more frequent opportunities of awakening to a love of learning, better help and guidance in their efforts to acquire and use the glorious inheritance of knowledge which had been left them, better and more numerous living examples of men devoting their whole lives to the extension of the domain of truth, and seeking their highest reward in the consciousness that their exertions have benefited their fellow men, and are appreciated by them.

A young man who is daily qualified for the work of teaching the investigation of some particular branch of science, and who wishes to devote himself to it, will become a member of an association of men selected for their known devotion to learning, and for their ability to teach the methods of investigation in their respective subjects. Around this central group is arranged a frequently changing body of youths, who trust to them for encouragement and guidance in their respective studies.

Our young investigator finds it necessary to study again more carefully many parts of his subject, and to examine accurately the evidence of various conclusions which he had formerly adopted, in order that he may be able to lead the minds of his pupils by easy and natural yet secure steps to the discovery of the general truths which are within their reach. He goes over his branch of science again and again from the foundation upwards, striving each time to present its essential particulars more clearly and more forcibly, arranging them in the order best calculated to stimulate an inquiring mind to reflect upon their meaning, and to direct its efforts effectively to the discovery of the general ideas which are to be derived from them. He is encouraged in these efforts by the sympathy of his colleagues, and often aided by suggestions derived from their experience in teaching other branches of science, or by information respecting doctrines or methods which throw a light upon those of his own subject.

No known conditions are so well calculated to give a young investigator the closest and strongest grasp of his subject of which he is capable as those in which he is placed while thus earnestly teaching it in a college; and inasmuch as a thorough mastery of known truths is needed by every one who would work to advantage at the discovery of new truths of that kind, it will, in most cases, be an object of ambition to the ablest young investigators to get an opportunity of going through the work of teaching in a college, in order to improve themselves to the utmost for the work of original research. There is, however, another advantage to them in having such work to do; for the best way to ascertain at any one time what additions may be made to a science is to examine the facts which have been discovered last, and to consider how far they confirm and extend the established ideas of the science, how far they militate against those ideas. An investigating teacher is constantly weaving new facts into the body of his science, and forming anticipations of new truths by considering the relation of these new facts to the old ones.

When our investigator has thus got a thorough mastery of his science and new ideas for its extension, he ought to have the opportunity of turning his improved powers to account by devoting more of his time to original research; in fact he ought to teach research by example more than hitherto, and less by elementary exercises upon known facts. If he has discharged the duties of his first post with manifest efficiency, he will be promoted, either in his own or some other college, to a chair affording more leisure and facility for original research by his own hands and by those of his assistants and pupils. Some investigators may find it desirable to give up after a while all teaching of previously published truths, and confine themselves to guiding the original researches of advanced pupils, while stimulating them by the example of their own discoveries. But most of them will probably prefer to do elementary teaching work from time to time, for the sake of the opportunity of going over the groundwork of their science, with a knowledge of the new facts and enlarged ideas recently established.

Now it must be observed that such a system as the above, once developed to its proper proportions, so as to send annually to secondary schools many thousands of poor children who would otherwise never enjoy such advantages, and so as to train to original investigation a corresponding proportion of them, would not only provide more young investigators than would be needed for systematic teaching functions, but would also give a partial training of the same kind to many whose abilities proved to be insufficient, or whose tastes were not congenial to such pursuit. Some would be tempted by an advantageous opening in an industrial pursuit or in the public service to break off their studies before completion, and others would find, after completing their training, a position of that kind more desirable or more attainable than a purely scientific appointment. Not only would much good of other kinds be accomplished by this circumstance, but we may say with confidence that the system could not work with full advantage for its own special purpose of promoting the advancement of science if it did not diffuse a knowledge of the truths and methods of science beyond the circle of teachers.

There is an urgent need of accurate scientific knowledge for the direction of manufacturing processes, and there could not be a greater mistake than to suppose that such knowledge need not go beyond the elementary truths of science. In every branch of manufacture improvements are made from time to time, by the introduction of new or modified processes which had been discovered by means of investigations as arduous as those conducted for purely

scientific purposes, and involving as great powers and accomplishments on the part of those who conducted them.

Any manufacturer of the present day who does not make efficient arrangements for gradually perfecting and improving his processes ought to make at once enough money to retire; for so many are moving onwards in this and other countries, that he would soon be left behind.

It would be well worth while to establish such a system of scientific education for the sake of training men to the habits of mind which are required for the improvement of the manufacturing arts; and I have no doubt that the expense of working the system would be repaid a hundred times over by the increase of wealth of the community; but I only mention this as a secondary advantage of national education.

A system of the kind could not expand to due dimensions, nor could it, once fully established, maintain itself in full activity, without intelligent sympathy from the community; and accordingly its more active-minded members must be taught some good examples of the processes and results of scientific inquiry before they can be expected to take much interest in the results achieved by inquirers, and to do their share of the work requisite for the success of the system. I need hardly remind you that there are plenty of other strong reasons why some such knowledge of the truths of nature, and of the means by which they are found out, should be diffused as widely as possible throughout the community.

You perceive that in such educational system each teacher must trust to his own exertions for success and advancement; and he will do so if he is sure that his results will be known and compared impartially with those attained by others. Each governing body must duly maintain the efficiency of its school or college, if support depend in some degree on the evidences of that efficiency; and it will try to improve the school if it knows that every improvement will be seen and duly appreciated.

The keystone of the whole structure is the action of the State in distributing funds carefully among schools and colleges proportionally to the evidence of their doing good work which could not be continued without such aid.

I am inclined to think that the State ought, as far as possible, to confine its educational grants to the purpose of maintaining and continuing good work which is actually being done, and rarely if ever to initiate educational experiments; first, because it is desirable to encourage private exertions and donations for the establishment of schools and colleges upon new systems, or in new localities, by giving the public full assurance that if any new institution establishes its right to existence, by doing good work for a while, it will not be allowed to die off for want of support; and, secondly, because the judicial impartiality required in the administration of public funds, on the basis of results of work, is hardly compatible with an advocacy of any particular means of attaining such results.

On the other hand, experience has shown that special endowments, which tie up funds in perpetuity for a definite purpose, commonly fail to attain their object under the altered circumstances which spring up in later generations, and not unfrequently detract from the efficiency of the institutions to which they are attached, by being used for objects other than those which it is their proper function to promote.

When there is felt to be a real want of any new institution for the promotion of learning, men are usually willing enough to devote time and money to the purpose of establishing it and giving it a fair trial. It is desirable that they should leave the State to judge of their experiment by its results, and to maintain it or not, according to the evidences of its usefulness. No institution ought, for its own sake, to have such permanent endowments as might deprive its members of motives for exertion.

The State could not, however, discharge these judicial functions without accurate and trustworthy evidence of the educational work done at the various schools and of its success. For this purpose a record must be kept by or under the direction of every teacher of the weekly progress of each pupil, showing what he has done and how he has done it. Official inspectors would have to see to these records being kept upon a uniform scale, so that their results might be comparable. The habit of keeping such records conduces powerfully to the efficiency of teachers; and, for the sake of the due development of the teaching system, it ought to prevail generally. Having such full and accurate means of knowing what opportunities of improvement pupils have enjoyed and what use they have made of those opportunities, Government ought to stimulate their exertions and test their progress by periodical examinations. It is of the utmost importance to allow any new and improved system of instruction to develop itself freely, by the exertions of those who are willing to undertake the labour and risk of trying it on a practical scale; and the pupils who acquire upon such new system a command of any branch of science, ought to have a fair opportunity of showing what they have achieved and how they have achieved it. An able and impartial examiner, knowing the new systems in use, will encourage each candidate to work out his results in the manner in which he has been taught to work out results of the kind.

Examinations thus impartially conducted with a view of testing the success of teachers in the work which they are endeavouring to do, have a far higher value, and consequent authority, than those which are conducted in ignorance or disregard of the process of training to which the candidates have been subjected; and we may safely say that the examination system will not attain its full usefulness until it is thus worked in intimate connection with a system of teaching.

In order to give everyone employed in the educational system the utmost interest in maintaining and increasing his efficiency, it is essential that a due measure of publicity be given to the chief results of their respective labours. Schools and colleges ought, to a considerable extent, to be supported by the fees paid by pupils for the instruction received; and every professor being in part dependent upon the fees of his pupils will have a direct interest in attracting more pupils to his classes or laboratories. The fame of important original investigations of his own or his pupils, published in the scientific journals, is one of the natural means by which a distinguished professor attracts disciples, and the success of his pupils in after life is another. His prospects of promotion will depend mainly on the opinion formed of his powers from such materials as these by the governing bodies of colleges and by the public; for if each college is dependent for success upon the efficiency of its teaching staff, its governing body must do their best to fill up every vacancy as it arises by the appointment of the ablest and most successful professor whom they can get; and any college which does not succeed in obtaining the services of able men will soon lose reputation, and fall off in numbers.

There are, however, further advantages to the working of the system to be derived from full publicity of all its more important proceedings. It will supply materials for the formation of a sound public opinion respecting the proceedings of the authorities in their various spheres of action. A claim for money might be made upon Government by the rulers of some college upon inadequate grounds; or a just and proper claim of the kind might be disregarded by Government. Neither of these things will be likely to happen very often if the applications, together with the evidence bearing on them, are open to public scrutiny and criticism; and when they do occasionally happen, there will be a natural remedy for them.

If I have succeeded in making clear to you the leading principles of the plan to be adopted for the advancement of science, including, as it necessarily must do, national education generally, you will, I think, agree with me that, from the very magnitude and variety of the interests involved in its action, such system must of necessity be under the supreme control of Government. Science will

never take its proper place among the chief elements of national greatness and advancement until it is acknowledged by that embodiment of the national will which we call the Government. Nor can the various institutions for its advancement develop duly their usefulness until the chaos into which they are now plunged gives place to such order as it is the proper function of Government to establish and maintain.

But Government has already taken, and is continuing to take, action in various matters affecting elementary popular education and higher scientific education, and it would be difficult to arrest such action, even if it were thought desirable to do so. The only practical question to be considered is how the action of Government can be systematized so as to give free play to the natural forces which have to do the work.

By establishing official examinations for appointments and for degrees, Government exerts a powerful influence on the teaching in schools and colleges, without taking cognizance, except in some few cases, of the systems of teaching which prevail in them. Again, it gives grants of public money from time to time in aid of colleges or universities, or for the establishment of a high school under its own auspices. Sometimes it endows a professorship. In taking each measure of the kind it is doubtless influenced by evidence that is in itself a good thing, calculated to promote the advancement of learning. But a thing which is good in itself may produce evil effects in relation to others, or good effects incommensurate with its cost. Thus examinations afford most valuable aid to educational work when carried on in conjunction with earnest teachers; yet when established in the absence of a good system of education, they are liable to give rise to a one-sided training, contrived with a special view of getting young men through the examinations. If no properly educated young men were found for a particular department of the public service, and an examination of all candidates for such appointments were to be established for the purpose of improving the system of training, candidates would consider their power of answering such questions as appeared likely to be set as the condition of their obtaining the appointments, and they would look out for men able and willing to train them to that particular work in as direct and effective a manner as possible. The demand for such instruction would soon be supplied. Some teachers would undertake to give instruction for the mere purpose of enabling candidates to get through the examination; and by the continued habit of such work would gradually come to look upon the examiners as malignant beings who keep youths out of office, and whose vigilance ought to be evaded by such means as experience might show to be most effective for the purpose. Once this kind of direct examination-teaching has taken root, and is known to produce the desired effect of getting young men through the examinations, its existence encourages the tendency on the part of the candidates to look merely to the examination as the end and aim of their study; and a class of teachers is developed whose exertions are essentially antagonistic to those of the examiners.

There are no doubt teachers with a sufficiently clear apprehension of their duty, and sufficient authority, to convince some of the candidates that the proper object of their study should be to increase their power of usefulness in the career for which they are preparing themselves, by thoroughly mastering up to a prescribed point certain branches of knowledge; and that until they had honestly taken the means to do this and believed they had done it effectually, they ought not to go up for examination nor to wish to commence their career.

But it is desirable that all teachers be placed under such circumstances that it may become their interest as well as their duty to co-operate to the utmost of their powers in the object for which the examiners are working. For this purpose their records of the work done under their guidance by each pupil ought to be carefully inspected by the examiners before framing their questions, and ought to be accepted as affording the chief evidence of the respective merits of the pupils.

This is not the place for considering how the general funds for an effective system of national education can best be raised, nor how existing educational endowments can best be used in aid of those funds. It is well known that some colleges of Oxford and Cambridge are possessed of rich endowments, and that many distinguished members of those universities are desirous that the annual proceeds of those endowments should be distributed upon some system better calculated to promote the advancement of learning than that which generally prevails. Indeed we may confidently hope that, true to their glorious traditions, those colleges will be led by the high-minded and enlightened counsels of their members to rely upon improving usefulness in the advancement of learning as the only secure and worthy basis of their action in the use of their funds, so that they may take a leading part in such system of national education as may be moulded out of the present chaos.

But the foundations of a national system of education ought to be laid independently of the present arrangements at Oxford and Cambridge, for we may be sure that the more progress the system makes the more easy will become the necessary reforms in the older universities and colleges.

It is clearly undesirable that Government should longer delay obtaining such full and accurate knowledge of the existing national resources for educational purposes, and of the manner in which they are respectively utilized, as may enable it to judge of the comparative prospects of usefulness presented by the various modes of distributing educational grants. It ought to know what has been done and what is doing in the various public educational establishments before it can judge which of them would be likely to make the best use of a grant of public money.

We have official authority for expecting such impartial administration of educational grants; and it cannot be doubted that before long due means will be taken to supply the preliminary conditions.

You are no doubt aware that a Royal Commission was appointed some time ago, in consequence of representations made to Government by the British Association on this subject, and it is understood that its instructions are so framed as to direct its particular attention to the manner in which Government may best distribute educational grants. The Commission is moreover composed of most distinguished men, and we have every reason to anticipate from their labours a result worthy of the nation and of the momentous occasion.

In speaking of public educational establishments, I refer to those which by their constitution are devoted to the advancement of learning without pecuniary profit to their respective governing bodies. The annual expenditure requisite for keeping up a national system of popular education will necessarily be considerable from the first, and will become greater from year to year; but once Englishmen are fully alive to the paramount importance of the object, and see that its attainment is within their reach, we may be sure that its expense will be no impediment. England would not deserve to reap the glorious fruits of the harvest of knowledge if she grudged the necessary outlay for seed and tillage, were it even ten times greater than it will be. It is no use attempting to establish a national system on any other than a truly national basis. Private and corporate funds inevitably get diverted from popular use, after a few generations, to the use of the influential and rich. A national system must steadily keep in view the improvement of the poor, and distribute public funds each year in the manner best calculated to give to the youths of the poorest classes full opportunities of improvement proportional to their capacities, so that they may qualify themselves for the utmost usefulness to their country of which they are capable. The best possible

security for the proper administration of the system will be found in the full and speedy publicity of all the particulars of its working.

It has been frequently remarked that a great proportion of English investigators are men of independent means, who not only seek no advancement as a reward of their labours, but often sacrifice those opportunities of improving their worldly position which their abilities and influence open up to them, for the sake of quietly advancing human knowledge. Rich and powerful men have very great temptations to turn away from science, so that those who devote their time and money to its service prove to us how true and pure a love of science exists in this country, and how Englishmen will cultivate it when it is in their power to do so.

Now and then a youth from the poorer classes is enabled by fortunate accidents and the aid of a friendly hand to climb to a position of scientific activity, and to give us, as Faraday did, a sample of the intellectual powers which lie fallow in the great mass of the people.

Now, the practical conclusion to which I want to lead you is, that it rests with you, who represent the national desire for the advancement of science, to take the only measures which can now be taken towards the establishment of a system of education worthy of this country, and adapted to the requirements of science. In the present stage of the business, the first thing to be done is to arouse public attention by all practicable means to the importance of the want, and to get people gradually to agree to some definite and practicable plan of action. You will, I think, find that the best way to promote such agreement is to make people consider the natural forces which have to be systematized by legislation, with a view of enabling them to work freely for the desired purpose. When the conditions essential to any national system come to be duly appreciated by those interested in the cause of education, means will soon be found to carry out the necessary legislative enactments.

The highest offices in the State are on our present system filled by men who, whatever their political opinions and party ties, almost infallibly agree in their disinterested desire to signalize their respective terms of office by doing any good in their power. Convince them that a measure desired by the leaders of public opinion is in itself good and useful, and you are sure to carry it.

And, on the other hand, England is not wanting in men both able and willing to come forward as the champions of any great cause, and to devote their best powers to its service.

I may well say this at Bradford after the results achieved by your member in the Elementary Education Act.

Objections will of course be raised to any system on the score of difficulty and expense, more especially to a complete and good system. Difficult of realization it certainly must be, for it will need the devoted and indefatigable exertions of many an able and high-minded man for many a long year. Only show how such exertions can be made to produce great and abiding results, and they will not be wanting. And as for expense, you will surely agree with me that the more money is distributed in such frugal and effective manner, the better for the real greatness of our country.

What nobler privilege is attached to the possession of money than that of doing good to our fellow men? and who would grudge giving freely from his surplus, or even depriving himself of some comforts, for the sake of preparing the rising generation for a life of the utmost usefulness and consequent happiness?

I confidently trust that the time will come when the chief item in the annual budget of the Chancellor of the Exchequer will be the vote for National Education; and when in some later age our nation shall have passed away, when a more true civilization has grown up and has formed new centres for its throbbing life, when there are but broken arches to tell of our bridges and crumbling ruins to mark the sites of our great cathedrals—then will the greatest and noblest of England's works stand more perfect and more beautiful than ever; then will some man survey the results of Old England's labours in the discovery of imperishable truths and laws of nature, and see that her energy and wealth were accompanied by some nobler attributes—that while Englishmen were strong and ambitious enough to grasp power, they were true enough to use it for its only worthy purpose, that of doing good to others.

I must not, however, trespass longer upon your time and your kind attention. My subject would carry me on, yet I must stop without having half done justice to it.

If I have succeeded in convincing you that a national system of education is now necessary and possible, and in persuading you to do what you respectively can to prepare the way for it, I shall feel that the first step is made towards the great result.

Parliamentary and Law Proceedings.

The Liverpool Butter Case.—Report of Professor Anderson.

At the Liverpool Borough Police Court, on Thursday, September 11th, before Mr. Raffles, the charge against Mr. George Kelly, of selling adulterated butter, was finally disposed of, after being in several forms before the court since December last, when the summons was first laid. On the 18th of that month the Liverpool health committee issued a summons against Mr. Kelly for selling adulterated butter, but the magistrate dismissed the case. An appeal against the decision was then made to the Court of Queen's Bench, and resulted in the case being sent back to the police-court for a decision upon its merits. But there was a conflict of opinion between the public analyst, Dr. Campbell Brown, and Mr. Martin Murphy, principal of the Liverpool College of Chemistry, as to the quality of the butter. It was decided to refer the matter to a third gentleman whose testimony should be held conclusive, and accordingly several eminent analysts were applied to, but they declined to undertake the examination. Ultimately, however, Professor Anderson, of the University of Glasgow, consented to analyse the butter, and the professor's report upon it as follows was now read:—

"I have carefully examined and analysed a sample of butter sent by Messrs. Anderton and Ellis, for the purpose of ascertaining whether it is adulterated, and find it to contain:—

Fatty matter	84·77
Curd	1·12
Salt	5·65
Water	8·46
	100·00

"As far as the results of chemical analysis are concerned, this sample of butter presents no special peculiarities. The salt is present in almost exactly the proportion in which it is said to be used in the best dairies—namely, one ounce to the pound of butter. The water is not excessive, and the curd only a very little above the proportion usually found in good butter. It is therefore obvious that neither salt nor water—the two substances most generally employed as adulterants—have been used in this case, and if any foreign substance be present it must be some inferior variety of fat.

"I have therefore directed my attention most particularly to this point, and in examining the different processes described in books for detecting foreign fats in butter, I am bound to say that I have found the whole subject in an exceedingly unsatisfactory state. Microscopic examination is the process on which the greatest reliance is placed. Ordinary butter under the microscope is seen to consist entirely of exceedingly minute granules, in which no trace of crystalline structure can be detected; while all ordinary fats, such as tallow, lard, etc., are completely crystalline, and consist of small radiated groups of needle-shaped crystals. The appearance of these crystals

does not afford any means of determining the nature of the fat in which they are formed, for the constituents of all fats are so similar in external characters that they cannot be identified except in those cases in which they contain some peculiar substances. Thus, tallow and cocoanut oil may be distinguished in a rough manner by their peculiar smells, which are really due to the presence of a small quantity of certain odorous fats and of other odorous principles the nature of which is still very imperfectly understood.

"If the mere presence of a crystalline fat is to be taken as conclusive evidence of adulteration, then this sample of butter must undoubtedly be considered as adultered. But it appears to me that there are other matters to be taken into consideration which must materially modify this opinion; and of these the proportion which these crystals bear to the whole mass of the butter is a matter of primary importance.

"It is here necessary for me to point out a very important difference between a chemical analysis and a microscopic examination. In the former, the different constituents are actually separated, and their relative proportions determined by weight. In the latter, the separation and weighing of the different substances is impracticable, and any estimate of the relative proportions of the different constituents is a matter of judgment and opinion, the value of which mainly depends on the experience of the individual, and is at best no more than an approximation. After careful and repeated examination, I am of opinion that the crystals contained in this sample of butter certainly do not exceed five per cent. of its whole weight, and are probably considerably less than that quantity.

"Now, it appears to me that the facts just stated are entirely opposed to the view that these crystals are the result of deliberate adulteration. The person who has made up his mind to adulterate is not likely to be satisfied with the additional profit which would be obtained by the addition of five per cent. of the cheapest fat that could be purchased, and it is scarcely necessary to say that the number of fats which could be profitably used to adulterate a butter which, I understand, is sold at 7*d.* per pound is necessarily extremely restricted.

"A number of experiments which I have made, chiefly in connection with this case, further lead me to doubt how far the presence of crystals in butter can be considered as an indisputable proof of adulteration. I find that nothing is easier than to make pure butter assume a completely crystalline appearance under the microscope, so that the eye cannot distinguish it under the microscope from tallow. On the other hand, tallow can be converted into a state in which under the microscope it might possibly pass for genuine butter. It further appears to me by no means certain that genuine butter when kept for a long time may not to a certain extent acquire a crystalline character. I have been unable to find any facts bearing on this opinion in books, and, of course, have not had time or opportunity of making any experiments on the matter. But it is well known that a similar change takes place in other substances, and there are various circumstances which make me think it not impossible that it may occur in butter.

"As the result of my whole examination, I am forced to come to the conclusion that there is no evidence to show that this sample of butter is adulterated. It is undoubtedly of most inferior quality, and I am not surprised that suspicion has arisen as to its genuineness; but I am not prepared to describe it as adulterated, and, in fact, believe that much of its present peculiarities are due to the length of time it has been kept.

"(Signed) THOMAS ANDERSON.

"University of Glasgow, 6th Sept., 1873."

Mr. Raffles said he was very much obliged to Professor Anderson for the trouble he had taken in conducting the analysis, and, after the opinion expressed by the professor, the only course to adopt was to dismiss the summons.

An application on behalf of Mr. Kelly for costs was refused.

Obituary.

NÉLATON.

One of the last and not the least distinguished of the late Emperor Napoleon's *entourage* has just passed away in Auguste Nélaton, who for the last fifteen years of his life enjoyed the reputation of being the greatest of European surgeons. A pupil of Dupuytren, he early showed himself worthy of such a master. He educated himself in the whole circle of medical science, and graduated as M.D. at the University of Paris before making pure surgery the business of his life. He became connected with the Hôtel Dieu, and rapidly drew around him an enthusiastic audience by the clearness, comprehensiveness, and practical bearing of his clinical prælections. So numerous were his classes, including as they did not only students in their novitiate, but elderly practitioners, French as well as foreign, that it was difficult to get near enough to him in his morning rounds. He was a model operator, especially careful and circumspect in diagnosis, while swift and sure-handed with the knife. After-treatment—that walk of surgery to which justice has been rendered only of late years—was always a matter of paramount importance with him. He rarely lost a case; and such was his reputation for success, that Paris owed to the attraction he possessed for patients from all parts of the world, not a little of her floating population. The Emperor's belief in him was unbounded. After putting the Italian and English surgeons to shame by extracting from Garibaldi's foot, in 1862, the bullet which they had denied to be present, he was telegraphed for from Paris to Switzerland to attend the Empress and suite, who had sustained a carriage accident. By this time he was high in court favour, which was still further enhanced by the skill and courage he showed in curing the Prince Imperial of a deep-seated abcess in the hip, which no other surgeon had diagnosed. The Emperor, departing from traditional usage, made him a Senator—an act as creditable to himself as to Nélaton; while he also promoted him to the rank of Grand Officer of the Legion of Honour—a distinction shared by only two other medical men, Ricard and Larrey.

Nélaton did not write much. But the books he has left, notably his treatise on 'Surgical Pathology,' are models of method, comprehensiveness, and clearness of exposition. For the last two or three years the cares of a practice, which usually brought him in £20,000 a-year, began to tell upon him, and symptoms of heart disease declared themselves. He retired from active life, though still giving advice occasionally to favoured clients, and for a time it was thought that the relaxation from work and the quiet of his country *villeggiatura* would restore him to health. But dropsy set in; and after several weeks of suffering he expired on Sunday, the 21st instant, in his sixty-seventh year.

We regret to have also to record the death, on Monday, September 15, of Mr. Jonathan Chater, Pharmaceutical Chemist, of Watford, from epilepsy. Mr. Chater was one of the founders of the Pharmaceutical Society, and for several years acted as one of its local secretaries.

Orient.—The seeds sent are anatto seeds (*Bixa Orellana*).

"*Scott.*"—The question is open to doubt. The infusion may have been intended, or the water may have been omitted. But similar prescriptions have been dispensed in London.

J. N.—Yes. The new regulations are to come into force October 1, 1874.

R. D. M.—The preparation mentioned, if made strictly according to the British Pharmacopœia, will retain its shape.

W. Ballard.—In July, 1874.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Mason, Newbould, Proctor, Ballard, Nicholson, H. M. C., S. X., "Pharmacien."

PHARMACEUTICAL RESULTS OF THE CALCUTTA BOTANIC GARDENS.

Acclimatization of Ipecacuanha.

(Concluded from page 242.)

As to the introduction of ipecacuanha into European pharmacy, it only dated from the end of the seventeenth century, about fifty years after the publication of Pison's work, entitled 'De Medicina Brasiliensis.' Up to this time, though the most important properties of this root were known, the profession hesitated to make use of it; and even a little later some accidents following the inconsiderate use of it were the cause of its falling almost completely into disuse. It was only when a French merchant, named Grenier, had brought to Paris a quantity sufficient for making the following experiments that all prejudice disappeared, and the "root of Brazil" took that place in the medical world which it deserved.

The physician Adrien Helvetius, with whom Grenier had united to facilitate the adoption of this remedy, induced no doubt by the example of the brilliant fortune which cinchona had just procured to the Englishman Talbot, succeeded in his turn in interesting Louis XIV. in the fate of ipecacuanha.

It was in consequence of the experiments made by his order in the Hôtel Dieu of Paris, that the advantage to be derived from the use of ipecacuanha in certain diseases, and specially diarrhœa and dysentry, was finally proved; and the remedy which up to that time had been kept more or less secret was from that moment, thanks to the munificence of the great king, made publicly known.

I have said that tradition refused to Europeans the merit of discovering ipecacuanha, but none can ever contest that of their having immensely extended the limits of the region where it is gathered. I will pass over here in silence the first steps taken towards these discoveries to refer at once to those of later years.

The most recent works which treat of ipecacuanha only indicate its existence in those parts of the Brazilian empire which adjoin more or less immediately the Atlantic Ocean; for example, the provinces of Para, Maranhao, Pernambuco, Bahia, Espirito Santo, Minas Geraes, Rio de Janeiro, and Sao Paulo, in all of which, on a larger or smaller scale, the precious root is gathered. Thus defined, the region of cephaëlis would have natural enough limits, since commencing at the equinoctial line and going southwards, it stops almost exactly at the tropic, on the the east it appears confined by the Atlantic, and on the west to a great extent by the high lands of the interior. These limits, however, are happily entirely hypothetical. Now, indeed, we know that the region of *Cephaëlis ipecacuanha*, far from being limited to the comparatively narrow strip along the sea shore, possesses, on the contrary, a much wider range of longitude than of latitude, since it extends to about 25 degrees into the interior of the continent, or to 50 degrees longitude west of Paris, that is to say, almost to the confines of Bolivia. Credible observers have even assured me that the plant has been discovered in the forests of this republic in the province of Chiquitos, but I have not myself observed it beyond the Brazilian frontier. The fertility of the newly discovered districts is after all such that they alone are almost sufficient to supply the European market.

From the little that I have said it will be seen that almost the whole of the new addition made to the field of production of ipecacuanha is to be found in the immense province of Matto Grosso. It was in the year 1824 that the first plants of *Cephaëlis* were discovered in this part of Brazil, in the neighbourhood of Villa Maria, a little village situated on the left bank of the Rio Paraguay. They were recognized by a doctor of Matto Grosso, who accompanied the "Guarda-Mor" sent to test the auriferous sands of Rio Cabaçal, but for a long time no one thought of making the plant an object of commerce, and the utmost expected was that its use as a medicine would spread to a small extent in the country. Later, towards the year 1830, an old forester named Motta, who had acted as guide to the expedition, and who himself gave me the details, recognized the same root in the forests which bound Rio Suputoba, and drew the attention of a merchant of Villa Maria to it. The latter, struck with the similarity between this root and that which was gathered with so much profit in the sea-bound provinces, sent samples of it to Rio de Janeiro, and from that moment the collection of it commenced. The forests in which the *Cephaëlis* thrives have a peculiar character, which it is difficult to forget; this is due to the presence of several remarkable vegetables. Almost all those of Matto Grosso are situated in the valley of the Paraguay, above Villa Maria, or even in those of the affluents which it receives at this part of its course. In order to be able to judge better of the parts inhabited by such an interesting plant, I went myself to one of these forests, situated on the Rio Cabaçal. Six days of navigation through a bower of verdure brought me to the end of my journey. I had quitted the Rio Cabaçal some hours previously by a little river which flows into it, the Rio Vermelbo, on the banks of which a little *hangar* of leaves of the palm indicates that the commencement of the domains of the *Cephaëlis* is reached. This place has received the name of Port de Rueno; it was more than a year since any one had visited it.

The woods which immediately adjoin the river are situated too low for the *Cephaëlis* to succeed there, and when the river is in flood the soil is covered to a very considerable distance from the banks, a state of matters which often lasts during several months of the year. The growth of other vegetables is, however, only the more active; and when I entered on the path which leads towards the interior, I soon found myself in the heart of a vegetation of the most grievous description, which, without the large knives with which my Indians were armed, would have formed a barrier difficult to break through. The bamboos, in particular, have here in this part of the forest formed such a compact network that I almost became entangled like a fly in a spider's web. However, at about a mile-and-a-half from the river banks the ground begins sensibly to rise; the soil now consisted only of sand, slightly humid and impregnated, if I may so speak, with the *detritus* of vegetables which have replaced its surface. Some new features of vegetation showed at last that I had reached a botanical region rather different from that which I had just quitted. Several species of palms with which I had not met up to that point, arrested my attention, particularly *Euterpe oleracea*, or "palmetto molle," with a slim, tall trunk, and the *Enocarpus bacaba*, with distichous leaves, were there conspicuous, and entirely replaced the *Cocos capitata* which had accompanied me until then. Still further, in places where the

depressed surface allowed some affluent source of the river to filtrate, there appeared in the midst of *Mauritia* and tree ferns the *Iriartea exorrhiza*, very striking on account of the disposition of the aerial roots, which its trunk produces at fully two metres (six feet) above ground, and which descend obliquely to it, forming so many natural supports upon which the tree rests. It is specially in the firm ground that surrounds these little marshes, and in the perpetual shade of those other trees which grow in company with the vegetables that I have just named, that the *Cephaëlis* delights. It is a small shrub, with a stem plain and bare towards the base, where it is often bent and more or less radical; its leaves, generally close to the top of the plant, give it some resemblance to the *Daphne* of our woods.

The *Cephaëlis* rarely grows singly; it is much more common to find a number of plants clustered in the form of a loose round bush, which the collectors of *poaya*, or *poayeros* (as they are called), know by the name of *redoleros*. In gathering the root of the *Cephaëlis*, the poayero seizes with one hand, and if possible at one time, all the stems which form a bunch, whilst with the other he drives somewhat obliquely into the soil and under the base a strong pointed stick called *saracoa*, with which he afterwards makes a see-saw movement. The mass of earth which imprisons the roots is thus raised, and when the operation has been dexterously made, all the roots attached to the bunch are at once obtained, and almost without fracture. The poayero then separates the part used, shakes it lightly free from the adherent earth, and puts it in a large bag, which he carries for this purpose suspended at his side; then he proceeds to attack another clump, and so on. A workman who possesses all the requisite qualities may, under the most favourable circumstances, gather in a day about fifteen kilograms of ipecacuanha; but the harvest of an ordinary labourer seldom exceeds five to six kilograms; some even scarcely collect three or four in the same space of time. The season also influences considerably the facility for the work.

In the rainy season the earth being much more easy to till, the operation of gathering goes on much more rapidly, and the root then obtained is not only heavier but is less fragile than in the dry season. Towards the fall of night, the workmen dispersed in the forests, and who are, as I shall be able to say later on, under a unique direction, reassemble at the camp. Each poayero then pours the result of his labours into the hands of a steward, who weighs and spreads it upon hides to dry. The more rapid this last process, so much the more successful is it; and as far as is possible it is carried out in the full blaze of the sun. In favourable weather the root is quite dry at the end of two or three days at the most, always supposing that during the night it is sheltered from the dew. When ipecacuanha has been dried slowly, or packed when still somewhat damp, its surface is always more or less mouldy, and it does not break so sharply as when the opposite is the case; nor has it the resinous and roseate appearance which characterizes it when it has had all the wished for care.

The ipecacuanha harvest continues throughout the whole year, but it generally relaxes a little in the rainy season, because of difficulty often experienced in drying the produce. Many extractors, however, prefer this time of year because of the great facilities for gathering it. Now, as the flowering takes place exactly at this season, that is about the months of February and March, there is no doubt, as M. Martius observes, that the fruit of the plant must suffer; and if nature had given to the *Cephaëlis* only that means of multiplication which it has in common with all plants, the usual mode of collection would have been fatal to it. Happily for humanity it has been otherwise decided. It appeared to me that the *Cephaëlis* was much more seldom reproduced by seed than by another process, of which I ought now to speak. No one is ignorant of the great power of reproduction which exists in the roots of some of our garden plants, particularly in that of *Maclura* and of the *Paulownia*. We know that the roots, however small we may cut them, have the faculty of reproducing a new individual from each of the fragments; one may almost compare them in this respect to algæ, or to certain polypes. Well, this is the case to a certain extent, with the root of the *Cephaëlis*. It is by a true system of cuttings, which the poayero makes in spite of himself at each spot, when he effects the uprooting of a plant, that the latter reproduces itself. Each fragment which remains accidentally in the ground after the operation is sufficient to renew the plant. The intelligent poayeros of Matto Grosso, who are well aware of this peculiarity, never fail, when they shake the earth off the plants which they have just taken from the ground, to leave intentionally the roots which have been accidentally broken; and most of them are even careful before rising up to rapidly refill the hole caused by the extraction. Hence it is probable enough that this mode of vegetation in round clumps does not belong normally to the *Cephaëlis*, but that it is owing to that kind of manipulation to which it is subjected, and which, as we see, far from destroying it, appears, if it is done with a small degree of intelligence, to tend to multiply it all the more. Still it must not be thought that the *reboisement* of the forest of ipecacuanha (if I may be allowed to use the expression in connection with such a small vegetable) takes place year after year. According to the most distinct information I have obtained on this subject, about three or four years must necessarily elapse before a district which has been cleared can be again harvested with equal profit.

The gathering of ipecacuanha has just the effect —contrary to what generally takes place in like cases—of submitting the *Cephaëlis* to a kind of accidental culture, eminently suited for its preservation, and the circumstances that I have quoted are not the only ones that have contributed to this happy result. Another plays perhaps a no less important part, that is, the burning of the forests. Before this was vigorously practised the ground was so encumbered with the numerous vegetable remains which accumulated there, that not only did the seeds of the ipecacuanha not find within their reach suitable soil, but it often even happened that full grown plants were in time choked. On the other hand, the extraction of the root was rendered more difficult owing to the necessity of raising each spongy layer before being able to reach the true soil, owing to the existence of the leaves which are now destroyed. One sometimes sees a forest fire in the ipecacuanha region last for several months consecutively.

In conclusion I may say that when the root is dry it is broken into smaller fragments, shaken in a sieve to separate them from the sand or earth which may still adhere to them, and finally put in bales for convenience of transport. Many of the extractors of

Villa Maria construct the boats which are to serve as the means of conveyance in the very forests where the ipecacuanha is gathered. The collection of ipecacuanha in the Matto Grosso only commenced, as I have said, ten or twelve years ago, although it was well known before that period. That first collected was sold on the spot at the rate of 2 francs 60 centimes per pound, and in Rio de Janeiro more than double. This high price attracted a numerous population to the forests of the Upper Paraguay, and after a certain time there was such an immense quantity of the drug in the Rio market that nobody would look at it; it was verily a *drug* in the market; instantly its price fell at least a franc. From 1835 to 1837, 150,000 kilograms of ipecacuanha were taken from the neighbourhood of Villa Maria; the forests were then occupied by from 1200 to 1500 gathering; men, women, and children, bond and free, advanced several days' journey into the forests of Paraguay, and there spent whole months in uprooting the plant. The average price of the "arrobe," about 14½ kilograms, was then from 50 to 60 francs at Villa Maria, and from 78 to 90 francs at Rio de Janeiro. Afterwards from the glut in the market, the enterprise was suddenly and almost completely abandoned; then little by little the price mended, and the poayeros gradually returned to the woods. Now that the produce yearly obtained amounts to about 1000 arrobes, or 15,000 kilograms, its value remains almost stationary. At Villa Maria ipecacuanha of good quality brings in about 25 to 30 francs the arrobe, and conveyed to Rio, from 76 to 80 francs.

THE NEW SYRUP OF THE IODIDE AND TINCTURE OF THE CHLORIDE OF IRON.*

BY JOSEPH P. REMINGTON.

The so-called tasteless iron combinations, which have recently been brought to notice by J. L. A. Creuse, of New York, have attracted much attention of late, and an entire revolution in the manner of making a most useful class of preparations has been threatened.

The advantages claimed for the innovations are numerous: freedom from *nauseous* taste (they cannot certainly be called tasteless), ready solubility in water, non-liability to change in dispensing, little or no destructive action on the teeth, miscibility without decomposition with bark and other desirable tonic preparations.

Setting aside for the present the theories which may be brought forward to prove their composition (the *rationale* of new compounds often being mere collections of symbols twisted into a shape that will explain on *paper* a reaction), the first thoughts that occur to a practical pharmacist in connection with them, are:—

Can they thoroughly replace the old and disagreeable remedies that have been prescribed for years past?

Can desirable processes be devised whereby every pharmacist may make in his own store the new preparations?

Is the claim for stability sustained by experience?

It is the intention of the writer to attempt to answer these questions.

First, in regard to replacing the old remedies. Iodide of iron has been used constantly since 1824, and it is regarded as one of the very best alterative and tonic preparations; yet the objections to its use are numerous, and were it not for its intrinsic merit it would have slept long ago in an unhonoured grave; it is always unpleasant to take, even when freshly prepared, and becomes more so as it gets older.

In practice, but few pharmacists prepare their own syrup; reliance is placed on the general market, and the results, of course, are variable. A syrup one week or two years old may be purchased, possessing various degrees of colour and acridity (agreeing better, however, in the latter quality), and neither the patient nor physician are probably aware of the cause, and practitioners are frequently debarred from prescribing for delicate persons and children on account of the disturbance to the digestive organs.

The new syrup of the iodide of iron does, in the writer's opinion, remove the objection to the old preparation. It has fallen to his lot to make about twelve gallons of the improved syrup at various times, which has been dispensed, and has been used by physicians in their practice for the usual diseases where the old syrup was indicated.

It seems to answer well in scrofulous and syphilitic diseases, in obstinate skin affections, and as an internal remedy where morbid secretions of the glands exist, but particularly for delicate females and children of scrofulous habit requiring an alterative tonic. Its taste is pleasant; the teeth were not discoloured and the digestive functions were not disturbed by its use in any of the cases that were reported. A formula for the preparation is subjoined, which is based on the researches of Creuse in this direction.

New Syrup of Iodide of Iron.

Take of—

Re-sublimed Iodine	378·9 grains.
Iron Wire (card teeth)	90 „
Distilled Water	2 fluidounces.
Citric Acid (dry)	408 grains.
Potassium Carbonate (pure)	475 „ or q. s.

Weigh accurately 252·6 grains of the iodine, and place in a beaker or flask of at least four fluidounce capacity, then add to it the card teeth and half a fluidounce of distilled water, cover the beaker with a watch-glass, and agitate occasionally until the liquid has acquired a green colour and lost the smell of iodine (care should be taken about this point—all the iodine should be in the state of a ferrous salt); filter the liquid from undissolved iron, rinse the iron with a small quantity of the distilled water, pour on the filter, and finally rinse the filter; now add to the filtrate the remaining 126·3 grains iodine, and allow it to dissolve; it forms a rich, ruby-red solution. Place 406 grains of the citric acid in a small evaporating dish, add one and a half fluidounces of distilled water, and apply heat until the acid dissolves and the liquid boils; without removing from the fire add, by small portions, sufficient potassium carbonate to neutralize, avoiding an excess; if a slight excess should happen to be present, correct it by adding the two grains citric acid reserved. Now pour as much of this solution of potassium citrate while hot into the red solution as will change the colour to a bright green, and make up the measure to twenty-six fluidounces with simple syrup. The finished syrup contains about five grains of the salt in each fluid drachm, and the dose would be from one-half to one teaspoonful.

The new tincture of the chloride of iron can replace the old, with advantage, in most cases where the tonic effects are alone desired, without any styptic action.

New Tincture of Chloride of Iron.

Liq. Ferri Chloridi, U.S.P.	1 fluidounce.
Citric Acid	544 grains.
Sodium Carbonate	1000 „ or q. s.
Water (distilled)	1 fluidounce.
Alcohol	a sufficient quantity.

Dissolve the citric acid in the distilled water, and heat to the boiling-point, gradually adding the sodium carbonate until the acid is saturated (the quantity varies with the amount of moisture present in either), mix with the iron solution, which will now acquire a beautiful green colour, and make up the measure to four fluidounces with alcohol.

One of the strongest points in favour of this series of preparations is that they can be made to offer a great variety of desirable combinations. The finished green

* From *The American Journal of Pharmacy* for September, p. 385.

solution of iodide of iron may be evaporated at a low heat, and, as suggested, a salt formed which can readily be made into pills of three grains each, and, of course, requiring no insoluble coating to protect them; it may be dissolved in water in almost any quantity, forming a simple solution, or in syrup to form a syrup of the iodide of iron of any required strength. It may be administered in combination with compound tincture of cinchona and compound tincture of gentian, or it may really, *when added*, put some virtue in the numerous tonic elixirs that are being prescribed so largely throughout the country.

A formula is appended for an elixir which has acquired some sale in Philadelphia. The writer does not wish to be considered as endorsing it, however.

Elixir of Gentian with Chloride of Iron.

Tincture of Chloride of Iron (new) .	6 fluid-drachms.
Tincture of Cardamom	½ fluidounce.
Fluid Extract of Gentian	3 fluid-drachms.
Alcohol	2 fluidounces.
Oil of Cinnamon (true)	1 drop.
„ Coriander (fresh)	1 drop.
„ Anise	1 drop.
„ Orange	3 drops.
Simple Syrup	3 fluidounces.

Water, sufficient to make sixteen fluidounces.

Dissolve the oils in the alcohol, and having mixed the other ingredients together, incorporate all thoroughly, adding sufficient water to make one pint, and filter. Dose: a dessertspoonful. This preparation contains five minims tincture of the chloride of iron in each dose; enough gentian is present to flavour the elixir somewhat, and give it part of a name, and not enough to injure the greatest desideratum—a pleasant taste.

LITTLE THINGS.*

BY ALEXANDER FORSYTH.

There is indeed a veritable world of wee things, animal as well as vegetable, far below our field of vision, that the naked eye hath never seen. Although these subjects are minute they are not the less perfect, and we marvel at seeing things of such little power, and having a sphere of action so limited, exhibit under the microscope so much design, and such elaborate workmanship. Why is that insect roaming at large inside a bellflower no larger then a mustard seed? Is he impregnating the flower, and sipping honey to reward him for his pains? The flower had need of his neat service, and he had need of the flower; and when gardeners isolate flowers, they have to do the work of impregnation, as best they may, with a camel-hair pencil, and thus learn the use of little things.

In attempting to convey accurate ideas of plant life to beginners, I think we miss an important clue by teaching first the development of plants from seeds, whereas the seeds themselves are only a kind of middle state of plants, well adapted for transit, but by no means the beginning of plant life. Certain pollen masses show under the microscope like finely rounded snowballs with outstanding hairs, and no one doubts that the pollen falls on a moist medium, a bed of nectar, and so fertilizes the seed. It is worthy of remark that the dryness essential to the welfare of the pollen, and the moisture equally essential to the healthy character of the stigma, do not interfere with each other, although often less than a hair-breadth apart. Dr. Lindley quoted the speech of a bishop, who said, "the grass had a flower although it was a very small one." Now if any one will examine an ear of wheat when in bloom, and see two bodies about half the size of a cheese mite dangling from a hair almost invisible, and is told that every grain has to be thus treated before we can get either seed or bread corn, he will see of what service small things are, and learn upon what a slender thread our staff of life is hung.

* From the *Gardeners' Chronicle*.

If we turn to cryptogamic plants, and examine the structure of ferns, we find the first botanical link missing; and the spores of ferns acting like the pollen of flowering plants, and falling upon a moist surface, vegetate. In the first appearance of ferns from spores there is no likeness to the parent plant, and some ferns, such as the elk's-horn, have false, or radicle, leaves always. Flowering plants seem to suckle their young by providing starch and sugar, oil, etc., for them to begin their new life with. I would advise beginners to use the microscope, and mark well the difference between the flowerless and the flowering plants, and upon that solid foundation, which no one dares to impugn, let him begin to build, first fishing for small fry to catch how ferns live and propagate their species, for they all attain that important end; and when he has mastered the simplest forms, let him try the next step higher, but by all means let him begin at the bottom of the ladder.

No one can proceed a single inch in the science of plant life—if that science is to be a guide to successful practice—until he has studied the use and service of water. When we see the cells of plants under the microscope, they seem largely composed of water. In the old-fashioned cucumber frame we often see aërial roots protruding from the "hill," white and crisp, like frost on glass; and we know that these roots owe just as much to the "mother liquor" of water in the form of hot vapour, as tadpoles owe to the water of their pond. These delicate aërial roots exhibit above-ground the action that is constantly going on underground, and the activity with which tissue is formed where water and where warmth are not wanting. The botany of books does not hold up to the reader the immense importance of the water to the feeders (spongioles), and of the feeders to the plant, for the rearing of trees like the willow by truncheons, and bushes like the elder by rods, and the whole art of propagating by layers and cuttings, the increasing of succulent plants by their leaves, and of plants generally by seeds, all depend upon getting them to root first. To do this, some, like the truncheons, must be buried; others, like the layers, must be lightly covered, whilst the succulents are left bare on a bed of sand; but one and all must either strike root or die—but see how each sets about this essential work. The succulent, being a bag of water, will root freely without any covering, in dry sand; whereas, the truncheons, twigs, cuttings, and seeds would every one die under the same treatment. Hence the need of a constant supply of moisture, for the microscope clearly shows, as has already been said, that every cell of every root owes more than half its volume to water. Surely, then, there is some art in watering. It is not a watering and done with it that plant life requires when in active growth, but a constant supply of moisture. It is painful to see a clumsy hand watering plants, as he would swill a yard or extinguish a fire. The gentle rain has no body of water beyond its single drops, and they take time to fall, and fall so lightly, that the risk of injury to the foliage is reduced to the minimum, whilst the summer cloud acts the part of a parasol or sun-shade. This, then, is the pattern for watering in perfection.

But when we talk of gentleness in watering, and of constant watering, we have only to look at the loving dew taking into its bosom nightly every blade of grass, and taking every leaf as it were with both hands into its embrace, for the dew seems to rise as well as fall, and all night long it acts like a wet-nurse to both surfaces of the leaf. Surely this moisture is needed, otherwise it would not have been so kindly bestowed; but what a small quantity is here spread over a large space. The ivy on the ruin wall, and the rue in its limestone crevice, get their full share of gentle dew; but the rose that has passed the night bedewed in tears, which it will take the morning sun some hours to dry up, will show the full-bloom flower sweet as well as fair, and plead the cause of looking well to little matters. The practised eye will see the rose leaf carrying the bell at every point, and by that little index know that all is well.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 4, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SCHOOL OF PHARMACY.

THE transition from the holiday occupations of the Conference meeting to the more severe business of another session has this year been so sudden that it is almost with a sense of surprise one finds the inaugural address to the students claiming attention while the echoes of the Conference address are still lingering in our ears. But there may be some advantage in the unusual and accidental approximation of these two important features of the pharmaceutical year, since they are both characterized by reference to the changes recently introduced in the School of Pharmacy, and since the tendencies of the comments on those changes in the two addresses are somewhat different. These circumstances may, therefore, operate beneficially by attracting more general consideration of the subject of education than might otherwise have been the case.

Mr. BRADY, speaking as President of the Pharmaceutical Conference, has emphatically given expression to the opinion that the changes in question are not calculated to conduce to the promotion of that high-class education, the attainment of which has always been the avowed aim of the Pharmaceutical Society. On the contrary, he considers that the new arrangements point solely to increased facilities for obtaining the minimum amount of knowledge necessary for passing the Minor examination. To anyone acquainted with Mr. BRADY'S aspirations in regard to the position of British pharmacy and its followers, or with his labours to advance it, there cannot be any ground for surprise that he should view with suspicion and distaste measures which in any degree fall short of the high standard he would desire to see established. In this respect we heartily sympathize with the feelings which prompted his recent comments; but at the same time we cannot share with him the opinion that the altered educational programme can only promote that "dull, low mediocrity which above all things it should be our aim to avoid."

Under existing conditions it seems imperative that regard should be had to the present legal standard of pharmaceutical qualification, and that, however high may be the aims of the Society for the future, its action for the time being must necessarily and properly be directed towards making the legal minimum of qualification, as far as possible, adequate for the purposes it is intended to serve.

We heartily concur with Mr. BRADY'S approval of the suggestion that the Minor examination should be made a matriculation for students entering the School of Pharmacy at Bloomsbury Square, and that it should be recognized only as a qualification for assistants at the most; but we cannot perceive any reason why the excellent principle of "thoroughness" should not also be acted upon, so far as practicable, in regard to the Minor examination, and that amount of technical education which is necessary to enable students to pass it.

For our own part, we entertain a higher opinion of the examining body than would be consistent with the notion that mere superficial and ephemeral knowledge is sufficient to enable candidates to pass even the Minor examination, and we think it would be setting too low a value on the attainment, even of that standard of qualification, to suppose that mere "cram" can be sufficient to satisfy its requirements.

In Mr. SANDFORD'S remarks on this subject the considerations we have here alluded to seem to have been taken into account. He is equally emphatic in his recommendation that the word "thorough" should be the motto of both students and teachers, and in urging that this principle should be observed in the course of study requisite for the Minor examition he does not at all overlook the desirability of its being regarded only as a preliminary step. Hence he characterizes the change that has been made in the educational arrangements of the Society as being merely a termination of pecuniary or profitable interest in education. There are many reasons to justify this course now, and one of the strongest arguments in favour of it consists in the fact that its adoption does not in any way involve disregard of the Society's original object, that the Major qualification should be obtained by all who desire to practise pharmacy on their own account.

THE BENEVOLENT FUND ELECTION.

AT the meeting of the Council on Wednesday last, it was resolved that, in consequence of the recent death of Mrs. HANNAH GREAVES having occasioned a reduction in the number of annuitants on the Benevolent Fund, two annuitants shall be elected at the forthcoming election on the 24th inst., instead of one, as had been previously advertised.

SPECIAL GENERAL MEETING OF THE PHARMACEUTICAL SOCIETY.

WE are requested to call attention to the official notice on the first page of this week's Journal, issued in compliance with a resolution of the Council, passed on Wednesday last, to the effect that a Special General Meeting of the Members of the Pharmaceutical Society will be held on Wednesday, the 22nd instant, for the purpose of considering and, if thought proper, confirming the alterations in the Bye-Laws made in accordance with the wishes of the Privy Council.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL,

October 1st, 1873.

MR. ALEXANDER BOTTLE, VICE-PRESIDENT, IN THE CHAIR.

Present — Messrs. Atherton, Baynes, Betty, Brown, Frazer, Hampson, Mackay, Owen, Radley, Robbins, Sandford, Savage, Schacht, Shaw, Urwick, and Williams.

The VICE-PRESIDENT stated that the President would not be present in consequence of the very serious condition of his friend Sir Edwin Landseer.

The minutes of the previous meeting were read and confirmed.

Two associates who had neglected to pay their subscription within the proper time were ordered to be restored to their status on payment of the subscription, together with a fine of one shilling.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

Fletcher, Frederick William ...Totton.
Rammell, Edward.....Byculla, India.

Chemists and Druggists.

Bulmer, Richard Porter .....Pocklington.
Kemp, John .....Lincoln.
Payne, Jacob Hugh .....London.

ASSOCIATE.

The following having passed the Minor examination was elected an "Associate" of the Society:—

Rutter, Thomas Dixon.....Scarborough.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination were elected "Apprentices or Students" of the Society:—

Amery, John.....Taunton.
Gibson, John Chambers .....Manchester.
Howells, William .....Llandovery.
Stedman, Harry Bernard.....London.
Todd, George.....Durham.
Wilson, Erasmus .....Southsea.
Gostling, William Ayton .....Diss.
Mitchell, Charles A.....London.

FINANCE.

The report of this Committee was read and adopted, and sundry payments of salaries and accounts were ordered to be made.

LOCAL SECRETARY AT STOCKPORT.

Mr. Hervey Lowndes was elected Local Secretary for Stockport, in the room of Mr. A. H. Shaw, resigned.

BENEVOLENT FUND.

The report of this Committee was read, and in accordance with its recommendations the following grants were made:—

To a Registered Chemist in Sheffield, who has suffered for some years from the effects of an accident, £10.

To a Pharmaceutical Chemist in Dublin, in very distressed circumstances, £10.

To a Chemist and Druggist at Carmarthen, in very bad health, £5.

AN ADDITIONAL ANNUITANT.

Mr. ROBBINS proposed that in consequence of the recent death of an annuitant, Hannah Greaves, the Council should proceed to elect three annuitants instead of one. He thought more might be done with the funds at their disposal, and with a view to see what really might be accomplished he had procured the Government annuity tables, which gave the following result. Taking the average age of the annuitants when elected at 60, he found that the sum necessary to purchase an annuity of £30 for a man was £316 15*s.*; for a woman, £368 5*s.*, or a mean of £342 10*s.* If therefore they were to place ten annuitants on the fund, it would only require £3425 to provide for them. When the Benevolent Fund was started it was said that they must have a given sum before they could consider themselves safe in granting any annuities, and £10,000 was the sum mentioned. When that was obtained it was considered proper to grant ten annuities. No doubt it was right to have a certain sum in hand to begin with, but the amount mentioned was sufficient to provide annuities for ten persons, not for their lives only, but for all time. He thought there should be some limit to that process, and that they should cease to provide for all time, which simply meant that chemists and druggists in the future should not be required to provide for their own poor at all. The fund now consisted of between £13,000 and £14,000, and consequently there was sufficient to provide ten annuities for all time, and ten more for the lifetime of the annuitants; and this supposing they got no more subscriptions at all. He would propose therefore that three annuitants be elected, instead of one.

Mr. OWEN seconded the motion.

Mr. SHAW doubted whether the resolution was quite in order, as notice had been given of one election only.

The SECRETARY said there were five approved candidates, and he thought it would be open to the Council to arrange for the election of as many as they saw fit.

Mr. WILLIAMS said the question opened by Mr. Robbins was a very wide one, and ought, in his opinion, to be submitted to a committee. It would be a very serious thing to make up their minds suddenly to sacrifice a large portion of their capital.

Mr. URWICK thought the amounts mentioned by Mr. Robbins referred to sums to be actually paid down on the granting of the annuity, and was thus a sinking of the capital. He did not think it would be right to elect an annuitant without having sufficient funds invested to pay his annuity.

Mr. OWEN asked if the annuities granted absorbed all the income.

Mr. URWICK said that there was scarcely sufficient to pay the last annuitant put on the list.

Mr. OWEN said that very much altered the case.

Mr. ROBBINS said if it was the feeling of the Council, he would move the appointment of a committee on the subject.

Mr. BROWN said this was a very important question, and one which was occupying a great deal of attention just at present. As he understood Mr. Robbins' argument, he advocated the purchasing of annuities with the capital of the Benevolent Fund rather than the paying of annuities out of the interest received from that capital, because he stated that for £3425 ten annuities could be purchased. To his mind this would be a most improper expenditure of the capital of the Benevolent Fund, and one which he should never in his capacity as trustee of that fund sanction for one moment. The only proper and just principle in such cases, and the only one acknowledged in the operation of other societies contemplating similar objects, was that the capital should be invested, and the interest received therefrom devoted to the payment of the annuities to the individuals selected to receive them. In the next place, he understood Mr. Robbins to advocate the election of annuitants, although the necessary amount of money to pay the annuities was not invested, and that also seemed to him a departure from the only right and just principles of action; he could not conceive how it was proper to elect a person to an annuity when the capital was not invested to meet it, and some day it might happen that there would not be funds sufficient to pay it. It could not be said that they did not relieve all the deserving cases which came before them, for the Council were always ready to accept the recommendations of the committee who inquired very carefully into every application. No doubt there was a good deal of interest just now excited as to the investment of the Benevolent

Fund, and he thought a great misapprehension existed in the minds of many persons as to the propriety of the action taken by the Council in connection with those investments. He thought therefore it would be very well if, through the JOURNAL or by some other means, a better impression could be produced on the minds of gentlemen throughout the country, for it was a very poor reason for withholding contributions to the fund to state, as had been stated, that it was invested so as only to produce 3 per cent. interest. He did not think such a reason ought to prevail for a moment in restraint of charity, and he should be very glad indeed if such allegations were no longer made as a reason for not contributing. At the same time, he should like the arguments to be fairly set forth in the JOURNAL, showing that the Council had been guided by sound and safe principles, and that they had adopted the only legitimate course in preferring absolute security—although with a lower rate of interest—to greater returns, where the safety would not be so unquestionable. Their great desire was to keep the capital in a secure form, though the interest might be a little lower than in a more risky kind of investment. That was the only proper way of acting, considering, as they ought, not only the best interests of the present, but of the future also. He did not wish in the slightest degree to restrain the discretion of the Council in the distribution of these funds, but at the present time, at any rate, he thought they ought to adhere strictly to the rule which had been laid down of only electing annuitants when they had sufficient funds invested to pay their annuities, and certainly they ought not, by purchasing annuities, to depart from the principle of keeping their own capital.

Mr. ROBBINS said there seemed some little misunderstanding as to his proposal. He did not wish at all to diminish the capital from £13,000 to £10,000, but he was sure that the more there was given the more would be received in contributions, and already there was a large sum coming in annually. Nor did he propose, as Mr. Brown seemed to think, to buy Government annuities, but that they should continue to be their own bankers as hitherto. He simply adduced the Government tables because they were admittedly correct, as a basis for his argument. He did not advocate the diminishing of the amount already invested in any way, but there was a large amount coming in annually, and, as he had shown, ten annuitants would only require the sum of £342 each to secure an annuity for their lives, or for twenty annuitants £600 annually, still leaving more than £400 at their disposal for casual relief and to swell the funds already invested. He should be very pleased to propose the appointment of a committee to go into this subject and report to a future meeting of the Council.

Mr. URWICK said, as he understood, Mr. Robbins wished to pay the annuities out of the funds subscribed, but the fact was they had given that month quite as much as the amount of contributions, so that the question really was whether it were wise to cut off these occasional grants to deserving members, and replace them by annuities.

The discussion then dropped, and it was resolved—

> "That, in consequence of the death of Hannah Greaves having occasioned a reduction in the number of annuitants on the Benevolent Fund, the Council hereby resolve to elect two annuitants at the ensuing election."

RESIGNATION OF MR. MOSS.

A letter from Mr. Moss was read resigning his post as Demonstrator of Practical Chemistry, in consequence of his having accepted an appointment in the laboratory of a large wholesale house in London. Mr. Moss stated that he hoped still to contribute to the evening meetings of the Society.

HOUSE COMMITTEE.

The minutes of this Committee, in reference to the repairs and alterations now going on, were read and adopted.

LIBRARY, MUSEUM AND LABORATORY.

The Report of this Committee was read, containing various recommendations as to the conditions upon which the apparatus, etc., the property of the Society, should be handed over to the Professors for the purpose of lectures and otherwise. The Report was unanimously adopted.

PARLIAMENTARY.

The Report of this Committee stated that the solicitor advised that the alteration in the bye-laws made in accordance with the wishes of the Privy Council would require to be read three times at the Council, and to be then submitted to a special general meeting. The Report was received and adopted. The new bye-law with reference to the appointment of examiners, as agreed to at the previous Council meeting, was read the second time, and it was resolved—

> "That a Special Meeting of the Council be called on the 22nd inst., at 11 a.m., for the purpose of reading the new Bye-Law a third time, and that a Special General Meeting be convened on the same day, at 12 o'clock—noon—for confirmation of such Bye-Law."

The VICE-PRESIDENT said two questions had been put to him by Mr. Frazer with regard to future examinations. In the first place, Would past and future Minors who passed before October, 1874, be able to pass the Major examination on presenting themselves, without regard to their age? It appeared to him there could not be any doubt upon the subject.

Mr. MACKAY said the question seemed to be, Could a young man who had passed his Minor examination when he was nineteen, before October, 1874, go up for the Major even although he were not twenty-one.

The VICE-PRESIDENT said it appeared to him that whenever a candidate presented himself he must conform to the regulations in force at the time being.

Mr. FRAZER said he had no doubt many cases would arise similar to the one he had in his mind, when putting the question, of a young man passing the Minor when about nineteen years of age and going up for the Major shortly afterwards.

The VICE-PRESIDENT said the bye-law was very clear,—after the 31st December, 1874, no person could be admitted to the Major or Minor examination who had not attained the full age of twenty-one. The next question was whether those who passed the present Minor examination before December, 1874, and who went up for the Major examination after that day, would be examined in the subjects embraced in the present or the new Major examination. As to that also there could not be any doubt; they would come under the regulations in force at the time.

Mr. FRAZER said he asked the question, because in the new Major examination the number of subjects had been considerably reduced, whilst those in the Minor had been correspondingly increased, so that by passing the *present* Minor and going in for the *new* Major, the candidates would escape a considerable amount of work.

Mr. BETTY said he believed that was quite understood, for he knew some young men who were intending to avail themselves of the advantage thus afforded.

PROVINCIAL EXAMINATIONS.

The SECRETARY having read the report of the Board of Examiners made to the Council in August last,

Mr. SANDFORD moved the resolutions of which he had given notice, as follows:—

> "That, on the suggestion of the Board of Examiners, so far as regards the examination of candidates for the Jacob Bell Memorial Scholarships, and for the Pereira Medal, and the prize of books, embodied in the report of the Board submitted to this Council on the 6th of August, the Council hereby rescind so much of the regulation agreed to in October, 1872, as will enable future candidates for the Jacob Bell Memorial Scholarships to answer the questions set

for the examination provided for these scholarships elsewhere than in London or Edinburgh."

"That the examination for the Pereira Medal and prize of books shall be wholly conducted by the Board of Examiners in London or Edinburgh only."

When the report of the Board of Examiners came before the Council he gave notice of this motion, and also added to it a further resolution with regard to the Preliminary examination, which he had since thought better to disconnect and bring on as a separate motion; dealing simply in the first instance, with the candidates for the Jacob Bell Memorial Scholarship, the Pereira Medal, and the prize of books. At the same time, what would apply to one case would very much apply to the other. There had always been a feeling in his own mind that these examinations should not take place in the country, because it seemed to him rather too loose a method of conducting any examination at all. He said this without the slightest disrespect to the local secretaries, but the Pereira Medal was the highest honour which the Society had to offer, and if it was not worth the while of candidates to come to London or Edinburgh to pass the examination it was not worth having. On the other hand, if it were taken by a man who passed his examination in the country as now allowed, he should consider it most unfair to those who competed before the regularly constituted Board in London. He could not discuss this question without mentioning certain things which had come to his knowledge as to the method of superintending the Preliminary examinations in the country, for these examinations for prizes were conducted in the same manner; the papers being sent down to the local secretaries. There was sufficient evidence of irregularity in these examinations in many instances, because for one reason the local secretaries were all chemists and druggists, and could not leave their business for two or three hours to sit by a young man while he answered the papers sent down to him. They might be called into their shops, and would be obliged to go, if, as sometimes happened, there was no one else properly qualified to attend to customers. Evidence had been adduced, showing that local secretaries did sometimes absent themselves, sometimes appointed a deputy (but that was without the consent of the Council); and sometimes they changed the time of the examinations. Now these objections would apply as much to the Pereira Medal as to the Preliminary examination. It had also been pretty clearly shown that in some cases candidates had copied the answers of one another, either in the presence of the local secretary or when he was away. It was therefore extremely improper that examinations of such importance as those they were now considering should be conducted so loosely.

Mr. MACKAY seconded the resolution, simply because the examinations referred to were of such a scientific character, and because he knew that on some occasions and in some places there were very grave difficulties in the way of the local secretaries giving the time required for complete *surveillance* of the candidates whilst engaged in answering the questions. He was not, however, prepared to endorse the resolution which was to follow as to the Preliminary examinations.

Mr. WILLIAMS said it was important that this matter should be discussed with as much knowledge as possible, but at the same time he could not but bear in mind that no man had ever yet succeeded in obtaining the Bell Scholarship who was not thoroughly worthy of it He believed it was the same with regard to the Pereira Medal. He should like to know how many on an average competed for the Pereira Medal in the country and also for the Bell Scholarship.

Mr. SANDFORD said the latter had never been competed for in the country, but such competition might take place under the new regulations.

The SECRETARY stated that there were usually about five or six candidates altogether for the Pereira Medal.

Mr. SCHACHT said it was rather strange that the Board of Examiners, as was now stated, found insuperable difficulties in the way of carrying on satisfactorily that which never yet had occurred.

The SECRETARY said the difficulties had occurred with regard to the Pereira Medal and the prize of books, and it appeared the same thing would occur with the Bell Scholarship, the competition for which the Council had proposed should take place in the same manner.

Mr. BAYNES asked if there were any evidence showing that unfit men had obtained these honours.

The SECRETARY said the Board of Examiners had had ample evidence of the very unsatisfactory manner in which some of the Preliminary examinations had been conducted, and as regards the last examination for the prize of books and the Pereira Medal they considered that they had reason to be dissatisfied in some instances with some of the certificates.

Mr. WILLIAMS said it appeared the Council had adopted the suggestions respecting the Bell Scholarship on the recommendation of the Board of Examiners, and now before they had been tried the Board declared them to be impracticable.

Mr. URWICK thought if a failure took place they should have the grounds of it fairly placed before them. He thought all young men in the country should have the greatest facilities afforded them for competing for those prizes.

Mr. HAMPSON thought it would be very unwise in the Council to come to a hasty conclusion on this matter. The resolution contemplated a great change, and the Council had no evidence before it that the examinations had not been satisfactory. And even if there had been something not quite satisfactory in the examinations as conducted it did not necessarily follow that the entire system should be changed; it was quite possible to issue new and more stringent regulations, which would successfully remove every objection. He had the strongest feeling of opposition to this change on general grounds, because it showed what he considered an objectionable tendency to centralization. These examinations being carried on or supervised in the country had a general good effect upon the various places in which they were held, and he should be glad if the system could be extended; in fact if it could be done he should like to see a prize given to the best candidate in each county. If necessary, a committee might be appointed to thoroughly investigate the question, but he certainly hoped this great change would not be made without thorough and substantial reason.

Mr. SCHACHT entirely agreed in the position taken up by the last speaker, and he, as a country member, should feel that the whole of the country portion of the Society were unfairly treated if such a resolution were passed. Mr. Sandford very properly said that these prizes were amongst the highest honours the Society had to award, and because they were the highest honours he thought country associates and members should be as far as possible encouraged to compete for them. It was very convenient for Mr. Sandford to drop the last portion of his original notice of motion, but the whole thing being presented originally showed necessarily what it would lead to if they passed the first portion. He knew some members of the Board of Examiners were opposed to the Preliminary examinations being held in the provinces, as at present, but he, for one, thought it would be a very disastrous thing if they were discontinued. He felt sure that it would be the easiest thing in the world to obtain a whole cloud of supporters of the present system of Preliminary examinations, and very few less in opposition to the resolution now brought forward. At the same time he entirely agreed that they should do their best to make the supervision of the examinations complete and perfect, but he saw no difficulty in that being done. No doubt those local secretaries who were alleged to have failed in their duty had only to be informed as to what their duties really were, and a provision made by which, if unavoidably compelled to be absent, certain conditions should be

observed which would equally guarantee the correctness of the proceedings, and all irregularities would be removed. The same kind of thing was constantly going on with regard to the examinations under the Science and Art Department. He thought, therefore, the best plan would be to refer the matter for further consideration to the Board of Examiners and a committee.

Mr. BROWN said he did not know whether the resolution would not be negatived entirely, but otherwise it would be desirable to propose an amendment in the spirit of the suggestion just made. Every member of the Council would wish to pay the utmost respect to the Board of Examiners, but in order to act wisely and prevent hasty legislation, he thought further consideration should precede any resolution. It was quite possible there might be some grounds of complaint as to the manner in which the examinations were conducted in the country, but probably that arose, not from incompetency but from a little confusion and want of definite ideas as to the proper duties of the local secretaries. He looked with some jealousy on centralization, which no doubt might have its advantages, but the general distribution of examinations throughout the country excited a certain amount of emulation which was, in his opinion, very useful. He would therefore propose as an amendment—

"That the proposal to restrict the examination for the Jacob Bell Memorial Scholarship, the Pereira Medal and the prize of books to London and Edinburgh be referred to the General Purposes Committee, who shall meet a deputation from the Board of Examiners and discuss the question and report to the Council."

Mr. SHAW quite sympathized with the remarks of Mr. Schacht and Mr. Brown with regard to country members who were now in possession of certain privileges which it was not desirable to deprive them of. He should like to have heard more reasons given for making such a change, but if there were any defect in the present arrangements it would be competent for the committee or the Council to take them into consideration.

Mr. BAYNES said there might be cases where the local secretaries failed in their duties, but because such instances occurred it did not follow they must uproot the present system altogether. Why should they not amend the weak places? The subject had been discussed several times in his neighbourhood, and the general opinion seemed to be that there should always be two persons present, and he thought there would be no difficulty in getting a member of the Society to join the local secretary on such occasions. But if the matter were referred to a committee, they would no doubt devise a plan which would do away with existing objections.

Mr. RADLEY also supported the amendment. He thought there were several points in the instructions given to the local secretaries which might admit of amendment, and it was also a great pity that any one should be appointed to such an office contrary to his own wishes, or if he did not feel himself capable of properly discharging the duties. His notion was that these examinations might be held in certain districts, and not quite so much individualized, and he also suggested that a fee should be paid to the local secretary on each occasion, so that the Council might have a better ground for calling him to account in case of any irregularity.

Mr. SANDFORD said he could hardly be considered hasty in bringing forward this question, since it had been before the Council for two months, and the notice had been published in the JOURNAL. As to the centralization, to which Mr. Schacht objected, there was no organization in the country for carrying out the business of the Society, and in such a matter as examinations a clear, definite, well-defined system was required, which could hardly be the case whilst they simply depended on local secretaries, the great mass of whom were totally unknown to all the members of the Council. There might be one here and there who was known; but he should like to have the whole list of names read, and see how much the Council really knew of the great majority of them. As to their not having been informed of what was expected of them, each one was provided with a paper of instructions, giving very full particulars as to the rules to be observed. Even the payment of a guinea each would not prevent them being called off to attend to other engagements. No doubt the amendment would be carried, and probably in the result the question would be properly ventilated and examined, but he thought it would come more regularly if he declined to withdraw his motion.

Mr. BROWN said the amendment was not proposed in any spirit of hostility whatever.

On the question being put, the amendment was carried by a large majority.

Mr. SANDFORD said he thought, from what had been said, he had better withdraw the motion respecting the Preliminary examinations.

Mr. WILLIAMS suggested that that subject also should be referred to the committee, to discuss with the deputation from the Board of Examiners.

Mr. SANDFORD said he should be very glad if that could be done.

Mr. HAMPSON objected to this. He should oppose the resolution *in toto*.

Mr. BROWN thought this matter had better stand over for a time.

Mr. ATHERTON thought this was the most important part of the question, and would naturally form the chief topic of discussion with the deputation from the Board of Examiners.

After some further discussion, Mr. SANDFORD moved the resolution of which he had given notice, as follows, in order that an amendment might be proposed to it similar to that just carried:—

"That, after the 31st day of December, 1874, the system of conducting the Preliminary Examination by sending papers of questions, to be answered by candidates in the presence of local secretaries in different parts of Great Britain, shall be discontinued, and that persons applying to be registered as apprentices or students who cannot produce certificates of having passed the examination of some legally qualified examining body, approved by this Council, must appear before the Board of Examiners in London or Edinburgh for examination."

Mr. WILLIAMS seconded the resolution.

Mr. BETTY said they were all indebted to Mr. Sandford for the spirit which had actuated him in bringing forward this important matter, and for the courage with which he had proposed such a radical measure. The great point, in his mind, to be considered, was what really was the business of the pharmaceutical body, and the duties imposed upon them by the Act of 1868. If they were not an examining body, and had not a sacred trust confided to them by the legislature, what was their *raison d'être?* They had no right to existence, and if they did not watch the efficiency of their examinations, whether Preliminary or the subsequent ones, for what purpose did they exist? He would therefore propose an amendment:—

"That the question of the present system of conducting the Preliminary Examinations in the country be referred for consideration to the General Purposes Committee and the deputation from the Board of Examiners."

Mr. ATHERTON seconded the amendment.

Mr. SCHACHT asked what case had been made out for such a resolution. Not a single thing has been stated with reference to the manner in which the Preliminary examinations were conducted which could make it necessary to send any such matter for re-consideration at the hands of any one. His own experience in the matter, which was not very great, was very strongly in favour of continuing the present system, and in this he was supported by his neighbour, Mr. Stoddart, the local secretary for Bristol. Now and then no doubt they heard vague statements of mistakes having been made and irregulari-

ties occuring, but it was just possible, perhaps, that some mistake might occur even within those walls, but that would be no reason why the entire system should be broken up. The Board of Examiners had not memorialized the Council on this subject, although they had about the other matters, and he thought, therefore, it was quite premature to move in the matter. He should oppose both the amendment and the original motion.

Mr. FRAZER entirely sympathized with Mr. Schacht, feeling that no case had been made out. He should oppose the motion both because it involved a vote of censure on the local secretaries, and also because it would offer another barrier to the entrance of young men into the business. They were, in his opinion, getting too restrictive, and before long would find themselves involved in great difficulties. By high fees and high examinations they had cut off the present stream of druggists, many of whom were leaving the business to go into higher callings, and now they were stopping the springs and preventing young men entering. In this question there was involved a sort of feeling that the present examinations were not sufficient, but it must be remembered that the candidate who passed the Preliminary had no standing in the Society as a scientific body until he passed the Minor. They must have hands to conduct the commercial part of their business, and it would not do to place too many obstacles in the way. With regard to the efficiency of the local secretaries, and so on, it had been stated that some of the candidates assisted each other, but he did not attribute much importance to that, seeing they were all of the same class, and he did not think they would get much assistance from one another. He could not express how strongly he felt the absurdity of their pleading guilty in this manner even before they were accused.

Mr. HAMPSON expressed himself in perfect accord with the last two speakers, and thought trouble was being made where none really existed. They could not expect a perfect system, and he did not believe one existed even in Bloomsbury Square. Still if sufficient evidence were brought forward that there was a grievance, it would be their duty to inquire into it, but he did not think anything like evidence had been brought forward to justify the opening of this question at the present time. He knew some persons were in favour not only of doing away with the Preliminary examinations but the local secretaries themselves, and he feared this would be the first step in that direction, which he should consider a most fatal one.

Mr. BROWN could not see what cause had been shown for taking up this discussion. It was quite true, as had been said, that the Preliminary examination gave no status in the Society, and it would not be wise to throw any further impediment in the way of procuring apprentices. There was already a general complaint of difficulty in that respect, and although some made a great merit of not taking apprentices it would be a very unfortunate thing if that rule became general. If these Preliminary examinations were confined to London and Edinburgh it would be a great expense and inconvenience to parents and also to young men themselves. He hoped therefore that first of all the amendment would be negatived and that the original motion would then be disposed of in the same manner, so that the subject might be allowed to drop for the present at any rate.

Mr. WILLIAMS said there was no idea of making the examinations more stringent, but simply of having them properly superintended. Nor was it true that the Board of Examiners had not complained of the present system, for the Report before referred to by implication involved the inference that they were not satisfied with the fairness with which local examinations were conducted. It seemed to him a great pity to have one question referred to the committee and the deputation and not to allow them also to go into this other and more important question. He should therefore support the amendment, although he had econded the motion as a matter of form.

Mr. BETTY thought it would be a very strange thing if they negatived this amendment after carrying the previous one, seeing that the Preliminary examinations were conducted in precisely the same manner as the others ; the only difference being that in the one case they had perhaps five candidates and in the other something like five hundred. If it was worth the while of the Council to submit the question of the mode of conducting an examination affecting five individuals to a special committee, it certainly would be only right to consider how those same regulations affected five hundred.

Mr. SANDFORD thought the committee would not find it at all difficult to consider the two things together. It was not quite true that no reasons had been given for complaint, for the Secretary had in his possession ample reasons, which, however, he could not discuss there, though he should be quite ready and prepared to do so in committee. It had been said that irregularities might occur within that building, but it would be much more easy to correct them in a single house than in perhaps three hundred houses scattered all over the country. He hoped, therefore, the amendment would be passed.

On a division, the amendment was carried by a majority of one, the names being as follows :—

For : Messrs. Atherton, Betty, Mackay, Radley, Robbins, Shaw, Sandford, and Williams.

Against : Messrs. Baynes, Brown, Frazer, Hampson, Owen, Schacht, and Urwick.

The amendment was then put as a substantive motion and carried.

THE SOCIETY'S CALENDAR.

Mr. URWICK moved, in accordance with notice :—

"That Messrs. Churchill be invited to procure advertisements for the next Calendar of the Society."

He said the calendar was a heavy charge to the society, and it was thought the expense might in some measure be defrayed by advertisements.

Mr. BAYNES seconded the motion.

Mr. MACKAY said that it appeared the Glasgow University Calendar contained a goodly number of advertisements.

Mr. WILLIAMS thought it would be a disgrace to the Society to insert advertisements in the calendar; he would rather not publish it at all.

Mr. BROWN also strenuously opposed the motion, and in accordance with his suggestion, Mr. Urwick withdrew it.

Mr. WILLIAMS suggested that the new Calendar should not be issued until the amended bye-laws had been confirmed, which was agreed to.

PHARMACEUTICAL MEETING.

Wednesday Evening, October 1st.

The Opening Meeting of the Session 1873-4 was held at 17, Bloomsbury Square on Wednesday evening last. The chair was taken by the Vice-President of the Society, Mr. Alexander Bottle.

The CHAIRMAN expressed his regret at having to fill such a position, in consequence of the unavoidable absence of the President, through the death of an old, valued, and intimate friend—Sir E. Landseer.

The following list of donations to the Library and Museum was taken as read, and the thanks of the Society were voted to the donors :—

Des Aconits et de l'Aconitine : from M. Patrouillard,—On the Eucalypts of Australia, by C. Hofmann,—The Toilet of Flora (1784) ; Memoirs of the Botanick Garden at Chelsea (1820) : from Mr. W. Young,—Specimens of Nature-printed Ferns : from Mr. H. C. Baildon,—Report on the Caoutchouc of Commerce, with Memorandum by Dr. Brandis : from Mr. J. Collins,—Fortsetzung von L. Gmelin's Handbuch der Chemie (sundry parts) : from Professor Redwood,—A Monograph of Ebenaceæ : from W. P. Hiern, M.A.,—Eleventh Annual Report of the Birmingham Free Libraries' Committee,—Hygiène

Élémentaire ; La Matière Médicale chez les Chinois ; De l'Ostréiculture : from Dr. J. L. Soubeiran,—General Index to the American Journal of Pharmacy,—A Sketch of the Geology of the Neighbourhood of Banbury : from Mr. T. Beesley, F.C.S.,—Skin Diseases, an Inquiry into their Parasitic Origin and connection with Eye Affections, also the Fungoid or Germ Theory of Cholera : from Mr. J. Hogg,—Glasgow University Calendar, 1873-4,—Two MS. Prescriptions : from Mr. H. Whitfield,—History, etc., of the College of Pharmacy of New York : from Mr. P. W. Bedford.

Specimens of Cape Saffron ; Bush Tea ; a small kind of Buchu Leaves ; and Cape Aloes : from Mr. J. H. Leslie, of Cape Town,—Specimens of White and Black Mustard Flour ; The Husks of Mustard Seed ; and Fixed Oil of Mustard Seed : from Mr. Greenish,—Specimens of Indian Medicinal Plants for the Herbarium : from Mr. George Pugh,—A Mounted Specimen of Chondodendron Tomentosum, consisting of leaves, root, stem, and fruit ; a fine Specimen of the Fruit of the same Plant : from Mr. D. Hanbury,—Specimens of Persian Stick Opium : from Mr. D. Howard,—Specimens of Cinchona Barks, representing the commercial sales of this year : from Mr. J. E. Howard, —Specimens of Indian Sarsaparilla ; and of Gum, gathered in Ceylon from the Blue-Gum Tree : from Mr. A. P. Balkwill,— An abnormally developed Pear : from Mr. S. Steele, —An abnormally developed Cucumber : from Mr. Baijent.

Mr. D. Hanbury exhibited some large leaves of Chinese rhubarb, *Rheum officinale*, the plant, which had been recently brought to Europe, and cultivated, he believed, at Paris and also at Kew ; also specimens of the fruit of grains of Paradise (*Amomum Melagueta*) from the West Coast of Africa, but ripened in this country, he believed, for the first time.

Professor Redwood's Report upon the Chemistry and Pharmacy Class.

The Chairman then called upon Professor Redwood, as the Senior Professor, to present his Report with regard to the Chemistry and Pharmacy Class.

Professor Redwood said it was not a very unusual thing for those who were entering on a campaign to have to announce losses or reverses at the outset, and to purchase experience at the cost of failure, but in that Institution they were accustomed to meet from year to year and each time to commence a new campaign with the announcement of successes. They marshalled out their forces ready for a new encounter, and set before them those who had distinguished themselves in previous engagements. He thought it would be found on the present occasion that their successes had not been less signal than heretofore. They had good men to announce to them who were worthy of the honours about to be conferred upon them, and he had no doubt there were equally good men present who were ready to take their places in the school, and would be prepared to receive similar honours next year. His subject was a large and comprehensive one, and he had no doubt they would agree with him in thinking that taking the range of physics, even the comparatively small part of it comprised in their programme, together with practical pharmacy, and the wide range of inorganic and organic chemistry, it need not be considered any discredit to a student, if out of a large number of questions, embracing different parts of these subjects, he should fail to furnish answers so generally correct that they should contain from 60 to 80 per cent. of matter to which exception could not be taken. The ladder by which their prizes were reached consisted of 100 steps ; at the top was perfection, at the 80th step was the highest prize, and at the 60th step the lowest. Those who attained to these elevations must manifest a large amount of knowledge, and it might truly be said, "All honour to the prizemen." But it must be admitted that there was a certain amount of luck in success. There was no man living who could answer any question that might be put to him on such a subject as chemistry. Much, therefore, of the success on these occasions must depend upon the extent to which the questions propounded happened to accord with the strong points of the student. He who succeeded must be a good man, but he who failed did not thereby necessarily indicate any discreditable want of knowledge.

The student who had obtained the highest prize in his class was undoubtedly one of the best they had ever had, and would do honour to pharmacy if it offered sufficient inducements to him to continue to apply his energies in that direction. Of the others he could say from his personal knowledge of them—and in making the award he knew not who the men were whose answers he was valuing—but knowing them now he could say that their position at the examination very inadequately represented their merits, which might be attributed partly, perhaps, to the fact that they had not the choosing of the questions, and that he had happened to choose the wrong ones for them.

Mr. Sydney Plowman, the first prizeman, had obtained 87 marks out of 100; the next, Mr. Cleaver, having only 73 marks, had not quite, but very nearly, obtained the bronze medal, and he therefore only had a certificate. Mr. Bascombe, who stood third, was also in a similar position ; but they were all good men and deserved all and more than all they obtained.

Chemistry and Pharmacy.

Hours—Ten till One and Two till Five. Standard Number of Marks, 100.

1. What are the qualities required in a good balance, and upon what points in the construction of the balance do those qualities depend ?

2. When was the metrical system of weights and measures introduced ? What was the natural object referred to as the basis of that system ? What is the measure derived from that object called ? What relation does the *litre* bear to that first measure ? What relation does the gramme bear to it ? Does the natural object referred to afford a reliable means of testing the correctness of the measures used in this system ?

3. When was the modern British system of weights and measures first established by Act of Parliament ? What was the object referred to as the basis of that system ? What is the measure derived from that object called ? What relation does the grain bear to that first definite measure ? What relation do the ounce, the pound, the pint, and gallon bear to the grain ?

4. What is the theorem of Archimedes relating to the effect of immersing a solid body in a liquid, and how would you prove it to be true ?

5. What is the composition of the mineral called Iceland Spar ? What is its crystaline form ? What effect does it produce on a ray of light when the ray passes through it in the direction of its optic axis, and also when it passes through two parallel faces of the crystal ?

6. What is a Nicol's prism, and for what purpose is it used ?

7. Explain the dynamical theory of heat, and what is meant by the mechanical equivalent of heat.

8. What is the highest temperature to which a liquid or an extract can be heated in the process of evaporation in a water-bath, and also in a steam-bath, as described in the Pharmacopœia ? Is there any difference in the amount of

heat expended in the vaporization of a pound of water evaporated by boiling with free exposure to the air as compared with its evaporation *in vacuo?*

9. From what source is phosphorus obtained? How is it manufactured? What are its characteristic properties? How is ordinary phosphorus converted into the red amorphous condition? Describe the production of phosphoric acid, with any remarks you may have to make on the process.

10. What is the substance used in medicine under the name of hypochlorite of sulphur? Describe its physical characters and composition.

11. How is hydrofluosilicic acid obtained? What is its composition?

12. What are the principal natural sources of potash? Describe the production of carbonate of potash from these sources, and state what are the most probable impurities of the products so obtained. Describe the production of *liquor potassæ*, with any remarks you may have to make on the process.

13. Describe and comment upon the process of the Pharmacopœia for the production of tartarated antimony, and give its composition.

14. Describe the compound ammonias, and show the relation they are supposed to bear to the natural alkaloids.

Report of Professor Bentley on the Botany and Materia Medica Class.

The Chairman then called upon Professor Bentley to state the results of the examination in the Botany and Materia Medica Class.

Professor Bentley said most persons were accustomed at that season of the year to take what was called recreation, and he had recently spent seven weeks in the country with that object, though, as he had only enjoyed about five fine days during the whole period, and had been at work about nine hours a day, many persons perhaps would think he had not been very fortunate in his pursuit of pleasure. However that might be, he always considered it a recreation in the truest sense to attend in Bloomsbury Square on such occasions as the present to meet a number of new friends as well as old ones. He would not repeat a tale, not thrice told, but twenty-three times told, in making his report as to the class of Botany and Materia Medica, but would say nothing more than that which he always had to say—the class had been everything he could desire. This year also he could speak with particular satisfaction, because he had taken especial means to estimate the diligence of the class by instituting weekly examinations throughout the whole Winter Session, so that he was not only able to speak of the regularity of attendance, but of the attention with which the students listened to the lectures, and of the progress which they had made. With regard to the prize examination, he could cordially agree with his esteemed colleague, Professor Redwood, as to the great merit of the answers given. No honours had ever been awarded in connection with these classes which had not been thoroughly deserved, for four-fifths of the total marks were required in order to entitle a candidate to the silver medal, three-fourths for a bronze medal or certificate of honour, and three-fifths to a certificate of merit. This examination being *vivâ voce* as well as written, he had to give an additional number of marks, and the whole number therefore was 125. Out of that number Mr. Plowman obtained 115, and he therefore thoroughly endorsed what had already been said, that that gentleman would do honour to any profession, though he hoped he would never leave pharmacy. He could also speak of the other prize students in the highest terms. Mr. Cleaver, who had obtained the bronze medal, was worthy of high honour, and the same might be said of Mr. Bascombe, who had been awarded a certificate of honour. Those gentlemen who had obtained certificates of merit, Messrs. Luff, Greenish, and Compton, were somewhat younger; he was perfectly satisfied with the progress they had made, and he had no doubt that on some future occasion they would obtain still higher honours.

Materia Medica and Botany.

Botany.

Hours from Ten till One.

1. What are the substances contained in young cells? Describe the general structure, size, and form of *starch granules*, and show how Maranta starch or West Indian arrow-root may be distinguished from sago meal and potato starch.

2. What are the distinctive characters between roots and stems? Define the following:—Rhizome, bulb, corm, tuber, tubercule, epiphyte, parasite, and spongiole.

3. What do you understand by determinate, indeterminate, and mixed inflorescences? Define a spike, locusta, spadix, umbel, capitulum, amentum, raceme, panicle, cyme, and verticillaster.

4. What is the fruit? How would you distinguish small fruits from seeds?

5. Give the essential characters of the following natural orders, and enumerate the official plants which they respectively contain: Papaveraceæ, Rutaceæ, Convolvulaceæ, Polygonaceæ, Iridaceæ, and Melanthaceæ.

Materia Medica.

Hours from Two till Five.

1. What are the distinctive characters of aconite and horseradish roots? Give the botanical names of the plants which yield them, the natural orders to which they respectively belong, and state their properties, active constituents, and official preparations.

2. What are the botanical and geographical sources of pareira root? Describe its general and chemical characters, its properties and uses, and enumerate its official preparations.

3. What are the botanical and geographical sources of copaiba? Describe how it is obtained, its general and chemical characters; mention the substances which have been substituted for or employed as its adulterants, and the means by which they may be detected.

4. What is saffron? and what are its botanical and geographical sources? Describe the manner in which it is obtained and prepared for use, its general characters, the substances used to adulterate it, and the means of detecting such adulterations.

5. What is ergot? Describe its development, general characters, properties and uses; and enumerate its official preparations and their doses.

Professor Attfield's Report on the Practical Chemistry Class.

The Chairman then called upon Professor Attfield for his report in reference to the class of Practical Pharmacy.

Professor Attfield, in presenting his report, said, that during the past session ninety-nine students of practical chemistry had worked in the laboratories: twenty for the whole session of ten months, about the same number for five months, the others attending for shorter periods. With very few exceptions, these students worked with a genuine desire to obtain lasting knowledge, and not merely for ephemeral information, such as would enable them to pass the Minor examination. As might be expected of such pupils, their attention was well sustained throughout the session, and their conduct was, in a word, that of

gentlemen. At the end of July some twenty-three or twenty-four remained in the laboratories, of whom fourteen decided to enter for the prizes. Two retired as soon as they saw the list of questions, two more at the end of the first of the two days' examination, and the other ten competed. Three obtained less than sixty marks, and were therefore out of the running altogether; and of the seven remaining, eighty-six marks were obtained by the gentleman whose name had been already thrice heard, Mr. Sydney Plowman. Seventy-nine marks were obtained by Mr. Frederick Bascombe, seventy-seven by Mr. Blake, seventy-six by Mr. Fletcher, and the same number by Mr. Thomas E. Greenish; sixty-eight by Mr. Rimmington, and sixty-seven by Mr. Wood. In accordance with the rules made with regard to the distribution of prizes, the Council had awarded the silver medal to Mr. Plowman, the bronze to Mr. Bascombe, certificates of honour to Messrs. Blake, Fletcher, and Greenish, and of merit to Messrs. Rimmington and Wood.

Practical Chemistry.

Hours—Ten to Five. Books and Memoranda permitted.
Standard Number of Marks, 100.

1. Some "mineral water" is placed before you. Ascertain the nature of the salts it contains.
2. Report on the purity of samples of the following preparations:—

Powdered Tartaric Acid.
Powdered Borax.
Phosphate of Iron.
Calomel.
Sulphate of Zinc.
Carbonate of Sodium.

3. How much nitrate of silver is present in one fluid ounce of "the lotion?"
4. Make a complete qualitative and quantitative analysis of the "scale" compound supplied to you.

Note.—Manipulation as well as results will be scrutinized.

The Herbarium Prize.

Professor Bentley, being called upon to give in his report with regard to the Herbarium competition, said he regretted that so few collections had been sent in; at the same time, he was by no means discouraged, because it involved a great deal of labour to make such a collection, and many young men had very limited time at their disposal. He did hope, however, that on future occasions he might have to report that more collections were submitted; but he feared it sometimes happened that many persons heard that a fine collection was coming in just as it was whispered about that a good man was going to compete for a prize, and, as a consequence, many who were admirably qualified to compete, with a little faint-heartedness gave in. His advice to students always was, whenever they had honestly worked, whether in the class-room or in any other way, to try for all the distinctions open to them, and in the long run they would not be disappointed in this, at any rate, that if they did not get the prizes they would get substantial reward in other ways. He had to speak of two apprentices—one, Mr. Bibbings, who sent in a very good collection, comprising 430 plants, and to whom, on his recommendation, the Council had awarded the silver medal. Those who knew the difficulty of collecting plants, drying, preserving, and naming them, and considered that this was done by a young apprentice in the hours he took from recreation, would agree that great credit was due for such a performance. A certificate of honour had also been awarded to Mr. Conrad William Wright for a very creditable collection of plants, and he also well deserved the distinction awarded to him. He hoped that these young men would be induced to prosecute still further the science which they had begun so favourably.

The Vice-President then proceeded to distribute the various prizes to the successful candidates, remarking on the satisfaction which the Council felt in having at the top of the list one of the Bell Scholars. Mr. Sydney Plowman, he said, held out a bright example to young men who were about commencing their studies, since he had competed for the Bell Scholarship with very little assistance except his own persevering industry; and with regard to the other competitors, if they had failed to obtain the highest honours, perhaps because they had such a strong competitor to grapple with, they would carry away from that institution such groundwork of scientific knowledge as would enable them to show to the world that Bloomsbury Square could send out lights from its interior, as well as put in plate-glass windows in the front.

The Pereira Medal.

The Chairman then said that the highest honour the Society could confer—the Pereira Medal—had been awarded to Mr. Sydney Plowman, and he had great pleasure in handing it to him in the name of the Council.

The following were the questions for this examination:—

The Pereira Medal.

chemistry.

Time allowed—Three Hours.

1. Describe the best processes for eliminating the alkaloids of opium. State the physical and chemical properties of the more important of these alkaloids, and mention some of the compounds obtained from them by decomposition.
2. A powder presented for analysis is found to contain chloride, bromide, and iodide of potassium. State minutely the processes which you would adopt for determining the percentage of each constituent.
3. Explain the meaning of the terms isomorphous, isomerous, and homologous, and give a few examples in illustration of your answer.
4. An acid solution contains antimony, arsenic, and tin. How would you separate and identify each?

botany.

Time allowed—Three Hours.

1. Name and describe with examples the different kinds of fruits met with in the natural order Rosaceæ.
2. Explain the terms decussate, distichous, and fascicled as applied to the arrangement of leaves.
3. Describe the arrangement of the parts of the flower in an orchis, selecting an example.

materia medica.

4. Whence comes the eucalyptus recently employed in pharmacy? What is the natural order to which the plant belongs? Mention the species and the products used, and give any particulars you may know respecting them.
5. What plants produce the varieties of ipecacuanha? and what other plants produce roots having more or less similar properties? State the physical characters by which they are respectively distinguished.
6. Define manna. What are its botanical and geographical sources? and what are its constituents and properties?

The Prize of Books.

The Chairman said that the Prize of Books com-

peted for by those who had passed the Minor examination in honours during the year had been awarded to Mr. Walter Tearle.

The following were the questions for this examination :—

PRIZE OF BOOKS.

Time allowed—Two Hours.

State the best method of dispensing the following prescriptions, assign the reasons for the same, and write the labels in suitable language :—

℞ Bals. Copaibæ ℥iij.
Pulv. Acaciæ,
Pulv. Sacchar. āā. ℥iij.
Liq. Potassæ ℥j.
Tinct. Opii ℥iss.
Aqu. Cinnam. ad ℥iv.
M. ft. Mist.

Cuj. cap. coch.j med. ter die, dos. sensim augend. prout caput aut ventric. ferre queat.

℞ Ferri Iodid. gr. xij.
Quinæ Disulph. gr. xxiv.
Ext. Taraxaci q. s. (state quantity).
M. ft. pil. xxiv. capt.j ter die inter sing. dos. mistur.

State the specific gravity of æther purus B. P. and the process for purifying æther.

Describe and explain the B. P. process for making quiniæ sulphas.

State the B. P. process for making tinct. lobeliæ ætherea.

Enumerate the preparations of the Pharmacopœia which contain magnesia and its compounds, and state the strength of them.

THE JACOB BELL MEMORIAL SCHOLARSHIPS.

The CHAIRMAN announced that the Senior Bell Scholarship for the ensuing year had been awarded to Mr. Sydney Plowman, and the Junior to Mr. E. J. H. Thring.

The questions for these examinations were as follows :—

SENIOR BELL SCHOLARSHIP.

Time allowed—Three Hours.

LATIN.

1. Parse—In his rebus circiter dies decem consumit, ne nocturnis quidem temporibus ad laborem militum intermissis.

2. Translate into English—Subductis navibus castrisque egregie munitis easdem copias quas ante præsidio navibus reliquit : ipse eodem unde redierat proficiscitur.

ARITHMETIC.

3. Subtract $\frac{3}{8}$ of a crown from 1·59375.

4. Find the value of $\frac{5}{16}$ of a cwt. ; $\frac{3}{4}$ of a lb. avoirdupois ; $\frac{4}{5}$ of a mile.

5. Find the square root of $\frac{1000 \cdot 10001}{1000}$, and the cube root of ·03.

ENGLISH.

6. State your views as to the correctness or otherwise of the following :—The Queen, our ruler and governor. Mary Edwards is the author of this book.

7. Write some remarks on the advantages of the study of the exact sciences.

CHEMISTRY.

Time allowed—One Hour.

1. A solution contains zinc, alumina, and manganese. How may the presence of each be proved ?

2. How may pure methyl alcohol be prepared ? Explain the action of strong sulphuric acid upon it.

3. When a beam of light undergoes refraction by a prism, you obtain a coloured image which is termed the prismatic spectrum. Describe the spectrum and explain what peculiarity is observed in the spectra of coloured flames.

BOTANY.

Time allowed—One Hour.

1. What is the commercial nutmeg ? Describe and name the coverings that envelop it in its natural state.

2. Give the distinguishing characters of the natural orders—*Labiatæ*, *Scrophulariaceæ*, and *Boraginaccæ*.

3. Name and give the meanings of the terms which are applied to describe the margins of leaves.

4. What is the difference between a rhizome and a soboles ? Give an example of each.

MATERIA MEDICA.

Time allowed—One Hour.

1. What is *Ergota B. P.* ? Describe it. What is the pharmacopœial test for its powder, and what does this test indicate the presence of ?

2. From what sources can beberine and berberine be prepared ?

3. Describe cochineal and its adulterations,

4. What are the botanical and geographical sources of the official and commercial kinos, and how would you distinguish them ?

JUNIOR BELL SCHOLARSHIP.

Time allowed—Three Hours.

LATIN.

1. Translate into English—Perfacile factu esse illis probat conata perficere, propterea quod ipse suæ civitatis imperium obtenturus esset : non esse dubium quin totius Galliae plurimum Helvetii possent : se suis copiis suoque exercitu illis regna conciliaturum confirmat. Hac oratione adducti inter se fidem et jusjurandum dant, et regno occupato per tres potentissimos ac firmissimos populos totius Galliae sese potiri posse sperat.

2. Parse the last twelve words of the preceding paragraph.

ARITHMETIC.

3. Multiply $\frac{8}{9}$, $\frac{16}{24}$, $\frac{27}{30}$, $\frac{45}{60}$ together.

4. Divide 31·5 by ·126 and 5·2 by ·32, and prove the correctness of each result by fractions.

5. The value of the paper required for papering a room, supposing it $\frac{3}{4}$ of a yard wide, and $4\frac{1}{2}d$. a yard, is £2 3*s*. $1\frac{1}{2}d$. ; what would it come to, if it were 2 feet wide and 4*d*. a yard ?

ENGLISH.

6. Write a few remarks upon the value or otherwise of competitive examinations.

CHEMISTRY.

Time allowed—One Hour.

1. Give the proportions of the principal constituents of the atmosphere, and explain the more important part they play in the economy of nature.

2. Explain what is meant when we say that chlorine is a monad, oxygen a dyad, nitrogen a triad, and carbon a tetrad.

3. What is the action of strong sulphuric acid on nitrate of potassium, and dilute sulphuric acid on ferrocyanide of potassium, when heat is applied ?

BOTANY.

Time allowed—One Hour.

1. Into what sub-classes is the class *Dicotyledones* divided, and what are the distinctive characters of each ?

2. Describe the leaves of *Digitalis purpurea*, *Verbascum thapsus*, *Uva-ursi*, and *Buxus semperrirens*.

3. Give the botanical names and the natural orders to which the following plants belong—black hellebore, white hellebore, common celandine, lesser celandine, common speedwell, woodruff, black bryony and white bryony.

MATERIA MEDICA.

Time allowed—One Hour.

1. What are the botanical and geographical sources of the following drugs ? Name the parts of the plants used

in medicine, and state how those that are not natural products are manufactured :

Guarana,
Camboge,
Cotton Wool,
Cowhage.
Huile de Cade,

2. What is the official process for making *Infusum Calumbæ?* Why is it so prepared, and how can it be improved?

3. Describe the decomposition which takes place in the manufacture of volatile oil of mustard.

The Inaugural Sessional Address.

The following Address to the Students about to commence their studies in the School of Pharmacy was then delivered by Mr. George Webb Sandford :—

Mr. President, Ladies, and Gentlemen,—

My colleagues in the Council of the Pharmaceutical Society at all times extend to me great indulgence and great favour—great indulgence in bearing with my many shortcomings ; great favour in thrusting honour upon me—sometimes honour which in my judgment should be given to others, especially when it involves a duty to be performed which would be better performed by others than by me.

During my long connection with the Council I have seldom had a higher honour conferred on me than in being entrusted to give a few words of welcome to the students who are this day entering on the course of technical instruction provided in this Institution by the Pharmaceutical Society.

Under protest I have accepted the trust, but I shall need the same indulgence from this meeting which I have told you I so uniformly receive in the Council, for the remarks I am about to offer will neither be made interesting by examples of the wonders of science, nor adorned by flashes of wisdom crystallized in the poetic language of gifted men.

It is my purpose rather in a very plain way to speak to the young students of the necessity of embracing the opportunities now within their reach of acquiring such knowledge as will enable them in after life to stand side by side with men of science—opportunities of mental culture which must assuredly give them a better position among their fellow men.

There is perhaps one circumstance connected with the opening session which seems to make it appropriate that an old member of Council should address you this evening, and I am therefore the more reconciled to taking on myself the duty.

The circumstance to which I allude is this epoch in our history when the Pharmaceutical Society ceases to have a *pecuniary* interest in the education of rising pharmacists.

To me this is an especially interesting circumstance. Some of you may remember that when my friend Mackay delivered his admirable address at the opening of the session, in 1871, he startled his audience by anticipating this change ; but though I had long contemplated this, and spoken of it as the right and proper course for the Society to take, I was was not sanguine enough to expect to see it accomplished so soon.

I describe this change as exclusively the relinquishment by the Society of *pecuniary* interest in education, I mean pecuniary benefit therefrom, and I cannot too strongly guard all who may feel anxiety on the subject against supposing for a moment that the change implies the relinquishment of any other interest.

I feel it the more necessary to do this, because I am sorry to find an adverse opinion has recently been expressed by one whose judgment deserves all consideration. The Ex-President of the Pharmaceutical Conference prognosticates that "*the recent change can only promote that dull, low mediocrity which above all things it should be our aim to avoid*" ; that instead of stimulating "*extra-academical teaching*," we shall put it beyond the power of others to compete with professors, who will be subsidized free tenants of the Society's premises. I must confess that the advantages given to our professors are at the outset diminished rather than increased, and as to the effect of their possessing any advantage over other teachers, it is but reasonable to suppose that circumstance would necessarily compel greater exertion on the part of "*extra-academical*" teachers to make their schools efficient and attractive.

Thirty years ago, when education was declared by the founders of this Society to be the only true foundation on which we could depend, no means of diffusing that education existed, save in the establishments of a few honourable exceptions to the then dark condition of British pharmacists. Apprentices were taken professedly for instruction "*in the arts and mysteries*" of the trade, but, practically, chemistry as a science, or even chemistry as applied to pharmacy, was never taught.

The education of a chemist and druggist was then virtually five years' apprenticeship in the country and three or four years' employment as an assistant in London.

I look back to this as my own experience, for I had become a member of the Pharmaceutical Society, being in business and fully occupied, before the School of Pharmacy existed. I look back and contrast my opportunities with those of the young friends whom it is my privilege to welcome here this evening.

To supply the deficiency then existing, the Society wisely employed the funds at its disposal to establish a public school, at which a knowledge of chemistry, pharmacy, botany, and materia medica might be acquired.

Education was not compulsory, and at the first awakening it could scarcely be expected that private teachers would risk their time and money to found schools at which it might be acquired. So the Society stepped in ; first, with lectures by the best men of the day—Pereira, Tod Thompson, and Fownes—to which students were admitted at an almost nominal fee, and afterwards with the School of Practical Chemistry.

A good criterion of the success of such an institution is to be found in the position taken by its pupils in after-life, and I am proud to look through the list of honourable men who have since issued from this school imbued with a love of science, advancing the credit of pharmacy throughout the length and breadth of the land, promoting the desire for, and carrying the means of education to all quarters of Great Britain—men who shine forth as bright examples to the youth of the present day, the brighter because education which is now compulsory was with them but voluntary.

Circumstances are altered now. The public expect to find intelligence in those to whom they entrust

matters affecting their health, nay even their lives; and the Legislature in a protecting spirit says,

"*It is expedient for the safety of the public that persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists, should possess a competent practical knowledge, of their business, and to that end . . . . . should, before commencing such business, be duly examined as to their practical knowledge, etc., etc., etc.*"

There is a homely old saying that one man may take a horse to the water but a hundred cannot make him drink, and so it might have been said, prior to the passing of the Act of 1868, as to the acquisition of pharmaceutical knowledge. Not that the Society had any reason to complain of want of progress, even under the voluntary system; it was sufficient to provide for, promote, and ultimately obtain such compulsory enactments as now *compel* all to drink at the fountain of knowledge. I may perhaps be told that the compulsion does not go far enough; that it compels only the acquirement of as much knowledge as will enable a candidate to pass a short ordeal in the examiners' room. This may indeed to some extent be true. But where is the remedy, or rather where the supplementary force which is really and truly to advance pharmacy, and consequently pharmacists, to a proper position in this country?

That remedy has been pointed out by those good men whom I have mentioned, and now it lies with you young gentlemen who are entering this establishment to perfect the knowledge which I hope you commenced storing during your term of apprenticeship; when I say "*perfect*" your knowledge, I use that expression in a very limited sense, for I am sure the oldest and most accomplished pharmacist in this room will agree with me that in science a man's knowledge is never *perfect*, the earnest pursuit of it leads us on, *entices* us on, and convinces us day by day that we have yet more to learn.

It is said, "*Poets are born, not made;*" but it is not so of chemists. Careful reading, honest work, many failures must be the training of the successful student: the very failures are of infinite service if we seek for the "why and the wherefore" of those disappointments. The non-attainment of an expected result may sometimes lead to a most interesting discovery, and to an observant mind will be no discouragement though it may for the time perplex. In tracing the cause of present failure future success is rendered more certain and more gratifying.

I remember listening to the eloquent address given to the students in this room by my accomplished friend Mr. Brady, to whom I have already had occasion to allude, but less in accord than I now do, an address which was calculated to make all other men fearful in venturing on the task he so well performed on that evening, and if all the noble sentiments uttered by him were forgotten—which God forbid they should be—save one word, that word, that golden word,—"thorough"—would be worthy to be the motto both of students and teachers. Taking that as a motto none would rest content with that surface polishing of which we have heard so much of late under the designation of "cram,"—that little superficial teaching which may possibly carry a man through his examination, but which can never properly qualify him for the high and onerous duties he is about to undertake.

I told you, gentlemen, that the Society relinquished but one interest in this school in making the recent change; and I may tell you with equal confidence that their full determination is that the education imparted in it shall be *thorough*.

The known, and often published, opinion of our Professors on this point should at once be an assurance of this.

I even fear their continued assertion that they do not undertake to "*prepare* students for the examination," may be taken too literally and deter some young men from becoming their pupils, because undoubtedly it must be a great object with all who enter our business to be able to pass the examination.

I admire the honesty of the Professors who make this bold disclaimer, but I conceive it is not literally true. I venture, on the contrary, to assert that they do prepare candidates for the examination in the best possible way. What they really mean is that they do not help a candidate to *cheat* the examiners. In the School of Practical Chemistry, for example, I have heard of students—no, I will not so misapply the word *student*—but I have heard of young men endeavouring to select for themselves from the curriculum arranged by Professor Attfield, subjects on which they thought it most likely they would be examined. If they had previously mastered the elementary part of the course such a selection might be well enough, but what I understand the Professor to mean when he says he does *not prepare candidates for examination*, is simply that he does not consent to any such alteration of his curriculum unless he is fully satisfied that the applicant has mastered the rudiments, and for myself, as a member of Council, I may say that if I had thought otherwise the vote which I gave so heartily for his appointment would have been unhesitatingly withheld!

That you must pass the Minor examination is a great truth patent to all you who are now entering on this special part of your education; this which I may call the public part of your training.

That examination is the gate which will admit you, and without passing which you cannot be admitted to the roll of qualified practitioners of pharmacy. But remember I pray you that to get through the first gate should not be the *ultimate* object of your exertions; having succeeded in passing it you will indeed be safe so far as having secured the right to assume the title and practise the trade of a "chemist and druggist," but I trust there is not one whom I am now addressing who will rest content without passing the second gate, or Major examination, and obtaining for himself the diploma of a "pharmaceutical chemist."

I think I hear some one saying, "*What good? I only want the right to carry on my business.*"

The man who only wants that right is, I fear, one who would be content to be sufficiently "*coached*" up to cheat the examiners into the belief that he was a qualified man. He forgets that, as I said just now, the public expect to find intelligence in those who dispense their medicines. There is in store for him a *continual examination*, by his customers, the failing to pass which would be as humiliating as the failure to pass his examination in this house.

It cannot for one moment be disputed that year by year the public are becoming better acquainted with the relative value of the two titles. "Pharmaceutical Chemist," and "Chemist and Druggist."

This fact was very forcibly brought home to me on

one occasion when I was working hard to promote the passing of the Pharmacy Act. You know, of course, that it was deemed necessary to enfranchise these two classes which I have mentioned. Our trade is unfortunately but a small one, and there are many localities in which the population is so scanty, or the general health so good, that no great demand for physic rewards the chemist of the district.

I was calling on a Member of Parliament one morning and endeavouring to enlist his sympathy in our cause, when in reading the copy of the Bill I had put into his hand, he suddenly said :—

"*But what does this mean, I see you have two grades; two examinations!*" And when I told him why it had been deemed only just and necessary to make such a provision, he said, "*Oh, I entirely agree with you as to the necessity of enforcing education, but I don't like these two grades; I suppose you think London and large towns must have Pharmaceutical Chemists, and Chemists and Druggists will be good enough for the little places. I think our lives in the Country are as valuable as yours in London!*"

Although I might be able to convince my friend that the "Minor examination" would be such as would ensure sufficient technical knowledge in the man who passed it to make him a safe dispenser, I left him imbued with the idea that all dispensers should be Pharmaceutical Chemists. I give you this anecdote just to show the tendency of public opinion, and not to depreciate Chemists and Druggists, of whom we have doubtless many excellent specimens.

I might surely in urging you to the more extended prosecution of study, depend very much on the greater interest which it must give you in the every day occupation of your future lives. It is not given to all men to astonish the world by brilliant discoveries, but short of that, it must be admitted that the daily avocations of a Pharmaceutical Chemist afford a rich field for intelligent observation, a great opportunity for usefulness to our fellow-men. You cannot think too highly of this latter fact.

In entering the profession on which you are now starting you have before you a high and honourable occupation, in which it will be yours to administer to the necessities of mankind in a most important particular.

A dispenser of medicine is a member of the noble medical profession. Always remember, I pray you, that although members of that profession you must not account yourselves qualified to assume the position or to exercise the duties of its higher branches, or you will cease to acquit yourselves honourably in your department.

In the army there are generals, field-officers, captains, and subalterns, each with their appointed duties, and the success of a campaign depends on the concerted action of the different grades. So in the medical profession. It is for the physician to prescribe and the dispenser to obey his instructions. According to my judgment, the moment the dispenser attempts to reverse this order of things, and to usurp the province of the physician, he gets into mischief; he assumes a duty for which he is not qualified, to his own disgrace, to the public disadvantage, and manifestly to the disadvantage of his class. Nothing can be more certain than that it is of the utmost importance that the prescriber should have perfect confidence in the dispenser, that there should be a mutual good understanding between them, and it is to me equally certain that this confidence and this good understanding must be destroyed if the dispenser be not a man of intelligence, an honourable worker in his department, and careful not to outrage the discipline of the profession.

Possibly some of my older friends here may say, "*Why dwell so much on professional ethics, or rather, why lead these young students to imagine that they are entering a profession? — Chemists, after all, are but tradesmen!*" This may, perhaps, be said by some who in their vocation have achieved for themselves a better claim to be regarded as professional men than the generality of their brethren. I am not quite sure that our worthy President will not move a vote of censure on me for misleading rather than guiding the students of the session.

My young friends, I would by no means mislead you. Ours is indeed a trade, and if you lose sight of that fact, or try to obliterate it from your minds you will commit a grievous error. It happens that the occupation of a chemist has both a professional and a trading character, and while, on the one hand, we must endeavour to acquire such an amount of special education as will fit us for the more elevated part of our duties, we must, on the other, avoid being thrown off our balance by any false notion of dignity.

I was struck the other day by the remark of a man who had recently lowered himself, according to the judgment of some of his associates by the purchase of, and most devoted attention to, a retail trade. He said, "*I do not look to my occupation for dignity, I take my dignity to my occupation.*" And so you should carry to the counter that sound technical knowledge which you are about, I hope, to acquire here, applying it earnestly to the wants and welfare of your customers, and adding thereby dignity to the trade on which you have entered.

There is in trade itself nothing which is beneath the dignity of an educated man—nay! there is in our trade especially great scope for winning regard and esteem; it is only in descending to that which is dishonourable that a man becomes dishonoured. I know it is the belief of some that when you educate a man beyond a certain point you give him aspirations which cannot be satisfied in trading pursuits; that mental culture and manual labour do not associate. If that be true, it becomes a very serious question to whom we shall in future look for labour, now that mental culture for all is the universal cry.

The labour falling to our lot is skilled labour. Give an uneducated man a prescription to dispense in which the ingredients require to be put together in a certain order, and the mixture will probably be sent to the patient with masses of resin adhering to the sides of the bottle, or a powerful alkaloid precipitated. Let the same mixture be prepared by one who understands his business, and the result will be entirely different. The *unmixed mixture* might in some instances fail in doing the work desired by the prescriber, and in some even do mischief; but in any case such variations in the appearance of medicine destroy the confidence of your customers, militate against your individual success, and bring discredit on pharmacists as a class.

Gentlemen, I need say nothing to you who have to live by your trade of the mischief thus falling on you individually, but I should like to impress on you the high moral obligation of sustaining the credit of your order.

The better qualified you are by education to fulfil your duties, whether you call them professional or

trade duties, the more completely will you do this. The higher your capabilities, the more will that spirit of jealousy, which in years gone by kept "two of a trade" apart, disappear; the more knowledge you possess, the more anxious you will be to make that knowledge the common property of your class.

This has, I think, been proved by the gatherings of the Pharmaceutical Conference. Associating with your fellow students in the laboratory, the angles which are apt to protrude in isolated shops will wear down, and it will be to you not only a school of chemistry, but also a refining and elevating society. I have been naturally brought much in contact with the Professors, and it has been no small pleasure to me to hear them speak of their classes; of the marked intelligence and gentlemanly feeling pervading their pupils; you have heard pretty much the same from them this evening, but less in detail than it has reached me. I rejoice greatly in this, because although one has undoubted pride in pointing to brilliant examples, perhaps the greater and more abiding pleasure springs from a contemplation of the *general* advancement of the class to which we belong.

Various circumstances may have helped us on in this matter; there has indeed been progress in society generally, but I cannot help attributing our special improvement very much to the fact that of late years uneducated youths have been kept out of our business by the necessity of passing the Preliminary examination at the outset. I hope, even in my time, to see the day when no master will sign articles with an apprentice until he has given such evidence of early training.

This is indeed a matter of much greater importance than you may think. Once launched in the business as an apprentice, a youth has a duty to his master which must be performed, and if not well performed, the master's duty to his apprentice—*which I would most emphatically affirm to be no less binding*—will be the less likely to be liberally carried out. Thus the time at an apprentice's disposal for study, even under the most favourable circumstances must have a limit and will scarcely more than suffice for necessary technical study.

How then will he fare if during his term of pupilage he has to prepare for his Preliminary examination? He will be like the man who has to carry through life a dead weight of debt, always pressing him down, always debarring him from seizing opportunities at the right time.

But this is not all; good school training prepares the mind to receive impressions, to discriminate between them, and to utilize the information presented to it. The lad whose mind has not been so cultured is altogether at disadvantage when he enters on the true business of life and so, beyond the fact of having arrears of work to perform, is less able to perform well the proper work of the season.

My duty this evening is to speak to the students who are about to avail themselves of the opportunities offered by this institution; but I cannot deny myself the pleasure of reverting for a moment to those who have been introduced to us as the prizemen of the past session. They have been congratulated on their success by more able tongues than mine, but no one can more heartily bid them "God speed" on their future career than I do. Their names have been added to that list of worthies which adorns the calendar of the Pharmaceutical Society, and the very fact of their being so enrolled must ever be an incentive to them to press onward in the course they have so well begun. Every step in the right direction will advance them, and advance the body to which they belong, and I trust to see them in their turn taking that active share in the work of our Society which so many of the prize men of former years have already taken. To you of the future I would hold them up as encouraging examples. You who will be their successors in the lecture-room and laboratory must all strive to be their successors in the prize list, that those who are spared to come here twelve months hence to see the medals and certificates of the next session distributed may as heartily congratulate you. I say you must all strive; I know you cannot all win according to the common notion of winning; that if there be but one silver medal for competition in a class it is an impossibility for more than one man to take it, but if all the competitors cannot *win* all must *gain* by the process of striving.

On the motion of the Vice-President a vote of thanks was passed to Mr. Sandford, which he briefly acknowledged.

The VICE-PRESIDENT announced that the next evening meeting would take place on the 5th of November.

Parliamentary and Law Proceedings.

POISONING BY LIQUOR STRYCHNIÆ.

An inquest has been held in Belfast, on the body of a man named Thomas Shaw. From the evidence it appeared that the deceased had been in delicate health and had consulted Dr. M'Keown, who had prescribed liquor strychniæ in doses of seven drops. The wife of deceased deposed that on the day of his death he took a dose about two o'clock, immediately after his dinner, that she saw him drop the seven drops and that she counted the drops. A few minutes afterwards he gave a yell and jumped up, calling out "The medicine!" and asking for butter, of which he swallowed some, and he also drank three tumblerfuls of hot water, and vomited. Mr. Brady, surgeon, was called in but the man died shortly afterwards in a convulsive fit.

Mr. Brady deposed that he thought the symptoms of strychnine poison were present; also that the dose was a legitimate one for an ordinary case, but that he would not venture to give it to a man suffering from disease of the heart. He thought there was a proper interval between the morning and afternoon doses. Half a grain was the smallest dose of strychnine ever known to kill a person, and that would correspond with sixty minims of liquor strychniæ.

Dr. M'Keown described the circumstances under which he prescribed the solution, and said that he considered the medicine prescribed perfectly safe and would give it again for a similar case. He would not consider heart disease as contra-indicating strychnine. The deceased smoked and had tremor of the muscles and defective vision. He considered he laboured under dimness of vision from toxic causes. He had often prescribed strychnine, and seldom commenced with less than seven drops. One patient was taking twelve drops. He thought the symptoms were consistent with strychnine poisoning, but the dose ordered was totally inadequate to produce any such effects as those described. He had no doubt deceased had somehow taken a very large dose.

The jury returned the following verdict:—"That deceased came to his death from the effects of an overdose of strychnine; and, that the overdose of strychnine was taken through some mistake on the part of the said Thomas Shaw."

The foregoing is abstracted from a report in the *Ulster Examiner;* where a letter also appears written by Dr. M'Keown, stating that although there should only have been two doses, or fourteen drops, absent from the bottle, an accurate measurement in the presence of the jurors showed a deficiency of one hundred and twenty drops.

Alleged Case of Child Poisoning by Mistake at Leith.

On Saturday, September 27th, John Addinell, dispensing chemist, Leith, was apprehended in connection with a case of alleged child-poisoning which took place on the previous Tuesday. Lime water, ordered for the child, was sent for to Mr. Addinell's shop ; but there are said to be reasons for concluding that the medicine given was morphia and not lime water. At the *post-mortem* examination of the body, Drs. Henderson and Garland took possession of the child's stomach and other internal organs for analysis. Pending further inquiry, Mr. Addinell has been ordered to find bail to the extent of £50.—*Edinburgh Courant.*

BOOKS RECEIVED.

The Owen's College, Manchester, Calendar for the Session, 1873-74. From the College.

The Druggists' Stock and Price Book, comprising the Drugs, Sundries, and Proprietary Articles in General Use, with Ruled Columns for Stock-taking Purposes, and for recording the Cost and Retail Price of every Article kept in Stock. Arranged by Messrs. Frazer and Green. London: J. and A. Churchill. Glasgow: Frazer. 1873. From the Authors. Two sizes.

La Matiere Médicale chez les Chinois. Par M. le Docteur J. Léon Soubeiran et M. Dabry de Thiersant. Précédé d'un Rapport à l'Académie de Médicine de Paris par M. le Professeur Gubler. Paris: G. Masson. 1874. From the Authors.

Obituary.

Notice has been received of the death of the following :—

On the 20th September, 1873, Dr. Julius Martiny, of Suhl. Julius Martiny had been an Honorary Member of the Pharmaceutical Society of Great Britain since 1856.

Dr. J. Evans, of Dawson Street, Dublin, died suddenly at Harrogate on the 15th, where he had gone for the benefit of his health. This well-known and respected citizen was the original partner in the firm known as Bewley and Evans. Having dissolved partnership, Dr. Evans at the time of his death had two establishments open in connection with his son. These establishments were conducted upon the most advanced principles, the late proprietor combining with his scientific knowledge a wonderful capacity for business. He was a Doctor of Medicine, and the originator of many well-known proprietary articles, of which the best known was his malt extract. He had issued a little work upon 'Recent Remedies in use in Medicine,' and was a member of the Pharmaceutical Conference. His remains were removed to Dublin and interred in the burying ground of the Society of Friends, of which body he was a member.

On the 8th September, at his residence, Willow Bank, Green Heys, Manchester, aged 68, Henry R. S. Jewsbury, formerly of the firm of Jewsbury and Bevan, Chemists, Manchester.

On the 6th September, 1873, Mr. Joseph Bettison, Pharmaceutical Chemist, of Chesterfield. Mr. Bettison had been connected with the Pharmaceutical Society since 1853.

On the 18th July, 1873, Mr. Charles Compton, Pharmaceutical Chemist, of Brewer Street, Golden Square, London. Mr. Compton was one of the Founders of the Pharmaceutical Society.

On the 7th April, 1873, Mr. George Rich, Chemist and Druggist, of Swinton, Yorkshire.

On the 26th September, 1873, Mr. Edward H. Crumpton, Chemist and Druggist, of Cornwall Road, Westbourne Park.

Notes and Queries.

[350.] DR. WILSON'S HAIR WASH.—In reply to *A. C.* I forward the following as the formula for Erasmus Wilson's Hair Wash. My authority is Wilson's 'Skin Diseases,' 5th edition, page 773 :—

Lotio Capillaria Stimulans.

℞	Olei Amygdalæ Dulcis	℥ j.
	Liquoris Ammoniæ Fortius . . .	℥ j.
	Spiritus Rosmarini	℥ iv.
	Aquæ Mellis.	℥ ij.

Misce, fiat lotio.

James R. Gardner.

[359.] STEEL OF ANTIMONY.—In reply to "*Nescius* :" — According to Quincy's 'Dispensatory' — "Steel of Antimony" is "Regulus Antimonii Martialis," and is directed in Gray's 'Supplement' to be prepared as follows :—Upon 1½ lbs. of small nails, heated to redness in a crucible, throw a mixture of 1 lb. of common antimony, 4 oz. nitre, and 2 oz. tartar ; melt and pour out ; separate the regulus and remelt three or four times, throwing 2 oz. of nitre upon it each time.—J. Tully, Jun.

[361]. ETHEREAL SOLUTION OF NITRATE OF SILVER.—Will you kindly favour me with the form for ethereal solution of nitrate of silver ?—W. Reeves.

[*** A solution of various strengths—5 gr. to 30 gr. or more in ℥ j—of nitrate of silver in Spt. Æther. Nitrosi, is used for the purpose of painting a greasy or perspiring cuticle. It has the advantage of giving a uniform coating where an aqueous solution would collect in globules on the surface.—Ed. Pharm. Journ.]

[362.] COCHINEAL COLOURING.—Can any correspondent give me a good form for solution of cochineal for colouring ?—E. Nicholson.

[363.] INDELIBLE MARKING INK.—Can any one give me a recipe for Indelible Marking Ink for Linen without Nitrate of Silver ?—G. L. N.

[364]. PERMANENT DEPILATORY.—Can any reader furnish me with a form for a *permanent* depilatory ? The arsenical preparation recommended in Beasley's 'Receipt Book' has been tried, but it is not permanent in its effects.—"*Granum.*"

The following journals have been received :—The 'British Medical Journal,' Sept. 27 ; the 'Medical Times and Gazette,' Sept. 27 ; the 'Lancet,' Sept. 27 ; the 'London Medical Record,' Sept. 27 ; 'Medical Press and Circular,' Sept. 27 ; 'Nature,' Sept. 27 ; 'Chemical News,' Sept. 27 ; 'Gardener's Chronicle,' Sept. 27 ; the 'Grocer,' Sept. 27 ; 'Journal of the Society of Arts,' Sept. 27 ; 'Grocery News,' Sept. 27 ; 'Produce Markets Review,' Sept. 27 ; 'Ulster Examiner,' Sept. 29 ; 'Leith Observer,' Sept. 29 ; 'Richmond (Va.) Daily Dispatch,' Sept. 17 and 18 ; 'Richmond (Va.) Engineer,' Sept. 17 and 18.

Correspondence.

Pareira Brava.

Sir,—The thanks of pharmacists are due to Mr. Hanbury for his able and interesting contributions to your pages.

A perusal of the two papers referred to brought to my recollection a circumstance that occurred during the present year.

A visitor to this place called with a prescription which he was desirous should be prepared with great accuracy, his physician having directed him to take it to a certain house at the West End, where it had already been dispensed more than once.

[Copy.]

℞ Decoct. Pareiræ,
Tritici repentis, āā . . . ℥iv.
M. Sum. ℥j bis in die.

Next day the gentleman called again, saying he "thought the medicine could not have been correctly dispensed, as it was bitter, whereas what he had before taken was void of taste and simply mucilaginous." I in reply said, "it ought to be bitter," and in corroboration produced Dr. Pereira and two other eminent authorities.

My customer wished for another bottle of the medicine, for the doctor's inspection, at the same time promising to let me know his decision. In a few days the gentleman called again, and informed me that the doctor had said, "Most likely the London chemists were right," thus implying that the suburban chemist was wrong. A protest against such a verdict would be useless, but in order to satisfy myself I obtained a sample of the drug from the house in question. It proved, as I expected, the spurious article so correctly figured by Mr. Hanbury.

I beg to enclose a portion of the said sample, also a specimen of the root employed by me in preparing the decoction.

The moral to be drawn from the case is not very obvious, but it would appear that a qualified medical practitioner is not averse to amusing his patient by dosing him with inert drugs (let us hope the case was not serious), or to sacrificing his reputation as an intelligent prescriber; but what could the *Lancet* not say of the arrogance of a chemist who dares to set his judgment against an M.D.? Surely "hanging" would be too good for *him*.

SIRIUS.

Richmond, S.W., September 9th, 1873.

Cocoa.

Sir,—I fully concur with the remarks in the article on "Cocoa," on p. 245 of the PHARMACEUTICAL JOURNAL. I am glad that the magistrate dismissed the summons in the suit there referred to, and that he did not regard soluble cocoa as an *adulterated* article. Now, as such articles as cocoa, mustard, etc., are generally sold by country chemists I, for one, should like to see some definition of the term "adulteration" by legislative enactment, for to my mind *prepared* mustard ought to be regarded as *unadulterated*, and even more so than *prepared* cocoa. On referring, however, to the case of a grocer at Sutton, Surrey, who was summoned and convicted on the 18th August (PHARMACEUTICAL JOURNAL, p. 176) for selling mustard alleged to be adulterated, I find that, according to the report of the evidence in the case, the article sold was of the very best quality used (double superfine), and I never heard, in about fifty years' experience, that the *genuine* mustard was approved of as a condiment, but merely as an external appliance. I do hope that something effective will be done, and that very soon, too, to save me and my brethren from such vexatious, troublesome, and personal public exhibitions for selling so simple a condiment as prepared mustard, an article which, according to an old established firm (Messrs. Keen and Co.), has been manufactured by them for upwards of 100 years. Why such and similar prepared articles should now be deemed adulterated I cannot understand. Should Messrs. Colman gain the suit in a superior court on the case granted to them by the magistrate, and I hope they will, it will not only give satisfaction to themselves, but also to the public generally.

According to the strict letter of the law my humble opinion is that even violet powder, granulated citrate of magnesia, and other preparations are cognizable under the Adulteration Act, they being sold by names that they in reality are not.

"FAIR PLAY."

Shoreham, 29th September, 1873.

Dispensing Misdemeanour.

Sir,—In the Hammersmith Police Court a few days since a medical gentleman, whose name did not "transpire," applied to Mr. Woolrych for a summons against some chemist, in or about Hammersmith, for incorrectly dispensing a prescription, the statement being that an expensive ingredient was left out and some other substituted, whereby some possible injury might result to the patient for whom the medicine was intended. So far the anonymous "medical gentleman" speaks according to his knowledge, but as he follows this with the remark that such is the *usual* practice of chemists, I venture to express an opinion that the "medical gentleman" is altogether wrong, and I think such an injurious accusation should not be allowed to go forth without the "flattest" of contradictions. I am speaking of course only of my own experience, but I feel sure I am also expressing the opinion of all conscientious chemists; moreover I have a business in the locality, and notwithstanding that I have, I believe, the confidence of my customers, I have been asked many times since if such has been my practice, *i.e.*, to omit expensive ingredients in a prescription.

It is, I suppose, too much to ask the chemist accused to explain the matter, as, right or wrong, the public are easily alarmed at any possible quibble about their prescriptions, but I *should* like to hear the other side as I feel convinced another light would be thrown on the matter.

SMILAX.

*** We have endeavoured to obtain some definite information respecting this case, but have not yet been successful in doing so.—ED. PHARM. JOURN.

"*Compositæ*."—(1) *Inula Conyza*. (2) *Athyrium filix-fœminea*. (3) Probably *Lastræa filix-mas*. It is necessary to send fronds of ferns entire and in a state of fructification.

S. C.—*Torilis Anthriscus*.

"*Labiatæ*."—We should think a licence would be necessary: but recommend you to apply to the Inland Revenue authorities at Somerset House.

G. (Bangor.)—(1) *Œnothera biennis*. (2) *Bidens cernua*. (3) *Bidens tripartita*. (4) *Helminthia echioides*. (5) *Lepidium ruderale*. (6) *Centaurea nigra*. (7) *Stachys palustris*. (8) *Polygonum lapathifolium*. (9) *Linaria minor*.

"*Pharmacien*."—(1) *Ballota nigra*. (2) *Lycopus Europæus*. (3) *Bidens cernua*. (4) *Calamintha clinopodium*. To ensure the proper naming of plants it is necessary that specimens in flower should be sent.

S. P. S.—(1) Yes. (2) All such works are necessarily expensive; but they may be consulted at the Library, 17, Bloomsbury Square, or a number of dried plants may be seen upon application to the Curator of the Museum. (3) We believe that a general knowledge of both is required.

G. K. (Bottisham).—(1) Iron pyrites, the staple material now used in the preparation of oil of vitriol. (2) Probably the precipitate is the sulphate of magnesia, thrown out of solution by the spirit. (3) See Attfield's 'Chemistry,' 4th edit., pp. 61 and 62.

F. W. Andrew.—No Universal Pharmacopœia has yet been published, the nearest approach to it being the collations of formulæ by Jourdan and Hager.

J. J. Harrison.—We believe that Messrs. McDougall claim to hold patents for various preparations of carbolic acid. For more definite information we should recommend you to apply to the Patent Office through an agent.

E. Smith.—We cannot undertake to recommend rival proprietary preparations.

"*Apprentice*."—See an article on the subject in the present series of the Journal, vol. ii., p. 531.

H. M. C.—You probably would obtain the formula by direct application to the prescribers.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Baldock, Hemmings, Rudd, Ekin, Barrett, Cottrill, F. W. Smith, Mason, Harper, Druce, Rowell, Kinninmont, Iverach, B. B., F. A., "Juvenis," "Ignoramus,"

ACTION OF WATER UPON THE RESINOID PRINCIPLE OF OPIUM.*

BY L. PÉRIER.

Soubeiran, in his *Traité de Pharmacie théorique et pratique*,† has pointed out that the proportion of water put into contact with crude opium exercises an influence upon the solution of the resinoid principle, oil, and narcotine, but that the resulting modifications of this action are little known. The author has found that at any rate the proportion of water employed plays an important part in the solution of extract of opium, as shown by the following experiments :—

(1) 120 grams of extract of opium was divided into two equal parts ; one half was treated with 120 grams of distilled water at 15° C., the other half, with 250 grams of water at the same temperature. At the end of six hours, assisted by agitation, solution was complete in both liquids, and they were filtered through paper. The first only left a few bubbles of blackish matter ; the second abandoned six grams of oleo-resin.

(2) The first solution was then evaporated to dryness and the product divided into two parts ; one was put into a small quantity of water (about twice its own weight), the other into 1000 grams. After twenty-four hours, the concentrated liquor was quite limpid and without deposit, but the dilute liquor had deposited a considerable residue.

(3) 30 grams of extract was dissolved in water, under the conditions prescribed in the Codex (ten times its weight of water at 15° C.). The solution was at first muddy, a black granular precipitate covered the bottom of the vessel ; but upon evaporation in a water-bath the extract again became homogeneous, and afterwards dissolved in 30 grams without any deposit. In its turn, this solution threw down a precipitate when double its own volume (60 grams) of water was added, and the precipitate was augmented commensurately with the addition of more water. Afterwards, concentration reproduced a normal extract, soluble without residue.

(4) The quantity of water employed gave rise to a regular progression in the phenomena of solution and precipitation. If, for example, five grams of extract of opium were put into ten grams of distilled water, the portion which was first dissolved left in suspension a granular deposit. In proportion as the liquid became saturated this deposit was effaced, until at last no more remained undissolved. The maroon black liquid, a layer of four centimetres of which was impermeable by sunlight, did not require filtering ; if it were sometimes scarcely clear yet it did not deposit. With five grams more water a turbidity was manifested which was not completely removed by shaking. At the maximum of 20 grams of water the deposit commenced ; towards 30 grams, and after standing for an hour, the deposit was nearly doubled ; at 50 grams (ten times the weight of the extract) it ceased, and the liquid was no longer troubled by fresh additions of water.

The whole of the resin however could not be removed by water from solutions of opium. Thirty grams of extract which no longer gave a precipitate upon the addition of water, yielded 2·5 grams of black resin when treated with ammonia. Although in this case the extract was the product of a fourth maceration, the phenomenon occurred, but in a less degree, under ordinary conditions.

It thus appears that the same matter will alternately pass through a filter without residue or leave an enormous residue, according as the quantity of water employed is small or large ; also that the precipitation ceases when the weight of the menstruum is about ten times greater than that of the substance. It is even possible to dissolve in a very concentrated cold solution a deposit that has not been obtained from it. Finally, that the heat of a water-bath will restore the homogeneity destroyed by an excess of water, an observation that is not in accord with what has been written by other authors. The constant results obtained during his experiments have induced M. Périer to formulate his conclusions as follows :—

(1) The quantity of distilled water at 15° C. in which extract of opium is dissolved has a direct and certain influence upon the partial elimination of the resinoid matter.

(2) Concentrated aqueous infusions of extract of opium do not give any notable precipitate, except with the lapse of time ; dilute solutions, where the weight of the menstruum exceeds twice that of the matter dissolved give as much more residue as the proportion of water is increased from two to ten.

(3) Water, in whatever quantity, does not precipitate the whole of the resinoid matter ; a certain portion yields only to ammonia.

(4) The residue of extract of opium treated with cold water re-dissolves in the concentrated mother solution, and heat, instead of aiding in the separation of the resin, oil and narcotine, reconstitutes the homogeneity of the extract.

REACTION OF SUGAR AND SULPHURIC ACID WITH SOME ALKALOIDS.*

BY R. SCHNEIDER.

Having observed that morphia produces a beautiful blue coloration under the simultaneous influence of sugar and sulphuric acid, the author extended his investigation to other alkaloids.

Morphia.—When a drop of sulphuric acid is added to an intimate mixture of one part of morphia with six or eight parts of sugar, a very intense purple colour is produced, which after half-an-hour passes to violet, then to a blue-green, and finally to a dirty yellow. These changes of shade are due to absorption of moisture, for they may be induced instantaneously by the addition of a drop of water. This reaction is of great delicacy. To use it for the detection of morphia in a solution, a single drop should be taken and sugar added to it to saturation ; a drop of sulphuric acid is then placed by the side of it, and when the two drops are made to meet the coloration takes place.

Codeia.—With codeia also a purple is produced which passes to violet, and then to yellow-brown.

Narcotia and Narceia.—These substances, under the same conditions, do not give any very characteristic reaction ; they produce brownish colorations.

Quinia and its salts produce a brown colour. In the presence of water no coloration is produced, but there is simply an increase in the quinine fluorescence.

* *Journal de Pharmacie et de Chimie* [4] vol. xviii., p. 223, from the *Bull. Soc. Chim.*

Strychnia, *Brucia*, *Atropia*, *Colchicia*, and *Picrotoxia* give no characteristic reaction.

Aconitia.—When a drop of moderately concentrated solution of sugar is added to aconitia, and then a drop of sulphuric acid, a zone of a beautiful rose colour appears at the surface of separation, which passes rapidly to violet, then to brown. This is a valuable characteristic. It might, it is true, be confounded with codeia and morphia; but it differs from the latter in that chloroform or benzine removes it from an alkaline solution; from codeia by its dissolving in boiling water.

Delphinia gives a spot of yellow-brown, surrounded by a dirty green zone. Upon the addition of water the brown passes to green. This is a characteristic reaction.

THE SPONGE TRADE OF THE OTTOMAN ISLANDS.

From a short report which has just been issued on the trade and commerce of the Ottoman Islands in the Archipelago, for 1872, we glean some information with regard to the native trade in sponges. It appears that, with few exceptions, in which the owners of sponge-boats had capital, all the funds required for the equipment of these boats were furnished by native money-lenders, and that important foreign capital, especially British and French, has latterly been invested in diving apparatus since the introduction of this new mode of fishing for sponges in these islands. It is noticeable, too, that a large French firm, whose operations in this trade were on a very extensive scale, have of late somewhat reduced their trade, while, on the other hand, the use of British-made machines continues to increase; and it is mentioned that there is a decided preference on the part of the natives to work with British rather than with French diving apparatus. The whole of the machines now employed in the Ottoman Islands is upwards of a hundred. Owing to the depressed prices at which sponges have been sold during the last few years, and which have prevented divers from paying their debts to the native money-lenders, the latter, although in possession of bills for important sums of money, have not a sufficiency of cash to equip all the boats suitable for the sponge fishery. Notwithstanding these adverse circumstances, the quantity of sponges obtained of late has exceeded that of former years, in consequence of the more abundant crops and improved diving apparatus. At the Island of Halki, for instance, where ten years ago the produce in sponges was hardly £10,000 a-year, it amounts now, with the same number of boats, but working with diving apparatus, to nearly £20,000, thus showing a very important augmentation. It is mentioned, however, that the produce in sponges seems more than sufficient for the demand; and if all the available boats in these islands could procure the required money to enable them to go fishing, the extra quantities of sponges which would then encumber the markets would lower the price of the article to rates which would prove ruinous to the divers.

The average market prices of sponges for the present year are shown per oke (equal to $2\frac{3}{4}$ lbs.) in the subjoined table :—

Countries.	Fine.	Honey Combs.	Hard Brown.
Bengazi . . .	40/0	17/6	8/0
Mandruha . .	48/0 to 64/0	19/0 to 21/0	10/0 to 12/6
Syria	29/0 „ 32/0	11/0 „ 12/6	4/0 „ 5/0
Caramania . .	24/0 „ 32/0	9/6 „ 11/0	3/3 „ 4/0
Cyprus. . . .	—	11/0 „ 12/6	—
Crete	24/0 „ 32/0	11/0 „ 12/6	—
Rhodes and other Ottoman Isles	24/0 „ 32/0	8/0 „ 9/6	—
Greece. . . .	12/6 „ 16/0	6/3 „ 8/0	—

Bengazi and Mandruha sponges are not sold by weight, but by piece; for the sake of comparison, however, their prices are proportioned to okes. Bengazi fine sponges are exceedingly scarce.

The prices quoted in the foregoing table, although higher than those of the two preceding years, are still considered rather low, and Hellenic sponge-boats, which used to bring and sell their crops in the markets of the Sporades, now abstain from doing so. In fact, owing to the reduced prices offered in these islands for sponges, several of the most enterprizing native sponge-dealers decided, two years ago, instead of selling their sponges in the local market, to convey them to Europe, and retail them on their own account from place to place. There is not a single country—even Sweden and Norway—which these sponge-dealers have not visited, in order to sell their goods. A few of them journeyed even as far as America, while some settled in London, where their countrymen ultimately brought the quantities which they had not been able to dispose of in their peregrinations. These attempts having been so far successful, there has been of late a slight increase on past prices. It is stated that the value of sponges sent annually to Great Britain is no less than £70,000.

THE COMPOUNDS OF CANTHARIDIN.*

In a thesis presented at the University of Dorpat in 1865, C. Bluhm concluded from his researches that cantharidin existed in cantharides, partly in a free state and partly in a state of combination. The free portion he extracted by means of alcohol, ether, or chloroform. That in combination was found to be nearly insoluble in these solvents, and was obtained by the addition of sulphuric acid, or better still by boiling the cantharides with magnesia, so as to combine all the cantharidin with magnesia, and then setting the cantharidin free by sulphuric acid. The whole of the cantharidin could then be dissolved out by ether or chloroform. This he proved by several experiments.

Twenty grams of powdered cantharides were exhausted with boiling 92 per cent. alcohol, and the alcoholic solution reduced by distillation to one-tenth its original volume. This alcoholic extract gave an amount of cantharidin only 0·092 per cent. of the weight of the cantharides. But the powdered cantharides thus exhausted with alcohol, being afterwards boiled with calcined magnesia and water, then dried in a water-bath, and finally rubbed up in a mortar with ether and dilute sulphuric acid, yielded a further 0·122 per cent. of cantharidin. After this treatment, alcohol, ether, and chloroform failed to remove any further quantity of a vesicating compound, and upon evaporation gave no traces of the crystalline needles of cantharidin. The double operation therefore yielded 0·214 per cent. of cantharidin, under conditions which the author considered clearly proved that it existed in the cantharides in a partial state of combination. M. Bluhm supposes, without giving proofs, that the cantharidin which is not removed by alcohol from cantharides exists in the natural state in combination with magnesia.

Again the cantharides powder was mixed with one-third its weight of calcined magnesia, and a sufficiency of water, and boiled. It was then evaporated to dryness in a water-bath at 212° F. The dried mass, pulverized, and boiled with water, gave a brown extract having an alkaline reaction from which ether removed nothing perceptible. A fresh treatment of this extract with ether and dilute sulphuric acid yielded 0·0674 per cent. of cantharidin. The water therefore had not nearly dissolved the supposed magnesian compound. Afterwards, the cantharides powder treated directly with ether and dilute

* From an abstract by M. Méhu in the *Journ. Pharm. Chim.* [4], vol. xviii., p. 68.

sulphuric acid gave a fresh yield of cantharidin amounting to 0·2195 per cent. Altogether, therefore, it contained 0·2868 per cent. of cantharidin.

The compounds of pure cantharidin with magnesia, baryta, oxide of zinc, and the oxides of the alkaline metals were referred to by Bluhm in 1865. They have since been described by Dragendorff and Massing.

Cantharidate of Potassium.—This salt may be prepared by treating during several hours a gram of cantharidin, 0·5735 of pure caustic potash, and 80 c.c. of water, in a water-bath at 212° F. The operation must be continued until the complete solution of the cantharidin, which will require three or four hours. Alcohol does not answer for the purpose so well as water. The aqueous solution of cantharidate of potassium, evaporated in a water-bath, leaves a saline residue of radiating crystals, having a pearly lustre, but not having a clearly marked form. The salt is not hygroscopic. 100 parts of water at a temperature of 15° to 20° C. dissolve 4·13 parts; 100 parts of boiling water dissolve 8·87 parts; 100 parts of alcohol, sp. gr. 0·820, at 15° to 20° C. dissolve 0·03 part, whilst 100 parts of boiling alcohol of the same strength dissolve 0·92 part. Ether and chloroform dissolve only very small proportions. Its aqueous solution has an alkaline reaction.

A first analysis of cantharidate of potassium gave 61·70 per cent. of cantharidin, 31·66 per cent. of potash and 6·64 per cent. of water. The formula

$$\left.\begin{matrix} H \\ C_5H_6O \\ K \end{matrix}\right\} O_2$$

requires 63·55 per cent. of cantharidin, 30·61 per cent. of potash, and 5·84 per cent. of water. The formula

$$\left.\begin{matrix} H \\ C_5H_6O \\ K \end{matrix}\right\} O_2 + \tfrac{1}{2} H_2O$$

requires 60·05 per cent. of cantharidin, 28·92 per cent. of potash and 11·03 per cent. of water.

A second analysis gave (by decomposition with hydrochloric acid) cantharidin 59·95, potash 29·47, and water 10·58 per cent. A third gave catharidin 61·61, potash 30·49, and water 7·90 per cent.

A further analysis made upon 0·320 gram of cantharidate of potassium dried at 100° C. gave 0·1868 gram of cantharidin by hydrochloric acid. The aqueous liquor from which this precipitation had taken place, shaken twice with chloroform, gave upon evaporation of the latter 0·0195 gram of cantharidin. The potassium was estimated by means of perchloride of potassium. The result of this analysis was cantharidin 62·79 per cent., potash 30·22, and water 7 per cent.

The experimenter did not succeed in producing a cantharidate richer in base: alcohol removed the excess of potash and left a neutral cantharidate of potassium. Neither could an acid cantharidate of potassium be obtained.

The vesicating action of cantharidate of potassium is most energetic: 0·00034 gram of this salt dissolved in one hundred times as much water, applied to the skin upon a square centimetre of linen produced a very strong vesication; 0·00017 gram dissolved in two hundred times its weight of water applied in a similar manner produced a vesication very similar to that caused by a blistering plaster; 0·00011 gram dissolved in three hundred times its weight of water still produced upon the skin some small vesicles; 0·000088 gram dissolved in four hundred times its weight of water produced a strong redness without blisters; 0·00006 gram dissolved in five hundred times its weight of water no longer produced more than a slight redness.

It does not appear to be possible to heat cantharidate of potassium above 100° C. without undergoing a perceptible loss in weight; there is loss of cantharidin, especially in the presence of vapour of water.

Cantharidate of sodium.—This salt is prepared like that of potassium. It crystallizes confusedly, and is not hygroscopic. 100 parts of water at 15° to 20° C. dissolves 4·01 parts; the same weight of boiling water dissolves 6·22 parts. It is slightly soluble in alcohol and insoluble in ether and chloroform. Its aqueous solution has an alkaloid reaction. 0·3645 gram of the salt dried under the receiver of an air pump lost 0·0037 gram at 100° C., and 0·0063 gram at 110° C. Its analysis gave for 100 parts: cantharidin, 64·27; soda, 24·45; water, 11·27. The formula—

$$\left.\begin{matrix} H \\ C_5H_6O \\ Na \end{matrix}\right\} O_2 + \tfrac{1}{2} H_2O$$

corresponds to 66·66 per cent. of cantharidin, 21·09 of soda, and 12·24 of water.

Cantharidate of Lithium is prepared like the two preceding salts. 100 parts of water at 15° to 20° C. dissolves 3·8 parts; the same weight of boiling water dissolves 5·96 parts. Analysis gave—

	I.	II.
Cantharidin	81·76	82·00
Lithia	12·75	13·15
Water	5·50	4·85

Cantharidate of Barium is obtained by pouring iodide of barium into a solution of cantharidate of potassium. This salt is white, crystalline, nearly insoluble in cold water, alcohol, and ether. It contains in 100 parts 50·25 parts of cantharidin, 41·85 parts of baryta, and 7·9 parts of water.

Cantharidate of Strontium is prepared in the same manner by means of chloride of strontium and cantharidate of potassium. It is also nearly insoluble in water, alcohol, and ether. 100 parts of the salt contain 55·60 parts of cantharidin, 36 parts of strontia, and 8·4 parts of water.

Cantharidate of Calcium is obtained by mixing a solution of cantharidate of potassium with a solution of chloride of calcium. It resembles cantharidate of barium, takes a crystalline form, and resists well a rather high temperature. About 140° or 150° C. it commences to decompose, giving a slight sublimate of undecomposed cantharidin; on analysis 100 parts gave 66·75 parts of cantharidin, 20·725 parts of lime, and 12·525 parts of water. The formula—

$$\left.\begin{matrix} H_2 \\ (C_5H_6O)_2 \\ Ca_2 \end{matrix}\right\} O_4 + H_2O$$

requires 68·05 per cent. of cantharidin, 19·45 of lime and 12·50 of water.

Cantharidate of Magnesium is obtained directly by heating during several hours 1 gram of cantharidin and 0·25 gram of pure calcined magnesia, with 30 c.c. of water in a sealed glass vessel, at a temperature of 100° C. Gradually the greater part of the magnesia disappears, and is replaced by small crystalline masses. One part of the cantharidate is in solution, the other part is obtained by washings with distilled water. The filtered solution of cantharidate of magnesium gives upon evaporation long, pike-shaped, crystalline needles. 1·47 gram of the salt dried under the receiver of an air-pump lost 0·0014 at 100° C., and 0·002 gram at 110° C. This cantharidate dissolves more easily in cold water and cold alcohol than in those liquids when boiling. It is insoluble in ether and chloroform. 100 parts of water at 15° to 20° C. dissolve 0·24 and at 100° C. dissolve 0·02. The aqueous solution has an alkaline reaction, and its vesicating action is very energetic. The salt keeps well in the air, and is not decomposed by carbonic acid. It is precipitated by the alkaline carbonates, carbonate of magnesium, and an alkaline cantharidate being formed, sulphate of copper gives sulphate of magnesium and a green crystalline precipitate of cantharidate of copper. One hundred parts of cantharidate of magnesium gave upon analysis 67·2 parts of cantharidin, 15·10 of magnesia, and 17·7 of water. The formula—

$$\left.\begin{matrix} H_2 \\ (C_5H_6O)_2 \\ Mg_2 \end{matrix}\right\} O_4 + 2H_2O$$

requires 67·59 per cent. of cantharidin, 13·79 per cent. of magnesia, and 18·62 per cent. of water.

The *Cantharidate of Zinc* has much analogy with that of magnesium. 100 parts of water at 15° to 20° C. dissolve 0·41 and at 100° C. only 0·24 parts. 100 parts of alcohol at 15° to 20° C. dissolve 0·12, and at 100° C. no more than 0·04. Analysis gave in 100 parts 59·82 of cantharidin, 23·55 of oxide of zinc, and 16·63 of water. It is prepared by heating cantharidin with an excess of oxide of zinc and water, in a tube closed at both ends.

Cantharidate of Cadmium is obtained with difficulty by heating oxide of cadmium with cantharidin, the direct combination being nearly *nil* at the end of twenty-four hours, even when operating at the temperature of boiling water. By double decomposition iodide of cadmium and cantharidate of potash gave a cantharidate of cadmium with excess of base. The neutral salt was obtained with the neutral sulphate of cadmium and a completely neutral alkaline cantharidate. When a great excess of sulphate of cadmium was employed the precipitate contained free cantharidin. The analyses were not concordant; it appeared evident that the operation had not succeeded in isolating in a state of purity the neutral and the basic cantharidates of cadmium.

Masing and Dragendorff prepared and analysed a large number of other cantharidates, namely, those of glucinium, aluminium, cobalt, nickel, iron, chromium, copper, lead, mercury, silver, palladium, tin, and bismuth; they were generally obtained by double decomposition. These compounds were nearly insoluble in water, some of them were crystalline, others amorphous; but their investigation is very incomplete.

OPENING OF OWENS COLLEGE, MANCHESTER.

At noon on Tuesday last the academical session of Owens College was opened in the Chemical Theatre, in the presence of a large assemblage. The Duke of Devonshire presided.

His Grace, after officially pronouncing the opening of the building, said it afforded him the greatest satisfaction to offer his congratulations on the completion of the buildings. In the course of his remarks he said that the success of any institution depended in a very large measure on its local habitation, and on its adaptation to the work that has to be carried on within it. Amongst all the public buildings which adorn the streets of Manchester, or which minister to the various requirements of its vast population, there could be none of which we may more confidently anticipate an important influence on the future destinies of the community, or which will reflect greater credit upon the enlightened public spirit of Manchester and the district of which it is the centre. Though Owens College had now been somewhat more than twenty years in existence, and although its friends are entitled to view its present position with very great satisfaction, he was much mistaken if its further progress and development are not greatly promoted and accelerated now that it had come into possession of the ample accommodation which that building provided. It might, therefore, he thought, confidently be anticipated that that day would form a most memorable epoch in the history of Owens College. The work which originated in the late Mr. Owens' munificent bequest, was a work the magnitude of which had, perhaps, sometimes not been sufficiently appreciated. It was Mr. Owens' design to found a college in which instruction should be given in all the branches of knowledge which were taught at that time, or should thereafter be taught, in the English Universities. How that bequest had been utilized could now be seen. His Grace expressed his admiration of the wise and steady determination with which the principles of the College, as defined by its founder, had been steadily kept in view. But though much had been done much still remained to be achieved, yet he anticipated that the liberality and generosity of the public would supply the funds that would be required to complete the great work. His Grace concluded, amidst cheers, by formally declaring the building open.

Principal Greenwood then delivered an able address on the advantages and aims of the studies that will be pursued within the walls of the College.

Mr. T. Ashton, Chairman of the Owens College Extension Committee, said the duty that now devolved on him was a very simple one—namely, to hand over to the governors of the College the building which had been erected under the care of the Extension Committee and of himself as their chairman. It would have been a matter of great satisfaction to the committee if they could have delivered up the building in a more complete state, especially as regarded the outside, but he believed that they had succeeded so far in preparing the interior that the work of the session would begin on the morrow with no practical inconvenience to either professor or student. Every provision, both for student and professor, would be found most complete, and the students would have to inhabit certainly the most complete and the best set of academical buildings that had yet been raised in this country. It was impossible to speak too highly of the talent and ingenuity which the architect had shown in devising the means for the end, for the readiness with which he had made every provision for the requirements of a very exacting body of scientific professors, and for the unwearied assiduity and diligence which he had shown in carrying out the details of the building. On behalf of the Extension Committee he had to thank Mr. Waterhouse for the exhibition of other qualities, which had made working with him extremely pleasant to them. He hoped the meeting would warmly express to Mr. Waterhouse their thanks for the great labour he had bestowed on the building. He was afraid, however, that a very serious duty still remained to be performed. When the bills of that building were all paid he believed they would find an adverse balance on their books of about £20,000. He had to say, however, that since he entered that room the amount had been reduced by the very munificent donation of £1000 from Mr. H. B. Jackson, and also by a donation of £100 from the son of one of the oldest trustees, Mr. Fletcher. He would be extremely glad to receive a good many thousand pounds more. As they were aware, that building was only a part of a still greater scheme. When the Extension Committee was first appointed its members were thought to be rather too sanguine when they asked the public to find them £150,000; but the public had done that, and his colleagues and he were very much inclined to go to them again with very great confidence that they would get another £150,000. He believed that as the growing importance of the College was appreciated, and as the enormous advantages which it conferred on the district were more clearly seen, there would be no difficulty whatever. In fact, he was quite sure that if good work was done, and people saw that it was useful, there were plenty of men in the country who would take care that no institution was starved. He had the greatest confidence, though he might not live to see it, that there would be seen within the walls of Owens College, before thirty years had passed, from fifteen hundred to two thousand students. That was a number the district ought to send to enjoy the advantages of the high education Owens College afforded.

Professor Roscoe expressed the thanks of the teaching staff to Mr. Waterhouse, the architect, who briefly responded.

The Bishop of Manchester commented upon the supreme interest and importance in this vast community of the objects which the College had been established to promote.

The subsequent speakers were Professor Scott, of the Independent College, Sir J. Kay-Shuttleworth, Sir Benj. Brodie, Dean Lake, Mr. C. S. Roundell, Rev. W. Gaskell, and Dr. Stoner, of the London University.

The High Sheriff of the county moved, and the Earl of Ellesmere seconded, a vote of thanks to the President, which was carried with cheers, and the assembly separated.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 11, 1873.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

AMERICAN PHARMACEUTICAL ASSOCIATION.

IT will be seen from the report published at page 296 that the meeting of this body has passed off with its usual success, and that there is no abatement of the interest with which the annual gathering of our Transatlantic brethren is regarded. This year there have been all the customary features of attraction. In the first place there was a goodly array of papers, which, to judge from the titles, will furnish copious material for subsequent digestion. Then excursions, speech-making, and a ball contributed to the entertainment of the visitors and afforded opportunities for establishing friendships and mutual intercourse which cannot fail to be of benefit to the individuals concerned, as well as to the promotion of the art they practise.

At Richmond the municipal authorities appear to have been prominently associated with the local pharmacists in the endeavour to offer a hearty welcome to the members of the Association, and although it seems some apprehensions were entertained that a meeting in the South might prove premature at the present time, it is satisfactory to learn that everything went off with the greatest harmony and cordiality.

If it be permissible to institute any comparison between the American and British meetings which have but recently exchanged simultaneous friendly greetings, we would point to the number of papers brought forward at the former in response to queries propounded in order to stimulate original investigation as constituting a feature of the American meeting which we would do well to imitate here.

There is also another point in connection with the Richmond meeting which will interest many who have not yet attended a meeting of the British Pharmaceutical Conference, and that is the number of ladies who were present. The MAYOR took occasion to thank the members for their good taste in bringing with them the fair representatives of their art, adding that the ladies were never a drug in the market, and though he, as an old bachelor, might consider them a dose, he must admit that they were sugar-coated; certainly they were elixirs, and nobody would dare say they were unofficial.

AN EXPIRING SCHOOL OF PHARMACY.

AT the recent opening of the University of Durham College of Medicine, in Newcastle, the Council in their report drew attention to the means afforded by the College for tuition in practical pharmacy. They pointed out that a class for instruction in this branch of knowledge was founded a few years since, but that it had received only a limited attendance from the pharmacists of the town and neighbourhood for whose benefit it was intended. From the smallness of the class during the past year the Council had resolved that in future unless a sufficient number of names be entered for attendance no lectures should be given on this subject.

This announcement is but a sad repetition of the experience gained in Manchester when attempts were made to establish something like a School of Pharmacy in connection with OWENS College, and it indicates a state of things which requires serious consideration. Not long ago we had to refer to the astonishing fact that a talented practical pharmacist, in the position of lecturer on the subject he is so well able to teach, should have found himself addressing a class of *one only*, and it is with great regret that we learn this indifference on the part of those who should eagerly avail themselves of such opportunities is likely to add one more instance to the failures that have hitherto attended efforts to establish pharmaceutical education in the provinces.

CHINESE OPIUM TRADE.

WITH regard to the Chinese opium trade, it appears that the price of opium has not materially varied during the last few years, and a few dollars more or less, except in occasional instances, would represent the difference of one year over another. Taking, however, the quotations for the past few years, we find that in 1871 Patna opium was quoted at 610 dols. 24 c. per chest, and in 1872 at 652 dols. 21 c.; Benares, 1871, 588 dols. 20 c. per chest, 1872, 634 dols. 80 c.; Turkey, 1871, 609 dols. 86 c., 1872, 547 dols. 98 c. per chest. It will be perceived from these quotations that prices advanced somewhat during the past year, though not to any very material extent. Attention was called in China some few years ago to the alleged increase of native-grown opium, and fears were entertained that it would in time seriously affect the foreign. The result has shown that such anticipations were not altogether without justification. Large quantities of opium are produced in Szechuen and several other provinces, but the policy of the Chinese Government is to discourage the growth of the article, and even lately edicts have been published in the *Peking Gazette* denouncing it. Under any circumstances, it is confidently stated that the native can never compete with the foreign opium, as it lacks the strength and flavour of the latter, and is principally used for mix-

ing purposes by the very poor, who cannot afford to purchase the more expensive descriptions of the product. Again the opinion is expressed that the use and abuse of this drug are generally exaggerated. Estimating the total import into China at 12,800,000 lbs. during the year, surely that is not so gigantic an amount for a population numbering, more or less, about 400,000,000. The fact, indeed, appears that the use of opium in China is confined to narrower limits than is generally imagined, and excess in its consumption is the exception, not the rule. As regards the imports of opium into China during the past year we find that the import of all sorts—Patna, Benares, Malwa, Persian, and Turkey, amounted to 91,206 piculs, or 80,438 chests—equal in English weight to about 12,799,000 lbs. Of this quantity over 146,000lbs. passed the Canton Custom House last year. There is, however, a great deal more than this quantity brought into that province, being smuggled through Macao or the coast line, by which the tariff duty of 45 dols. a picul, and the war tax of 15 dols. a picul, are avoided. The imports, it may be mentioned, do not vary much, thus showing that the consumption of foreign opium does not increase to that alarming extent which the opponents of its use appear to think. We learn, however, from Hankow that amongst the articles which have decreased in import of late years opium figures prominently, and this is attributed to the growing tendency of the Chinese to use the native article, their preference for which is not wholly due to its greater cheapness. Taking into consideration the amount of extract obtainable from the drug, Malwa was very little dearer last year than the best native opium, the average price of Malwa being 460 taels per chest. A similar quantity of the best native opium would cost about 360 taels, but the former yields 80 per cent. of extract, while the latter yields only about 60 per cent. It is believed that the mildness of the native article is the principal cause of the growing preference for its use; and the Chinese say that it is much easier to give up temporarily, or to abandon altogether, the habit of smoking native than that of smoking foreign opium; upon somewhat the same principle, we suppose, that it is easier to relinquish the use of light wines than ardent spirits.

With regard to the growth of opium in the province of Szechuen, it is estimated that the net value of the article there produced is about 35,000,000 taels, although this amount must only be considered as approximative. There are in Chang King alone over 3000 opium smoking shops, which each pay a license of 300 cash per month to the local magistrate. The Chang King opium guild also pays a monthly likin duty of 2500 taels to the Provincial Government. A recent Imperial decree is said to have abolished this likin duty on native opium, the growth of which was to be strictly forbidden; but this decree perhaps may only concern these provinces where the poppy is so extensively cultivated as to leave no opportunity for the production of cereals. The *Peking Gazette* of the 17th December, 1872, contained an edict issued in consequence of a memorial addressed to the Throne by the Governor General of SHENSI and RANSUH, praying that the cultivation of the poppy might be prohibited. In this edict the memorialist is strictly enjoined to forbid poppy culture within his jurisdiction, as being contrary to law; and it further states that "should there be any among the people, greedy for gain, who secretly grow the plant, as soon as the shoots appear above ground, orders are to be issued for it to be pulled up to the last stalk." The edict concludes thus:—"The same strict prohibition applies to all the provinces, and all offenders will be punished, that the food of the people may not be interfered with." Although the prohibition of poppy culture by Imperial edicts has in former years been practically inoperative, there is reason to believe that the edict above referred to will prove more efficacious, for the orders given are more explicit and imperative.

The Acting-Commissioner of Customs of Newchang has also reported that a similar decree, directing the destruction of the poppy crop in the province in which that port is situated, and the adjacent districts of Mongolin, had in many places been carried into execution.

MESQUITE GUM.

A GUM known under this name in Texas, the produce of *Prosopis glandulosa*, Torr., and perhaps of some other species, has lately attracted some attention in America from the fact of its having been found to be almost identical with gum arabic, so that it has been used for medicinal and technical purposes, more especially in the preparation of mucilage gum-drops, jujube paste, etc. It is in Bexar County that the largest quantity is produced. The species most common in that locality grows to a height of from twenty to forty feet, forming a trunk of about eighteen inches diameter. The wood is very hard, close-grained, and durable, and is used as a furniture wood. The gum exudes from the stems and branches of the trees. During the past year as many as 12,000 pounds of the gum were gathered in Bexar County, and as many more between that and the coast. No gum is said to be gathered west of Bexar, and it is hardly known east of the Brazos.

WE learn from the *Garden* that a fine specimen of the camphor tree, about twenty-five feet high, is now growing in the open air in Mr. Fox's garden at Pengewick, Falmouth.

The Composition of the Air of Sewers and Drains.

BY JOHN J. NICHOLSON, F.C.S.

It is only during the last few years that attention has been drawn to the agency of sewer gases in the production and transmission of typhoid fever and other epidemic diseases; consequently the nature of these gases and the composition of the air in the interior of the sewers have not often been subjected to any scientific examination.

Now that the subject has been brought more prominently before the public, these examinations will doubtless become more numerous; as from the variable nature of the compounds it will be only by tabulating and comparing a great number of analyses that any useful information can be obtained.

I offer this first experience of mine as an item of evidence on a subject that I consider of great importance, which will repay a more thorough investigation than it has yet received.

In 1871, Sunderland, in common with many other towns, suffered from a visitation of small pox, the severity of which was partly attributed to a want of ventilation in the sewers. In the same year, borrowing powers were applied for to extend the sewerage to the new parts of the town; in consequence of which application an official from the Local Government Board was sent down to make the necessary investigations.

This gentleman attached considerable importance to the aforesaid absence of ventilation, and made it an imperative condition that this state of things should be remedied, recommending several plans that were considered successful in other towns, but leaving it to the corporation to adopt what they thought best.

The ideas and method on which the Sunderland sewers had been constructed were directly opposite in principle to those now insisted on. According to the highest sanitary authorities of twenty years ago the sewerage system was perfect, every joint perfectly cemented, every outlet securely trapped, and every precaution taken, at a great expense, to keep the enemy underground; and all done by the express order of the then Local Government Board.

The Health Committee, in whose province this matter fell, before making such a complete reversal of all their arrangements, wished to ascertain the actual state of the air in the interior of the sewers, and employed me for that purpose. I made the examination at the end of September, 1871, obtaining the air by fixing a bell-mouthed pipe, of about ten inches' diameter, into the wall of one of the main sewers at its upper end, from this I carried up a small pipe into a temporary house erected near the spot, and drew the air out with an aspirator, taking care to have every joint air-tight, and to draw out a few thousand cubic inches every time, before commencing.

This sewer drains a considerable section of the town, and was selected for examination because it was considered more thoroughly trapped than any of the others, and has its outlet in the river, under water at all times except the low water of spring tides.

The average composition of the air in this sewer I found to be :—

Nitrogen.	Oxygen.	Carbonic Acid.	Sulphuretted Hydrogen.	Ammonia
81·1	18·4	0·5	traces.	traces.

Specific gravity 1001·5; greatest amount of pressure with advancing tide, one fifth of an inch on a fine water gauge representing $\frac{1}{100}$ of an ounce to the square inch of surface.

When these results were obtained, there were still wanting the means of comparison with other towns; the only information I could meet with on the subject consisted of two analyses kindly furnished me by Dr. Letheby, one made by himself in the London sewers, in 1858, and the other in the same year at Paris by M. Gaultier de Claubry. On comparing these, which I have arranged in a tabular form, I found that we were not in so good a condition as London in 1858, but very much better than Paris.

The amount of sulphuretted hydrogen and carbonic acid was much less than I expected to find, and I was rather surprised at the specific gravity being so low; all the writers that I have seen on the subject of sewer gas mention it as being a dense, heavy compound, that will almost fall through the air unaltered; but I have not before seen an actual estimation of its gravity.

With regard to the efficient ventilation of the sewers, I drew the following conclusions :—

1st. That we must not place too much reliance on the schemes proposed and plans adopted in other large towns, as we have absolutely no data at all as to the state of the sewer gases there, while we know there are many essential differences in the manufactures carried on, the position of the town, and the disposal of the sewage, all of which tend to prevent comparison between any two towns.

2nd. As we know that the gas will pass through the water traps into the houses, in a greater or less degree, our obvious principle of ventilation may be stated concisely. Make every possible communication between the sewers and the open air, and guard just as carefully every connection with the insides of houses. By numerous openings the little pressure there is will be removed, so that a less quantity will pass through the traps, while that will have been so diluted by the diffusion of air through the sewers as in a great measure to have lost its noxious effects.

3rd. There is not sufficient pressure in the sewers to force the gas to any great height in narrow tubes, so that the nearer the openings are to the ground the more readily will diffusion be carried on, and the more numerous the openings are the more will the gas be diluted both inside the sewers and when it issues out into the air.

The ventilation was carried out for the whole length of the sewer I had examined, by perforating the iron cover of each man hole with circular openings, while each flushing pipe and lamp hole on the smaller branches was covered with a grating instead of a solid piece of iron.

There was thus an opening obtained to the outer air at an average of every one hundred yards of the sewer and all its branches.

After this had been completed and in operation for some months, I made a further examination of the air at the same place in February, 1873, under as nearly as possible the same conditions of weather, when I found a change in the proportions of all the constituents; it now contained :—

Nitrogen.	Oxygen.	Carbonic Acid.	Sulphuretted Hydrogen.	Ammonia.
80·35	19·37	0·23	None.	0·05

Specific gravity, 998·75.

The proportion of oxygen was nearly one per cent. higher, representing an improvement of 37 per cent. on the analysis of 1871.

The carbonic acid was ·27 per cent. lower, showing an improvement of 54 per cent., and I was not able to obtain the slightest indication of the presence of sulphuretted hydrogen.

The greatest difference I found was an increase in the quantity of free ammonia, which could now be estimated easily, and the specific gravity was considerably lower,

owing no doubt to this larger proportion of ammonia and the reduction in the amount of carbonic acid.

From these data I arrived at the conclusion that a large body of air enters the sewer at the ventilators, and, becoming mixed with the gas that is formed there, dilutes it and renders it more rapidly diffusible at every opening.

	Nitrogen.	Oxygen.	Carbonic Acid.	Sulphuretted Hydrogen.	Ammonia.

Mr. Howarth (Manchester) : I wish to ask Mr. Nicholson whether he thinks that long shafts are not effectual in the ventilation of sewers ?

Mr. Nicholson (Sunderland) : My experience shows that the nearer openings are to the ground the better the ventilation, and the higher the shafts are the more difficult it is to ventilate effectually, unless—which does not often happen—there be a pressure of gas sufficient to force it up to the top of the shafts.

Mr. Savage (Brighton): This subject is very important to us at Brighton, because for some years we have been draining into the sea, and my belief was that for all practical purposes the drainage was perfectly innocuous and effective. However, from what appeared in the medical publications, it was considered necessary to send the drainage over an extent of seven miles, and we have now sewers constructing that length, with only a fall of three feet in a mile. With reference to the subject of the paper, the course adopted in our main sewer is to have a supply of charcoal renewed from time to time at the man-holes, and then to have shafts erected here and there for the ventilation of the sewers. But notwithstanding all these precautions, some of which have not, however, been entirely carried out, a great nuisance still exists on account of the mode by which these gases—which are constantly escaping—get into inhabited houses. We had traps constructed, and made all sorts of arrangements, but no perfect mode was adopted for excluding these gases. The only course that now seems open to us, is to have independent shafts, continued to the top of the houses to carry off these noxious gases. I know of no other process likely to prove effectual, though the objection to that one is its expense.

Professor Attfield (referring to questions put by Mr. Howarth) : I believe a proposition has been made for ventilating sewers by using lamp posts as shafts, but it has not been acted upon, as there are several objections to its adoption. I should like to ask Mr. Nicholson whether he has made any experiment—any direct experiment—upon the organic gases of sewers and drains ? No doubt it is extremely valuable to have indirect evidence as to the condition of the air found in sewers and drains by estimating the amount of oxygen contained in that air ; but at the same time I think it is highly desirable that we should have some direct evidence on that point. I therefore wish to ask Mr. Nicholson, whether he has made any experiment of that kind, whether he has tried the effect of sewer gases on solutions of nitrate of silver, Nessler reagent, permanganate of potassium, or such bodies ?

Mr. Nicholson : I have not yet had an opportunity of making such experiments.

Mr. Martindale : If the theory be a true one that diseases such as typhus fever and small-pox are conveyed by germs, perhaps the use of cotton wool as a filtering medium might, if applied in this case, tend to show some deposit of organic matter valuable for analysis.

Mr. G. F. Schacht (Clifton) : The most promising method with which I am acquained is one that provides shafts containing not a few gas-jets, but a considerable body of fire. The effect of that arrangement would be at once to produce a current and to destroy the vitality of all germs which might be the vehicles of disease. That strikes me as by far the most useful plan that has yet been suggested. The differences in the inorganic constituents of the air hardly seem likely to produce any great difference in the healthfulness of a neighbourhood. It is to the organic contaminations we must give our attention, and their submission to the fiery ordeal I have just mentioned would, without doubt, deprive them of all power for mischief.

Mr. Bottle (Dover) : One plan is to pump the gases from the sewers, by using engine chimney shafts for that purpose wherever permission to do so can be obtained, in every case passing the sewer gas through the furnace. In towns like Bradford, where chimney shafts are as common as trees in the country, there should be no difficulty in getting manufacturers to allow the air of sewers to pass through their furnaces. That, I think, would have a beneficial effect.

Mr. Ekin (Bath) : There is no ventilating shaft like the kitchen chimney. Two or three years ago some gas tar was thrown down the outlets of a sewer in the lower parts of the town in which I reside, and in a very few minutes the smell of the tar was perceived in the houses in the upper parts of the town, at least half a mile away from the places where the gas tar was thrown in. The inhabitants at once sent complaints to the gas works, believing that the smell was due to an escape of gas. In another case too some impure and offensive carbolic acid was thrown down a drain by a friend of mine who did not know how to get rid of it in any other way. The people in the immediate neighbourhood on that occasion also sent word to the gas works complaining of an escape of gas. These instances give one an idea of the great pressure there must be in the sewers. I once ventilated a soil pipe in my own house by carrying an inch and a-half gas pipe from it to the top of the house above the chimneys. When the opening in the soil pipe was made you could hardly hold your hand over it, the pressure was so great. Water does not effectually keep out the gases, for after a time I have found that it becomes saturated, and the gases pass through, as may be proved by suspending over a trap a piece of blotting paper saturated with a lead salt.

Mr. Williams (London) : With regard to the gases passing through a layer of charcoal, is it not necessary that the charcoal should be kept damp ? If so, there is some difficulty in the use of charcoal even.

Mr. Stott (Halifax) : At the Halifax Union Workhouse, on account of the prevalence there of small-pox, we have adopted the plan of ventilating the shafts by passing them into a very high chimney, and the plan has proved so successful that the party who suggested it is about to patent it.

Mr. Kershaw (Southport) : In our district we have adopted these charcoal pans, and find that they are not effective.

Mr. Baldock (South Norwood) : There are several important points involved in Mr. Nicholson's paper. Some views that have been expressed by the author are in direct opposition to certain statements made by other writers on the subject, and notably by Dr. A. Carpenter, of Croydon, who published a series of letters on this subject in the *Times* about twelve months ago. Then, and also, I believe, at the present time, the practice was to run a small pipe up the side of the house. My own opinion is that the gases would not choose that circuitous mode of exit, because there must necessarily be considerable pressure in the sewers in order to carry off the gas in that way ; and that that pressure does not always exist is proved not only by Mr. Nicholson's statements, but also by an expedient adopted at Croydon known as the charcoal grating. From this it is argued that the pressure is

sometimes into the sewer, and not out of it, which state of things is known by the fact that the surface of the charcoal is occasionally covered with a light pulverulent dust. I think the fact is rather overlooked that many of the traps are dry, and unless there be a rainfall, they will readily admit gas under slight pressure when in close contiguity to the sewers.

Mr. SUMNER (Liverpool) : In confirmation of what has been stated by Mr. Ekin, I may say with regard to gases passing through traps, that at a very early period in the petroleum importation, a great quantity of petroleum was stored by the dock side at Liverpool, in the lower part of the town. An accident occurred in the carting of some of this petroleum, and some friends of mine living in the upper part of the town, three-quarters of a mile away, perceived the gas through the traps of their houses. My friends examined the traps and were satisfied they were full of water ; yet the smell of the petroleum was so perceptible that they had no difficulty in deciding where the escape came from. The best preventive of pressure from the main sewers, I have found, is a curved pipe, as large in diameter as your drain will admit, near its junction with the sewer.

Mr. BOTTLE (Dover) : With regard to the escape of gases from sewers, very much depends upon the direction of the wind. When blowing in a direction contrary to the fall of the main sewer, I have found that the pressure within the sewer, and consequently upon house traps, has been materially increased. I believe also that the dip of the ordinary house traps is not sufficient. Many of them do not dip more than one-eighth of an inch, and a small piece of house flannel, or other similar substance, acting as a syphon, rapidly empties them.
