The association of the candidates for admission into the Naval Medical Service with those for the Military in a common course of instruction at Netley will exert an important influence upon both Medical Services. It has been followed as a natural consequence by the appointment of Sir Alexander Armstrong, the Director-General of the Naval Medical Department, to a seat in the Senate of the Army Medical School. This change will probably in due course lead to others. As the number of specially trained Medical Officers of the Navy increases, a proportion of the Professorships and Assistant-Professorships in the School will fall to their share—the Presidency of the Senate, even, may devolve upon the Naval Medical Director-General of the time—so that eventually the School will entirely lose its claim to the title of "Army Medical,"—whether for good or evil remains to be seen. We confess to some forebodings on the subject, and

are, indeed, surprised that the War Office authorities should have so readily assented to the initiatory steps of a proceeding which will leave with them a merely divided authority in an institution which, in its origin and development, has been so purely military as the Army Medical School at Netley.

THE WEEK.

TOPICS OF THE DAY.

THE Hampstead Hospital Inquiry drags its slow length along, and bids fair to rival in length the Titchborne case itself. We still must reserve our comments on the main facts which have come to light, but we cannot refrain from expressing our regret that the defendants of the management of the Hospital should have sought to damage the cause of the accusers, and to divert attention from the real points at issue, by bringing against the Assistant Medical Officers the irrelevant charges of writing pasquinades, keeping dogs, and rat-hunting. These things, if they were proved most abundantly, would make not one iota of difference in the grave charges of mismanagement which are laid at the doors of the Hospital authorities. The faults or follies of Medical subordinates, even if they laid them open to the most adverse judgment, cannot excuse one tithe of the accusations made against the management of the Hospital. It remains, however, to be seen whether these accusations can be rebutted by the evidence for the defence.

Zymotic disease is steadily declining in London. The total of deaths was 1390, or 5 above the corrected average of the same week in the last ten years. From small-pox 51 persons died, and 153 from diarrhoea. Last week the deaths from diarrhoea were 205, and from small-pox 89. There were, however, 23 cases of death from enteric fever, a number above the average.

An account has lately been sent over by the Calcutta correspondent of the *Times*, of a family of hairy people, a mother and her children, who are said to be living in Mandalay, the capital of Burmah. A letter which appeared in the *Times* of Thursday purports to be written by a gentleman who saw the woman in Mandalay in 1859. He gives the following account of what Mr. Darwin, we suppose, would consider an excellent instance of recurrence to original type:—

"When I was at Mandalay in 1859 I saw this same woman and three of her children. The eldest and youngest were hairy like their mother, while the second, like his father, presented no such peculiarity. The husband was a man who, report said, had been induced to wed this woman to become possessed of the marriage portion which the King of Burmah had promised to bestow upon her on her bridal day. The bridegroom was a plucky individual at any rate, though his motives may have been somewhat mercenary. The hairy woman, whose name I now forget, had a pleasant and intelligent face; there was nothing whatever repulsive in it. The hair on the face and breast was several inches long; on the forehead it was parted in the middle and blended with that of her head. Of a light brown colour on her cheeks, it paled gradually towards the bridge of her nose and the centre of her lips, chin, and neck. Those of your readers who have a copy of Colonel Yule's narrative of the Embassy to Ava will see a good likeness of the woman and a description of herself and family."

The Calcutta correspondent of the *Times* writes that the woman's father was hairy. The persistence of the peculiarity through three generations, if so it be, would have furnished a telling fact in support of the argument of the late Dr. Prichard, that the production of the different characteristics of different human families was due, in part at least, to accidental, or apparently accidental, peculiarities becoming permanent.

Dr. Cholmeley has been appointed one of the Medical Officers to the Eagle Insurance Company, in place of the late Dr. Cursham.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE meetings of the session commence this year in October, but, in consequence of the backward state of the alterations going on in the Society's premises, the first meeting will not be held until Tuesday, October 24.

DEATH FROM CHLOROFORM.

A DEATH from chloroform, as in the case of other accidents, seldom comes alone. Of late, we regret to say, several instances have occurred in London and the country. On Thursday week an inquest was held on the body of a drayman, aged 34, at the Manchester Royal Infirmary, who, when admitted into the Institution, was suffering from a fracture of the leg. Mr. J. G. Gordon, House-Surgeon, attempted to set the limb, but, after several trials, failed, as the deceased shrunk from the operation. Mr. Gordon suggested that chloroform should be administered, and the patient assented. A rag sprinkled with chloroform was accordingly placed several times in contact with the face of the deceased, and Mr. Gordon frequently essayed to adjust the limb, but the deceased could not be got sufficiently under the influence of the anæsthetic, and each attempt was unsuccessful. The pulse of the patient suddenly ceased to beat. The usual remedies for resuscitation were resorted to, without effect. Mr. S. Buckley, Physician's Assistant, made a post-mortem examination of the body, and discovered fatty degeneration of the liver and kidneys. The brain was softened, and the heart flabby and much dilated. The witness was of opinion that death resulted from "shock to a dilated heart, whilst deceased was under the partial influence of chloroform." He considered the chloroform would not have had a fatal effect if the heart had not been so diseased. Verdict accordingly.

DEATH OF DR. BEAUPERTHUY.

As our readers are aware, Dr. Milroy has recently, on the recommendation of the Royal College of Physicians, been despatched by the Colonial Office to the West Indies, in order to investigate the reality of the alleged cure of leprosy by a procedure which Dr. Beaupertuy has for a considerable time adopted, the expenses of the mission being defrayed by the joint contributions of the colonies interested in the matter. He was instructed, first, to visit Demerara, where Dr. Beaupertuy was then engaged in putting his procedure in force, in order that he might have the opportunity of personal communication with him before proceeding through the other colonies on his tour of inspection. We understand that he was received in the most cordial and friendly way by Dr. Beaupertuy, who impressed him with a feeling of great respect for his truthfulness and earnestness. We regret having to add that in a letter received from Dr. Milroy, dated September 5, he states that this indefatigable French Physician, whom he had seen two days before in perfect health, had just suddenly died of apoplexy. Dr. Milroy intended shortly to sail for Barbadoes.

SPREAD OF DISEASE THROUGH CARELESSNESS.

It is useless for the authorities to provide means for the prevention of the spread of infectious diseases so long as the public will not take advantage of the means thus offered them. The utter carelessness of some persons is marvellous, as is proved by recent reports of police-office proceedings. The last case in point occurred a day or two since, when a magistrate fined a young woman 40s. for taking a lady suffering from small-pox to the Hampstead Hospital in a cab, instead of sending for an ambulance, which could have been readily procured at the workhouse or the Hospital. The defendant was also ordered to pay 30s. to the cabman for compensation for loss of time and the use of his cab for three days, during the process of disinfection. The defendant did not pay, and was properly sent to prison for fourteen days.

ARMY MEDICAL SCHOOL, NETLEY.

THE winter session of the Army Medical School was opened on Monday, the 2nd inst. The opening address was delivered by Professor Parkes. The class consists of fourteen candidates for the Medical Service of the Army and nineteen for that of the Navy. Three Surgeons-Major, eight Surgeons, and fourteen Assistant-Surgeons of the Army Service are also about to go through the course. We observe that the candidates for the Naval Medical Service during the present session are on exactly the same footing as regards pay, appropriate uniform, etc., as the candidates for the Army. During the previous session the Naval candidates were actually Assistant-Surgeons, having been gazetted on passing the preliminary examination in London; they were borne on the books of one of her Majesty's ships at Portsmouth, and received the full-pay of their rank, and therefore occupied an anomalous position towards their fellow-candidates, as well as the officers of the Army Medical Staff at Netley. We are glad to learn that the Naval candidates of the previous session, who are now doing duty at Haslar Hospital, are favourably mentioned by the authorities, and are said to be doing credit to the training which they received at the Army Medical School.

THE LATE SUICIDE AT KINGSLAND.

THE painful circumstances connected with the suicide at Kingsland are still fresh in the minds of our readers. We have on more than one occasion commented upon the facts, and have expressed our opinion that a coroner under ordinary circumstances had no right or power to order the examination of women for the purpose of detecting crime. In the case before us, the Coroner has explained satisfactorily that no coercion was employed, and that one of the women in the house desired that she might be examined. The Medical gentlemen, however, who acted—at all events, if not under the summons or warrant of the Coroner, certainly with his sanction for what they did—have been held up in various quarters to severe animadversion and reproof; clearly, we think, most unjustifiably so. A judge is supposed always to be acting under legal powers, and the Surgeons who were engaged at Kingsland were unquestionably impressed with this conviction. It is gratifying to us to record that at the annual meeting of the Herefordshire Medical Association, held last week at Hereford, the following resolution was passed unanimously:—

"That this Society hereby expresses its sympathy with Messrs. Barnet and Chattaway in the painful position in which they have been placed by the unjust comments which have appeared in several publications upon their conduct in the recent case of suicide at Kingsland. This Society is of opinion that their conduct, acting as they did under the written order of the Coroner, was marked throughout by delicacy, kindness, and propriety."

CHARITY AND INDEPENDENCE.

THERE is no more difficult question than the one relating to the dispensing of gratuitous advice in our Medical charities. There is no charity so much abused, and none the exercise of which tends to demoralise the recipient more hastily or effectually. We have noticed on several occasions the large sums which have been subscribed by the working-men of Birmingham for the extension of the Queen's Hospital. We are not altogether gratified with the proceeding. To some extent, it is worthy of commendation: but is it altogether beneficial either to the Hospital or to the working-classes? We scarcely think it is; and it is liable to be much misapprehended. Will not these working subscribers demand, as it were, that as a right which is in reality a favour? Is it not to be feared that this "system" may merge into a large Hospital club, and thus inflict great injury, not only on Surgeons in general practice, but also on the subscribers themselves? It will be curious to watch the result of the proceedings, and to determine whether the example set by the Queen's Hospital at Birmingham should or should not be followed.

THE SOCIETY FOR THE SUPPRESSION OF VICE,

IN their report for the year just issued, refer "to the urgent need they have of assistance to carry out the important work they have taken in hand." Amongst the worst enemies of the public and the Profession are those heartless and illiterate quacks who, under the assumption of a title, prey upon the pockets and healths of their victims. One extract from the report before us will show that the Society has done good service to public health and morals, and that it is entitled to the warm support of the Profession—

"Great complaints having been made to the Society of the distribution in the streets, as handbills, of pamphlets, published under the title and name of Dr. H—, under pretence of giving Medical advice, these books being filled with details and descriptions of the most offensive and indecent character, and utterly unfit for circulation, especially among young persons—a summons was applied for as well against the man distributing them as against Dr. H—. On the hearing of the case, the Society obtained a decision from the magistrate that the distribution of such articles was illegal, whereupon the whole stock was delivered up for destruction, and Dr. H—'s undertaking accepted not to offend again, to come up for judgment when called upon, and to pay the costs of the application."

MIDDLESEX HOSPITAL.

AT a general meeting of the Governors of the Middlesex Hospital held on Thursday, October 5, Mr. Andrew Clark was elected to the Assistant-Surgeoncy rendered vacant by the elevation of Mr. George Lawson, who at the same meeting was made a full Surgeon to the Hospital. There were nine candidates for the appointment, some of whom are already distinguished for work they have done. We, however, commend the staff for recommending to the Governors a gentleman who, having received the greater part of his clinical education and held the senior resident appointments at the Hospital, promises to make a careful and successful pursuit of Surgery. Nothing can be a greater encouragement to the students and tend more to improve a Medical school than the knowledge that all the highest appointments of their Hospital are open to those who will seek them by intelligence and hard work.

YOUTHFUL SOLDIERS.

"SEND me men, not boys," wrote the great Napoleon on one occasion, when he required more soldiers in his Italian campaign. He had found from experience that the youthful conscripts could not bear the fatigue and privations of war. The raw levies and volunteers who endured such hardships and privations under Dumoriez were men, not boys. The experience of our Indian army exemplifies in a remarkable manner the importance of sending to our eastern empire the full-grown and knit man. The *Pioneer* furnishes us with the following facts in illustration:—In January, 1870, a draft composed of one officer, one sergeant, two corporals, and sixty-eight privates arrived at Thayetmyo, Burmah, from England, for the right wing of the 76th Regiment. Their average age was 20 years and 23 days. From January to November, 1870, there were of this number eight admissions to Hospital, eighteen men of this draft were sent to India for change, nine died—eight from cholera and its effects. Of the eighteen men who were sent to India for change not one exceeded 21 years of age, and the ages of those who died of cholera did not exceed 20.

A USEFUL AND HEALTHY FLOATING HOSPITAL.

MUCH has been said against the *Dreadnought* Hospital ship with respect to its salubrity. Recent experience with the cases of small-pox on board that vessel speaks much in its favour. Since it was opened for the reception of persons affected with that disease, 1021 sufferers have been admitted, 1018 of whom were discharged cured, and only 3 have died. Should cholera appear in London, the *Dreadnought* is to be appropriated to the reception of patients.

HEALTH CERTIFICATES.

NOTHING is more important to the public interest than certain examinations which are made of the health of persons about to enter the public service. This is more particularly the case when a pension is attached to the office to be filled. The examinations in question may appear to be harsh in some individual cases, but on the whole they are fair and equitable. It is announced that no person will be appointed to the public service in India, according to the recent decision of the Governor-General in Council, to a grade eligible to pension, without a certificate from a commissioned Medical Officer in charge of a civil station, that he has no disease, constitutional affection, or bodily infirmity unfitting him, or likely to unfit him, for the public service.

UNHAPPY LIVERPOOL.

NOTWITHSTANDING the able and persevering efforts by the spirited Officer of Health for this town, disease is still very prevalent. The Workhouse Committee state that relapsing fever is on the increase in the parish, and that the number of patients now suffering from it is thirty-nine in excess of the ordinary accommodation provided at the Brownlow-hill Workhouse. In this emergency, special sheds, which are usually devoted to the reception of emigrants who may have fallen ill in transit through Liverpool, have been appropriated to the use of the fever patients. A similar increase of the disease is reported to the Toxteth Board of Guardians.

A NEW POINT IN THE VACCINATION ACT.

New points of difficulty are constantly cropping up in reference to the Vaccination Act. Last week, at Manchester, the Public Inspector summoned a man for not bringing his child to him to show that it had been properly vaccinated. The magistrates ruled that, before they could convict, the Inspector was bound to prove that the child had been vaccinated, but this he had not done, and the summons must, therefore, be dismissed. A member of the Board of Guardians who was present at the inquiry said that he had offered the same evidence as the above in other cases of the same character, and the Court had never before ruled as they had ruled now. It is not right that so much ambiguity should surround the meaning of an important Act of Parliament.

SANITARY STATE OF OXFORD.

PREPARATORY to the return of the undergraduates to Oxford, the authorities of the City and University have been most energetic in carrying out measures to improve the health of the town. The results have been beneficial. Dr. Child has been appointed Sanitary Inspector to the University, and has been assisted in his duties of examining the numerous lodging-houses by Mr. Edward Collins, who was formerly the Relieving Officer of Oxford. The reports of these gentlemen are highly satisfactory.

FROM ABROAD.—EFFECTS OF ELEVATION ON THE ANIMAL TEMPERATURE—M. DEMARQUAY ON TRAUMATIC TETANUS—MEDICAL PRACTITIONERS IN THE CONSEILS GÉNÉRAUX.

SOME time since (*Medical Times and Gazette*, October 9, 1869, p. 436) M. Lortet, of Lyons, made some interesting observations upon the effects produced on the economy by ascending mountains. Among these was the influence which this had in his person on the animal temperature. He stated that this was, when at Chamouni, $36\frac{1}{2}^{\circ}$ C., but that after a day's ascending, he having gained the Grands-Mulets, half-way up Mont Blanc, a considerable fall took place, whilst when, next day, he reached the summit, after great muscular exertion, the thermometer, placed under the tongue, only indicated 32° . On a second ascent he found it at $31\frac{8}{10}^{\circ}$. Dr. Forel, of Lausanne, feeling some surprise at this result, determined to test its

accuracy, and in the *Presse Médicale Belge*, September 24, we find an account of the results of the trials which he made. On leaving the Hôtel du Glacier du Rhone, at the foot of the Mayenwand, his temperature was 36.7°. Keeping the thermometer in his mouth, and reading it by the aid of a small mirror, he found that the temperature, stationary at first, slowly increased, and at the summit of the mountain reached 37.5°. After thirty minutes' rest it descended to 36°, and on the return by the Grimsel it again rose. A little puzzled by these results, Dr. Forel undertook a series of ascents, performing the rather difficult feat of always keeping the mouth closed over the thermometer, as he believed that M. Lortet, by allowing the cold air to gain access to his mouth, had given rise to the diminution of temperature which he has recorded. In this way he made more than fifteen ascents of the Glacier du Rhone, etc., and he always found the temperature rise during the ascents, as also during the descents. Whenever any falling was observed, the mouth had not been completely closed. Dr. Forel, it is true, has not ascended Mont Blanc; but, as some of his ascents reached as high as 3820 mètres, they amply suffice to prove the fact already known, that our temperature does not vary with altitude, and to show the cause of the fallacy of M. Lortet's observations, which seemed to contradict this position.

M. Demarquay recently addressed a short communication to the Académie des Sciences, giving an account of a new mode which he has adopted of treating traumatic tetanus. Having, he says, during the late siege lost many cases without being able to alleviate them, he resolved in future to try a new procedure. First bearing in mind the great susceptibility to cold manifested by these patients, and the aggravation of the suffering which this produced, he kept the two cases he now reports upon in a room heated to and carefully kept at a temperature of from 18° to 22° C. (64° to 72° F.). Next, in order to diminish the tonic and clonic contractions, which are in this disease so painful, causing the patient to assume such strange positions, and especially to subdue the trismus, which is one of the earliest manifestations of tetanus, as well as to relieve the pain of the wound and the convulsions of the stump, he performed, four or five times in the twenty-four hours, intra-muscular injections, as near as possible to the emergence of the nerves. These consisted of solutions of morphia diluted to a fiftieth part. At first each masseter was injected, as also the muscles of the neck on each side of the spinal column; and when the wound which had been the occasional cause of the tetanus was painful, an injection was thrown deeply into the substance of the muscles in its vicinity. Under the influence of these remedies the sufferings were speedily assuaged, and the patient was enabled to open the mouth, and by copious drinks relieve the tormenting thirst. By aid of these, too, and the raised temperature of the room, abundant transpiration was produced. After some hours the injections were repeated, the painful contractions being pursued wherever they appeared, throwing them into the substance of the muscles concerned. They were also made over the track of the nerves of the diaphragm, to subdue the spasm of this muscle, or along the course of the pneumogastric, with the view of relieving the difficulty of deglutition, which appears to depend upon contraction of the œsophagus. In this way the pains were assuaged and the thirst relieved, while the patient was able to be fed with broths, milk, and an increasingly substantial diet. One of the two cases was suffering when seized with tetanus from a deep wound of the calf in process of cure, while the other had undergone amputation of the leg. In both the tetanus to all appearance was very severe; and although, of course, two cases do not say much in favour of any mode of treatment, their successful issue justifies its being made known. Frequently subcutaneous injections of morphia, atropia, and curare have been tried, but, as far as

M. Demarquay is aware, no one has hitherto thought of carrying the curative agent deeply into the substance of the muscles. This is, he believes, both a novel and rational procedure.

As we are all aware, the elections for seats in the Conseils Généraux and Conseils d'Arrondissements are at the present time exciting great interest and exertions in France. This of course is chiefly in relation to political operations, and as a means of acting upon the opinion of the country. We are glad to find, however, from a recent number of the *Union Médicale* that there are a great number of Medical men among the candidates; and that journal proffers some very wholesome advice to those of them who may prove successful, counselling them to eschew politics and attend strictly to the numerous social duties which the office should entail. We had no idea that there were so many of these for which a Medical training supplies one of the best preparatives.

"We are rejoiced at these candidatures, and desire their success, for Medical men will be well placed in these Councils, and will be able to render therein most useful services. It is far preferable to find them there than in the Legislative Assembly, where they are lost among the politicians, lawyers, and rhetoricians. When we consider the nature of the most essential of the duties which devolve on these Councils, we are tempted to ask whether an intelligent and provident law would not have rendered the presence of one or more Medical men obligatory. Observe, in fact, what are the questions that come before them—public hygiene in all its applications, public assistance in all its forms, hospitals, hospices, bureaux for aid and charity, Medical assistance in the country, lunatic asylums, the salaried and encouragement of learned societies, the instruction of midwives, where the department is the seat of a faculty or school of Medicine, all that relates to such centres of instruction, the employment of women and children in factories, vaccination, epidemics, foundling and nurse children, the administration of mineral waters. These, and many other things like them, primarily relate to Medical competency, without the aid of which it is difficult to think how they can be disposed of. Medicine is 'social' science *par excellence*, for *social* here means science based on the principles which govern human societies, and not on the senseless and perilous Utopias of demagogic socialism.

"These candidatures, then, are quite legitimate, for the post may prove highly useful, on the condition, however, of eschewing, as far as possible, all ideas of party politics. Let us Doctors have but one policy—that of saving France; that of contributing to her physical, moral, and intellectual regeneration. We can do something towards this; I do not say much, in order to avoid all exaggeration and Professional boasting. If we desired it, thanks to the *cautionnement* which has, we know not why, been inflicted on our journal, we might deliver a political discourse on this matter; but may God and all the saints of Paradise preserve us from so dangerous a folly! Our wish is to keep strictly within the domain of Medical science, and it will not be our fault if this trenches on politics and sociology. What none of our brethren will contest is the magnificent prognostic of Descartes, of the inevitable perfecting of the human race through the science of Medicine. Well, let us be able ourselves to show that Medicine is worthy and capable of aspiring to such high destinies; and this will be brought about less by our mingling in the sterile agitations of politics, than in demanding those ameliorations upon which depends the realisation of the ancient but always present programme—*Mens sana in corpore sano*."

THE ITALIAN UNIVERSITIES.—There are in the kingdom of Italy seventeen Royal and four Free Universities. The Royal are those of Bologna, Cagliari, Catania, Genoa, Macerata, Messina, Modena, Naples, Padua, Palermo, Parma, Pavia, Pisa, Rome, Sussari, Sienna, and Turin. The four Free are Camerino, Ferrara, Perouse (?), and Urbino. Among these are following have Faculties of Medicine and Surgery, viz.:—Bologna, Cagliari, Catania, Genoa, Messina, Naples, Padua, Palermo, Pavia, Rome, and Turin. The total number of students registered for the session 1870-1 is 7238, those of Naples not being registered. Of these, Bologna has 568; Genoa, 412; Modena, 354; Padua, 1110; Palermo, 274; Pavia, 789; Pisa, 571; Rome, 726; and Turin, 1469.—*Gazette des Hôpitaux*, September 28.

THE HAMPSTEAD HOSPITAL INQUIRY.

SEVENTH DAY.—Continued.

THIS inquiry was continued on Thursday, September 28, before Mr. Henley and Dr. Buchanan, the Special Commissioners of the Local Government Board, at the Asylums Board Offices, Norfolk-street, Strand.

The Managers were represented by Mr. Montagu Williams, Mr. Humphreys, and Mr. Hammond; Mr. Collins, with Mr. Bucknill, represented the three Assistant Medical Officers who had written the charges against the Hospital management to the *Times*—Messrs. Greaves, Kynaston, and Aikman.

Our report last week broke off at a point in Mr. Aikman's evidence in chief. He had informed the Commissioners that he had made a complaint in writing that children under his care on August 5 had not been supplied with eggs, and that this complaint was returned to him with the word "bosh" written on it, and initialed by Dr. Grieve.

Mr. M. Williams said he should be prepared to show that the eggs in question were supplied half an hour later.

Mr. Collins: Then the order was not "bosh"?

Mr. M. Williams rejoined that the word "bosh" was placed on the high-flown language of the written order.

The witness proceeded to give another instance in which eggs were wanted for witness to inject into the stomach of a patient, but none were to be had, and he had to leave the Hospital for the night without doing this. The patient died four days later in the height of the disease. Then another case was that the steward refused to supply eggs for a patient, and witness spoke to Dr. Grieve on the subject, and he said that the steward was right in refusing them. The patient had eggs afterwards, but he was without for two or three days. The primary order in this case was countersigned by Dr. Grieve, and on witness writing "repeat" each day on the card, the eggs were supplied continuously for several days without extra countersign, and then they were stopped. A complaint in writing was made on August 12 by the witness that children whom he had not seen were still having eggs and wine, the nurse obtaining the eggs and wine without his orders. The children had been allowed to go out in the grounds without his permission. Another complaint was to the effect that medicines were not regularly administered. Witness was present on August 10, when a dispute arose between Mr. Kynaston, Mr. Greaves, and Dr. Grieve, which ended in Mr. Kynaston saying he should report Dr. Grieve, and Dr. Grieve saying, "Then I suspend you; it is an act of insubordination to threaten your superior officer."

Mr. Collins then made a demand that the affidavit made by the witness in the Stokes case should be put in.

After some discussion, the affidavit was read. It ran thus:—

"I am Assistant Medical Officer of the Hampstead Small-pox Hospital. I have been there in that capacity since May 1, 1871. I have read an article in the *Echo* newspaper of July 3, 1871, and I can identify the case of 'Louise,' to which the article refers, as that of Louisa Stokes, who was admitted into the Hospital on May 5, 1871. I saw her on the evening she came in, and she was then suffering from a very severe attack of small-pox, and in a very low state of health. She bore no marks of vaccination, and she had evidently been ill some time prior to her admission into the Hospital, and was altogether in a very reduced condition. I saw her thrice a day during the period she was in the Hospital, sometimes oftener. That would be to June 20, 1871, the day she was removed. Every possible care and attention was paid to her. She was not recovering rapidly or in a satisfactory state, and I therefore ordered the attention of the Medical Superintendent to the case. Everything was done for her that Medical skill could prescribe, and the Sisters in charge of her gave her every care and attention that could possibly be given. I never expected she would recover. She recovered from the primary disease of small-pox, although she had the complaint so severely; but as her convalescence did not progress as satisfactorily as I could wish, I thought it desirable that she should be removed, in the hope that change of air might do her good. She had one eye seriously affected as a consequence of the disease, which is not an uncommon occurrence in so severe a case of small-pox as that of Louisa Stokes. I dressed her eye, and everything was done that could be devised to save the sight. Notwithstanding that a water-cushion was supplied by my directions, she was suffering from bedsores, which were unavoidable. The very emaciated condition of the child predisposed her to contraction of the limbs; so much so that she could not turn in bed with-

out assistance, or straighten her limbs; neither could I do so without putting her to such pain that I thought it desirable to leave her alone.

"JOHN AIKMAN."

Cross-examined by Mr. Williams: It was on July 24 that my two colleagues were dismissed, and it was then I sent in my letter of resignation. The letter sent to the *Times* was a joint composition, and was written in our room at Hampstead. We meant by the last paragraph in the letter—"Had we remained we should have trusted to our own energies to keep down mismanagement"—that we should have done our best. We should not have published the letter if we had remained. We arrived at the determination to send the letter long before Dr. Grieve took the management out of our hands. (The witness was handed his written reports.) I do not find in my written reports any complaint which comes under the head of the first charge in the letter to the *Times*. I never wrote any one report to come under that head (the tying down of children). I thought the tying down decidedly improper. If that tying down rubbed off some portions of the eruptions, as I saw it do sometimes, it was certainly damaging to the recovery of the patient. Mr. Williams pressed the witness to answer why he did not, if he considered the tying down injurious to the patients, report in writing. Mr. Aikman said that they had no written form of report at that time, and that he complained constantly to Dr. Grieve. "The first written report I made was on June 23, and after that the practice diminished. I have reason to believe that the tying down went on in some few cases. I saw it until I left. I went on May 1 to the Hospital. I have been present when a patient was strait-waistcoated, but never when one was tied down." Mr. Aikman said that he had assisted Sister Caroline on one occasion in putting on a strait-jacket, and showed her how to do it securely, and that to supply the place of a broad band he had directed that a sheet should be used. He allowed that the sheet was fastened to the bed. The sheet was applied to a woman who had been previously maniacal. That was her history before her then illness. I showed Sister Caroline how to use the sheet properly. The patient thus restrained had a very mild attack of the disease, and she was tied down because of her maniacal tendencies. I made complaints to Miss Harrison, Sister Caroline, Bonfield, and others. I did complain as well to Sister Agnes and others. I did not disapprove the use of the strait-waistcoats in all cases, but I disapproved their use without Medical advice. He owned that he had seen the Committee of the Hospital officially, but he had not considered it necessary to say a word to them about the practice of tying down which he so much reprobated, even though he knew the practice existed. The condition, too, of the wards with regard to the milk remained something like what he had described, and still he did not report in writing when it became his duty to report in writing all his complaints.

Mr. Williams read a letter written by the witness to the *Times* in reply to one by Mr. Wyatt. The letter said—

"1. In answer to our repeated representations, we were officially informed by the Medical Superintendent that neither the local nor the general committee would consider any complaint regarding the management of the Hospital made to them by the Assistant Medical Officers. 2. We were officially informed that our only mode of complaint was to furnish him with the facts in writing on the back of the Assistant Medical Officer's daily report. 3. I beg to refer the Committee and the Medical Superintendent to the above-mentioned reports, where they will find full details of the facts mentioned in our letter officially reported at the date of their occurrence." The letter was signed "John Aikman," and appeared in the *Times* of September 2.

The witness had heard the reports of his colleagues read over to him in their room, and he was asked to take up the reports of himself and his colleagues—the reports he had referred to in his letter to the Editor of the *Times*—and point out the "full details" of the facts mentioned in the previous letter—the letter which had been the means of this inquiry being held. The witness went over the reports, and he found that complaints were made on three only, and these had reference to the shortness of milk in certain wards at night. He acknowledged, "When I wrote the letter I believed complaints were more numerous written in the reports." The witness was then questioned as to the reason why he had not made complaints in writing. He acknowledged that he ought to have reported the case of one of the children found dead. He still maintained that the meat was bad, but he did not think it his duty to report the complaints of the patients and nurses in that form. "There was no recognised authority for me, as a paid servant, to report to, for I did not regard the Committee as my authority

Dr. Grieve was my superior, and I did not report to him after his saying that the nurses were the people to complain. All the heads I wrote upon to the *Times* existed throughout my being there. The reason I did not write before was because it takes a long course of endeavours and only after a great many other means are exhausted that I consider such a proceeding justifiable. I heard the Committee issued fortnightly reports. I did not think it was my duty to report to the Committee. I never tried the Committee, but my colleagues did, and they were dismissed. It was on the day they received their dismissal, *post hoc propter hoc*. I did not hear their complaint; but I saw the letter, and the Committee would not hear the charges."

Mr. Williams: I will read the letter they sent. It is dated July 24, 1871, and is addressed to the Chairman of the Hampstead Hospital Committee. It said—

"Sir,—We, the undersigned Assistant Medical Officers, having been informed by Dr. Grieve that he is about to bring charges of disobedience and insubordination against us, beg that the Committee will proceed to a thorough investigation of such charges in our presence.—We beg to remain your most obedient servants,—WILLIAM GREAVES; A. E. KYNASTON."

Now, what do you mean by saying that their dismissal followed their complaints?

The answer was, the witness had reason to believe that the Committee would not listen to complaints. He went on to reply to questions,—I never made a complaint in writing of the filth of the beds, nor did my colleagues, and these existed in July and August. I never saw the filthy state of the towels and the vermin. If this condition of things existed, it does not necessarily follow that I should have seen it. It is very probable I should have seen it.

Dr. Buchanan: Can you help seeing vermin on the towels in the wards?—There were no towels in the wards. I have seen vermin there.

By Mr. Williams: The vermin were brought in by patients, generally by children; and when there it is hard to eradicate them. About the want of nurses in the month of August, when the Hospital was tolerably full, the case of the child with the bad head occurred. I did not trust to the memory of the nurse with regard to the treatment of the head—it requiring carbolic acid and oil. The number of nurses was very considerably inadequate to the requirements of the ward at that time. There is a column in the cards over the patients' beds for "treatment"; but poultices and such like would not, I consider, be necessary to put on the card. Dr. Grieve once told me that a water-pillow was not to go upon the card. It was the sole duty of the Sisters to remember those things. My duties would take me from ten o'clock in the morning until sometimes one o'clock. At one time I was done at half-past eleven. This was after seeing Dr. Grieve in the bedroom. Then the after-duties were somewhat irregular and variable. The second visit would begin about half-past eight, and would only be to the wards and to dangerous patients, and I left the Hospital at about ten at night.

In further examination he was asked whether he could not have stopped and put the carbolic oil on the child's head, and so have relieved the sufferings of the child, and assisted the nurse, and he said that if he had done so he might have done it all round. With regard to the filthy wards, he said they were continuous; and then a letter was put into his hands, and he owned it was in his handwriting. This proved to be a testimonial to a nurse named Daly, whose ward, he stated in the letter, he always found in order, and "invariably clean," with other praise of a high character.

The cross-examination was then adjourned until Friday.

EIGHTH DAY.

On this day the cross-examination of Mr. Aikman was resumed by Mr. Montagu Williams. The witness was first asked questions upon certain testimonials given by him and his fellow Assistant Medical Officers to different nurses—viz., Nurses Jenkins, Shufflebottom, Etaby, Meredith, Manning, Fury, and Harris. He admitted that the nurses to whom testimonials were given were the majority of the principal nurses. He said he believed that in every case in which testimonials were given they were thoroughly deserved. He had only tasted the beef-tea once, and had not tasted it in the children's wards. Mr. Aikman was then examined at great length on his affidavit as to the condition of the child Stokes. He defended the substance of the affidavit, and reiterated its truth; but he said that one reason why he had recommended the child's removal from the Hospital was because the child was insufficiently nursed.

He had not stated that the child was insufficiently nursed because he was not asked.

If you recommended that the child should be removed because you thought she was insufficiently nursed, why did you not say so in this affidavit?—Because I was not asked, and I only answered what I was asked.

I will take that answer. You knew this was on a charge of libel that you were making an affidavit before a magistrate, and yet you say nothing about this insufficient nursing?—I could say about it, or not, as I chose.

You mean to say you can swear to facts or keep them back as you choose?—Yes, I could swear or not swear what I liked.

You swore this in your affidavit,—“She recovered from the primary disease of small-pox, although she had the complaint so severely; but as her convalescence did not progress so satisfactorily as I could wish, I thought it desirable that she should be removed, in the hope that change of air might do her good.” Now, Sir, having refreshed your memory as to what you have sworn, do you think you had her removed because of “hope that change of air might do her good,” or because of the bad nursing you say she was receiving?—Both.

Then now, in point of fact, you say the article against which your affidavit was drawn was true?—Well, there were faults.

Now, don't you think that if you had added to your affidavit—to that part of it where you speak of her being removed “in hope the change of air might do her good,”—the words “and because of insufficient nursing,” you would have justified the *Echo* article then and there?—I do not think so.

Then, why did you not have these words put in your affidavit?—Well, Dr. Grieve was aware of it, and could have asked for it. I am not sure it was not said.

The witness was also cross-examined as to his statements respecting the non-supply of eggs when ordered, and the insufficient quantity of milk; also in reference to finding the child who had died, and the dead body of the man in the bath-room, but nothing new was elicited.

He was next examined as to some placards of the pasquinade type which had been hung up on the walls of the sitting-room of the Medical officers. Of the following one he said he was the author, though he did not stick it on the wall:—

“Wanted, three active and unscrupulous young men, utterly devoid of any principles of honour. Applications must contain *cartes* and fighting weight, as the Superintendent is a man of little physical but immense mental power. All applications must contain previous experience with bullies, but strict secrecy as to the treatment of colleagues must be sworn to. These qualifications, with a total oblivion as to personal honesty, will be sure to secure the situation for the most enthusiastic applicant.”

He was also examined in reference to the quantity of beer drunk by the three Assistant Medical Officers. He emphatically denied that they had drunk seventeen pints and a half of beer a day. He was also asked about some rat-killing by dogs which took place on one occasion at the back of the Hospital, at which the Assistant Medical Officers were present.

Mr. Aikman said, “It is not true we kept fighting-dogs. There has not been a single complaint, that I am aware of, against us, about our drinking too much beer, about keeping dogs, and such like.”

Mr. Collins read a minute from the report of the Committee of the Hospital to the whole Board, the minute being dated July 31 last. It stated that the Committee had given notice to dispense with the services of the whole staff at Islington (referring to the closing of the Convalescent Home), and also of the reduction of salaries to the Medical Superintendent, chaplain, matron, and house steward, “in accordance with the arrangements made with them when the establishment was opened.” The Committee thought it due to the chief officers to express their sense of the zeal displayed by the staff in simultaneously working the two large establishments over a period of eight months, during which more than 5000 patients had been treated. The minute proceeded to say that as the Medical Superintendent had expressed his opinion that by the closing of the Islington Convalescent Home he hoped, with the reduced number of patients, the establishment at Hampstead could be worked with one Assistant Medical Officer, the Committee had given Mr. Greaves and Mr. Kynaston notice that their services would be dispensed with, and Mr. Aikman having tendered his resignation, it had been at once accepted, and the Committee were taking steps to supply his place. Mr. Collins put it to the witness whether any other reason than the reduction in the

staff was ever given for dispensing with the services of his colleagues, and the witness replied—after some discussion had arisen as to the question being permitted, the witness not having been present when the notices were given—that the morning after he heard Dr. Grieve say that he was commissioned by Mr. Wyatt to say that the reduction in the staff was the sole reason for dispensing with the services of his colleagues. This was after the “rat business” and after the allowancing of beer.

Dr. Buchanan then put some questions to Mr. Aikman in reference to different parts of his evidence, but no answers were elicited which in any degree materially affected his evidence given in chief.

At the termination of this day's proceedings the inquiry was adjourned until Monday, October 2.

NINTH DAY.

Mr. Aikman being recalled,

The Chief Commissioner then asked him: You have said you thought the tying down injurious when it rubbed off the small-pox sores. Do you know of anyone who was materially injured by such rubbing off?—I cannot say that; but I have seen portions of the eruption rubbed off.

Understand my question, and answer it as closely as you can. My question to you is to find whether you think any patients had their recovery materially impeded by this?—Well, it is an extremely difficult question to answer, and I will answer it by saying that I do not know of any case in which I could trace any injury leading to a fatal result. That is the best answer I can give you.

Did you ever see the skin of any patient lacerated deeply by the tying down?—I never saw that.

I want to know whether any one had a temporary or permanent injury owing to this tying down?—Well, I have seen the skin rubbed off.

Was it deeply lacerated?—Oh, no; the skin was only rubbed off.

Was it any worse than is caused by a child scratching itself?—Not any worse.

He was then questioned about the management of a Hospital in Glasgow, in which he had served, as compared with that of the Hampstead Hospital. He said: At Hampstead I have had to complain of dead bodies being left in wards. I remember a body in Ward 3 being left there nearly all day. It was that of a person who died shortly after the morning visit, and was there at four o'clock when I made an afternoon visit. It must have been there about five hours. It was removed when I made the evening visit. I made no complaint of that to Dr. Grieve. I spoke to Sister Caroline about it. I think that is about the longest time I know of a body being left. I cannot remember any other. That was in July, and I do not remember the name of the person whose body it was.

The cross-examination of Elizabeth Haynes, a nurse, whose examination in chief was taken last week, was then commenced. The first part of the cross-examination was an attempt to throw a doubt on the reliability of the witness by eliciting the fact that she had some pots of jam in her possession, which, however, she said were her own property, as they were given to her when a patient in the Hospital, before she became a nurse. In reference to a child whom she represented as dying a few hours after having been taken out to play, the following information was elicited:—“Children who were too ill to walk were taken out on beds and placed in the sun. I never heard the Doctors order children to be taken out into the open air; but I have taken children out by the orders of Sister Agnes, and the one I referred to as dying soon after going out I took out and put on the bed in the air. This was about four o'clock in the afternoon, and its name was Sarah Smith. The child might have been out in the morning. I fetched her in on the same day at half-past twelve to dinner. I had taken her out in the morning, and I did so as well in the afternoon. (The evidence in chief of the witness was here read, and it was shown that she gave twelve o'clock as the time when she took the child out “to play.”) What I meant to convey by “to play” was that I placed her on the bed to play with other children. The child was dressed by Sister Agnes. I am certain this was Sarah Smith. I do mean to say she was out on the day she died. The child, Sarah Smith, was not unable to sit up, for she used to sit up sometimes. She sat up on the bed and played with the others the day she died. Then I mentioned a child, Alice Mary Clayton. I did say that this child was ordered a bath at ten o'clock in the morning, and that the child was dead in bed at a quarter past twelve. The child did

not die on Sister Agnes's lap while she was washing and dressing it.

The next witness was a man who had been a patient—Thomas Jones, a mechanical draughtsman. He deposed to having seen patients tied down, to the scanty supply of milk, to the nasty taste of the beef-tea, to the bad character of the food, to the filth and damp of the sheets, to the vermin, the dirty state of the clothes provided for convalescents, and to the insufficiency of the washing apparatus. He produced a copy of a letter of complaint which, he said, had been signed by sixteen patients, and had been sent to a daily paper, but which had not appeared.

At the end of this witness's cross-examination, Mr. Williams said he did not wish to point out to the other side how they should conduct their case, but he hoped they would follow out the evidence they had lately brought forward (referring to Mr. Aikman and the nurse's evidence) by continuing this class of witnesses.

Mr. Bucknill replied that his side proposed to continue the evidence of patients, Mr. Aikman and Haynes being introduced through others being absent. His side proposed to exhaust the patients first before taking other evidence.

Mr. Williams added that his side's patience had been already exhausted.

The case was then adjourned until Tuesday.

TENTH DAY.

The witnesses examined on Tuesday were J. G. Palmer, a wine and commission agent, William W. Todd, a printer, and Elizabeth Fowle, the wife of Mr. Fowle, watchmaker, each of whom had been a patient in the Hampstead Hospital. The two men gave evidence which supported the statements of other witnesses as to the tying down of patients by nurses without Medical orders, the scantiness and bad quality of certain articles of food, the filth, vermin, and insufficiency of nurses.

Mrs. Fowle, who said she had heard of this inquiry from the newspapers, and who came forward to volunteer her evidence, gave a similar account. She had gone into the Hospital with her baby, who had the small-pox as well as herself. She described the sheets of the bed in which she was first placed as filthy in their condition; and she deposed to seeing a woman, who subsequently died, tied down. She complained of the shortness of milk in this ward; and she found it very short, she said, as she wanted it frequently. She did not always get it when she wanted it; she was told “presently,” or that there was none. At other times she had water given to her to add to the milk “to make it last.” In witness's opinion Nurse Meredith was not in a fit state (being, as the witness said, pregnant) to perform her duties as a nurse, and she was greatly less energetic than the night nurse, and less kind.

Mr. Williams remarked that Nurse Meredith received from the Assistant Medical Officers the highest testimonials.

The witness proceeded to give, as an instance of the want of attention on the part of Nurse Meredith, that a girl in a dying state asked for milk for five hours without getting any, and then witness gave her some, getting out of bed to do this act, for which Nurse Meredith stopped her beer. The girl mentioned died at two o'clock the next morning after this. Witness's child was taken worse on March 9, at a time when witness was getting better. The child, which was 16 months old, was once taken away and placed in an empty bed, but on being brought back on witness asking for it, Nurse Meredith said she brought it back on the condition that no more trouble was given to her by the witness. Witness had asked repeatedly for clean linen, and was told that no one could be got to wash the linen, and, therefore, “sbift” must be made. Witness “made shift” with the pillow-cases, and though she had some clean linen every day, the state of her child would not permit her to keep herself clean. She asked for water, but she could not get it. Her child died on the 11th, and to the 14th from that date she did not touch water. She went from that ward to No. 8 (convalescent ward), and though a bath was there she could not use it, as the water in it was almost black. The patients were told not to interfere with the bath as it was out of order, but as many could wash as the water would permit. Her clothes were not changed when she went to No. 8 Ward, and at that time her dress was stiff up to her arms with filth. There was no day nurse in the convalescent ward—not that she saw, and her bed in this ward was in a filthy state. She was asked by the patients in the ward if she had looked for the “Hampstead donkeys.” She did not know what was meant, but on looking into the bed she found three—live vermin she meant. The sheets were in a

dirty condition—dirty from use and dirty otherwise. She had to wait for clean clothes to wear, and so was obliged to use the bed. Then, the meat she was given was bad, served out in coarse and vulgar-looking pieces; it was like cats'-meat, and it was very badly cooked. She said she would decidedly say that what the patients got for a ration would not represent six ounces of uncooked meat. The patients, one and all, complained of the quantity and quality of the meat; on one occasion the patients placed all their rations back, and on that day not one ate her rations. The potatoes were very bad—always diseased. She was very weak when she left the Hospital, and she attributed that weakness to want of food. Though Nurse Meredith might have acted to Mr. Greaves's "entire satisfaction," as stated in the testimonial read, she had not so acted to the patients under her. Mr. Greaves was deceived in his view. Mr. Kynaston, in speaking of Nurse Meredith as a "faultless" nurse, was also deceived. Witness did not think she was deceived in her estimate of the nurse. The bread in the Hospital was very good; but the butter was not so good—it was salt, and not well-tasted. It was not "fresh" butter. All the time she was there the butter was bad. It would not astonish her at all to hear that some said it was good, for tastes varied. The potatoes were hard—they were old—but she would not expect new potatoes in March. She heard one patient complain to Dr. Grieve for the whole of the ward about the meat being very bad, and not fit for a dog. He said nothing, but walked on. She complained once to Mr. Greaves of not having milk for her baby, and he called the night nurse, who was called the kind nurse—not Meredith—and told her to get some for witness and her baby. The Medical man visited the ward morning and night, but she did not remember seeing a Medical man visiting Ward 8—not visiting the patients—the whole four days she was there.

By the Chief Commissioner: There was no improvement in the meat after the complaint to Dr. Grieve that she knew. There might have been, but she did not taste it. The tea, coffee, and beef-tea were very bad. She complained of the bad quality of the food given rather than of the quantity, for her appetite was bad and she could not eat all she had. When on low diet she had about a pint of milk a day for her child—she did not require it for herself; but it was more difficult to get of a night, and she only got half a pint during the night hours. Her child was an unvaccinated child.

Re-examined by Mr. Collins, the witness said that Mr. Greaves, who attended her, was most attentive.

In reply to Dr. Buchanan, the witness said she could not remember seeing Mr. Greaves in the wards between the hours of the night visit and the morning visit. She also replied to some general questions.

The inquiry was adjourned until Wednesday.

ELEVENTH DAY.

This day was taken up with the examination of Thomas Ellestie, a waiter; George Tidbury, a tailor; Edward Wilson, a chairmaker; Arthur Partridge, a bootmaker; and Edward Benyon, a draper's assistant. With the exception of the last-named witness, these persons were all kept at the Hampstead Hospital at the expense of their parishes. They gave evidence confirmatory of that given by the previous witnesses in the principal details. One patient, Arthur Partridge, deposed to having been allowed to stand three-quarters of an hour naked in the receiving-ward. His clothes were taken away, and he stood half an hour before a damp shirt was brought to him, and then a quarter of an hour whilst he was drying it.

Edward Benyon, the last witness examined, paid for his maintenance whilst in the Hospital. He gave his evidence in a perfectly calm, unexaggerated manner. He said he had a damp shirt given to him on going in; and he deposed to seeing patients tied down. He also spoke to the shortness of milk while he was on low diet, and when on ordinary diet the meat given was "like guttapercha," and was little in quantity. Then, when a person died, the body was not removed until about an hour after the man died, although the body might stink very much. The bread given in the Hospital was "very fair," but the butter was very bad. He complained to Mr. Jones, the wardsmen, who told him to tell the cook. He complained of the dirty condition of the bath in the "hut" wards, and stated that these were covered with loathsome vermin and filth. One of the general complaints which the witness made was that the hut patients were kept without their dinner until three o'clock in the afternoon, because the meat was not cooked.

Questioned by Dr. Buchanan, the witness said the day nurses came on at six and the night nurses went off duty at half-past

eight. The day nurses did not go round the wards and see how the patients had been going on during the night, nor did they go round with the night nurse to inspect the patients. They did not inquire of the night nurse how the patients were going on, and he was only asked once by a day nurse as to how he was. The day nurse never gave medicines before breakfast. He never remembered an instance of a ward being left without a nurse, for one at least would be there in the early morning, putting the beds straight. The patients got nothing for breakfast but tea and bread-and-butter. The night nurses went off duty before the breakfast was served, and the day nurses occupied themselves with handing the food about, but they did not feed the patients. There were many patients who could not sit up and help themselves, and he thought he had seen about four at one time so unable to sit up. These had a little-table from which they could reach their bread-and-butter. He did not see any patients too ill to do this.

The witness was further examined by the Medical Commissioner respecting the manner in which the general routine of the ward-work was carried out, as to the emptying of slops, the sweeping of wards, making of beds, and such like, part of which work, it transpired, was done by convalescents. Clean linen, he said, did not come in every morning, and he had seen some come in twice in five days. He had seen the beds made for every patient; but he did not see nurses wash the patients. He never saw one washed by a nurse, nor was the discharge from their skin attended to in any way. He had seen the nurses cut some patients' hair; but he did not see them apply anything to the head. The Sister of the ward used to see the night nurse every morning—the night nurse waiting to see the Sister. The Doctor's visit was at about the same time every day—always at about eleven o'clock in the morning. After that was over there were preparations for dinner, and for this the nurses cut the bread, and about six patients who were up took the dinners to those who were in bed. Between one o'clock (that was after dinner) to the tea-time the nurses had little to do, generally sitting down reading. The Sister gave the medicines. The nurses generally, when sitting down, would attend to the call of any patient. He considered the patients were fairly taken care of during the day.

Dr. Buchanan: Do you consider the nurses were over-worked?—Oh, dear no.

How long do you think it would take them to do the work they did in the ward if they had not to wait upon patients?—About an hour and a half.

You think the day nurses might have done their work in an hour and a half?—I do.

The witness then proceeded to state further that the night nurses came on at half-past eight at night, and then the day nurses left; but they did not go round to any particular cases. He never saw wine or whisky in the ward. A man in the next bed to him was ordered whisky, but he did not get it. There was only one night nurse between Wards 4 and 5, and her work lay principally in No. 5. He never saw her sleeping during the night. He never saw Mr. Greaves between night and morning enter the ward.

REVIEWS.

An Introduction to Pathology and Morbid Anatomy. By T. HENRY GREEN, M.D. Lond., M.R.C.P., Lecturer on Pathology and Morbid Anatomy at Charing-cross Hospital Medical School, and Senior Assistant-Physician to Charing-cross Hospital. Pp. 304. London: H. Renshaw.

THE more one reflects, the more one is surprised that it was only the other day pathology was made compulsory in our system of education. One would have supposed that the study of the processes of disease and their results would have at all times formed one of the subjects of study; and yet in too many instances the lecturer on pathology had to lay his facts before the scantiest of audiences; and too often in the post-mortem room the pathologist's consisted of the dissecting-room porter. Recently, however, pathology has made giant strides, not only as regards the increase of our knowledge, but also in popularity, insomuch that certain others of the departments of Medicine (notably therapeutics) are in danger of being left in the hands of those least able to take care of them; and yet, with this increased and increasing popularity, the study of the subject was rendered by no means easy, owing to the want of any text-book abreast with the knowledge of the age. It is true valuable monographs existed, and we had much admirable material in the *Transactions* of the

Pathological Society; but to the student these things were like *caviare*, and to refer them to any one of these was, indeed, to place strong meat before babes. One of the most popular text-books of its time—Dr. Wilks's work on Pathology—has long been out of print, and now sells for twice its original cost; Jones and Sieveking's Pathology was the pathology of the past; Chance's translation of Virchow is long since out of print. In short, did a student ask what book to study, the teacher could but tell him to attend regularly in the post-mortem room, and to listen carefully to his lectures; as for home study, that was impossible. Now, both words of advice were good. The post-mortem room is, undoubtedly, the place to teach and the place to acquire a knowledge of morbid anatomy. But facts are not everything: a man requires something whereby to string them together, so as to render them useful in practice—in this every doctrine comes in. It is not possible for the student to remember everything told him in the lecture theatre; to complement that, home reading is required, and in pathology no English text-book was to be had. Could the student read French we might refer him to Cornil and Ranvier for Morbid Histology; if he was also a German scholar we might tell him to take Rindfleisch or Förster, or Klebs or Lücke—all good books in their way, but sealed to the many.

In common with other teachers, Dr. Green felt the want, and set about remedying it. He had that best of all guides as to what was required—experience; thus he has carefully endeavoured to supply what is necessary for the student, and no more. The book Dr. Green has produced aims at being essentially a student's book, and its purpose is admirably fulfilled. After a careful study of its contents, we can find nothing to which we can object; not very much, its end being kept in view, we should care to add. It is well done; everything being thoroughly and conscientiously worked up to the latest date. But though a student's book, we commend it to men of larger growth. Practitioners whose time is valuable, and whose leisure is of the scantiest, will here find in the smallest compass a clear exposition of modern pathologic doctrine, which they will do well to study, if only to see how much things have changed since their student-days, and are still changing. Let us cite, as most important to them, the various kinds of degenerations, the doctrines of tuberculosis, the grouping of the new growths, the process of inflammation as manifested in different structures, the effects of embolism, etc. All these are here well and carefully discussed; the various steps in the different processes being clearly explained. One virtue of the book, so far as the student is concerned, is its dogmatic character. By assuming the tone of a master, it is possible to teach the student something; the knowledge that this man says one thing, and that man another, is the most useless of acquirements. Nevertheless, that it may be in a man's power to follow up the study of any particular subject, references to the prime authorities are desirable, and in a certain fashion Dr. Green has seen to this by giving a list of works in an appendix: to these the advanced student may refer, but the original worker must look to monographs, magazine papers, and what not, if he desires to know what has been done before him; but, as already stated, this book is not intended for such.

Were we to select the portions of the book which strike us as being of most interest we would point, among others, to that in which new growths are treated, and to the careful way in which malignancy is considered apart from structure. Cancer, it is pointed out, is a specific form of new growth, very malignant no doubt, but nearly approached in this respect by certain of the sarcomata. Then, again, inflammation is very well done; the different forms of inflammation of the lung have received the attention they deserved, and are very clearly described. Tubercle and embolism will also well repay perusal; but we do not know that we can do better than refer the reader to the book itself—it will well repay him. To the student of Medicine we say more: let him, for a time at least, make it his constant companion.

It is officially announced that cholera has entirely ceased at Hamburg.

THE returns of the Paris lunatic asylums, just issued, show a diminution in the amount of madness, and suicides have, since the first investment of Paris, become unusually rare. On the other hand, a sort of idiotic stupor prevails to a considerable extent, especially among women, owing, it is alleged, to the successive shocks given during and after the siege to the nervous system.

GENERAL CORRESPONDENCE.

VACCINATION IN MAYFAIR.

LETTER FROM DR. PROTHEROE SMITH.

[To the Editor of the Medical Times and Gazette.]

SIR,—Believing the following facts to be of sufficient interest for publication, I have been induced to send them to you. The population of the Mayfair and Hanover-square districts, as taken at the last Census, was 31,720 persons. Though probably several cases of small-pox occurring in these districts may have been removed out of them to Hospitals, yet still, the small amount of mortality from this disease registered for the half-year ending June, 1871 (two being the total number), speaks favourably for the quality of the vaccination by puncture for some years past. This has been recognised by the Privy Council in awarding to Mr. Jay, the public vaccinator, two grants—one in 1868, of £16, and another in July of this year, of £15 17s.

The following table shows the number of persons vaccinated by the public vaccinator during the last twelve months ending June 30, 1871:—

	Primary.	Secondary.	Total.
1870.—July 1 to September 30	45	4	49
October 1 to December 30	43	1	44

THE EXTERNAL USE OF BICHLORIDE OF MERCURY.

LETTER FROM DR. TILBURY FOX.

[To the Editor of the Medical Times and Gazette.]

SIR,—I must protest, in answer to Dr. Dowse's letter, against the use of the word "lotion," as applied to the solution of bichloride of mercury which I sometimes use in ringworm. The remedy is classed with *vesicating* parasiticides in the formulary of my work. I have made a separate group of "*milder parasiticides* for ordinary use," with the very object of preventing anyone from using the stronger parasiticides without due caution or regarding them as lotions. I commend to the notice of your readers an article in the *Practitioner*—which, by the way, I did not write—on the general question of the use of mercurial applications in ringworm. I am, &c.,
43, Sackville-street, W. TILBURY FOX, M.D., F.R.C.P.

DOMESTIC SANITATION.

LETTER FROM MR. CHARLES ORTON.

[To the Editor of the Medical Times and Gazette.]

SIR,—I believe it is an acknowledged fact that enteric fever may be caused in any residence by the escape of sewer gases through the water-closet. It is not here necessary to consider whether such gases have resulted from decomposing fever-matter or not. Now, however well trapped sewers may be, gases will escape more or less frequently. Would it not be advisable, then, to construct the closets so that the pipes might be flushed by disinfectants, and a layer of disinfectant fluid be left in the pan? The flushing with disinfectants might be dispensed with if another smaller cistern, or even bottle, holding concentrated disinfectant could be connected with the pan, and could be made use of easily—for to many people it is too much trouble to attend to sanitary matters.

And now that I have mentioned sanitary matters, allow me to have a kick at local boards of health. Removed as far as we are from Medical journalistic eyes (though not too far, if they only knew what good they would do if they came and looked around and then spoke up about such unimportant places), we suffer greatly in mind and body, though not, perhaps, in pocket. Here is a nice pleasant little town of 16,000 souls, where manure and the contents of the gutter cess-pools are left on the high roads for days together. I may add that the ratepayers sanction the Local Board of Ill-health in their extravagance of having two scavengers for 16,000 inhabitants, many of them Irish.

Need I say that we are never free from preventible diseases.

A few comments from you would be thankfully received, and repeated by many besides.

I am, &c., CHARLES ORTON,
Hon. Medical Officer to the
North Staffordshire Infirmary.
Newcastle-under-Lyme, Staffordshire, Sept. 24.

OUR DISINFECTANTS.

LETTER FROM DR. A. FARR.

[To the Editor of the Medical Times and Gazette.]

SIR,—It is a deplorable fact that so few Medical men are in a position to give anything like a satisfactory answer to the question—"Which is the best disinfectant?" No sooner is a substance discovered supposed by some individual to possess extraordinary disinfectant or antiseptic properties, than it is launched forth to the public, and, like a quack medicine, "kill or cure," its sale becomes proportionate to the publicity which is given it. Now, is it not probable that we have been in error about our disinfectants; that we have voted a bane that which has been the antidote, or *vice versa*; and that it remains to be proved whether or not He who locked up the poison, barium, in the earth, in the form of an insoluble salt, that all life on its surface—animal and vegetable—might not be swept away, has ordained that a substance so universally diffused as chlorine is the element which will be discovered in the end to be the best agent in preventing the spread of disease? But the *ipse dixit* of one man is not sufficient to settle a question so vitally important as this; and nothing short of a scientific inquiry directed by our Government is due both to the public and the Profession.

I am, &c.,
88, Waterloo-road. A. FARR.

THE TESTIMONIAL TO SIR JAMES PAGET.

[To the Editor of the Medical Times and Gazette.]

SIR,—The Profession will learn with unmixed satisfaction that it is in contemplation to present a testimonial to Sir James Paget on his elevation to the baronetcy. It is very honourable to St. Bartholomew's Hospital that this proposal should have emanated from thence; but, Sir, the scientific world recognises Sir James Paget as belonging to it and to the Profession at large, and I am persuaded that the Profession at large will gladly endorse this recognition if opportunity be conceded it to participate in the movement. The main question which naturally presents itself is—What form should such a testimonial most appropriately take? Passing over the familiar and well-worn expedients of a piece of plate or a portrait, as less worthy emblems of a feeling like this, would it not be more in unison with the character of the recipient, as well as more distinctly expressive of their appreciation of it by the givers, if a Paget Fund were established in connexion with the British Medical Benevolent Fund (of which Sir James Paget is already a trustee, and his sympathy with its purposes so thoroughly known), in order to found one or more annuities for ever, for the support of aged and destitute members of the Profession, or their widows, to be chosen from the most deserving and necessitous in the same careful manner as that in which the other annuitants supported by that institution are at present selected; or in any other way which Sir James might himself suggest?

Will you permit me, through your valuable aid, to submit this for general consideration; and whether it would not for all time enhance the honour we desire "to render to whom honour is so justly due," to identify with it a help in need to the less successful of our brethren in the race of life?

I am, &c., H. F. S.

OBITUARY.

CHARLES ALEXANDER HARRIES, M.R.C.S.

WE regret to record the death of Mr. Chas. A. Harries, of Bath. This gentleman was born February 19, 1808. He was engaged in the practice of his Profession upwards of forty years. An ardent lover of science, a man of genial and amiable disposition, ever ready with a cheering smile and kindly word, a zealous discharger of every private and public duty, he won the respect and affection of a very large circle of patients and friends. He was a Town Councillor for many years, and rendered valuable services to his fellow-citizens. So attached was he to his work that, although ailing for some time, he

only ceased his labours a few months since, being compelled to resign his practice by the progress of cardiac disease, which terminated fatally on September 22, 1871.

NEW INVENTIONS.

COCKING'S PATENT POROPLASTIC SHEET FOR SPLINTS.

THIS new form of splint promises to become extensively useful. If not quite original, it certainly possesses advantages over all previous similar inventions. To use the language of the patentee, "It is elastic, light, porous, flexible, plastic, and economical; is made of all required strengths and sizes, and consists of a felted substance in sheets; is plastic when softened by heat, and becomes rigid when cold, and can be resoftened any number of times without injury; rapidly and easily manipulated, the most difficult splints requiring but a few minutes to complete; is very well adapted for metal attachments, and is thus a very valuable material for interrupted splints. There is no glue used in its composition, and the gums with which it is stiffened are quite harmless."

It is seldom we are able to endorse a patentee's account of his own invention, but in this particular instance we can do so without reservation. To Practitioners in the country and the colonies, "Cocking's Splint" will be of the utmost service. It has already been used with success by many of our leading Surgeons, and has been found to answer all that was either required or expected. Its very moderate price also commends its general use to Surgeons.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received their Certificates to practise, on Thursday, September 28, 1871:—

Elam, Shrofield, 40, Woburn-place, W.C.
Mountaine, John, Wise's Hill, Sunday's Well, Cork.

The following gentlemen also on the same day passed their first Professional examination:—

Bennett, William Edward, Guy's Hospital.
Evans, John, London Hospital.
Nix, Edward James, Charing-cross Hospital.

At the Preliminary Examination in Arts, held at the Hall of the Society on September 29 and 30, 159 candidates presented themselves, of whom 66 were rejected, and the following 93 passed and received Certificates of proficiency in general education—viz., in the first class in order of merit:—

First: E. J. Morshead. Second: H. P. E. Freund. Third: A. C. Routh. Fourth: A. S. Eccles, J. C. Hayward, F. Nicholls, and H. C. Taylor. Eighth: H. R. H. Bigg, F. S. Edwards, F. G. Hayes, P. Hookham, J. L. Jaquet, W. B. Johnson, R. D. Perry, and Thomas Tomlinson. Sixteenth: J. R. Blackie, L. Druitt, C. G. Emson, E. Ground, A. G. Lacy, Stephen M. Smith, and J. Wishaw.

In the second class, in alphabetical order:—

Anderson, L. M.	Davies, A. M.	Martwaring, W. H.
Ashe, P. W.	Downing, H. P.	Martyn, Ernest.
Baber, H.	Ferguson, D. W.	Moore, Joseph W.
Bartlett, Henry.	Foresythé, William.	Mugliston, T. C.
Bell, T. A.	Francis, E. G.	Pinnell, Richard.
Biale, J. S.	Gray, Walter.	Poland, J. H.
Bigg, George S. K.	Grigg, W. H.	Rigby, P. A.
Blair, Archibald.	Hambleton, G. W.	Risk, R. R. T.
Blake, H.	Harris, Howard.	Roberts, Alonzo.
Bouton, G. C.	Harding, A.	Roberts, John T.
Bonsall, G. R.	Hatch, W. R.	Robins, Harvey.
Bowen, A. L.	Hodgson, Alfred.	Rule, G. F. H.
Bowling, C. J. L.	Holmsted, C. A.	Scholfield, W.
Brown, Francis W.	Humphry, Reginald.	Steele, Richard.
Brown, Thomas L.	Jones, Robert Dennett.	Stephenson, John J.
Burlton, A. H.	Jones, William.	Swaine, John G.
Burton, H. C.	King, N. T.	Symons, John.
Butler, G. W.	Knight, J. Tomlinson.	Thomas, John.
Campbell, W. F.	Lampray, J. J.	Tomlinson, Henry Thos.
Chadwick, G. R.	Lane, S. E. H.	Townsend, Charles P. G.
Chamberlain, E. T.	Lawson, John.	Wade, Ethelbert.
Crofts, H. B.	Lewes, Joseph.	Ward, Austin George.
Dacosta, Edmund.	MacLaughlin, E. H.	Wilson, Arthur Frank.
Daniell, H. E.	Malpas, D. D.	

APPOINTMENTS.

*. * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

KISBY, WILLIAM J., L.F.P.S., L.M., L.A.H.—Apothecary to the Gort Workhouse and Dispensary.

LOW, ROBERT BRUCE, M.D.—Medical Officer for the Messingham District of the Glanford Brigg Union.

MORISON, BENTHAM P., M.R.C.S.E., L.S.A., L.R.C.P., L.M. Edin.—House-Surgeon to the Hereford Infirmary, *vice* J. Bevan, F.R.C.S.E., resigned.
 ROWORTH, ALFRED THOMAS, M.R.C.S., L.S.A.—Surgeon to the Grays District of the Orsett Union.
 STRAFFORD, THOS., M.R.C.S., M.R.C.P.—Resident Surgeon to the Worksop Dispensary, *vice* Edward J. Cooke, B.A., M.B., T.C.D., resigned.
 TIBBETTS, R. W., M.B., M.R.C.S., L.S.A.—Surgeon to the Bristol Police Force.

NAVAL APPOINTMENTS.

ADJUTANT.—In accordance with the provisions of Her Majesty's Order in Council of February 22, 1870, the undermentioned officers have been placed on the retired list of their rank from the dates mentioned against their names:—Staff Surgeons Charles T. S. Kenern, September 22; Andrew Murray, September 22; and Joseph Henderson, M.D., September 27.

BIRTHS.

BENNETT.—On September 29, at The Grove, Lymm, Cheshire, the wife of Charles Fredk. Bennett, M.D., of a son, stillborn.
 BOGG.—On September 28, the widow of Dr. E. Beverley Bogg, R.N., of a daughter.
 CORNER.—On September 3, at Manor House, Poplar, the wife of F. M. Corner, Surgeon, of a daughter.
 CREIGHTON.—On September 25, at Charlotte-street, Hull, the wife of Robert Creighton, R.N., Surgeon H.M.S. *Invincible*, of a son.
 DICKSON.—On September 1, at Bhangulpore, the wife of Lindsay Dickson, M.D., Bengal Army, of a son.
 FARRINGTON.—On October 1, at The Moat, Penshurst, Kent, the wife of W. H. Farrington, M.D., of a son.
 MOORE.—On October 2, at Brunswick-square, Brighton, the wife of William Withers Moore, M.D., of a daughter.
 SEALEY.—On August 1, at Nelson, New Zealand, the wife of W. B. Sealey, of a daughter.
 WOOD.—On September 28, at Wood-villa, Shirley-road, Southampton, the wife of Dr. Wood, of a son.

MARRIAGES.

BEAVAN—MARKHAM.—On September 27, at the district church, Riverhead, James Beavan, F.R.C.S., of Hereford, to Elizabeth Ward Markham, of Brooklands, Riverhead, Sevenoaks, Kent, daughter of the late T. Markham, Esq.
 DARLEY—ALLEY.—On September 27, in Coolock Church, county Dublin, Frederick Alexander Darley, Esq., Captain Bengal Staff Corps, eldest son of Benjamin Guinness Darley, M.D., Greenfield, Coolock, to Dorothea Elizabeth, second daughter of Thomas Alley, Esq., of Artaine House and New Park, county Dublin.
 DOBREE—BRIDGE.—On September 27, at the parish church, Wellington, Samuel Dobree, Esq., of The Priory, Wellington, Somerset, to Mary Mitford Tozer, daughter of S. Franklin Ridge, M.D., of Old Court, Wellington.
 GROOM—WOOD.—On September 24, at the parish church, Ore, Leonard Groom, Surgeon, to Rose Wood, of Hastings.
 HARLEY—WILLIAMS.—On October 3, at the parish church, Saffron Waldon, Edward Harley, L.R.C.P.L., to Gladys Powys Williams.
 PITTOCK—BENNETT.—On September 21, at Brixton, George M. Pittock, M.B. Lond., of 23, Cecil-square, Margate, to Emma Jenkins Bennett, niece of Richard Jenkins, Esq., J.P. of Margate.
 POWNALL—DIAMOND.—On September 14, at the Cathedral, Quebec, Robert Pownall, Esq., of Montreal, to Mary Margaret, eldest surviving daughter of Dr. Diamond, F.S.A., of Twickenham House, Twickenham, Middlesex.
 SKENE—ANDERSON.—On August 2, at Menzies Hotel, Melbourne, Thomas Skene, Esq., of Bassett, eldest son of the Hon. W. Skene, M.L.C., of Skene, Hamilton, Victoria, to Margaret Scott, second daughter of the late Alex. Anderson, M.D., of Jedburgh, Scotland.
 VALE—DUGDALE.—On September 28, at St. Mark's, Witton, near Blackburn, the Rev. W. Theodorice Vale, vicar of All Saints', Blackburn, eldest son of James Theodorice Vale, M.D., of Green House, Balderstone, to Anne, youngest daughter of Thomas Dugdale, Esq., D.L., of Griffin Lodge, Blackburn, Lancashire.

DEATHS.

BUTLER, CORNELIUS, F.R.C.S., at Brentwood, from the effects of an accident, on September 30, aged 82.
 GREIG, EMILY LUCY, the beloved wife of Charles Greig, F.R.C.S., of York-place, Clifton, and youngest daughter of the late Admiral Renwick, at Southerndown, Glamorganshire, almost suddenly, on September 30.
 KENNEDY, MARY ANN, the beloved wife of Angus Kennedy, Surgeon, Stratford Hall, Essex, at the residence of her son-in-law, on September 27.
 MEERES, MARIANNE EMMA, of Grove-place, Tottenham, widow of Thomas Meeres, Surgeon, at Ramsgate, of congestion of the lungs, on September 26, aged 66.
 PANTON, GEORGE, Surgeon, at Dorchester, on September 26, in his 56th year.
 REITH, MARGARET SKELTON MURRAY, wife of Archibald Reith, M.D., at 39, Union-place, Aberdeen, on September 22.
 SAVORY, JOHN, M. and L.S.A., of 22, Sussex-place, Regent's-park, and formerly of 143, New Bond-street, at Ely Grange, Frant, on October 3, in the 72nd year of his age.
 YOUNG, A. K., C.M., M.D., etc., at Southend, on October 1, aged 69.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
 CHARGING-CROSS HOSPITAL.—Assistant-Physician. Must have a Degree from one of the Universities recognised by the General Medical Council, and must be F. or M.R.C.P.L. Residence within three miles of the

Hospital is necessary. Applications and testimonials to Mr. H. Woolcott, Secretary, on or before October 24.

CORNWALL COUNTY LUNATIC ASYLUM.—Assistant Medical Officer. Must be duly qualified. Applications and testimonials to Mr. R. Adams, on or before October 14.

DEVON COUNTY LUNATIC ASYLUM.—Assistant Medical Officer. Applications and testimonials to Mr. T. E. Drake, Solicitor, on or before October 26.

DUDLEY GUEST HOSPITAL.—Resident Medical Officer. Must have both Medical and Surgical qualifications, and be registered. Applications and testimonials to the Rev. G. Y. Osborne, St. Edmund's Vicarage, Dudley, on or before October 14.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST.—Visiting Physician. Must be M.R.C.P.L. Applications and testimonials to Francis Baily, Secretary, 26, Margaret-street, Cavendish-square, W.

LIVERPOOL NORTHERN HOSPITAL.—House-Surgeon. Must possess both Medical and Surgical qualifications. Applications and testimonials to Mr. J. Unsworth, on or before October 16. Election on the 20th.

MARLBOROUGH UNION.—Medical Officer for the Second District. Candidates must possess the qualifications prescribed by the Regulations of the Local Government Board. Applications and testimonials to Mr. E. B. Merriman, on or before October 16. Election on the 18th.

POCKLINGTON UNION.—Medical Officer for the Pocklington No. 2 District. Candidates must be duly qualified and registered. Applications and testimonials to Mr. W. Silburn, on or before October 20. Election on the 21st.

ROYAL SURREY COUNTY HOSPITAL.—House-Surgeon. Must be duly qualified in Medicine and Surgery. Applications and testimonials to the Assistant-Secretary, Guildford, on or before November 6.

TIVERTON UNION.—Medical Officer for the parishes of Silvertown and Bickleigh. Candidates must be duly qualified in accordance with the Regulations of the Local Government Board. Applications and testimonials to Mr. C. M. Hole, on or before October 16. Election on the 17th.

YORK COUNTY HOSPITAL.—House-Surgeon. Must be duly qualified. Applications and testimonials to Mr. R. Holtby, on or before October 20.

WARMINSTER UNION.—Medical Officers for the Warminster District and Union Workhouse, and for the Corsley District. Candidates must possess the qualifications prescribed by the Local Government Board. Applications and testimonials to Mr. J. Merrick, Clerk to the Guardians, Warminster, on or before October 16. Election the same day.

WARRINGTON, BOROUGH OF.—Medical Officer of Health. Must be duly qualified, and be registered under the Medical Act of 1858. Applications and testimonials to Mr. G. T. Moore, Town Clerk, on or before October 7.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Bristol Incorporation.—Mr. C. H. Dowson has resigned the Second District; salary £100 per annum.

Dorchester Union.—The First District is vacant; area 1411; population 3760; salary £31 4s. per annum; also the Workhouse; salary £30 per annum.

Pocklington Union.—Mr. Danson has resigned the Second Pocklington District; area 25,555; population 2501; salary £20 per annum.

Weymouth Union.—Mr. F. C. G. Griffin has resigned the Melcombe Regis District; area 1548; population 6498; salary £45 per annum.

APPOINTMENTS.

Bridgwater Union.—John F. V. Bent, M.B., M.D., C.M. Edin., to the Broomfield District.

Stow Union.—John Wm. Harper, M.R.C.S. Eng., L.S.A., to the Fifth District.

Wakefield Union.—Wm. James Lorraine, M.R.C.S. Eng., L.R.C.P. Edin., to the Sandal Magna, Walton, and Chevet Districts; Benjamin Kemp, M.R.C.S. Eng., L.S.A., to the East Ardsley District.

ASSOCIATION OF CERTIFYING MEDICAL OFFICERS OF GREAT BRITAIN AND IRELAND.—The Fourth Annual General Meeting will be held at the Adelphi Hotel, Liverpool, on Friday, October 20, at 2 p.m. The members will afterwards dine together. Gentlemen intending to be present at the dinner are requested to notify the same to the Hon. Secretary, Mr. Stansfeld, Redland, Bristol, on or before Tuesday, October 17.

SIR ALEXANDER ARMSTRONG, K.C.B., has been appointed a member of the Senate of the Army Medical School at the Royal Victoria Hospital at Netley.

DR. HENRY S. WILSON, formerly Demonstrator under Professor Goodsir, at Edinburgh, has been appointed Demonstrator of Anatomy in the University of Cambridge.

CITY OF LONDON TRUSS SOCIETY, 35, FINSBURY-SQUARE.—The number of patients relieved during the month of September was 699, to whom 700 instruments were supplied.

DR. ELLIS has been exonerated by the St. Pancras Guardians from a charge of neglect brought against him by a man named Sturgeon, who has been in the syphilitic ward of the Workhouse Infirmary.

DR. PUCKLE, the Medical Officer for Lambeth, has resigned. We regret to say that the immediate cause of his resignation is ill-health. The vestry, on receiving the resignation, recorded their appreciation of the past services of Dr. Puckle, and expressed their regret as to the cause of his retirement.

WE regret to hear that Dr. Miller, Deputy Inspector-General of Hospitals in Scinde, has met with a severe accident through his horse taking fright.

THERE were 831 deaths in Paris last week. Forty of these were from bronchitis, 35 from pneumonia, 61 from diarrhoea, and 35 from typhoid fever.

SMALL-POX has been very prevalent on the Gold Coast, chiefly at Cape Coast Castle. The Executive were taking every sanitary precaution to stop the spread of the disease, and by the last advices it was thought to be on the decrease.

THE local authorities of Peterhead, Scotland, have decided to erect a public Hospital for the town.

THE annual meeting of the Royal Albert Hospital for Idiots was held at Bradford on Friday last. The gathering was numerous and influential. The report was most satisfactory; and the noble institution is progressing prosperously.

THE open Scholarship in Natural Science, of the value of £40 per annum for three years, recently established at St. Mary's Medical School, has been awarded to Mr. E. J. Edwards, and the Exhibition of £20 to Mr. Giles. Both these gentlemen are students of the University of London. The Scholarship and Exhibition are open to public competition, and are awarded every year.

UNIVERSITY OF CAMBRIDGE.—ANATOMY AND PHYSIOLOGY.—Professor Humphry gives notice of lectures and practical teaching as follows:—Lectures on Anatomy and Physiology in the new Museums, on Tuesdays, Thursdays, and Saturdays, at 1 p.m., commencing on Saturday, October 21. Lectures on Practical Anatomy on Mondays, Wednesdays, and Fridays, at 6 p.m., commencing on Monday, October 16. These, together with the Lectures on Anatomy and Physiology, constitute the course for M.B. and M.C., and for the Royal College of Surgeons. Microscopical Demonstrations on alternate Tuesdays, at 6 p.m., commencing on Tuesday, October 31. Practical Histology on Saturdays, at 11.30 a.m., commencing October 28. This, in conjunction with the Practical Physiology by Dr. Michael Foster, constitutes a course of Practical Physiology. Superintendence of dissections daily. Instruction on practical anatomy will be continued in the Christmas vacation.

THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At a meeting of this Corporation, held on the 2nd inst., the following office-bearers were elected for the ensuing year, viz.:—J. G. Fleming, M.D., President; George Buchanan, M.D., Visitor; John Coats, M.D., Treasurer; J. D. Maclaren, M.D., Honorary Librarian; James Dunlop, M.D., Vaccinator. *Councillors*: The President, *ex-officio*; the Visitor, *ex-officio*; William Weir, M.D., in terms of cap. ii., sec. 6, of Regulations; James Stewart, M.D.; Robert Scott Orr, M.D.; H. R. Howatt, M.D.; James Steven, M.D. *Board of Examiners*: Andrew Fergus, M.D., Chemistry; George Buchanan, M.D., Anatomy and Physiology; Robert Scott Orr, M.D., Medicine and Materia Medica; Wm. Leishman, M.D., Midwifery and Medical Jurisprudence; William Lyon, M.D., Surgery and Surgical Anatomy; Eben. Watson, M.D., Anatomy and Physiology; James Morton, M.D., Surgery and Surgical Anatomy; Robert Perry, M.D., Chemistry; P. A. Simpson, M.D., Midwifery and Medical Jurisprudence; Alexander Lindsay, M.D., Medicine and Materia Medica. *Clinical Examiners in Medicine*: The Physicians of the Royal Infirmary. *Clinical Examiners in Surgery*: The Surgeons of the Royal Infirmary. *Examiners in Arts*: John Coats, M.D.; James Steven, M.D. *Representative to the General Council of Medical Education and Registration of the United Kingdom*: John G. Fleming, M.D. *Inspectors of Drugs*: William Eadie, M.D.; James Morton, M.D. *Clerks*: Lawrence Hill, LL.D., and William Henry Hill. *Librarian and Secretary*: Alexander Duncan, B.A. *Officer*: John McFarlane.

NEGLECT OF VACCINATION.—On Tuesday an inquest was held at the College Arms, Camden Town, on the body of Joseph Mackey, aged 7 months, son of a feather cleaner, living at 100, Drummond-street, St. Pancras. It appeared the birth of deceased was registered in the usual way, but, owing to his suffering from whooping-cough, his parents did not have him vaccinated. He caught small-pox, and expired from its effects on the 30th ult. Mr. Frederick T. Coates, a Medical Practitioner, said he was called in to deceased on the 25th ult., and found him suffering from small-pox, and he expired from the disease. If deceased had been taken to him, he should have vaccinated him, notwithstanding the whooping-cough. There was no house-to-house visitation at St. Pancras. There were a number of children unvaccinated in the house in which deceased expired. The Coroner said the child had been registered, and the parish officials ought to look after the vaccination. It was disgraceful, in a large parish like St.

Pancras, that these matters should occur. Verdict—"Death from small-pox, accelerated by neglect of vaccination."

LONGEVITY IN ENGLAND.—There are recorded, in the return recently issued for the year 1869, the deaths of twenty-six males and fifty-three females registered as 100 years old or upwards when they died. Of the males, thirteen were aged 100, five 101, four 102, two 103, one 105, and one 106. Of the females, twenty-three were aged 100, thirteen 101, eight 102, two 103, five 104, one 105, and one 107. Twelve of these very aged persons died in London.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN SEPTEMBER, 1871.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
	Grains.	Grains.	Grains.	Grains.	Degs.	D.egs.
<i>Thames Water Companies.</i>						
Grand Junction	16.57	0.127	0.125	0.002	13.2	3.3
West Middlesex	16.53	0.030	0.112	0.000	13.3	3.3
Southwark & Vauxhall	16.27	0.077	0.111	0.002	13.0	3.3
Chelsea	16.80	0.081	0.125	0.002	13.4	3.3
Lambeth	17.27	0.077	0.110	0.002	13.8	3.4
<i>Other Companies.</i>						
Kent	27.23	0.010	0.196	0.000	20.0	5.6
New River	16.43	0.021	0.126	0.000	13.5	3.0
East London	15.27	0.051	0.135	0.000	12.1	3.5

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was more or less turbid—viz., in the case of the water of the Chelsea and the Grand Junction Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 116,327,971 gallons; and the number of houses supplied was 489,544. This is at the rate of 35.6 gals. per head of the population daily.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

*** Abstracts of the following Introductory Addresses are in type and will appear next week:—St. Mary's Hospital, by Dr. Alfred Meadows; Westminster Hospital, by Dr. W. R. Basham; Leeds School of Medicine, by Dr. Clifford Allbutt; Liverpool Royal Infirmary, by Mr. W. Carter; Queen's College, Birmingham, by Dr. Russell; University of Durham, by Dr. G. H. Philipson; Sheffield School of Medicine, by Mr. A. H. Allen, F.C.S.

Dr. Weber, Yokomairiro.—Your letter and enclosure have arrived.

L.R.C.S.I.—Cold baths and perchloride of iron.

Mr. R. Bowen, Bermuda.—Your letter, containing an enclosure, has come safely to hand.

F.R.C.S.—There are several blunders in the attempted analysis of the Calendar of the Royal College of Surgeons published last week in a Medical contemporary. Instead of a balance at the bankers' of £7 11s. 10d., as there stated, that sum represents the amount of expenditure over receipts. The absolute balance at the bankers' appears to be £1878 4s. 2d.

Plympton.—After a careful perusal of the case, we can come to no other conclusion than that Mr. Miles is entirely exonerated from all blame. Now, here are the facts:—A case of small-pox in the person of a young man, who had come down from London to visit his mother, occurred in the village of Plympton. The next day Mr. Miles saw him, and, after finding it impossible to place the patient in a position to be totally isolated, did, with the approval of a magistrate, at the request of the relieving officer, and with the consent of the patient and his mother, remove him to what are called the "infectious wards" of Plympton Workhouse. It now turns out that these wards are badly situated, badly built, and quite unsuited for isolating cases of infectious disease. The man died, and as many as eight persons in the house contracted the disease. It is a matter of complaint in some quarters that Mr. Miles did not acquaint Mr. Ellerly, the Union Surgeon, with the admission of a small-pox patient into the Workhouse; but Mr. Ellerly was informed of the circumstance within a very few hours. Mr. Ellerly asserts that the infectious wards were unfit for the purpose for which they were constructed, and that he would not have admitted the case into them on that account. The matter has now terminated, and we trust that the ill-feeling which appears to have been engendered between the two Surgeons and other persons will at once subside. No blame is attachable anywhere; some little error may have been committed, but the real offenders are the infectious wards, which assume to be what they are not.

Opium-smoking.—The San Francisco Chronicle gives the following account of opium-smoking by the Chinese:—

"We watched the operation of preparing and smoking a pipe of opium. The smoker has brought to him a tray on which is a light, a pipe, a small piece of wire, and a jar of pure opium; the wire is dipped into the opium, then applied to the candle and cooked until the perfume arising therefrom suits the smoker's ideas. It is then carefully kneaded on the surface of the pipe, the top of the bowl being covered, with the exception of a small hole in the centre; and when the correct consistency has been gained by a delicate manipulation with the wire, the opium is worked up into a ball about the size of a small pea, and inserted through the lid of the pipe. The smoker then reclines, and, placing the bowl of the pipe against the candle, draws away at the stem for a few seconds—the pipe is empty, and the performance repeated until the smoker becomes stupefied and falls back in a doze, to revel in the sensations arising from the narcotic. Its effects are described as being of a most exhilarating kind, and if only inhaled in small quantities it animates the spirits and gives energy to the intellectual powers, and is then followed by a state of quiet, pleasant languor until sleep succeeds; but it is only by increasing the dose that these effects are reproduced. The soporific effects are then of longer duration, and the symptoms of debility are greater, gradually but surely leading to softening of the brain."

COMMUNICATIONS have been received from— Mr. F. S. NEWBOLD; Dr. RIDGE; Mr. ABBOTT; Mr. C. ORTON; Mr. B. WILSON; Dr. FAYRER; Dr. ALLBUTT; Dr. OLDHAM; Mr. B. P. MORISON; Dr. PHILIPSON; Dr. CHEADLE; Mr. J. G. MORRIS; Dr. LETHBY; Mr. J. S. BIGGS; Dr. NEWMAN; AN OXFORD MAN; Dr. BASHAM; Dr. LITTLE; Dr. JOHN MURRAY; Dr. J. WARD COUSINS; Mr. METCALFE JOHNSON; Mr. F. TAYLOR; Mr. J. CHATTO; Dr. JAMES RUSSELL; Mr. REEVES; Dr. STRETCH DOWSE; Dr. F. R. HOGG; L.R.C.S.I.; Mr. STANSFELD; Mr. G. MILES; Mr. LAWSON TAIT; Mr. T. STRAFFORD; Dr. TILBURY FOX; Dr. GREEN; Professor RUTHERFORD; Mr. MAUNDER; Dr. PHILLIPS; Dr. COLE; Mr. G. LAWSON; Dr. DAY; Mr. LE GROS CLARK; Dr. GREEN.

BOOKS RECEIVED— Report of the Building Committee of the Prudhoe Convalescent Hospital—The Registrar-General's Thirty-second Annual Report of Births, Deaths, and Marriages in England—Allingham on Diseases of the Rectum—The Cathedrals and the Lancers' Bridge—Report of the Joint Committee on State Medicine of the British Medical and Social Science Associations—Knapp and Moss's Archives of Ophthalmology and Otology—Report of the Herefordshire Medical Association—Donkin on Diabetes and Bright's Disease—Clinical Society's Transactions, vol. iv.

PERIODICALS AND NEWSPAPERS RECEIVED— British and Foreign Medico-Chirurgical Review, October—Quarterly Journal of Microscopical Science, October—Cope's Tobacco Plant—Nature—Pharmaceutical Journal—Gazette Hebdomadaire—The Nelson Examiner—Monthly Microscopical Journal, October—Journal of Mental Science, October—Hardwicke's Science Gossip, October—Birmingham Daily Post—Westminster Review, October—Philadelphia Medical Times—The Western Morning News—The Bradford Observer—Food Journal, October—Chemical Review, October—Popular Science Review, October—Quarterly Journal of Science, October—Medical Press and Circular.

APPOINTMENTS FOR THE WEEK.

October 7. Saturday (this day). Operations at St. Bartholomew's, 1 1/2 p.m.; St. Thomas's, 9 1/2 a.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9 1/2 a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m. 9. Monday. Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2 1/2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m. 10. Tuesday. Operations at Guy's, 1 1/2 p.m.; Westminster, 2 p.m.; National Orthopaedic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m. 11. Wednesday. Operations at University College Hospital, 2 p.m.; St. Mary's, 1 1/4 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1 1/2 p.m.; Great Northern, 2 p.m.; St. Thomas's, 1 1/2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m. HUNTERIAN SOCIETY (Council Meeting, 7 1/2 p.m.), 8 p.m. Introductory Address by the President, and a Paper by Dr. Daldy. 12. Thursday. Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopaedic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m. 13. Friday. Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1 1/2 p.m.

CLINICAL SOCIETY, 8 1/2 p.m. Dr. Christian Baümler, "On Cases of Partial and General Idiopathic Pericarditis." Dr. Anstie, "Conclusion of a Case of Syphilitic Neuralgia, which was reported last Session," and "On a Case of Anaesthetic Leprosy." Mr. Nunn, "On a Case of Scrofuloderma treated by Woodhall Water." Mr. George Lawson, "On the Treatment of a Case of large Melanotic Tumour of the Eye extending into the Orbit." QUEKETT MICROSCOPICAL CLUB, 7 p.m. Extra Meeting, for Conversation and Exhibition of Objects only.

VITAL STATISTICS OF LONDON.

Week ending Saturday, September 30, 1871.

BIRTHS.

Births of Boys, 976; Girls, 913; Total, 1889.

Average of 10 corresponding weeks, 1861-70, 2031.8.

DEATHS.

Table with 4 columns: Category, Males, Females, Total. Rows: Deaths during the week (686, 704, 1390), Average of the ten years 1861-70 (638.6, 620.4, 1259.0), Average corrected to increased population (...), Deaths of people aged 90 and upwards (...).

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

Table with 10 columns: District, Population 1871, Small-pox, Measles, Scarlet Fever, Diphtheria, Whooping-cough, Typhus, Enteric (or Typhoid) Fever, Simple continued Fever, Diarrhoea. Rows: West, North, Central, East, South, Total.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Table with 2 columns: Observation and Value. Rows: Mean height of barometer (29.371 in.), Mean temperature (50.2°), Highest point of thermometer (65.6°), Lowest point of thermometer (41.9°), Mean dew-point temperature (46.6°), General direction of wind (Variable), Whole amount of rain in the week (3.34 in.).

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, September 30, 1871, in the following large Towns:—

Large table with 11 columns: Boroughs, etc., Estimated Population to middle of the year 1871, Persons to an Acre, Births Registered during the week ending Sept. 30, Deaths Registered during the week ending Sept. 30, Highest during the Week, Lowest during the Week, Weekly Mean of Mean Daily Values, Temperature of Air (Fahr.), Temp. of Air (Cent.), Rain Fall (Inches, Centimetres). Rows: London, Portsmouth, Norwich, Bristol, Wolverhampton, Birmingham, Leicester, Nottingham, Liverpool, Manchester, Salford, Bradford, Leeds, Sheffield, Hull, Sunderland, Newcastle-on-Tyne, Edinburgh, Glasgow, Dublin (City, etc.), Total of 20 Towns in United Kingdom.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.37 in. The highest was 29.73 in. on Saturday evening, and the lowest 28.77 in. on Thursday morning.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted above for that city, the population being assumed to be now stationary.

ABSTRACTS OF

THE INTRODUCTORY ADDRESSES
DELIVERED AT THE OPENING OF THE
MEDICAL SCHOOLS.

ST. MARY'S HOSPITAL.

THE Introductory Address was delivered by Dr. Alfred Meadows, of which the following is an abstract:—It is well for us all now and again to pause and ask ourselves the question, Whither do our scientific investigations tend? Do they help to confirm, or are they subversive of the cardinal points of Christian belief? If the former, then we may be sure that our method of working is right, our science true, and the knowledge gained to the world will live as long as truth endureth. But if the latter, we may be equally sure that what we think we have discovered is no discovery at all, and will prove to be but the baseless fabric of a dream.

We hear a good deal nowadays, and some people seem to take a special delight in talking about the conflict between science and religion. Now, I am not one of those who believe that true science is or can be in any way or degree opposed, either in theory or in fact, to what is called Revelation. I have too strong a faith in the latter, and too high a love of the former, ever to believe in such a possibility, or to entertain the shadow of a doubt as to their complete oneness in all essentials. It has always appeared to me a simple impossibility that true science and Revelation should ever contradict each other. Speculative science—or, perhaps I ought rather to say, speculative thought—may, and very possibly will, be frequently at variance with revealed truth. But true science, real scientific thought, and most of all, the demonstrative facts of science, never have done, and never will do, violence to the undoubted will of the Creator as exemplified in His revealed word. Reason herself revolts from such a thought. For what are we to understand by the terms Science and Revelation? It seems to me impossible to deny that, in regard to their relation to the Great Architect of the Universe, they are and must be absolutely identical. Science I take to be the discovery or demonstration of abstract truth in the laws which govern the natural world, and making deductions therefrom. But those laws must have had a lawgiver; there can be no such thing as self-made law; the very idea is an absurdity. Law, then, implies a lawgiver; and he who created the law must also have created that which the law governs; whether it be in the organic or inorganic world, in the animal or vegetable kingdom. In short, the whole realm of what we call Nature, governed as it is by law, witnesses to the Lawgiver as the author of its dynamical agency, while, at the same time, the material Universe, as we now see it, is a necessary consequence of the operation of law.

On the other hand, revelation is nothing more than the proclamation, through certain specified channels, of the laws or the machinery, if I may say so without irreverence, by which God wills to govern the moral world, and to bestow upon man a higher existence than his present life. In fact, if I might venture upon a parallel, I should say that Revelation is the scientific authority for the moral law, just as the recorded observations of facts in Nature become the scientific authority for natural law. Both authorities are of equal value as bases of truth and as expressions of the Divine will; and just as ignorance of natural science engenders among the proud and foolish contempt for scientific things, so ignorance of theological science is apt to engender, with the intellectually proud, indifference to sacred things.

In trying, then, to discover the secrets of Nature, to unfold her laws, and to lay bare her operations, we are all the while endeavouring, though we know it not, to extract as it were more and more of the Mind of the Creator as it lies hid in the works of His Hands. But what, I ask, is this but an attempt to complete another Revelation? And can we suppose that He, who is the author of the written Revelation of His Will, will contradict Himself in that other Revelation which man is permitted to read from the Book of Nature? If this contradiction were possible, then God would be proved to be a Being absolutely less trustworthy than many of His creatures. Such a thought is sufficient at once to negative the assumption, and therefore, I repeat, the idea of any opposition between true science and Revelation—in other words, between the observed Will of God in Nature and His recorded Will in Grace—bears on the face of it its own refutation. Conscious of this fact, the

man of science works on patiently and fearlessly, with full confidence that any discovery he makes is in reality an addition to a new Revelation, which is quite as much of God as is Holy Scripture itself. Such a thought should make us very jealous for the truth of science, very careful and painstaking in our observations, temperate in our discussions of disputed points, and, above all, guarded in our speculations; lest, in advocating what is not true, we not only do our best to perpetuate what is false, but we, in fact, slander the Lawgiver, just as much as he does who misrepresents the thoughts, words, or actions of his fellow-men.

I ought, perhaps, to make some apology, or to offer some explanation, for occupying so much of your time with what may appear to you to be a purely theological argument. But no one who is an attentive observer of the general current of thought in these days can fail to see that, while this is an age characterised especially by great enthusiasm in science and in religion, there are not wanting indications of an attempt to bring these two branches of knowledge into opposition. It seems to me, therefore, that it is the duty of those who are in any way connected with the teaching of science to insist occasionally, when opportunity offers, upon the close relation which exists between the two. Their union makes thought perfect; separate them, and you divorce science from what can alone add happiness to knowledge.

The subjects to which I wish now to direct your attention afford a remarkable illustration of the way in which these two enthusiasms are very unnecessarily forced into collision. I mean the subject of the Origin and Nature of Life. How did life first come upon this earth? What is its exact nature? To neither of these questions probably can, or ever will, any precise and accurate answer be given. But the subject is none the less interesting on that account, and its consideration may teach us one or two lessons; while at the same time anything connected with biology must ever be of the highest importance to us, whose lives are spent in endeavouring to maintain life, and to remove all that tends to destroy it.

In regard to the origin of life, it is, I suppose, beyond question that the earliest known geological record of the existence of life on this earth is to be found in the Laurentian strata of rocks. These, which are the earliest of all the known rocks, belong to what is called the Præ-Cambrian Period; and in them, within the last few years, there has been found a small fossil the organic nature of which was at first questioned, but it is now, I believe, generally admitted that this little creature belonged to the class of Foraminifera, and it has been christened with the name *Eozoon Canadense*. This is undoubtedly the oldest known form of living creature on the earth. We may not, however, affirm dogmatically that, because the geology of that period affords no evidence as yet of life other than that I have mentioned, therefore none existed; such a statement belongs to what I shall call speculative science, and he is a rash man who would speculate upon the condition of life on this earth at such a remote period.

Tracing life onwards, so far as geological records enable us to do, although there are at present a great many gaps in the series, yet I am not, I think, over-stating the case when I say that from the *Eozoon* onwards there exists in the successive strata of rocks evidence of a gradually ascending series of animals up to almost the highest vertebrata. Whether or not these are related to one another, and man to them all—whether or not the whole animal creation, from beginning to end, is to be regarded as one gigantic family, whose ancestral origin dates from the earliest geological period—is a problem which I certainly cannot pretend to solve. But even if it be so, and should it be demonstrable, as is so confidently predicted by some authorities, that man originally sprang from a shapeless mollusc, the thought need certainly not distress us over much, although it does not perhaps, at first sight, tend to raise our conception of self to be told that “man is descended from a hairy quadruped, furnished with a tail and pointed ears, probably arboreal in its habits and an inhabitant of the old world;” nor will our pride be encouraged by knowing that “this creature, if its whole structure had been examined by a naturalist, would have been classed amongst the quadrumana as surely as would the common and still more ancient progenitor of the old and new world monkeys,” because, it is added by the writer I am quoting, “the quadrumana and all the higher mammals are probably derived from an ancient marsupial animal, and this through a long line of diversified forms, either from some reptile-like or some amphibian-like creature, and this again from some fish-like animal.” But, in case this idea of the origin of our race is not enough to make us humble-minded, we are further told that “in the dim obscurity of

the past we can see that the early progenitor of all the vertebrata must have been an aquatic animal, provided with branchiæ, with the two sexes united in the same individual, and with the most important organs of the body (such as the brain and heart) imperfectly developed. This animal seems to have been more like the larvæ of our existing marine ascidians than any other known form."

Well, as I have said, if all this be true, and I must say it is a long way from being proved as yet, it does not appear to me in the least degree to affect man's present dignity, or his responsibilities to his conscience and his God. These are in no way touched by his mode of origin; for they arise out of his present condition, and are the natural outcome of that mighty, that stupendous act which was performed for him, and for him alone, when God became Incarnate. Speculative science cannot reverse the history of the Christian era, neither can it explain away facts which eyewitnesses have written for our learning. People tell us sometimes that Christianity must be a myth, because the Bible makes man to be such a noble act of creative power, whereas science, they say, shows him to have descended lineally from a marine ascidian. Having, therefore, such a degraded origin, they tell us, the whole theory upon which his eternal salvation is supposed to be based must be visionary; for why should his salvation be of such importance, and how, in the face of all that science tells us of his origin, are we to draw the line between the race of men who are to be saved and the brutes who are not. To all which I can only reply that Christianity is certainly not based upon any exalted estimate of man's origin; on the contrary, the same authority which tells me how he is to be saved actually makes him of meaner origin than do these speculators, for in that book I read, not certainly that man came from a marine ascidian, but that he was formed out of the dust of the ground. If, then, the argument be worth anything at all on the scriptural side, *a fortiori* is it on the scientific.

But, to return to my subject, assuming for the present that the first living creature on this earth was the *Eozoon Canadense*, the question we have to consider is, Whence did that life come? What, in fact, was the origin of life here? Professor Tyndall, in an essay "On the Scientific Use of the Imagination," says, "Life was present potentially in matter when in the nebulous form, and was unfolded from it by the way of natural development;" and he thinks "there are the strongest grounds for believing that during a certain period of its history the earth was not, nor was it fit to be, the theatre of life." He believes, moreover, that the probabilities are in favour of the earth being then in a nebulous, not a molten, condition; and that what he calls "creative energy" waited till the nebulous matter had condensed, and until other changes had taken place which fitted the earth to become the theatre of life, and then it—that is, "creative energy"—sent forth the fiat, "Let life be."

Now, that such an hypothesis as this should be gravely put forward in such terms by a man of Professor Tyndall's position, is, I think, a lamentable thing; and I would solemnly warn you who are just beginning your career of scientific study against being led away by such a flighty—for I cannot call it scientific—use of the imagination. What can be meant by the terms "natural development" and "creative energy" as employed in the passages I have quoted, except it be intentionally to exclude all idea of a Personal Creator in the first beginnings of life. Against such mischievous theorising I protest most earnestly; and I trust you will none of you be led away from the ancient landmarks of the Faith by reasoning such as this.

Sir William Thomson, in his recent address as President of the British Association, after remarking upon the condition of the earth when no life could exist upon it, and subsequently when, though fit for life, none was there, says, "we must not invoke an abnormal act of creative power" if we can find any other "probable solution consistent with the ordinary course of nature." But I would remark—first, that the word "abnormal" is here singularly out of place; for what right have we to suppose that the first act of the Creator's will in originating life on this earth was in any true sense an "abnormal act"? and, secondly, it appears to me the merest folly to attempt to explain the very beginning of a new order of things, such as must have been the first occurrence of life on the earth, by what is termed "the ordinary course of nature," for up to the time when life was first made manifest there was no "ordinary course of nature" in respect to it with which any hypothesis could be "consistent." But when, further, Sir William Thomson, unwilling apparently to recognise a distinct creative act, hazards the hypothesis that life may have been brought here by "countless seed-bearing meteoric stones moving about through space," and "carrying seed and living plants and

animals," and that if no life previously existed on this earth, "one such stone" might "lead to its becoming covered with vegetation," I think, really, if scientific men can gravely put forward such "wild and visionary" notions as these—to use an expression which Sir William himself suggested—then the sooner we look elsewhere than to science for explanations of these phenomena the better will it be. It may be true, as he says, that such an hypothesis "is not unscientific"; all I can say is, if it be not, so much the worse for science.

But, you will no doubt ask, what view have I to propound in place of those which I reject? I reply, that I believe no strictly scientific answer can be given to the question at issue, because we have no sufficient data upon which to found an opinion. But it seems to me impossible to separate the idea of mystery from the phenomena under consideration, and therefore equally so to find any explanation by a study of the laws of nature. At the time in question, as I have said, there was no Nature such as we understand it, and no reference to present phenomena can avail to explain what occurred when the circumstances were in no degree parallel. Any such attempt must be futile, and, inasmuch as we have no other data by which to judge, the inquiry must be barren and consequently useless. Life came—that I know. Nature does not explain it—that I also know; and no amount of induction from facts which we can now observe will avail to account for phenomena which occurred when no such facts existed. Revelation and Reason both alike tell me that God willed it, and it was so; but neither tell me—how.

I am well aware that this does not satisfy the natural craving for a more perfect knowledge. But we are surrounded by mysteries which we cannot fathom, and this I believe is one of them. There is often, methinks, greater wisdom displayed in knowing what we do not know, and greater courage in candidly confessing it, than in assuming a knowledge which we have not, and mistaking audacity for courage. A lady once asked a distinguished member of the French Academy of Sciences, "What is the use of being an Academician if you can't tell what comets are made of?" To which the learned man replied, "Madam, that I may be able to say, I don't know." Such a reply testifies, I think, far more to the true man of science than he who fritters away his imagination over impossible problems.

But if the origin of life be a difficult question, scarcely less so is that of its nature. What do we understand by Life? Is it merely a condition of matter, or is it a force? If the latter, can it exist apart from matter? Is it independent of other forces? or is it correlated with them? These are all most difficult, and, in more senses than one, most vital questions. I have only time briefly to indicate the answers which facts seem to warrant, and I shall not allow myself to wander in the realms of fancy. In all ages there has been—there is still—great diversity of opinion on this matter; but, in these latter days, the opponents may be said to range themselves into two hostile camps: the one advocating what is called "the physical basis of life"; the other contending for a vital force, principle, or essence, differing from and altogether independent of the ordinary physical forces. The former assert that the force or forces which operate in organised bodies, whether vegetable or animal, are the same that exist in the inorganic world: that, in fact, life is correlative with the other forces of nature, and may be, for ought we know, nothing but a modification of heat or motion. In like manner, according to this view, heat, light, electricity, motion, and chemical action are to be regarded as vital forces when they operate in living bodies; but only as physical forces when met with elsewhere.

In opposition to this, it is contended by the vitalists that life is as much a separate force as motion, chemical action, electricity, or light; that its operations are entirely confined to organised bodies; that its existence cannot be conceived apart from these; and though its operation is never manifested without a corresponding physical change, or the evolution of some physical force, yet that it is altogether independent of these—not correlated with them, not subservient to, but in truth dominating them all, and acting sometimes in direct opposition to some of them, in a way in which no other physical force could act. Such, I believe, is a fair statement of the opposing views of life which are entertained by the leading authorities in the present day; and you will not fail to note the relation which these views bear to the question I have already discussed—namely, the origin of life; and also to another question which is just now exciting great attention—namely, the doctrine of spontaneous generation. It is obvious that, if life is merely a correlation of physical force, spontaneous generation, and

even the creation of organised beings by physical agencies is not conceivably beyond the power of man to achieve. Therefore, again, it follows that the acceptance of this view does away with the necessity for a creative act, and makes it possible that the original beginning of life was due to the operation of ordinary physical forces.

But, if this question is to be determined by observation and experiment, not by inference or imagination, then undoubtedly the Scotch verdict of "not proven" must be accepted as against the physical hypothesis; for as yet there is not on record, so far as I know, a single experiment or observation in support of it. On the other hand, the whole of the observed phenomena of life, nutrition, growth, reproduction, etc., are totally unlike anything which is seen in the inorganic world—nay, in many respects these processes take place in direct opposition to the laws which govern the other forces. For instance, gravitation has no necessary influence upon vital action; on the contrary, vital action is not unfrequently exerted in opposition to it. Growth is thought by some to have its counterpart in the formation of crystals, but it is surely not necessary that I should refute this statement; while nutrition has certainly no parallel in the inorganic world, neither is reproduction comparable to any known physical process. While, therefore, I am ready to allow that many of the changes which take place in organised bodies are of a purely physical character, and resemble the same changes as they occur in inorganic bodies, yet I cannot avoid the conclusion that the processes to which I have referred are brought about by the operation of a force or forces which are unknown in the inorganic world. Nor do I see why actions so striking, so manifest and peculiar, should not be ascribed to the operation of a special distinctive force—just as electricity, chemical action, heat, motion, etc., are regarded as separate forces because of their manifest and peculiar actions; for aught we know, there may be other forces yet to be discovered in the inorganic world which will differ as much from the present known physical forces as these do from one another.

Again, the argument in favour of a distinct and separate force is, I think, greatly strengthened by the consideration of what takes place in an organic body when, as we say, life has fled. Then at once the physical forces, such as chemical action, which have been kept in check, if not by the vital force, at least during vital action, exercise an undisputed sway over the now dead body; and the result is that its component parts gradually but surely lose all trace of structural character, and are resolved into their ultimate chemical constituents: *construction* is at an end; *destruction* is rampant, and no power suffices to avert the catastrophe.

But you will of course ask, If the doctrine of the absolute indestructibility of force be true, what becomes of the so-called vital force when a living thing dies? Unless this can be explained, you may argue, the fact that various physical forces continue to operate in or upon the now dead body, though in a different manner to what they did in the living body, is presumptive evidence in favour of the purely physical, and against the vital, theory of life. I admit the cogency of the argument, and I frankly avow that I am not able to meet the objection definitely. It seems to me, however, either that the vital force, assuming for the moment its existence, differs from the physical forces in this respect, or else I must claim for it that, though a distinct and separate force, it may nevertheless be in some way correlated with them when the conditions of its action no longer exist. The latter view does not seem to me at all to militate against its individuality; and if this concession satisfies the physicists, then all I can say is—they are welcome to it.

I often think, indeed, that the controversy is, after all, much more one of words than of ideas, for when a recent writer on the physical side describes "vital energy" as "a mode of motion," and yet declares that "it manifests itself in modes peculiar to itself, and different from any of the other modes of energy with which we are acquainted," and allows the use of the term vital force "to signify this special mode of manifestation," I do not see what more the vitalists can want—although I submit that the idea of this vital force being only "a mode of motion" is but another illustration of the so-called "scientific use of the imagination."

While, then, it seems to me that the idea of a distinct and separate force governing the organic world, plant and animal alike, and called by the name "vital force," accords best with the actually observed phenomena of life, and may therefore be accepted as, if not true, at least highly probable; yet, on the other hand, even if "the physical basis of life," as it is called, could be actually proved, I should certainly dissent altogether

from the view which has recently been put forward by a very distinguished physiologist, to the effect that, as a consequence of such proof, "a complete and widespread revolution in religious belief" must necessarily occur. The writer to whom I am referring expresses his conviction that such a doctrine would be "scarcely reconcilable with the idea that man is made in the image of God," and therefore he adds "The idea of a God, of Divinity of every kind," must be abandoned, because "in such a scheme neither a superintending Providence, nor a personal God, nor Christianity, could have place"; for, asks this writer, "how could I believe that I was, nevertheless, designed and created by the power and wisdom of God?"

Now, I think that such language as this, coming, as it does, too, from a conscientious and thoughtful observer, is greatly to be deplored. I should, indeed, be sorry ever to make such a statement in regard to any scientific theory, no matter what its scope or tendency. The history of scientific beliefs is full of instructive lessons in this respect, and we cannot yet afford to dogmatise too narrowly on the connexion of science with Christianity in such a manner as to make the one dependent upon the other. This much, however, I do know, that on the principle which I have already enunciated, not even the clearest proof of the so-called physical basis of life, nor the actual demonstration of any single fact in science, however much it might seem to contradict my most cherished beliefs, would have the smallest influence in shaking my faith in the fundamental truths of Christianity. Regarded from a religious standpoint, it matters nothing to me whether the functions of my body or the growth of a tree are performed in obedience to what is called a physical or a vital law; neither am I concerned to know whether I sprang from a marine ascidian or from nothing, for I know that all laws and all matter, whether in the animal or the vegetable kingdom, the organic or the inorganic world, must have originated from the great Law-giver, and that He saw that they were good.

I have endeavoured then, gentlemen, very sketchily and imperfectly, I know, to give you some idea of the nature of that mysterious principle, force, power, property, or whatever you please to call it, which you are now called upon to study in its normal and abnormal manifestations in the human body, and which it will be your privilege and duty to guard, protect, and cherish, not only against the attacks of evil from without, but from those also within. We are too apt, I think, in the close study which we very properly give to the symptoms of disease, and the care with which we investigate its effects upon the tissues of the body, to lose sight of, or at least to undervalue, the fact that it is not so much material or organic as dynamical perfection which we should endeavour to maintain. Our whole course of study, dealing as it necessarily does with material objects, not only in physiology, but also in pathology and therapeutics, is apt to engender a too materialistic view of disease, and to obscure our view of the morbid processes by which disease is brought about, processes which are essentially deviations from the normal evolution of the life-force, whatever the nature of that force may be. It is so much easier to recognise the effects of what we call disease, the mind comprehends so much more readily what the eye sees and the hand can touch, that we are almost inevitably drawn to the recognition of the organic lesion as the alone cause of the patient's distress, and as the object towards which our remedial efforts should be directed. But it is certain that, if we inquire into the matter, we shall find in most cases evidence of what is called functional, or, as I would term it, dynamical derangement, long before the existence of organic lesion; and a little thought will suffice to convince us that functional derangement is but another term for the abnormal operation of life-force. For, as the force or dynamical agency which is inherent in the life-germ secures the normal growth and development of the body of which it is the germ, so deviations from that force necessarily lead to abnormal tissue change—in other words, to disease—either during growth and development, or in subsequent maturity.

Here, then, we see the importance of studying the laws which regulate the operation of that force, and their effects upon the bodily structure. By observing these actions during health, we may in time hope to gain some clearer conception of the causes of disease—those causes which at present are enveloped in so much obscurity that we can hardly be said really to know the *modus operandi* of any one of them. It is through the subtle workings of the life-force that minute tissue changes are produced; and it is here, therefore, that we must look for the earliest indications of the coming disease. When the grosser manifestations of organic lesion are apparent, it is then too late to trace out the ultimate cause of the

evil; and that which, if it could have been recognised and appreciated in its earliest stage, might, perhaps, have been combated successfully by a very simple remedy, now baffles and defeats all our efforts. Recent observations have shown how, by the thermometer, timely warnings of impending mischief are often given long before any other indications are apparent. It is in this direction that we must look for future advance in Medicine, and each one of you may, if you will, be of infinite service in this work. There is yet an abundant harvest for the honest, painstaking, humble labourer in the Medical vineyard. To this work I bid you go forth, full of bright hopes, and strong in your determination to overcome difficulties by patience, courage, and perseverance. But remember always that the one object of your lives should be to seek after and to maintain Truth. Be true to yourselves, and you will be true to your Professional calling, than which there is nothing higher or grander in this life. Truth should penetrate every act of your Professional as of your private life. It will make you careful in diagnosis and sound in therapeutics, because it will enable you to sift the apparent from the real, the false from the true. It will help you to weigh symptoms, to estimate them at their true value, and by knowing accurately—that is, truthfully—the inward conditions, of which symptoms are but the outward expression, you will be able, with full confidence, to apply the true remedy.

But success of this kind is only obtainable by the persistent practice of truth in every minute particular of your daily life. You cannot play fast and loose with truth and falsehood; for the one or the other will in the end be sure to prevail. And remember that "Falsehood is never so successful as when she baits her hook with Truth; and that no opinions so fatally mislead us as those that are not wholly wrong—just as no watches so effectually deceive the wearer as those that are sometimes right." Bear in mind, too, that a man who is always truthful cannot commit sin; for truth and purity go hand in hand; but falsehood is sin incarnate. As men of science, then, prove yourselves worthy of the name by steadfast devotion to truth; and in purity of life follow her example to whose blessed memory this School is named; so that when the time comes that you must change this life for another, you may bow your head in humble submission to Him who well knows how to recompense those who in the cause of truth have done what they could.

WESTMINSTER HOSPITAL.

THE Introductory Address was delivered by Dr. William R. Basham, who commenced by observing that it might be to the advantage of those now entering the Profession to have placed before them the relative position assigned to Medicine and Surgery among the other arts and sciences. These words were so constantly employed almost as convertible terms that it was expedient to give such a definition as would enable the student to comprehend clearly the position held by Medicine among other branches of human inquiry. The word "science" comprehended investigations into the powers and properties of matter—inorganic as well as organic—the mutual action of forces and masses—the laws of matter, statical and dynamical. The term "art" was applied to everything which was the product of the mental or manual skill of the individual. Science, properly so-called, was either deductive or inductive. The first comprised the exact sciences—mathematics; the second (inductive) included the natural sciences, or physics;—and the object of these was a knowledge of the laws of the material world.

The natural sciences were then classified, and the necessity for a knowledge of them to the student and Practitioner of Medicine was insisted on. It was shown that all these branches of knowledge rested on correct and trained observation.

The arts were then enumerated. They severally included whatever was effected or produced by the mental conception or the manual skill, or both, of individual minds, art producing combinations or effects which could not happen or exist except through the conceptions of individual intelligence.

The highest efforts or products of art might be accomplished without any specific knowledge of natural science. But when art was aided by natural science the result was greater perfection. But if science was not absolutely necessary to the existence of art, how different was it with the practice of Medicine. There was not one of the natural sciences, some knowledge of which was not imperatively required in medicine.

The aim and scope of medicine as an art were shown to be the preservation of the body in health, and the freeing it from

those evils and disorders which neglect of the laws which govern and minister to life most surely entailed. These could only be accomplished by a thorough knowledge of the nature and force of those laws. The first essential was a minute and searching knowledge of structure, both human and comparative; the second, a knowledge of the functions of the several organs. On a thorough knowledge of anatomy and physiology the whole fabric of Medicine rested.

It was shown that the vital forces were examples of the economy of the natural laws of the material world. Not only did these vital causes work in accordance with the physical laws, but they were evolved in strict obedience to, and dependence on, those laws. The functions of the heart, of the lungs, the action of the muscles, the structure of the eye and ear, were illustrations of the adaptability of structure and function to the laws of the natural world. The position of Medicine up to this point was that of a science strictly inductive.

The causes of disturbed functions were then glanced at: a definition of health was offered as a starting-point of comparison with the earliest manifestations of deranged or diseased structure or function. The scope of general pathology was thus mentioned as consisting of an inquiry into all the conditions, causes, symptoms, and results of disordered health, whether among individuals or among the mass. Allusion was made to epidemics. Medicine, as an art, had, from its earliest records, recognised the prevalence at times of particular types of disease. Tracing the origin, the mode of propagation, and the means of restraining epidemic forms of disease, was recognised as one of the most important duties of the Profession. Although little success had yet attended efforts to avert such epidemics as cholera or scarlet fever, yet over one fearful scourge the genius of Jenner had triumphed, and victory, complete and undoubted, had been the result of the contest between vaccination and small-pox. There could be no higher aim for any science than to stamp out the causes which favour the propagation of disease of whatever kind among the community. To investigate the causes of the unhealthiness of any given locality, to trace the development of disease to the co-operation of vice and ignorance, to propose means for the sanitary welfare of large and populous places, was the paramount duty of the Profession. But to accomplish this required a mind specially trained, one accustomed to exact and patient observation, skilled in all the collateral branches of Medicine—a chemist, a physiological one, conversant with the morbid agencies of air defective in purity, with its sources of contamination, with the influence of soil and drainage on animal health, with the qualities of water and its impurities; some knowledge of constructive art should also be added. The influence of particular kinds of labour on health, and the several diseases peculiar to special trades and occupations, also required attention. To perform these duties required a high-class Medical education, to which should be added sound judgment, a tact in dealing with the prejudice and ignorance of people, and a power to persuade by reasoning rather than of dictating by authority. After some remarks on the limited means of generalising on the action of remedies, and of establishing any definite law as to the certainty and exactitude of their action, moral probability, or (at most) moral certainty, was all that could be arrived at.

The lecturer proceeded to sum up the attributes of Medicine, both as a science and an art. It was a science in relation to the means and sources from whence it was derived, for it was built up of many, if not all, the other natural sciences. It was an art, however, in its exercise, and its value was proportioned to the scientific training, the tact, and judgment of the individual practising it. It was an art which, for extent and variety of knowledge possessed by its more distinguished members, was not exceeded, scarcely equalled, by any. Its utility was universal, for it was with advantage and benefit exercised in every region of the world, alike useful to all nations, peoples, or creeds. Medicine was the science of observation applied to the investigation of everything which related to the health of man, individually or socially. It was based on a thorough knowledge of the structure of man and of the chief families of the animal and vegetable world, to which must be added a knowledge of the laws pertaining to matter and force. The need for such wide and extended information had been fully recognised of late years by the altered course of study now recognised by the London University as necessary for the preliminary degree of Bachelor of Medicine. To be educated in such an art, brought to the possessor all the advantages and graces of an enlightened education. It trained the mind to understand the laws regulating the evolution of the germ out of which his organisation sprung. I

taught him the conditions governing nutrition, regulating development, or ministering to decay, the premature tendency to which it was the effort of the art to avert. As an art it dealt in no dogmas; it regarded as reliable and true only that which was susceptible of demonstration and proof. It sought no converts, for the essence of its teaching was, that its followers must be for ever students; for the words of Harvey were ardently accepted by all workers, "That all we know is infinitely less than all that remains still to be known." In this art there was no fealty sworn to authority, and only that which was ancient was loved which experience or science had proved to be true. The sciences on which this art rested could not be learnt from books alone. The fabric of nature and of the material world must be searched and studied, and each step the student made must be steadily from one demonstrated fact to another. The theories of incomplete observation were constantly tested by more numerous and reliable facts, and which scientific experiment eventually verified or ignored. Thus, gathering within herself the tributary streams of many branches of natural science, each contributing some truth or fact applicable to the interpretation of the laws of health and disease, Medicine might consistently take her place among the arts and sciences, and claim a prominent position among the most useful and beneficent of those scientific pursuits to which the intellect of man might be devoted.

QUEEN'S COLLEGE, BIRMINGHAM.

DR. RUSSELL opened his lecture with some passages from the chapter on the Cure of Melancholy, taken from Barton's Anatomy of that disease, on account of their presenting a more correct representation of the function of a Practitioner of Medicine than we often meet with in popular works, or than is exhibited in the thought of the present day. In place of imposing the entire responsibility, in the treatment of disease, upon the Medical adviser, the patient being supposed to have no part in the business, the author regards the patient as an active agent in effecting his own cure, reminding him that he has a duty to perform towards his Doctor as much as his Doctor has towards him; and that unless this reciprocal obligation be duly recognised, the relation which each bears to the other will be marred, and the benefit which such relation was designed to confer will fail of being attained. In developing the subject which these remarks suggest (the two-sided character of the Medical Profession—its relation to Medicine as a science, and its relation to the society in which the science is to be applied) the lecturer proceeded to comment on the effect produced in hastening or retarding the advance of Medical science by the state of general intelligence and education, noticing that, in narrating every step which has been made, the historian instinctively turns his eyes to the general condition of learning at the time; noticing, also, that in different parts of the world the character of Medical inquiry has taken its tone from the prevailing genius of the country in which it has been pursued. He briefly recounted the principal epochs in the history of Medicine, demonstrating as he proceeded that throughout its existence Medicine has been very much what the state of general culture has made it, rising with the extension of the scientific spirit, and falling when that spirit declined; and that this has been equally the case with Medical opinion, which has been in a large measure the reflection of the opinion of the age in which it is formed. In one respect, however, Medicine has stood in contrast with the surrounding philosophy—at least, in the early periods of its history; accepting Macaulay's characteristic of the ancient philosophy, that "it could not condescend to the humble office of ministering to the comfort of human beings," we may confidently oppose to this representation the aim consistently maintained by Medicine throughout her chequered career—that aim being the very one advanced by the same author as distinguishing the Baconian philosophy,—"fruit"—"the multiplying of human enjoyment and the mitigating of human suffering."

Dr. Russell proceeded to notice, also, the influence of science upon Medicine, taking his illustration from the science of chemistry at different epochs of its history, and then passed on to another view of his subject—one always of importance, but never of so great importance as at the present day. He observed that the evils with which Medical science has had to deal have been in large measure due to human passion, or to ignorance of the laws imposed by Providence for the preservation of health. The statement applies to disease in all its forms, for advance of knowledge shows us more and more

clearly to how great an extent the preservation of life and health is placed in our own hands; but it is illustrated on a large scale in the history of nations. The lecturer noticed the pestilences which occurred during the early epochs of the history of this country, always preceded as they were by famine, the latter sometimes the result of bad seasons, but rendered fatal in their effects by ignorance of agriculture; by bad laws and want of free communication between districts and countries—more frequently the consequences of foreign wars or civil broils, of the evil policy of kings and nobles, or of popular outbreaks against the violence of rapacious governors. Thence he passed to other causes of public disease connected with social and private life, bringing his notice down to the present time, when sanitary investigation is revealing a state of things in our crowded towns and in our ill-built and ill-regulated villages analogous in all essentials with the abuses prevailing at earlier periods of our history, when habits and modes of living are brought to light in some parts of England in this nineteenth century which could hardly have been more gross in the so-called barbarous periods of our annals. I say (said the lecturer) that it is of vast moment to the interests of humanity that both parties in these matters—the Profession and the public—should understand their share in the responsibility to be borne; an enlightened public must be the correlative of an educated scientific body, or nothing can be done.

But, besides the intellect, there is yet another element, powerful in determining the course of human conduct, which is closely involved in the relation held by the public towards the Medical Profession, and is mainly determined by the spirit in which the work of the Profession is regarded by them. I mean (said the lecturer) the character of its several members. Having commented upon certain conditions peculiar to the Practitioner of Medicine, Dr. Russell proceeded to observe that the position taken by the public towards the expounder of Medical truth has not always been consistent. Sometimes he is erroneously credited with possessing absolute truth, such as is attainable by the student of the exact sciences only, and his responsibility is estimated by this mistaken standard. Sometimes, on the other hand, he is regarded with absolute scepticism, because he does not, like Molière's M. Purgan, "believe in his set rules more than in all the demonstrations of mathematics, finding in remedies nothing uncertain, nothing difficult." In proportion as the student of Medicine has obtained a wider range for his view of the subject, has recognised the diverse relations which it bears to other sciences, and the complexity of the element to be considered, he has assumed a more modest tone. Yet, in view of the grave responsibilities resting on him, there are times when he is ready to take upon himself the language of authority. The conditions with which he has to deal are guided by the same fixed laws with those which govern the physical and moral world; and where such laws have been eliminated, he announces them with the authority of ascertained truth. And in the operation of these same laws is imposed a limit to his power. It is as impossible for science to avert the effects of sensuality upon the bodily functions as for the ethical philosopher to prevent it exerting its baneful influence upon the mind. Nor can Medical science be expected to shield individuals or a community from the consequences of violating the conditions of health. Foul drains will generate fever, let science talk as it will; overtaxed brains will fail, overstrained muscles will ache.

But when speaking less absolutely, the Medical adviser does, in fact, call upon those he addresses to accept their own share of responsibility. The interests with which Medical Science concerns herself are very closely interwoven with those moral and physical agencies which constitute the discipline of life, and regulate a man's moral position in the world; hence it is that the problems of health and disease so often appeal to men as free agents, and require those who receive the benefits of the Medical art to weigh the evidence submitted to them, and to allow due weight to the character of the witness. Let these things be considered, and the Profession will be judged by a fairer standard than that which is cited by Lord Bacon as being so erroneously applied to the Physician, and, perhaps, to the politician—"That he is judged most by the event, which is ever as it is taken; for who can tell, if a patient die or recover, or if a State be preserved or ruined, whether it be by art or accident?"

Dr. Russell concluded his lecture by advising the students that, as their pursuit had a closer analogy with the pursuit of politics than with that of physical science, in that it had immediate relation to man in his individual and social capacity, it was most important for them to attend to the formation of

character, as well as to the cultivation of their intellect; and he endeavoured to point out some particulars in which the discipline of the College and the spirit in which they pursued their studies would conduce to that end.

QUEEN'S HOSPITAL, BIRMINGHAM.

MR. FURNEAUX JORDAN delivered the Introductory Address. After some preliminary remarks, Mr. Jordan said:—Having learnt, then, all the basic truths of human health, as taught in anatomy, physiology, and human chemistry, you have entered here to learn your highest, and best, and life-long lesson—the truths of disease. A Hospital is a large arena in which you may witness physiology out of gear. I say physiology, because in its largest sense physiology includes anatomy and human chemistry. You will find here practical illustrations of every mode in which physiology can get wrong. You will see, in other words, a great variety of diseases, and see them investigated for definite and ulterior purposes. The objects and the results of such investigations you will be able to arrange under a few definite heads: The causes of disease; pathology, or the peculiar kinds of deviation from physiological health; diagnosis, or the discrimination of one pathological condition from another; and treatment, or the adoption of means for the removal or alleviation of disease. You will see here precisely that kind of work done which you yourselves will have to do in after-life. You will not only see everything done, but you will be taught, if you are able and willing to learn, to do all that you see others do.

And now comes the most important question that can be asked to-day. How are you best to be taught, and how are you best to learn, all about disease—to learn, in short, the science of Medicine? My reply is—In the same way in which you would best be taught and best learn any science, or art, or calling, or trade, or language, or anything which men can be taught, and which they can learn. I shall be glad if I have excited your curiosity to ask, What is this best way? I will answer by giving you in three words the opinion of, as I believe, the highest living authority on such a subject—the opinion, namely, of Mr. Stuart Mill. In learning anything, three things, he observes, are necessary—models, rules, and practice. The most difficult callings are best learnt as a child learns its mother tongue. It imitates such models as are near it, then it is taught rules, then it puts them into practice. If it be given the best models, taught the best rules, and afforded sufficient opportunities for practice, it best learns the language. The most successful clinical instruction, then, I venture with confidence to affirm, is that which supplies the best examples of how diseases are investigated, discriminated, and treated, which teaches the best and truest rules for the observation, detection, and treatment of disease, and which affords the fullest opportunities of imitating the examples, and applying the rules. It is the appropriate combination of these methods of study which leads to success. Both teachers and learners frequently adopt one method to the exclusion of all others. One teacher, if he can be called a teacher, for instance, will set an example only of what has to be done, and neglect to instil rules or give opportunities for practice. Another teacher is indifferent to the importance of models, but will supply rules, perhaps to an indefinite extent, in the shape of formal lectures, in a room in which there is not a single illustration of disease. Another will set examples and teach rules, but will not encourage the pupil to imitate the examples or apply the rules. I am compelled to say that pupils still more frequently fall into similar errors. A certain number are quite willing to witness the models, Medical or Surgical, and sometimes even to imitate them, but they shrink from the labour of learning the rules. These are the so-called practical men. Others see only the importance of the rules, and labour under the delusion that copious notes of systematic lectures and industrious reading by their own firesides will take the place of the imitation of models and of the practical examination of cases of disease. These are the so-called book-men. Incredible as it may seem, a few will neither witness the examples nor learn the rules or principles, but will actually in their own sweet way examine and treat cases. It is difficult to say other of these men than that they are vain and ignorant. It is our duty, as teachers, to set the example of how facts are ascertained. Every method we adopt is the application of some fact, or rule, or principle; and it is our duty to explain these to you. We have, or ought to have, a reason for everything we do; the reasons are the rules. Exacting, questioning, critical pupils develop care, accuracy,

and judgment in teachers. Good pupils develop good teachers almost as much as good teachers develop good pupils. Truisms often require repetition. I shall, therefore, say that a teacher must be full of information; he must be accurate; he must be ready in putting his ideas into words; his mind must be clear and direct; his language must be terse and to the point; he must love his work. But this is not enough. He must frequently point to the line which divides the known from the unknown. In teaching the known he must be, more or less, a dogmatist; in inquiring into the unknown he must be a student. But, as a student, he must frequently verify the known, and as a dogmatist he must ever remember that it is his duty to “encourage inquiry rather than enforce belief.” But the teacher (and the advanced pupil, too) is often in this difficulty—he has to decide for himself what is known and what is unknown. In examining the new views which are brought before his judgment in constantly increasing amount, it needs that he should be, as regards authority, not too deferential, nor too independent; neither too credulous nor too sceptical.

One great art in clinically teaching the rules or facts of disease is to classify them according to their importance. To interest and impress the student, it is necessary to group clinical truths very much as an artist groups objects in a picture. The large objects must be in the foreground—they must be well defined and stand in a good light; next to these are objects a little less noteworthy; and still further in the shade are smaller but still visible objects. So in disease—there are the large truths, the truths only a little less in size, and the crowd of smaller truths. To put these clearly in their proper place is a laborious, but a much more effective educational means than to relate a dull chronicle of facts. There is as much difference between the two methods as there is between Carlyle's “History of the French Revolution” and the driest chronicle that was ever written.

To get knowledge, however, is not enough. It is well to cultivate every nerve-function through which knowledge may be obtained. I may say, more, by way of parenthesis, that we err in unduly cultivating the ideational aspect of our nervous system. Because in pigs sensations predominate over ideas, we must not, therefore, grow ashamed of our sensations. There is at present a tendency to underrate animals, and to make ourselves as unlike them as possible. Man, however, was not intended to become a helpless bundle of ideas; although the paragon of animals, man is nevertheless an animal. Acuteness of touch, of the muscular sense, of sight and hearing, quick action, endurance, courage, are all necessary to give ideas their fullest value. Trained sight for the use of the microscope, ophthalmoscope, and laryngoscope; trained hearing for the stethoscope; trained touch for the detection of fluctuation, elasticity, doughiness, crepitation, and crepitus, are necessary adjuncts to trained observation and trained reasoning power. I have a strong impression that high nerve-functions run together. Oftenest in the same man are combined the most delicate touch, the truest eyesight, the keenest emotions, the clearest ideas, the strongest will, the promptest action.

But knowledge must be pertinent to our purpose. In the history of Medicine there is no pleasanter fact to contemplate than this. When Medical men have specially pursued sciences which only indirectly bear on clinical work, they have shaken off the responsibility of treating the sick. Men have been too magnanimous to grasp in one hand human life and high classics, or human life and botany, or human life and zoology, or human life and theology, or human life and active politics. Recreation and general culture are not unimportant. A rested and a cultivated mind will best pursue any profession. But if recreation and general culture rise to the first place, Medical science and human life will go down to the second.

Experience has constantly been used to imply something more than knowledge. It may be described in a Medical sense as something more than a keen personal knowledge. It is not a simple act of intelligence. Experience is knowledge intensified by feeling, emotion, life. An idea will pass away; an idea associated with emotion will remain. Disease which has been personally observed, personally pondered, personally treated, is the most vivid clinical experience. To get this kind of experience should be your constant aim. To be of value, clinical experience must be personal, intense, and thorough.

UNIVERSITY OF DURHAM.

THE Address was delivered by Dr. G. H. Philipson, M.A., and was devoted to the subject of Medical Education. The aphorism of Paley, that “education, in the most extensive sense of the

word, may comprehend every preparation that is made in our youth for the sequel of our lives," was commended as worthy of daily remembrance, and fitting as the lesson to be inculcated at the inauguration of a new session of Medical study.

The education of the College was contrasted with that of the School, an important difference being that the more self-imposed duties of the College gave place to the fundamental and rudimentary teaching of the School—the mind, in just proportion to its progress, being allowed liberty of action, and the responsibility being removed from the teacher to the taught; the lecturer being able to show the way, and to cheer and encourage by advice and sympathy, but the internal impulse was to be given, and the pilgrimage was to be made, by the student himself—the principle of self-culture and of self-reliance being all-important. It was always, however, to be borne in mind that the course of study and of the examinations were ordained by the authority which has power over the different licensing and qualifying bodies. Whatever the feeling, it would be for the student's welfare and after-success strictly to adhere to the course prescribed; for it was constructed, or it was capable of being used, in conformity with that which was the character of all sound education—namely, to impart useful knowledge and to cultivate the mind. The effect of Medical studies upon the intellect was then considered: first, with reference to the improvement of the powers of attention and of memory, and afterwards the faculty of judgment, observation, and reasoning—the labour of such cultivation, and the means whereby the difficulties could be overcome, being set forth by a reference to anatomy, physiology, and chemistry; the lesson of the value of an orderly arrangement being also drawn from the study of physiology and chemistry; and *Materia Medica* being instanced as a kind of trial or test of the mind, as far as such was concerned.

The necessity of cultivating the power of observation was also enjoined: it being stated that in studying Medicine, and still more in practising Medicine, as every disease was a problem half known, half veiled in darkness, and as every patient presented not only what was known, but something peculiar and special, the Practitioner of Medicine had to make a constant reference to his memory and to his judgment as to its nature and probable issue; it being to the discriminating exercise of observation that we are indebted for all that is known of the causes of disease, of the recognition and interpretation of symptoms, and of the distinctive features of different maladies.

The importance of constantly aiding the teaching of the lecture-room by the practice of the Hospital was then insisted upon. The two modes of study were to be conducted together; the knowledge contained in books was to be imprinted by the lesson of the ward; and the actual phenomena of disease were to give life and interest to the systematic description. Both were necessary; and no student would do justice to himself or to his art if he should neglect either mode of teaching. The half-uttered denunciations of the present day against systematic lectures were due to their bygone abuse and the former neglect of clinical teaching. But it must be evident to any candid man that both methods of instruction were really required, and that if they were made to complement and aid one another, the end in view would be best accomplished.

The student was advised to repress all independent inquiry, to accept what was told him without seeking to pass beyond it, and to be satisfied with what might be termed the routine of science, until he was quite sure that he would avoid confounding probability with ascertained fact. For, as in his case speculation could not be corrected by direct experiment, and as his imagination would not be kept within bounds by a sufficient breadth of knowledge, he would arrive at conclusions which were utterly untenable, and form inferences which a deeper study would have shown him to be impossible.

After alluding to the obligations of the Profession, its trials and difficulties, the lecturer concluded by saying, "that, as far as the intellect was concerned, the student in Medicine had need for exultation that he was about to enter upon a Profession which, if he would do justice to himself, would inevitably elevate and ennoble him. But as the intellect was the lesser half of man, and as the beauty of mere reason was not to be eclipsed by moral worth, the Profession of Medicine has to be entered upon, not merely with the view of increasing the perceptive and reasoning powers, but also the moral faculties, whereby he could act towards all men with faith, justice, and tenderness. In this spirit, if the student was true to himself, he would never have reason to regret that he had entered upon a Profession which had not only the power of cultivating the mind but also of purifying the heart."

"Yea, when the shattered globe shall rock in the throes of dissolution, still will he stand in his integrity, sublime, an honest man."

LEEDS SCHOOL OF MEDICINE.

THE Introductory Address was delivered on Monday, October 2, by the President, Dr. Clifford Allbutt, who said that, at their last meeting, it had been his pleasant task to congratulate his hearers on the approach of their holiday—a holiday which they had well earned by a year of excellent work. He hoped that they would now bring back with them the same free, joyous, and hopeful spirit to their work which they had enjoyed in their recreation. He was himself one who rejoiced in a holiday as much as any, but he thought there was one greater enjoyment, and that was the returning home with clear brain and steady pulse, full of courage for the duties before us. In the remarks which he should address to them, subjects which were called Medical in the strict sense would have prominence. But he would have his hearers remember that, ideally speaking, the art of healing was one; in student life, indeed, there should be no distinction. In practice, however, it was found that no human brain had ever been big enough, nor any human life long enough, to master the recent progress of more than one of the two great divisions in common use—Surgery and Medicine. The President said that no questions could be more urgent than the two which he would now endeavour to answer—viz., 1st, What is disease? and 2nd, Can we cure it? He then referred to the various ways in which these two questions had been answered in various ages of the world; and he pointed out how important the knowledge of the opinions of the past was to those who would really understand the present. During the present century, the rapid development of anatomical knowledge, and a growing sense of the awful complexity and mystery of the human frame, had deterred men from having a lively faith in their own power of usefully interfering with it. Hence a school who disbelieve in Medicine, and would leave all to nature. For his own part, the President held this doctrine to be as dangerous as the more ancient doctrines, which allowed men to undertake cures in rashness and ignorance. He believed, he said, that the supineness of the former school was nearly as fatal in its consequences as the over-zeal of the latter. For his own part, he believed the powers of Medicine—when guided by acute intelligence and tact, an extensive knowledge of remedies, and a wide acquaintance with science—to be astonishing to one who cannot but feel, on the other hand, the difficulties and the dangers of the work to be done. But he believed it to be of enormous importance to take care that the hand was guided by an active and observing mind, with the full light of modern observation and experiment, and, above all, by true conceptions of the nature of disease. Hence the urgent need of a true answer to the question—What is disease? At present a quite new answer was being prepared to this question. In times gone by, nay, even at the present time, there was one very common answer to that question—namely, that disease was something foreign to a man, something which had to be purged out of him, drawn out of him by blisters, expelled through the pores of his skin, or otherwise eliminated. This was like the old legend, to account for a man's wickedness—that he had accidentally swallowed the devil in a lettuce, and that, until the evil spirit was expelled, there was no hope for him. This theory of ejecting disease, and leaving a healthy body behind, still survives in common language, and guides the actions of numerous persons. But this theory must be given up, and its place taken by the view that the human body is like the solar system—a system of parts moving together in balance and harmony. In health, this movement should be so even that all our bodily functions go on unconsciously to ourselves; and disease, on the contrary, is that state when these movements are disordered either by some disturbance from without or by some failure within. The Medical art consists, then, not in the hope of expelling disease and leaving a sound man behind, but in learning the balance and harmony of the functions, detecting their first deviation from true running, and finding means for helping the system to recover its equilibrium. The President illustrated this point at some length in reference to the recent researches into the theory and treatment of fevers. He described the important information of disordered nutritive balance which the thermometer had revealed in these diseases, making their treatment in many cases impossible without watching the thermometer. He explained also how in this way it had been found that

death in many cases of fever was found to be directly due to the overheating of the system, and that this mode of death resembled that called sun- or heat-stroke, and could be induced artificially in animals. Hence the rational and wonderfully successful method of treating fevers by judicious applications of cold, or coolness, in exact proportions to the indications of the thermometer, a practice long ago recommended by our own Currie, largely extended within the last few years in Germany, and which has lately received brilliant illustration in some cases published by Dr. Wilson Fox. The next point which the speaker took up was that of the individual treated. The same disease in different persons presents often quite distinct features, and it is for the Physician to recognise this, and not to rely upon stock formulas, but to treat the individual as a whole. So different are constitutions that it might almost be said that the Physician never treated the same case twice over. The speaker suggested, however, that much more might be done by dividing people into classes, according to the chief varieties of constitution and temperament. He said that by recording and putting together all the various complaints which ran in particular families, an unsuspected relationship might often be detected between two diseases, which at first sight, and seen separately, appeared wholly different. By detecting this underlying affinity the master-key to treatment might be obtained. The various morbid tendencies of rheumatic, gouty, scrofulous families, etc., were then sketched, and a new class of persons was described, whom the speaker proposed to call the neurotic class. Persons having this hereditary constitution presented certain marked features, both in health and disease, which were enumerated and described. The President then addressed himself more especially to the younger students. He begged them to remember that at Leeds there was no intention of instructing them in systems of opinion, in dry dogmas, or in strings of hard words; but they would be taken to nature and to the bedside, and there so associated with their teachers that, on the one hand, the teacher would freely express to them his ideas, his difficulties, his doubts, and his ignorance, and would lead them to see the movement and springs of his own mind and knowledge; the student, on the other hand, would, by inquiries and criticisms, keep alive in the teacher a dread of standing still, a freshness of mind, and a continual openness to new ideas and discoveries. The teacher would give to the pupil accumulated knowledge and maturity of judgment; the student would infuse into the teacher flexibility of mind and renewed enthusiasm. In conclusion, the speaker earnestly called upon his hearers, old and young, to remember that, although it is the glory of the human intellect to measure itself with great problems and thus to prove its own right to handle them, this intellect is as foolishness, and all knowledge but as bitterness, if the heart go not with it. No keenness of eye, no elaboration of treatment, can suffice where a deep human sympathy goes not with them. They might not, and for the most part would not, be called to assuage romantic sufferings, or to minister to picturesque miseries, but to listen to the daily complaints of worn, listless women, to ease the hard cough of querulous age, to snatch from the grave the infant of large towns—that wan, squalid, shrivelled little lump of unmixed sadness. In a word, their work would lie for the most part among common, unlovely, prosaic men and women—among those who, not knowing goodness, have never learned to be grateful; and it was not for them now to enter upon such work as this if they could not feel that in their words and acts, slight and passing as these might necessarily be, yet spoken and done without self in them, they could show that deep compassion with all sufferers which comes simply from a sense of their common human brotherhood. In your own lives, the speaker said, strive not for things afar, cast not, as we are wont to do, all blessings save gold in the face of God, but learn to see and to delight in those simple pleasures which ambitious men too often trample upon. He is happiest who can gather flowers in every pasture; and man can find no better earthly reward when his work is done than cheerfulness and contentment.

LIVERPOOL ROYAL INFIRMARY.

THE Introductory Address was delivered by William Carter, M.B. It was directed partly to those who were for the first time entering on Medical study, and partly to those who, having nearly completed their curriculum, expected soon to be engaged in practice. With reference to the number and apparent difficulty of the subjects of study, it was recommended

that Captain Bobadil's excellent suggestion, whereby, with nineteen companions, he proposed to exterminate an army of 40,000 men—viz., by calling them out twenty at a time and running them through *seriatim*—should be carried out, and all difficulties would vanish. "Medical education differs from that preliminary education in which you have hitherto been engaged," said Dr. Carter, "as it does also from that of the sister professions of law and divinity, in being partly conducted by lectures and reading, and partly by demonstration and doing. Every one of the subjects of study on which you will have to enter has two distinct sides—one theoretical, the other practical—of which the first is only intended as a guide and introduction to the second; as both are meant, as well by the direct information as also by that education of hand and eye and judgment which they give, to introduce to the one great end of all Medical teaching: the alleviation or cure of disease." Having pointed out the kind of work on which they were about to enter, the lecturer drew the new students' attention to two or three obvious truths, which, because they were so obvious, were often disregarded. The first was, that whenever an hour was announced as the one when a lecture would be delivered, it was that hour, and not five minutes or even one minute after it that was meant. Simple as this seemed, it was astonishing how long many gentlemen were in comprehending it, and how industriously they seemed bent, by practising coming a little late to lecture every day, on forming the worst possible habit for a Medical man—viz., that of want of punctuality. A second obvious circumstance was, that they came thither to learn how to alleviate or cure disease; yet indications were abroad that not a few men failed all their lives long to apprehend this. The men whose minds rested in the mere intellectualities of Medicine, who investigated morbid processes and their results, and little more, were comparable to a scientific ship's carpenter who knew the structure of materials and the strain they would bear, and who, from his acquaintance with the laws of fluid pressure and motion, could tell to a minute when a ship with a hole of a certain magnitude in her side would founder, but who had never learnt how to stop a leak. The student studied chemistry and pathology, not that he might become a great chemist or profound pathologist merely, but a good Doctor—a better Doctor than in the long run he could be without them. The danger of disregarding experience because it had come to be a cant word in the mouths of many, who had had but little of it was pointed out, and the habit of systematic observation and note-taking of cases urged—the example of Laennec, who, when a pupil at La Charité, drew up a minute history of nearly 400 cases of disease, "that furnished the groundwork of all his future researches and discoveries," being quoted as an encouragement. With reference to reading, the mean between piling many books on the brains till they could barely move under the load, and the dependence on some miserable little duodecimo manual merely was recommended, and to the more advanced students the much-neglected study of the old masters of British Medicine was specially commended.

The second part of the address consisted chiefly of advice on certain points to those students who expected shortly to enter into practice, such as the rash giving of certificates, the unwarrantable adoption of specialities without special knowledge, the appeals to unprofessional people concerning matters strictly Professional, the publication of new methods of cure, and especially the enunciation of novel dogmas in Medicine from interested motives; and, lastly, the temptation to relax all serious mental effort after obtaining a diploma, which assailed many, and more especially those who, by residence in rural districts, were uninfluenced by the stimulus of competition. "But let me tell you plainly, gentlemen, that if, with human life to deal with, and the honour of a ceaselessly advancing Profession to sustain, you ever suffer yourselves to settle down into a careless routine, you will be morally guilty, and only less so than those who from interested motives disseminate principles directly injurious to life and health."

After thus alluding to questionable practices, the address concluded in another strain. "But there is a far nobler road open to you, gentlemen, and, having dealt so largely hitherto in warnings, I should like my closing words to be those of encouragement and hope—qualities really far more consonant with my own temper of mind, though in this address I have displayed so little of either. They shall be simply these: that if a man aspires to lead a really useful, honourable, and Christian life, no profession holds out to him so bright a prospect as ours. Its worldly honours, it is true, are not very great, and its material advantages, at the best, but moderate. Unlike the sister professions of law and divinity, it has no

higher sphere of nobility into which its aspiring men can hope to soar; but it has within its range scope enough for useful labour to satisfy the desires of anyone who reflects that after his short life must come a long and inevitable retrospect."

MANCHESTER ROYAL SCHOOL OF MEDICINE.

THE Introductory Lecture to the winter session 1871-2 of the Manchester Royal School of Medicine was delivered in the theatre of the institution, Faulkner-street, by Mr. R. T. Hunt, Lecturer on the Physiology and Pathology of the Eye. He said: I do not think that the allotted time can be better occupied than by explaining my views on the subject of Medical Education. These views may in some respects be different from those usually entertained, but may at least have the effect of inducing the student at the commencement of his career seriously to consider what method of study is the best adapted for the prosecution of that knowledge which will fit him for the future practice of his Profession. Public lectures, private study, and attendance in the dissecting-room and on Medical and Surgical practice in the Hospital, are the means of completing his education which are offered to the student. The utility of lectures has been acknowledged from the earliest times of civilisation, and as attendance upon them is required by all the examining bodies, it becomes the duty of every student not merely to be regular in attendance upon lectures, but also to reap all the benefit which may accrue from this mode of tuition. By directing the mind to a fixed subject at a fixed hour, the valuable habit of concentration of thought is much strengthened—a habit which will be found of the highest importance in the future practice of your Profession. A student may think that he will devote a certain portion of time every day to the study of some particular subject; and doubtless those whose minds are of a methodical and systematic character may be enabled to do so. But this is not the case with many. Something may occur to induce the deferring of the study of this subject to another hour, or even to another day; and when this insidious habit of procrastination is often indulged, the evils to which it may lead in the acquirement of knowledge, as well as in conduct through life, are incalculable. An attendance upon lectures at a fixed time is a great check, if not a complete remedy, for this injurious disposition of the mind. Connected with this part of the subject is a question upon which there is some difference of opinion. Is it useful or not to take notes of a lecture? A reply to this will require some modification, according to the nature of the lecture. It will at once appear that when a lecture consists in demonstration of the various structures of the body, whether healthy or morbid, or of models or drawings which illustrate these conditions, taking notes would materially interfere with that attention which ought to be given to the descriptions of the lecturer. The same remark will apply to lectures on chemistry, *Materia Medica*, and botany, but not to the same extent. In all these instances very short notes are quite sufficient, as an opportunity can be afforded to the student for after-examination. But a careful taking of notes of lectures on Medicine, Surgery, pathology, and Forensic Medicine, provided the notes are not too copious, will much facilitate private study. The limited number of lectures upon each of these subjects requires a condensation and arrangement by the lecturer, which will be an excellent guide to the student in directing him in his reading. Medical literature is of such vast extent that the student may well be perplexed by the first consideration of it. But assiduous attention in the first instance to all its elementary parts in the succession in which these are arranged in the prescribed course of Medical education, and confining as much as possible the attention to the elementary branches until these are thoroughly mastered, will be the only good preparation for afterwards acquiring a knowledge of the more difficult and complicated branches of Medical study. With regard to your reading, let it be confined chiefly to those subjects which have engaged your attention at lectures during the day, but restrict your evening studies to the revising your notes, and do not burn the midnight lamp. After the mind has been engaged all day in acquiring knowledge, it is not in so good a state for steady and serious reading as it will be on the following morning, after the refreshing sleep of the night. The ideas then are clear, the judgment sound, and by an hour or two of real study, not mere reading, the mind is admirably prepared for the labours of the ensuing day. On the contrary, night study can only be

carried on by a degree of excitement which, if long continued, both impairs the mental powers and is highly prejudicial to the general health. If the statistics of the after-life of those who have taken high honours at our universities could be obtained, I have not the slightest doubt that these would disclose a lamentable list. Some die from head affections, at a shorter or longer period after examination; the minds of others are so enfeebled as never to regain their full power, and very many die consumptive. Those who take a high position in life form the exception. The examples of the advantages of early morning study to men of science are numerous. I may mention John Hunter, Sir Walter Scott, and many others whose numerous publications are well known. The subject of collegiate Medical education has often engaged the attention of the Profession, and it is probable that the Medical students of Manchester will in future possess the advantages of university education by means of Owen's College. A very important question arises as to the time in the student's career in which these advantages can be rendered available. A student's time is so fully occupied, according to the present arrangement of Medical education, by strictly Professional studies, that attention to the classics, mathematics, or other departments of science would most materially interfere with that uninterrupted attention which his Medical studies require. From this it follows that the other branches of education should be considered as only preparatory, and consequently should be undertaken previously to the commencement of Medical studies. The arrangement of your studies is well adapted for the acquirement of that knowledge which is essential to the future practice of your Profession. Anatomy and physiology form the chief foundations of that knowledge which is afterwards employed in the treatment of disease and injury to the human frame. I fear that the attention of students of the present day is too much devoted to minute or microscopic anatomy, before having thoroughly acquired a knowledge of elementary anatomy. By elementary anatomy I mean that knowledge of all the structures of the body which can be obtained by teaching, by observation, and more particularly by dissection. I do not at all wish to discountenance minute anatomy, but during the course of Medical study it is much more material thoroughly to acquire the elementary knowledge before the student attempts microscopic examinations, except under the direction of his teacher. The results of these he will have described to him in the lectures, and he can rely upon these until the advance of Medical science clears up many difficulties connected with minute anatomy. Physiology, which is founded upon anatomy—the knowledge of structure necessarily leading to the use for which such structures are intended—will require your strict attention, and you will in its study at once observe how much remains still unsatisfactory of this important department of Medical science. You will meet with conflicting opinions and a great many different theories with regard to the functions of the various parts of the body. There being both true and false theories, it should be the business of every student, before accepting any theory, to see what there is to support it and what is said about it by those better able to judge of its correctness than ourselves. Sir Isaac Newton, for instance, no doubt greatly advanced the science of optics—indeed, almost all the rules of what may be called mathematical optics have only been the more distinctly proved correct by the lapse of time. But this does not apply to his theory of the real nature of light, which he supposed to be a material body that passed through transparent substances. According to the opinion of those best qualified to judge, the vibratory or undulatory theory is now proved to be the true one. If, therefore, a man of the transcendent talents of Sir Isaac Newton gave rise to a mistaken theory, scientific students should be very guarded in receiving any theory until it has been properly confirmed by experience. Among what I may presume to call modern fanciful theories are that ridiculous one of Darwin in regard to the origin of species, and of Huxley regarding vitality. Because these theories may be wrong,—and are wrong in my humble opinion,—that is no reason why we should rashly conclude that other theories presented to us are not right; but we should at all events remember that the only theory which is truly useful is that which is not made for facts but is founded on them. Only some minds are fitted to theorise and generalise, but even the humblest among you can record, from your own experience, facts which may prove valuable as supplying missing links in some theoretic chain. While appreciating in your work the value of such mechanical assistance as the microscope, stethoscope, and ophthalmoscope, you must not place too much reliance upon these aids, to the neglect of your own natural

means of acquiring information by observation in the science of anatomy, in post-mortem examinations, etc. With regard to the moral and general conduct of Medical students, so much has been published in the host of introductory lectures that I do not feel it in my power to offer anything new upon this subject. I can only offer my assent to the general views which have been taken, and say that my firm conviction is, that no man who is not a good member of society can be a useful and honourable member of our Profession.

SHEFFIELD SCHOOL OF MEDICINE.

THE Introductory Lecture was delivered by Mr. A. H. Allen, F.C.S., Professor of Chemistry. He commenced by observing that the modern Medical Practitioner was distinguished from the mediæval leech by a greater command of the forces of nature, of the discoveries of chemical and physical science, and by his far superior knowledge of anatomy and physiology. Probably the Physicians of the present day were as much sought after and as thoroughly appreciated as those of any former decade; but how wonderfully had the nature of treatment changed, and the amount of Doctor's stuff diminished. This was probably due to two or three distinct causes. Firstly, physiology was better understood, and the scientific Physician was loth to employ remedies, the mode of action of which he was at a loss to divine. Secondly, the extraction of pure alkaloids from their impure matrices, the use of concentrated preparations of iodine instead of the old remedy of burnt sponge, and the facility with which most active principles were now obtained in a state of purity, had naturally tended to diminish the amount and frequency of the doses prescribed. And, thirdly, the great heresy of homœopathy had caused Medical men to reduce the size of their doses, and to pay greater attention to diet than was formerly the case. In his opinion physics and chemistry should receive from Medical students far more attention than was at present devoted to them. Being the very groundwork of the various complex actions met with in the practice of Medicine, how could it be possible to acquire a thorough knowledge of those complex effects without an intimate acquaintance with the various natural causes which produced them? The more thoroughly the phenomena of life were investigated, the more definite and fixed became the idea that there was no such thing as vital force in the sense in which it used to be understood, and that all vital actions were directly or indirectly referable to well-defined chemical or physical causes. It was often argued that the real cause for certain observed effects was obscure and inscrutable, and that it was preferable in practice to trust to well-ascertained empirical facts without attempting to obtain assistance from a consideration of their origin. But was not the undeniable obscurity with which many of the phenomena of life and disease were enveloped, in a great measure the great consequence of the ignorance of the bulk of the practisers of Medicine of the discoveries in chemistry and physics? And if the general absence of physical and chemical knowledge continued, how could they hope that successful attempts would be made to unravel the secrets of vital action? Better to make use of such knowledge as they possessed, and walk in the dim and imperfect light which it gave them, than to trust to our acquaintance with the path, and be content to walk in the absolute darkness of ignorance that believed itself blissful. Believing, as rational men must do, that no effect was without its cause, they should leave no means untried to ascertain the reason why the various therapeutic agents produced certain physical results; and great as had been the advance made in that direction of late years, infinitely more still remained to be done; and the man who succeeded in solving any of the great problems that had hitherto baffled investigators, would undoubtedly be instrumental in saving infinitely more lives than he who was content to make a living out of the afflictions of humanity without the will or the power to advance the cause of Medical science, and thus indirectly benefit his fellow-creatures. The nature of infection was a subject on the border-land of biology, Medicine, and chemistry, and was one of special interest just now, when they were threatened with another of those fearful periodical scourges which the most extensive knowledge and elaborate precautions had so often proved powerless to avert. It was quite certain that not only cholera, but all zymotic affections were the result of bad sanitary arrangements unworthy of any community professing civilisation; and the epidemics from which we periodically suffered should not be regarded as visitations from Heaven, but as the direct and logical consequences of our own neglect of

sanitary matters, and our unpardonable habit of permitting privies and ashpits to exist in the midst of our densely populated towns. If everyone in times of epidemic disease could be induced to abstain from excess of either eating or drinking, would avoid all drinking-water which had not been previously boiled with enough permanganate to render it pink, would make a moderate use of disinfectants and antiseptics, and would remove all excrementary and other refuse matter without delay, they would hear comparatively little of the fearful mortality consequent upon the neglect of such obvious precautions—which, indeed, were very desirable even in the absence of epidemics. He hoped they might live to see the day when the elements of sanitary science would be taught with the three "R's" to every child in the kingdom.

The University of Dublin had recently gained a most honourable distinction by being the first to establish a much-needed degree in sanitary science, and the lecturer hoped this step in the right direction would meet with all the success it merited, and lead to similar advances in other universities.

ORIGINAL COMMUNICATIONS.

ON "FLAT"-FOOT.

By C. F. MAUNDER,
Surgeon to the London Hospital.

THE owner of flat feet often finds himself so crippled, and these members are frequently so great a source of pain, that I venture to illustrate a simple method of affording relief by detailing the history of an aggravated instance of the deformity.

R. S., now 24 years of age, was ill for a month with fever eleven years ago. Having recovered, he returned to his work as a gardener's assistant, and soon experienced pains and weakness about both inner ankles. These became worse, with "dreadful" pain when standing—not otherwise—and soon so bad that he could not put his feet on the ground. After resting for three days, he could manage to creep about for a day. He used to work in bandages, but with little benefit, and the cold douche and liniments were employed in vain. In this plight, and having been helpless and in pain for twelve months, the lad, then under the care of Mr. J. Stilwell, of Uxbridge, came under my observation. The feet presented the usual ungainly appearance of the deformity in question, the left foot having suffered most. "Frightful" pains arose on his attempting to stand, or on pressure being made on the soles. He was advised to wear, on each foot, a lace-up boot, and in the boot an arch built up on the inside, to serve as a support, and, as it were, raise the now sunken natural arch.

October 21, 1870.—To-day R. S. visited me for the first time since our former interview. He reported that the above contrivance allowed him to get about at once, with gradually decreasing discomfort, when at the expiration of six months all inconvenience had vanished while he was wearing the boots, but he was not quite at ease without them. The arch was made by laying one piece of leather upon the other, each fresh piece overlapping the former, till a mound rose up in the centre, and then this was fixed to the inner side of the boot. By adding a fresh piece of leather the height was from time to time increased. He wore out four pairs of these boots during two years, and then found the support no longer necessary. For the last nine years he has had no pain; his feet are strong, and he is a signal-man on the Metropolitan Railway, and on his feet ten consecutive hours daily. During the whole of this period he has been actively employed, and has even run a mile in less than five minutes for a wager.

This deformity is occasionally marked by hereditary tendency, but more frequently is independently acquired; and the anatomical structure of the part explains this. If from any cause whatever a start is given to a sinking of the arch of the foot, either by yielding of the plantar ligaments or weakness of the long muscles, which should help to hold the foot in its natural relation to the leg, the mere weight of the body, conveyed through the tibia to the astragalus, will constantly tend to push the latter forwards and inwards towards the ground, such being its natural tendency. During the acquisition of the deformity and ever after, if unremedied, the weight of the body is no longer distributed in due proportion by the astragalus to the other bones of the tarsus, but must be borne by itself and by the subjacent tissues. It will not, therefore, be a matter of wonder that severe pains result from stretching of and pressure upon parts

thus overtaxed, but even disorganisation of the joints may occasionally be expected. Such an instance has occurred to myself in the case of a lad, a butcher's assistant, on his feet all day. The patient came under my care through Mr. Holman, of America-square, and ultimately I removed his foot at the ankle-joint. The complaint often begins and progresses very insidiously, the sufferer complaining of pain about the inner ankle towards night, but he cannot put his finger on the spot. The commencing deformity may be recognised in its early stage by letting the patient stand with his foot and leg bare to the knee. An inward tendency and prominence of the inner malleolus, and a corresponding sinking of the external ankle, will be observed, whether the limb be viewed from before or from behind. The appearance of the boot, too, if it have been long worn, is characteristic, and was well illustrated in the case of an itinerant Wesleyan preacher referred to me recently by Mr. G. Weller. In this instance the deformity was almost *nil*, but I believed it to be incipient. With regard to treatment, should undoubted signs of inflammation be present, perfect rest must be given to the limb, and other means suitable to the individual case be resorted to. But in the absence of inflammation, moderate exercise should be allowed, lest all the structures of the foot and muscles of the leg lose tone and atrophy. Some form of mechanical appliance (not necessarily the one described), of which there are many in use, should be worn to support the arch of the foot. Every means of improving the general health should, of course, be employed.

New Broad-street.

A CASE OF ACUTE DROPSY WITHOUT ALBUMINURIA.

By FREDERIC TAYLOR, L.R.C.P.L.

ALTHOUGH cases of acute dropsy with albuminuria are by no means uncommon, yet I believe it rarely happens that a case is met with in which no signs of albumen can be discovered, and which cannot be referred to an affection of the heart or any other organ. Having lately had a case of this description under my care, I now give the particulars, some of which are of an interesting nature.

G. R., a labourer, a strong, healthy-looking man, aged 30, applied to me on March 20, complaining of rigors and chilliness, with pain in his limbs, attended by great febrile disturbance and cough. Upon questioning him, I found that he had been exposed to wet and cold a day or two before he applied to me. When I examined his chest, I could find no deviation from the natural sounds of the heart, or irregular movements or alteration of its force or pulsations. Finding, however, that there were slight wheezing murmurs, and that the breathing was rather embarrassed, I thought it proper to order him a mixture of chloric ether and acetate of ammonia.

On visiting him the next day, I found that he had passed a very bad night, the cough having increased, the breathing becoming more difficult, and the febrile disturbance greater. He also complained of a feeling of stiffness in his face, which had distinctive swelling, particularly about the eyelids.

March 22.—Passed a bad night. The face and eyelids were more puffy and oedematous, and the back of the hands and the arms slightly so. The cough was more troublesome, with expectoration of bronchial mucus and hurried breathing. I examined the urine carefully by heat and nitric acid, and was surprised to find not the least trace of albumen. The bowels not having been relieved, I ordered him a compound jalap powder, and small doses of opium with the mixture.

23rd.—Had a restless night. The eyelids, face, hands, and arms were more puffy and oedematous, the surface of the chest only slightly so, but the swelling of the areolar tissue was more marked on the thighs and legs. The breathing was performed with difficulty, the respirations being short and hurried. He also complained of headache, restlessness, pain and tenderness in the loins. There was no vomiting; the tongue was slightly coated; with a pulse of 85. The urine was scanty and very high-coloured, of specific gravity 1020, with very frequent micturition. The cough and paroxysms of dyspnoea were increased at night. The breathing-sounds through the chest were very indistinct, from moist, wheezy murmurs. I examined the urine, but there was no albumen to be found. As there had been no action of the bowels, I repeated the compound jalap powder.

24th.—Passed a bad night. I found the dyspnoea increased, micturition more frequent, cough more troublesome, and the

swelling of the areolar tissue greater. The bowels, however, were relieved freely. I examined the urine by heat and nitric acid, and also by nitric acid alone, but not the slightest trace of albumen was there to be found. I continued the same treatment for the next four days, during which time he remained about the same. I each day examined the urine, but there was no trace of albumen.

29th.—Passed a better night. Febrile disturbance diminishing, and the paroxysms of dyspnoea less often. There was still no albumen. Micturition was frequent, but the oedema the same.

30th.—Had a tolerably good night; the fever less, and the paroxysms of dyspnoea diminishing. Micturition was less frequent, but the oedematous swelling the same.

31st.—Feels better. The breathing was less difficult, the cough not so troublesome, and the dropsical infiltration of hands and face diminished. The bronchial expectoration was lessened in quantity, but the moist wheezing murmurs much the same.

April 1.—Passed a quiet night, the cough being better, and the paroxysms of dyspnoea not so frequent. The breathing was performed with greater ease, and the febrile disturbance less. The urine was more abundant, and lighter in colour.

2nd.—Had a good night, the breathing being much better, and he can now take a tolerably deep inspiration. The oedematous swelling was less. From this time he kept daily improving.

By April 5 the oedematous condition had nearly disappeared, and the dyspnoea had quite left him. By April 10 there was no oedematous swelling to be found on his face or lower extremities, or, in fact, any part about him. The cough had nearly left him, and the chest-sounds were natural, except very slight bronchial murmurs. By April 15 he was perfectly convalescent, and very soon after he was able to resume his usual occupation. From that time up to the present date he has been in perfect health.

From the beginning to the end of this interesting case I was unable to discover the least presence of albumen, although I was exceedingly careful in my examination, as from the symptoms present I felt certain that it was a case of albuminuria. Upon inquiry I found that the patient had never suffered from rheumatism or any other illness, and was in no way addicted to habits of intemperance.

From the commencement of this case there was no symptom indicating any pulmonary or cardiac disease. It would seem evident that the dropsical condition of the body was the result of an acute febrile attack, in which the kidneys were not affected otherwise than the condition indicated by scanty urine.

ANALYSIS OF ONE HUNDRED AND EIGHTY-TWO CASES

TREATED IN THE LOCK WARDS OF THE ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.

By JOHN WARD COUSINS, M.D. Lond., F.R.C.S.

Number of Patients admitted without any Constitutional Manifestations of Syphilis—127.

DISEASE OF GENITAL ORGANS ON ADMISSION—	
Vaginal discharge	73
Ulceration	54
LOCAL COMPLICATIONS—	
Bubo	5
Abscess of labium	3
Swelling of urethral orifice	5
Condylomata	10

Number of Patients admitted with Constitutional Manifestations of Syphilis—55.

DISEASE OF GENITAL ORGANS ON ADMISSION—	
Vaginal discharge	25
Ulceration	30
LOCAL COMPLICATIONS—	
Induration and enlargement of external organs	4
Sloughing ulceration	3
Induration, swelling, and chronic ulceration	5
Abscess of labium	2
Bubo	2
Condylomata	8

GENERAL COMPLICATIONS—

Ulceration of mouth and throat	8
Ulceration of extremities	3
Dermato-syphilis	16
Relapsing iritis	3
Phthisis	1

All the cases included in the table were treated in the Hospital between October 1, 1869, and May 31, 1870. The patients are divided into two classes: (1st) those who were free from any constitutional manifestations, and laboured only under local disease; (2nd) all in whom there were unmistakable signs of syphilis. The table also indicates the character of the local disease at the time of admission. By far the greater number of prostitutes are found labouring under only a morbid condition of the extensive mucous surface of the vulva and vagina, which sometimes extends to the lining membrane of the uterus. In many nothing can be detected but an unhealthy secretion covering the surface, and retained by the vaginal rugæ. This discharge is often abundant, and varies considerably in character; sometimes it is puriform, at others thin and semi-transparent. Occasionally redness and congestion of the external organs are seen extending just within the vagina; but in chronic cases the principal seat of morbid change is found to be at the upper part of this canal. Here the mucous surface is often granular and red, and bleeds on the introduction of the speculum. The os uteri is often swollen, patent, and indurated, but seldom tender on pressure. Sometimes the canal and cavity of the uterus are involved, and purulent secretion oozes freely from the os during the examination. A swollen and indurated state of the mucous membrane around the meatus urinarius is also occasionally seen. The swelling is usually red and prominent, involving the whole or a part of the orifice, and is quite free from excessive sensibility. The carunculæ myrtiformes are often enlarged in a similar manner. I am aware that the discharge of intractable gonorrhœa has often been considered to be in a great degree uterine, but in my opinion the diseased action extends to this organ much more frequently than is generally admitted. In a large majority of cases this disturbance of the mucous surface of the genital organs is essentially of a chronic character; for out of the whole number included in the table there were not more than two cases which presented symptoms approaching acute gonorrhœa. A large number of prostitutes labour habitually under chronic vaginal discharge, which is capable of exciting disease in the male.

Another table shows the number of patients admitted under my care with venereal sores without syphilis. It is probable that some of these patients may subsequently have exhibited some symptoms of syphilitic poisoning, but all the time they were under my treatment they were free from any trace of constitutional disease. Some part of the mucous surface was most frequently the seat of the ulceration, but a few sores were cutaneous. Some were inflamed and painful, with a red areola, and secreted a yellow discharge; others were raised and prominent, with granulations; and a few were indolent, indurated, and very obstinate in healing. The cutaneous sores were either superficial, secreting a thin discharge, or elevated and desquamating papulæ. It is my experience that hard or indurated ulcerations are seldom seen in women. In a few cases sores were found at the upper part of the vagina when their existence was little suspected, and some on the neck of the uterus, in close relation to the os, which was at the same time swollen and congested. These uterine ulcerations were always very superficial, and generally presented a red and granulating base.

In Class No. 2 are arranged the patients who laboured under constitutional disease. In twenty-five cases chronic vaginal discharge existed alone with some general manifestations of syphilis. In twenty-nine other patients some form of local ulceration was present, and eight were cases of great severity. Three were sloughing ulcerations, attended with grave constitutional symptoms, and the remaining five were chronic ulceration of the vagina, associated with hypertrophy and induration of the clitoris and labia; and this is one of the most intractable of all local syphilitic injuries. I believe that the enlargement and infiltration of the genital organs is a sure indication of a very deep constitutional taint. Four of the patients under this class were ultimately discharged from the Hospital under the certificate referred to in the 31st clause of the Contagious Diseases Act of 1861.

In one case that came under my care there was enormous labial hypertrophy, and the clitoris appeared as large as a child's head at the time of birth. This patient, strange to say, was pregnant, and I lost sight of her. (This case occurred among the out-patients.)

The cases of skin disease mentioned in my table were the ordinary papular and tubercular forms. There was one case of rupia simplex in a very young girl, associated with an obstinate eczematous and tubercular rash over many parts of the body. During her convalescence the peculiar stains were very persistent, and on several places on her arms they assumed the form of crescentic rings of different shades, the external ones presenting the deepest colour.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

UNIVERSITY COLLEGE.

THE students at this Hospital had the opportunity of witnessing several operations in the theatre during the first week of the new session. Those performed on October 4 were the following:—

Case 1.—Amputation at Knee-joint for Chronic Disease.

Mr. Erichsen amputated the leg of a young man at the knee-joint for old-standing disease of the joint. In his remarks upon the operation, he said that he had performed amputation rather than excision, as the latter treatment would have left the limb too short and too deformed to be of much use to a working-man; and he pointed out that in making the flaps—viz., a long anterior and short posterior—as the patella was ankylosed to the condyles of the femur, he had been obliged to dissect the skin from off it, instead of adopting the usual proceeding of taking the patella out from the soft tissues after the anterior flap had been fashioned. The ends of the condyles of the femur he had also removed, owing to a considerable amount of ulceration of the cartilage covering them. This he did not think was of much importance, as the medullary canal had not been opened, and therefore no extra amount of danger from osteo-myelitis would be incurred.

Case 2.—Encysted Hydrocele, and Hydrocele of Tunica Vaginalis.

This was a large tumour occupying the left side of the scrotum of an old man: it was the size of a melon, and had existed for twenty-eight years, though it had not increased for the last twenty years. The large swelling was divided upon the surface by a well-marked constriction, which gave the appearance of there being two sacs. Mr. Erichsen remarked that the diagnosis of the case from a scrotal hernia was easy, owing to the absence of any impulse on coughing, and to the presence of distinct fluctuation. He suspected that the constriction seen upon the surface corresponded with a division of the tumour into two sacs, and thought it very probable that one of the two divisions would prove to be an encysted hydrocele. This, he said, would be detected after the fluid was drawn off by the presence in the fluid from one or both the sacs of spermatozoa. The diagnosis as to the complete separation of the two turned out to be quite correct. From the smaller sac clear straw-coloured fluid escaped, and in this Mr. Beck found that spermatozoa were present. The larger cyst contained a much darker-coloured fluid, and no spermatozoa were discovered in it.

Case 3.—Partial Dislocation of Knee.

An interesting case of partial dislocation of the left knee-joint was next brought under the notice of those present. This was in a man about 50 years of age, who two months previously had slipped from off a ladder, and besides severely lacerating the soft parts of the calf of the leg and skin of the popliteal space, had dislocated the left tibia outwards and slightly backwards. The leg was fixed at nearly a right angle with the thigh, so that the calf of the left leg crossed over, and (the patient being on his back) rested upon the right leg an inch or so below the right knee; it was thus quite useless. There were, besides, the traces of an extensive skin wound in the situation alluded to, and considerable contraction of the tissues had followed the healing.

After alluding to the distinct history of the injury, Mr. Erichsen laid stress upon the importance of attempting at once to remedy the deformity; delay, he said, would render all endeavours hereafter useless and certainly unsuccessful, whereas now, only two months after the accident, and with the aid of chloroform, there was a fair prospect of producing a great improvement in the position of the limb. When the patient

was completely under the influence of chloroform, the left thigh was firmly held by an assistant, while Mr. Erichsen with his left hand firmly held upon the outer condyle, and his right hand grasping the foot, forced the foot gradually upwards and outwards, and by these means he brought the leg into a line with the thigh. A good deal of angular deformity, however, still remained, but this was due, not to any unreduced dislocation backwards, nor to contraction of the hamstring tendons, so much as to the contraction of the soft parts which had been injured at the time of the accident. To overcome this, therefore, he made no further attempt at the time, but hoped, by placing the limb upon a back extension-splint, to at length nearly or quite get rid of the angular deformity also.

Case 4.—Dislocation of Wrist forwards and to Ulnar Side.

This resulted from an accident some long time previously. The carpus was displaced on to the palmar aspect of the bones of the forearm and to the ulnar side, and the trapezium could be distinctly felt in front of and to the ulnar side of the end of the radius. Mr. Erichsen remarked that dislocations of the wrist, simple and complete, were very rare accidents, though not unfrequently cases of Colles's fracture were mistaken for such. Casts of some true dislocations of the wrist were, however, to be seen in the museum of University College, to one of which—a dislocation backwards—he especially referred. In attempting the reduction of such cases, a caution was given to the students not to employ any great amount of force, as much more was to be effected by moulding and intelligent manipulation than by a too liberal use of muscular effort. The truth of this doctrine was shown by the result; for after some backward, forward, and rotatory movement of the hand, with extension from the fingers and pressure upon the ends of the radius and ulna, a considerable improvement was made. The limb was then bandaged upon a pistol-shaped splint placed upon the extensor side of the forearm and hand, whereby the hand was retained away from the palmar aspect, and kept back upon the articulating surface of the radius.

Case 5.—Wood's Operation for Varicocele.

Mr. Berkeley Hill also operated on the same day upon a case of varicocele of the left side, in a young man, who was the subject of spermatorrhœa, and who admitted having practised masturbation to a considerable extent. Mr. Hill drew attention to the fact that varicocele was one of the ill-consequences which not infrequently resulted from the habit of self-abuse. He then explained the principle of the operation he was about to perform, and said that the effect produced by the plan he was about to adopt—Wood's operation—was that of the gradual division of the enlarged veins.

SATURDAY, OCTOBER 14, 1871.

THE INTRODUCTORY LECTURES.

THIS week our pages contain abstracts of several of the Introductory Addresses delivered in the Provincial Medical Schools. One of these, the able lecture of Dr. Clifford Allbutt, at the

Leeds School, we have already noticed. At Queen's College, Birmingham, Dr. Russell began his address with some quotations from a book very little read now a days, we suspect—Burton's "Anatomy of Melancholy." That quaint and learned old writer, in his chapter on the cure of melancholy, reminds the patient that he has a duty to perform towards his Doctor as much as his Doctor has towards him, and he points out that unless this reciprocal obligation be duly recognised, the relation between Doctor and patient will be marred, and the benefit which such relation was designed to confer will fail of being attained. Dr. Russell, in developing the subject suggested by his quotations, commented on the effect produced on Medical science by the state of general intelligence and education, and showed that the character of Medical inquiry in different parts of the world has taken its tone from the prevailing genius of the country in which it was pursued, and that "an enlightened public must be the correlative of an educated scientific body." Dr. Russell also pointed out that "the interests with which Medical Science concerns herself are very closely interwoven with those moral and physical agencies which constitute the discipline of life and regulate a man's moral position in the world; hence it is that the problems of health and disease so often appeal to men as free agents, and require those who receive the benefits of the Medical art to weigh the evidence submitted to them, and to allow due weight to the character of the witness." Dr. Russell's address may be very usefully read by the general public, as well as by Medical students.

We regret that we could not publish and comment on all the Introductory Lectures last week; for, in the rush and hurry of life, there is some danger of addresses nearly a fortnight old being overlooked. We hope, however, that both the Provincial and the London Addresses which we give this week will receive thoughtful attention; they will well repay it. Dr. W. R. Basham, at the Westminster Hospital School, usefully defined the terms "Science" and "Art," and pointed out and dwelt upon the attributes of Medicine, both as a science and an art. "It is a Science," he observed, "in relation to the means and sources from whence it is derived; for it is built up of many, if not all, the other natural sciences. It is an Art, however, in its exercise, and its value is proportioned to the scientific training, the tact and judgment of the individual practising it; an art which, for extent and variety of knowledge possessed by its more distinguished members, is not exceeded, scarcely equalled, by any. Its utility is universal, for it is exercised with advantage and benefit in every region of the world; alike useful to all nations, peoples, and creeds."

We very gladly publish a copious abstract of Dr. Alfred Meadows' Address at St. Mary's Hospital. It is a straightforward, fearless, and active-couraged confession of faith in revealed religion and in the revelation of true science, of ignorance concerning the mystery of life, of acknowledgment of the apparent finiteness of man's powers of research and comprehension, and of dissent from the scepticism of intellectual pride. Scientific observation and inquiry have received such potent aids in these days from man's mechanical skill, scientific knowledge has made such vast strides, and we have gained such an immensely increased command and control over the forces of nature, that we are apt, in our pride of intellect, to think that we can understand the why, the how, and the wherefore of everything; that things unseen are as clear to us as the things that we can see and handle; that "under our command is earth and earth's, and in our hand is nature like an open book." But it is well, and more than well, that it should be pointed out to our students that at any rate we have not yet reached this point; that God and Nature are not at strife, and that the revelations of true science do not prove the Bible to be a collection of myths, and the Christian religion a worn-out phase of education and thought, that has served its purpose, and must now be given up. "Knowledge

comes, but Wisdom lingers"; and in our love of Knowledge, and reverence for her use and beauty, we need reminding at times that she must, "if all be not in vain," move "side by side with Wisdom, like the younger child."

We venture to hold that Dr. Meadows has done good and true work in pointing out the difference between true science and speculation in science; in showing that the hypothesis of "the physical basis of life" is, as yet, "not proven"; and in boldly asserting that, "not even the clearest proof of the so-called physical basis of life, nor the actual demonstration of any single fact in science, however much it might seem to contradict my most cherished beliefs, would have the smallest influence in shaking my faith in the fundamental truths of Christianity. Regarded from a religious standpoint, it matters nothing to me whether the functions of my body or the growth of a tree are performed in obedience to what is called a physical or a vital law; neither am I concerned to know whether I sprang from a marine ascidian or from nothing, for I know that all laws and all matter, whether in the animal or the vegetable kingdom, the organic or the inorganic world, must have originated from the Great Lawgiver, and that He saw that they were good."

The whole of Dr. Meadows' Address deserves earnest and thoughtful perusal. It is particularly well calculated, we think, to be useful to young and eager minds entering on the study of science and of the mysteries surrounding our life; and while he fully recognises the conscientiousness and thoughtfulness of inquirers from whose conclusions he so much differs, he rightly warns students that "Falsehood is never so successful as when she baits her hook with Truth; and that no opinions so fatally mislead us as those that are not wholly wrong—just as no watches so effectually mislead the wearer as those that are sometimes right." We thank Dr. Meadows for his Address.

OFFICERS OF HEALTH AND UNION MEDICAL OFFICERS.

IN the address, at the opening of the Social Science Congress, delivered at Leeds on the 5th inst. by Mr. Hastings, President of the Council, that gentleman made some observations on the question of sanitary reform, and the appointment of Medical Officers of Health.

Mr. Hastings urged the importance of adopting large areas for sanitary administration, and the necessity for the employment of efficient Officers of Health, and he recommended that the salary offered should be such as would secure the services of Medical men of trained intellect and high character. He thinks that the remuneration attached to the office should be of such an amount as would enable the authorities to stipulate that the officer be rigorously debarred from private practice, in order not only that he might devote his whole time to the functions of his office, but that he should be free from private influence in the performance of his duties.

The services of such an officer could, in Mr. Hastings' opinion, be obtained by counties, but seldom or never by unions. He therefore suggested that the Officer of Health should be appointed for the county, as the rateable area of the county, supplemented by boroughs which would unite with it for sanitary as they now do for gaol and police purposes, could sustain such a Medical man at a cost under which the unions must break down.

He protested against the system under which it is proposed to place the sanitary welfare of the county in the hands of the Union Medical Officer, and—whilst admitting the services and merits of a body of men signally underpaid for their work, denied the social recognition of enrolling themselves in the civil service of the Crown, and struggling manfully in the great majority of cases, though beset with difficulties, to do their duty to the poor—he expressed his disbelief that these officials possess the qualifications necessary for sanitary work.

In support of this view, Mr. Hastings referred to an opinion expressed by his late colleague, Dr. Symonds, of Bristol, that very different acquirements from those which are successful in the treatment of sickness were required in a Medical Officer of Health. He said that it was not easy to see how Professional men, whose time and energies were absorbed in daily toil, could qualify themselves by that study "of all sanitary questions" which the Commissioners recommend as desirable for Medical Officers of Health, and that, even granting Poor-law Practitioners the necessary qualifications, they were under the grave disability of private practice.

On this point Mr. Hastings quoted from a minute of the General Board of Health, in December, 1855, relating to the duties and qualifications of a Medical Officer of Health, the following passage:—

"It will be well to debar him from the private practice of his Profession; first, because the claims of such practice would be constantly adverse to those of his public appointment, the duties of which (especially at the times of epidemic disease, when his official activity would be most needed) private practice could scarcely fail to interrupt and embarrass; secondly, because the personal relations of private practice might render it difficult for him to fulfil with impartiality his frequent functions of complainant; and thirdly, because, with a view to the cordial goodwill and co-operation of his Medical brethren, it is of paramount importance that the Officer of Health should not be their rival in practice, and that his opportunities of admonitory intercourse with sick families should not even be liable to abuse for the purposes of Professional competition."

Mr. Hastings was of opinion that, if this reasoning be sound—and he stated that much evidence had been collected both in our own country and on the Continent in its support—it followed that the Poor-law Practitioners who depend on private practice for their livelihood are not fitted for the functions of Health Officers.

The opinions of Mr. Hastings on this subject deserve full and careful consideration. We think, however, that some of his views, more especially with reference to the employment of Union Officers as Officers of Health, are open to question.

In the first place, as regards the suggestion that the Officer of Health should be appointed for the county, we consider that in order to secure a perfect supervision of its sanitary condition, it is essential that the district placed under the care of the officer should not be of a very extended area.

The difficulty of meeting the cost of an officer for a more limited area might, in our opinion, be obviated by combining the offices of Union Medical Officer and Officer of Health. This opinion, moreover, is generally in accord with the Report of the Royal Sanitary Commission. The evidence taken by that Commission is of recent date, and comprises the testimony of nearly all the best available authorities on sanitary matters. By such an arrangement the duties imposed upon the officer would be sufficient to require him to devote his whole time to their performance, and to justify the payment to him of a liberal remuneration for his services. Thus the two chief conditions demanded by Mr. Hastings could be fulfilled—namely, the debarment from private practice, and the allowance of a salary adequate to secure the services of thoroughly efficient officers—and the objections in this respect urged against the appointment of the present Union Medical Officers as Officers of Health would be met.

Moreover, by the very nature of his ordinary duties, a Union Medical Officer has his attention directed to the worst cases of bad sanitary arrangements in the habitations of the poor, and to the existence of dangerous nuisances which otherwise might escape notice. Moreover, by virtue of his position, he could with less obtrusiveness, and with less chance of encountering obstruction, initiate proper remedial measures. We consider that, as regards the practical carrying out of sanitary reform, he would have a distinct advantage in this matter over a Practitioner who was simply Officer of Health.

We do not propose to enter into the question as to whether

or not the present officers engaged for the purpose of affording Medical relief to the sick-poor possess the necessary qualifications for the post of Health Officer. This point may, doubtless, be open to much controversy; but if the offices were combined, the increased remuneration offered would tend to secure the most efficient men, and thus, in respect of each office, a further advantage would be gained to the community.

DISINFECTION BY HEAT.

A CONSIDERABLE number of public stoves, or disinfecting apparatus, as they are commonly termed, have recently been erected in and about the metropolis, thanks to the now waning small-pox epidemic. Vestries and other public bodies which had heretofore resisted the introduction of these articles on the score of so-called economy, but in reality of expense, suddenly found that heating-stoves were matters of prime necessity, no doubt greatly to the advantage of the makers. We have, consequently, a right to expect from the Metropolitan Medical Officers of Health valuable information as to the use of disinfecting chambers, not only as regards the cost of their working and the amount of work done, but above all as to their efficiency, the temperatures attainable with safety to the articles to be disinfected, and those necessary to secure destruction of the infective material. We sadly lack this last information, for nothing tangible appears to have been done in this direction, that we are aware of, since Henry published his classical experiments in the year 1832. The papers in which that illustrious philosopher described his researches are models of accuracy and clearness, and deserve to be better known than they appear to be. It appears to be the general opinion nowadays, however, that greater degrees of heat are required for disinfection than Henry found to be adequate. We do not know on what precise grounds this change of opinion is based, but are inclined to think that it rests vaguely on the results of experiments made on the action of heat upon the lower forms of animal life—experiments made rather with the view of determining the point at which all life ceases to exist than the temperature at which disinfection is achieved. Henry found that whilst a temperature of 120° F. was inadequate, one of 140° F. was adequate to render the vaccine virus inert. A heat of 204° or 205° F. rendered articles of clothing that had been worn by patients suffering from typhus fever quite innocuous; and he proved that, by exposure to a temperature not below 200° F. during at least one hour, the contagious matter of scarlet fever is either dissipated or destroyed. In these experiments of Henry's, heat alone was the agent employed; but it is customary nowadays to disinfect by the aid of such substances as sulphurous acid gas and carbolic acid, as well as heat, the articles to be disinfected being simultaneously submitted to the actions of heat and of the other disinfecting agent. It is believed that there is an advantage in this, for it is known that the lower forms of life are more susceptible to the combined influences of heat and a disinfecting substance than to the effect of either agent employed singly.

Dr. F. Crace Calvert has recently published, in the *Chemical News*, some new experiments bearing upon this question. He finds that germ-life is not completely destroyed in the presence of moisture at 300° F., whilst it is destroyed by a temperature of 400° F., a temperature quite sufficient to materially injure cotton and other fabrics. From this he draws the conclusion that no beneficial results can be obtained by the employment of public stoves as a means of destroying germ-life and contagion. We demur, however, to this conclusion. In the first place, heat is supplemented by other means in disinfecting-chambers. Again, although bacteria, etc., withstand a high temperature, the germs of disease may perhaps be much less resistant to heat and other destructive agencies. Henry's experiments seem to confirm this suppo-

sition. It is scarcely credible that the persons he describes as wearing the cast-off and disinfected clothing of scarlet fever patients could have escaped the disease had the disinfection (by a temperature of 205° F.) not been complete.

THE WEEK.

TOPICS OF THE DAY.

DR. JOHN LOWE, of King's Lynn, Norfolk, has been appointed Medical Attendant to the Prince of Wales' Household at Sandringham.

The announcement that the complainants in the Hampstead Hospital case had exhausted their funds, and were not prepared to continue the services of counsel during the remainder of the inquiry, is one not calculated to cause surprise. These young men have already spent the large amount of £400, and have produced a mass of positive evidence in support of their allegations. It seems difficult to conceive, however, that the public will allow the matter to rest where it is. The *Daily News* of Thursday announced that the inhabitants of Hampstead, who met on Wednesday last, under the presidency of Mr. McCullagh Torrens, to oppose the Local Government Board in their proposed utilisation of the sheds now occupied as a Small-pox Hospital for the purpose of receiving cholera patients, commenced a subscription for the continuance of the necessary legal assistance to the complaining Medical officers, and funds from other quarters will in all probability be obtained. It is most undesirable, especially for the management of the Hospital, that anything should be wanting to a thorough investigation. It may be readily understood that the Assistant Medical Officers are not concerned to cross-examine witnesses who may be called on the other side, for the simple reason that no amount of negative testimony, from patients who did not think themselves ill-treated, can detract one iota from the positive evidence of the patients already examined—so far, at least, as that evidence has been the statement of facts, and has not been shaken in cross-examination. We reserve our comments until the conclusion of the case, but we cannot refrain from observing, *pace* Dr. Buchanan, that it is not usual in a well-managed Hospital for Medical men to have to carry about corpses, and that the inquiry, as we understand it, is not one into the question whether the Assistant Medical Officers stepped out of their ordinary routine of duty in order to supplement the shortcomings of the wardsmen and nurses; but whether the Hampstead Small-pox Hospital was well or ill-managed, and in this case especially whether a dead stinking body was left for several hours, by the persons whose duty it was to remove it, in the bath-room of one of the wards. At the time of our writing, the decision of the Local Government Board as to the application made to them, that they would assign counsel to the complainants for the cross-examination of the defendants' witnesses, had not been received. No counsel for the complainants was present at the inquiry on Thursday, on which day Mr. Williams finished his speech, and Mr. Wyatt, the Chairman of the Hospital, was examined.

The papers during the past week have contained an account of a terrible murder of two children, committed by their mother, an epileptic, and in all probability of unsound mind. The woman is the wife of a labourer at Garnscombe, near Barnstaple. She had been left in her house with her two children, aged respectively 3 years and 9 months. She was seen to come out of her house dressed in her best clothes, and to run down the road. Having before used sticks in walking, her appearance attracted attention. On the neighbours entering her house, the children were found strangled. She remains apparently in a state of perfect indifference. We should like to know how many murders are committed annually by lunatics at large.

The Council of the Royal College of Surgeons holds its first meeting on Thursday next.

Dr. G. V. Poore is a candidate for the vacant Assistant-Physiciancy to the Charing-cross Hospital.

Miss Jex Blake's friends have subscribed £1000 to defray her expenses in the recent action with Mr. Craig. The lady announces that she intends applying £100 to found a Hospital for Women.

In the Health Section of the Social Science Congress at Leeds, Mr. Rawlinson, C.E., gave the meeting some valuable experience, obtained in the Crimea, on the subject of ventilation—

"They were probably aware that he had been sent out by the Government to the army in the Crimea; and out in the Crimea there was certainly room for an experiment upon the grandest scale. The mortality was something more fearful than had ever occurred with any army with which he had been acquainted. Our troops in the Crimea had suffered in the three months during the dreadful winter of 1854-5 at the rate of 700 per 1000—70 per cent.—during those three months. They saw starvation of various kinds—from want of necessary provisions and from actual exposure to the elements. The remedial measures that were taken in the first instance were, to send out a number of huts from England, at a very great cost, in lieu of tents; but these wooden houses had no sooner been inhabited than they became fever dens and pests of the very worst kind. And for this reason no instructions were given to provide isolation of each hut from the subsoil and to provide ventilation. The side walls were eight feet high, and the roof was covered with patent felt, which was water-proof; but, unfortunately, it was air-proof too, and, there being no arrangement for any ventilation at the floor, and the huts being arranged for twenty-five men, one-half of the occupants were down in fever, and sometimes it turned to putrid fever. There were some regiments with only one-half of their strength. The 79th was down with fever, and a most striking condition of affairs was found out in comparing the position of the 79th with that of the 42nd Regiment. Lord Clyde had gone with him for the first inspection, and he asked to be told the difference between the two regiments, there being very little fever among the 42nd. Upon investigation he found that the encampment was on a steep mountain-side, the greater part being oolitic limestone and dry, but there was a broad band of clay underneath. The 79th Regiment was on this band of clay, and the persons erecting the huts had excavated a level place into the bank of the hill-side, and, consequently, at the back it was three to five feet in height, sloping down at the sides; and no provision being made to keep the earth from the sides of the huts, they were like inverted bell-receivers, with the men inside and the damp soaking in under the floor. The 42nd, on the other hand, were on the rock, and they had been compelled to raise a false floor for the huts. He advised the shifting of the regiment, and from the time that it was shifted the new type of disease ceased, and only the men had to recover who were originally down. The huts, however, on this band of clay were not taken down; the quartermaster forgot that they were empty. The 32nd Regiment came from India and were quartered in them, and when they had been there fourteen days there were thirty-two cases of cholera. The wretched huts were still kept there, and a brigade of artillery having been sent into them, within thirteen or fourteen days there were thirty or forty dead with cholera. All this was simply want of ventilation and of proper sanitary provision."

VACCINATION DOTTINGS.

IN Islington last week the vaccinations were 138, the revaccinations 68. Permission was given by the authorities to prosecute three persons for neglecting to have their children vaccinated. A bill has been issued announcing a "grand concert" to be held at Barnsbury Hall, in aid of a man named Jones, whom, it was stated, the Guardians had prosecuted under the "iniquitous Vaccination Act." A dissenting minister at Southampton has been fined 20s. for neglecting to have his child vaccinated. He pleaded "conscientious motives," and the "fact," told him by a London Physician, that the abscess in the Queen's arm was the result of imperfect vaccination.

MEDICAL SCHOOLS OF PARIS.

MEDICINE, like all other professions and callings in Paris, has suffered materially from the late war. It was found, at the opening of the Schools and Colleges of Medicine last week in Paris, that the number of "entries" had diminished to a very great extent. One of the reasons assigned for this falling off is, that parents in the provinces are unwilling at present to send their sons to the capital. But there can be little doubt that the depressing influences of the war have had a marked effect in producing the decrease.

HEALTH OF NEWCASTLE.

THE rate of mortality in different towns and rural districts must, certainly, be dependent on causes more or less removable. In well-managed districts, in which sanitary laws and regulations are carried out, the rate of disease and mortality is always less. No doubt changes of temperature and other atmospheric influences, conjoined with the prevalence of epidemic diseases, raise the death-rate, but these are not sufficient to account for the vast differences observed in various localities. At the present time the prevalence of sickness and the rate of mortality are very remarkable. The Registrar, Mr. Bullock, says—"The mortality during the month of September was greater than it has been for some years. The number of deaths was fifty-six, giving an annual death-rate of over forty-three per thousand. No less than thirty-four were children under 3 years old. Fourteen of the deaths were from diarrhoea, five from scarlet fever, and five from measles." At the last meeting of the Board of Health of the town, the following interesting discussion took place:—Mr. Arthur Lecch asked if the Medical Officer could give any opinion as to the very high death-rate of the borough; was it in any way owing to a bad sanitary state of the town, or something in the atmosphere of a detrimental kind? Dr. Gooday said that he attributed the unusually large number of deaths among children to bad and improper nursing. It would be found that the deaths were those of children amongst the very poorest class, and the sickness prevalent was chiefly among them. No deaths had occurred among the children of rich people. He had himself seen Irish children who were allowed to run about the streets when they were suffering from scarlatina and measles. He knew of no nuisances, and nothing in the sanitary state of the town to account for the number of deaths. He considered there was something in the atmosphere all over the world, causing cholera in some parts, and small-pox, scarlatina, and the potato-blight in others. Mr. Bayley said that a gentleman who stood high in the Medical Profession had attributed the prevalent sickness to a bad sanitary state of the town. He therefore asked the Medical Officer if there were any sewers or nuisances of any kind which would affect the atmosphere injuriously. It was certainly extraordinary that the death-rate of the borough should be higher than in large towns, where there was so much more overcrowding and less fresh air. The sickness in the town was not confined to the poor; many children of persons in a better position, and where every attention was paid to cleanliness, were suffering from measles and other complaints. Dr. Gooday said that the prevailing diseases were such as children were liable to and had to go through, and which could not be prevented. What was wanted was that proper attention should be paid to them. They wanted warmth, and comfort, and care. Mr. Lecch said that the death-rate in some of the large towns was about twenty per thousand, whereas in Newcastle it now reached forty-three per thousand. That was a most unsatisfactory state of things. In his opinion steps should at once be taken to search out the sanitary state of the borough. He thought they were really bound to do something. Some time ago he proposed that a thorough inquiry should be made, and that was what they would have to come to, or the town would acquire a character

of a very bad kind. Mr. Bayley said that the Sanitary Committee had really done all it could, and, as chairman of that committee, he might state that if anything could be pointed out to improve the sanitary state of the town, he would see that it was at once attended to. The Medical Officer's report was received. A notice to remedy the nuisance alleged to be caused by the Newcastle sewage tanks, from the Stoke Improvement Commissioners, was read. The Surveyor said that the tanks had been deodorised before the notice was received.

ASSAULT ON A MEDICAL STUDENT.

A YOUNG gentleman—Mr. George M. Whitehead, of Preston, a student at St. Thomas's Hospital—when returning home on Sunday evening, the 24th ult., soon after eleven o'clock, from Hampstead, was, when within three minutes' walk of his own door, suddenly confronted by a man, who rushed out from behind a dead wall, and, with an oath, and the exclamation, "At length we have met!" aimed a blow at his breast, which, however, Mr. Whitehead fortunately received with his left arm, but at the same moment felt that he was stabbed. The knife clove right through the fleshy part of the forearm, and through coat, waistcoat, and underclothing, just puncturing the breast, but fortunately was not long enough to penetrate further. Mr. Whitehead, who is an athletic young man, at once collared the would-be assassin by the throat, and brought him down on his back, where he held him a minute or two with his knee, while he attempted to get hold of the hand holding the knife, hoping, also, that the noise would attract the notice of some passer-by. Nobody, however, came, and in the struggle the fellow got his right arm at liberty, and struck out, violently wounding Mr. Whitehead twice in the knee-joint severely. Mr. Whitehead is a diligent student at St. Thomas's Hospital. He is much respected, both by the staff and his associates at the Hospital, for his great amiability and sterling character. We are glad to hear from recent accounts that Mr. Whitehead is progressing most satisfactorily. The wounds are nearly all healed.

MELBOURNE UNIVERSITY.

GREAT dissatisfaction prevails in some quarters respecting the conduct of the Senate of Melbourne University in refusing to admit *ad eundem* certain gentlemen who were possessed of degrees obtained in the United Kingdom and at the University of Sydney. The authorities of the University of Melbourne say—"The applicants for admission *ad eundem gradum* had sent home money and purchased degrees in the United Kingdom, and, having imposed on the University of Sydney by these purchased degrees, they had obtained degrees from that institution without examination; and that by these degrees, purchased in this manner, these gentlemen were now endeavouring to gain admission into the Melbourne University under false pretences." Strong language and serious charges! It is incumbent, we think, on the authorities of the Melbourne University to mention the names of the British universities from which degrees were obtained simply "by money." Such institutions should be known, in order to be degraded and denounced as "mockeries, delusions, and snares."

A GOOD EXAMPLE.

ABUSE of public Medical charities is too commonly regarded as a venial offence; but it is as distinctly a fraud on the subscribers to Hospitals or ratepayers of unions as applying for bread or meat under a false plea of destitution. The evil is "too many-headed" to be dealt with in all cases successfully. Much, however, may be done to check it if proper steps be taken for that purpose. A move in the right direction has been taken by the Guardians of St. Olave's, Southwark. Having found that persons in comparatively good circumstances have been obtaining medicine from the two dispensaries

recently opened in the Union, the Guardians have ordered that bills be printed and circulated cautioning persons who are not destitute from applying for Medical relief, and it is their intention to prosecute in the first case of fraud which is detected.

ACTION OF ALKALIES ON PUS-CORPUSCLES.

"PUS-CORPUSCLES are mainly composed of albuminoids, and when treated with a solution of common salt, they are converted into a viscid gelatinous mass." To this announcement, from a memoir in the *Med.-Chem. Untersuch.*, noticed in the *Medical Times and Gazette*, September 23, p. 383, a correspondent directs our attention, pointing out that an incorrect impression, both scientifically and historically, may be conveyed, unless the facts, as long since well known in England, be stated. It would seem that the Germans have now discovered that common salt renders pus viscid; whereas the fact is that most alkalies and alkaline salts have this effect on all fresh primary cells of mammals, and probably of lower animals. In Professor Gulliver's second lecture at the College of Surgeons, reported in the *Medical Times and Gazette*, August 23, 1862, page 187, we find the following observation:—"The pale globules of the blood lose their shape permanently, and form a thick ropy compound, more or less transparent, when mixed with solutions of alkalies and their salts—a property which belongs to fresh and free pale cells generally. This ropiness or inspissation, produced by sal ammoniac, was considered by Mr. Hunter and Dr. George Pearson as the criterion of pus." And the same action of alkalies and their salts on the corpuscles of the thymus fluid, of lymph and chyle, and of pus, has always been described experimentally in England, as may be seen—*e.g.*, in the Sydenham Society's edition of Hewson's works, published in 1846, and in the English version of Gerber's "Anatomy," which appeared in 1842.

NAVAL MEDICAL SUPPLEMENTAL FUND.

AT the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on the 10th inst., Sir Edward Hilditch, Inspector-General, in the chair, the sum of £77 was distributed among the various claimants.

FROM ABROAD.—PROGRESS OF CUNDURANGO—THE ACADEMY OF MEDICINE AND INTEMPERANCE.

THE progress of the last new charlatanism in relation to small-pox cannot be better stated than in an article which we transcribe from the *New York Medical Record* of September 15:

"Those who shrewdly surmised that the official agitation of cundurango in the State Department at Washington was a puff preliminary to private speculation in the mysterious virtues of this plant, have had their prediction fulfilled sooner than they could have expected. It was, perhaps, fitting that the only person who has succeeded in discovering any efficacy in the administration of the drug should vindicate his superior acuteness by getting up a 'corner' therein; and, accordingly, Dr. Bliss has philanthropically abandoned the emoluments of private practice in the national capital, and devoted his energies to the diffusion of cundurango in New York, at the moderate price of \$100 per pound. It is to be regretted that the efforts of the Government to promote the success of Dr. Bliss's enterprise have been to some extent frustrated by the obstructive jealousy which notoriously governs the Medical Profession—the Physicians who were requested to buy cundurango having unanimously reported that they found it entirely inert, and analytical chemists having wickedly omitted to detect in the samples sent them any principle which could be supposed to possess a curative action. It is still more unfortunate that of the six patients treated with the new and infallible remedy, whose cases have been reported in the Medical journals, four have died before they were quite cured. But these, after all, are small matters from a commercial point of view, and Dr. Bliss is able to point triumphantly to the fact that two of his three recorded patients survived the ingestion of numerous doses, and would, perhaps, have recovered altogether if it were not that his stock of the drug was

exhausted at the most inopportune moment. He is, moreover, happy in the privilege of referring in his printed circular to Vice-President Colfax, whose opinion on any question of pathology or therapeutics must, of course, be accepted as conclusive. Having been at the pains of sending his partner all the way to South America to buy up all the cundurango wood that could be procured, it is natural that Dr. Bliss should attach a high value to a substance of which he alone appreciates the full merit, and that he should decline to sell less than twenty-five dollars' worth at a time, in order that the afflicted poor may be deterred from buying it in inadequate doses. The petty prejudices entertained by the Medical Profession generally against advertisements of a panacea for 'cancer, scrofula, and other blood diseases' (a) will not, we are sure, be allowed to carry weight with an enlightened public when opposed to an official correspondence between the Secretary of State and our consul at Equador; and the adverse reports of proverbially ill-informed army Surgeons, as well as the bigoted exclusiveness of the 'regular' Physicians in Washington, will be attributed to their proper cause—envy of the superior attainments of a gentleman who has forestalled his rivals in a great discovery, and who naturally wishes to turn this discovery to the best advantage."

It having become a very prevalent notion in France that many of the late calamities that have afflicted that country are intimately connected with the spread of the practice of drinking, both the Legislature and the Academy of Medicine have been turning their attention to remedial measures. M. Théophile Roussel, in his double capacity of Physician and Deputy, has brought the subject before both bodies. To the Assembly he suggested a long series of repressive measures, which have been favourably received by the Bureau to which they were referred; but we imagine the Assembly has too much practicable work cut out for it in various directions to allow of its attempting the difficult task of shaping these propositions into legislative measures, and at present they may be considered pretty much in the position of documents ordered to lay on the table of the House of Commons. He has got a step farther in the Academy of Medicine; for there M. Bergeron, the Reporter of the Committee, has prepared a voluminous *Avis au Peuple*, "On the Dangers incurred by the Abuse of Alcoholic Drinks." This, in fact, is almost a pathological treatise, in which alcohol is tracked through the economy as it pursues its ravages on the various organs, the whole catalogue of ensuing maladies being set forth. Those who are aware of the labour, expense, personal exertion and example, enormous combined action, and extraordinary amount of speechifying, whether of the demonstrative or persuasive varieties, that have been required to excite the public opinion that exists upon the subject in this country, must marvel at, and almost envy, the confiding simplicity of our *confrères* in believing that any appreciable good can be achieved by inditing and circulating throughout the country this wordy pamphlet, with its thirty-three elaborated—and often, to non-professional persons, unintelligible—propositions. However, the Academy, we believe, has the good sense to see that the distribution of this diffuse production would be useless, inasmuch as it never would be read, and intends to cut it down; but if even it does succeed in inducing its perusal, a very slight step in advance will have been gained. One of the critics aptly observes—

"M. Bergeron has but slight hopes of arousing the moral sense and the sentiment of human dignity. 'We must,' he says, 'resign ourselves to rely solely on fear, and constantly place before the eyes of all a true picture of the numerous and varied ills produced by drunkenness. None of those who in future become the victims of alcoholism must be able to invoke as an excuse their ignorance of the danger.' Now, does this ignorance really exist? We must be allowed to doubt it. The man who falls into drinking habits is perfectly aware of the danger to which he exposes himself, for he has no lack of examples before him. He may not be aware of the

manner in which alcohol operates on the economy, and the various diseases attributable to it; but he knows in a general way that its abuse destroys the appetite, paralyses strength, brutalises, and gives rise to incurable disorders. Question the drunkards in our Hospitals, and you will find that they are aware of the dangerous character of their habits, and at the very outside only seek in some sort to lessen their own culpability. It is rare for them to admit the use of the most noxious drinks, such as absinthe and certain alcoholic mixtures, etc.—they are aware that these are veritable poisons, and that indulgence in them only takes place under conditions of a moral decadence which as yet they deny. The temptations to which they succumb are not those which fear of disease suffices to restrain; and at first illusion is so easy, while at a later period, when disease supervenes, its origin is admitted with difficulty. An old inveterate drinker, who has resisted during long years the effects of his habits, is able to assure twenty drinking novices."

THE HAMPSTEAD HOSPITAL INQUIRY.

TWELFTH DAY.

On Thursday, October 5, the Local Government Board's Commissioners, Mr. Henley and Dr. Buchanan, resumed the inquiry into the management of Hampstead Hospital. The Asylums Management Board were represented by Mr. Montagu Williams and Mr. Humphreys, instructed by Messrs. Payne and Hammond; and the complaining late Assistant Medical Officers (Messrs. Greaves, Kynaston, and Aikman) by Mr. Collins and Mr. Bucknill, instructed by Messrs. Burton, Paine, and Hart.

The Chief Commissioner, on the opening of the Court, said that the Hospital books should be placed on the table for the reasonable use of both parties, but the books must not be taken away. He then appealed to Mr. Collins whether, since the evidence of Mr. Aikman (one of the Assistant Medical Officers), this inquiry had been carried any further. A mass of evidence certainly had been produced by Mr. Collins' side, but one witness was merely a repetition of another. It might be said by Mr. Collins' side that they wanted to show the extent to which the matters complained of had gone, but this, they should remember, would prove to be playing with a double-edged sword; for it could not be expected that the managers who took charge of these Hospitals under a very great emergency last winter, and were assisted by a number of benevolent and devoted ladies and a large body of officers, would do otherwise than bring a great mass of rebutting testimony to refute these serious charges, for these things could not be passed by unchallenged, and it was for Mr. Collins to say whether he was prepared to wait to cross-examine all the witnesses the managers might consider themselves bound to bring. Beyond this it was for Dr. Buchanan and himself to consider whether they, for their part, were justified in loading the depositions with a mass of matter a great deal of which really had nothing to do with the points at issue. At the same time, it was felt by his colleague and himself, as everybody must feel, that the character for veracity of these young men, the complaining Assistant Medical Officers, who were just starting in life in an honourable profession, had been seriously impugned, particularly as animus was imputed to them in taking the steps they had. Under this consideration, he, speaking for his colleague as well as for himself, had allowed great latitude to their side in presenting testimony in support of the charges made, but beyond this they could not go.

Mr. Collins said he had felt for some time that the witnesses lately called had spoken only to the same facts deposed to before; but the late Assistant Medical Officers, who, he mentioned, were conducting these proceedings at their own cost and at enormous expense, felt some difficulty in stopping evidence of this character without such an intimation as had now been given—for the other side had stated that three witnesses could be produced to speak for them for every one on this. He was not prepared that day to present the other two late Assistant Medical Officers, for he had other ex-patients to call, but he would present them on the next meeting.

The witnesses examined to-day were—John Bryant, chair-maker; Albert Ferguson, painter; a young woman named Kate Black; William Henry Clicker, a tailor; and Smith, a carpenter. These had all been patients of the Hospital.

Bryant corroborated the testimony of other patients as to the dirt, insufficient clothing for convalescents, and the bad character of the food.

(a) Dr. Bliss is too knowing a Practitioner to confine the operations of his remedy to a disease like small-pox, only of occasional prevalence.

Ferguson gave evidence as to filthy and damp linen being supplied to him, as to the bad character of the beef-tea, and as to the kind of force used to restrain a delirious patient. "He was tied down with the assistance of six convalescent patients, with three sheets, and the nurse, who was stout, sat upon his head."

The young woman, Kate Black, who seemed of a respectable class, gave general evidence as to being put into a dirty bed, and as to the foulness of the linen, and the unkindness of a nurse in not attending on patients; but she stated that this nurse was discharged. Then she deposed to instances of personal chastisement she had seen by nurses upon patients, these actions being "slaps" for dirtiness; and one of the persons so chastised was Letitia Gibbs. One person—a woman who was very ill—begged the nurse, the witness said, to be kind to her, for her time was not long in this world, and the reply made by the nurse was, "No, old girl, you will be off by the morning." The nurse who said this was named Price, and the woman spoken of did die in the morning.

The witness, questioned by Dr. Buchanan, said the nurses were not overworked, for they got others to do their work. She had seen the nurse feed patients, and feeding-bottles were used by some. With the exception of one night, when the nurse would not attend to her, witness had plenty of milk.

Clicker deposed to the insufficient supply of milk; and Smith to having been put into a bed which was claimed by another patient. He also said that, having been employed when convalescent in different parts of the Hospital, he found there was a different sort of meat supplied to different wards.

THIRTEENTH DAY.

Henry Drake Palmer, M.R.C.S. etc., of Nayland, Suffolk, called by Mr. Collins, stated that he went to the Hampstead Hospital, as Assistant Medical Officer, from April 13 until the arrival of Mr. Aikman on May 1. He had charge of No. 3 Ward for the female adults; No. 7, the children's ward; and No. 12, the isolated ward. There were sixty-four or sixty-six children in No. 3, and there were two nurses of a day and one of a night. One of the day nurses had been a patient, but he did not know whether she was on the staff at the time. He had seen delirious children tied down, and one he had seen tied down with a sheet twisted round its body. This was a practice he should not approve or order, and he told the nurse it was a great shame, to which the nurse replied that unless she did tie them down she could do nothing, for several would be getting out at once. Sister Agnes was the sister of the ward, but he could not remember that he had made any formal complaint to her. He had complained of the practice to all the attendants; still, he had shown the nurses a better mode of tying down, by securing the corners of the sheets to the four corners of the bedsteads, and he afterwards found his plan partially adopted. The supply of milk was often short in quantity of a night. The children were decidedly not so clean as private patients would be, and he saw vermin and "nits" in the heads; this was very common in the ward. He went on to relate that he pointed out a treatment for the heads, and he followed the practice he had seen in his experience at Guy's Hospital by recommending white precipitate ointment. He described finding a child dead in bed one night on going his rounds, and he said he called the night nurse's attention to it. She replied to him that she had only just come on duty, and did not know anything of it. The child was very ill in the morning when he saw it, but he was astonished to find so speedy a termination of the case.

By the Chief Commissioner: He could not remember the child's treatment, or what he had said to the day nurse. He would not trust his memory as to what had been done about it, and he had made no notes of what had occurred in the Hospital.

In reply to further questions by Mr. Collins, the witness said he had seen a woman, who was maniacal, strait-waist-coated without his orders, and she was raving continually for parts of two days and one night, disturbing, as he was told, the whole of the people in the ward. This was in the female adult ward, and it occurred when the ward was full of acute cases. It was impossible for the two day nurses in this ward and the one night nurse to attend the ward when all the beds were full of acute cases.

Examined by Dr. Buchanan, the witness said that in the children's ward he commonly saw both day nurses in the ward together during the day. The night nurse went round with him on his night visit. He had known many delirious patients in the children's ward at one time, and the nurse had told him that one in particular was difficult to keep from the fire. He

thought he might say that he had seen twelve children wandering in their heads, and they certainly would have come to harm if permitted to get out of bed. He had not seen any injury through tying down. He thought that a delirious child, even if tied down in the way he had recommended, would fret more than if it were one of three or four children wandering about the floor. He thought undoubtedly that the vermin must have come in with the children, but he did not "order" on the patients' cards the treatment of their heads, but should have left it to the nurses to use the remedies for the destruction of vermin. He did not remember whether carbolised oil was in use, and he never ordered it for heads. He ordered it for something else, and he thought that, being part of the treatment, he should put it on the head-card. He should have ordered white precipitate ointment for the heads in small-pox. He knew this was a mercurial ointment, but he should not have used it indiscriminately. The condition of small-pox patients was such as to lead to the multiplication of these vermin. Certainly, as this ointment could not be used in all cases, and as the condition of the patient was such as to lead to the increase of the evil complained of, the amount of this evil he saw in the Hospital was excusable—at least, to a certain extent. Carbolised oil would have been a better preparation than white precipitate, he thought, but he had never used it. At Guy's the students did not dress bedsores, and this was left to nurses. Undoubtedly bedsores were often of danger to the life of a patient. At Hampstead, while he was there, it was left to the nurses to dress bedsores. At Hampstead the Hospital was under a paid superintendent, with paid juniors under him, and thus differed from general Hospitals. The primary object of those juniors would be, in witness's judgment, the Medical treatment of patients suffering from small-pox. There was a difference between the view which should be taken of the duties of a Medical Assistant Officer at Guy's and a Medical Assistant Officer at Hampstead, for at the one the Medical officer was learning his Profession, in the other he was a Professional man. The Medical duties in the two cases he agreed were completely different. Even seeing that the dressing of bedsores was a thing which affected life, he still did not see that the difference between the two institutions was a reason why the paid officers at Hampstead should act differently to the unpaid Medical officers of Guy's in regard to dressing and looking after these bedsores. This duty of dressing bedsores was always left to nurses, and he regarded the junior officers at Hampstead as being in the position of visiting Physicians, the nurses being regarded as competent to perform this duty. Asked whether he would not have this opinion modified by the fact that at Guy's there was a body of trained nurses, while there were only half-trained nurses at Hampstead, he said he was not aware that the Hampstead nurses were not trained, though he knew some were convalescents. At the same time he desired to say that he did not think it *infra dig.* on the part of a Medical officer to dress a bed sore, and he thought a Medical officer might superintend such a case. Bedsores might be generally avoided if properly looked after; but it was not the duty of the Medical officer to strip the patients. It was, however, certainly the duty of the Medical officer to warn the nurse to look after bedsores. He should be greatly surprised to have a bed sore reported to him which when shown to him was three inches in diameter, and over the sacrum, and with a grey slough (the case of the child Stokes). That would be a neglect on the part of the nurse, for the nurse should have reported this earlier.

By the Chief Commissioner: The use of white precipitate would be improper at certain stages, and would be likely to lead to serious results. Pressed as to whether, having this before his mind, he would still say that the ointment should be left with nurses in a small-pox Hospital, the witness said, after giving several answers, that such was the case at Guy's, and he thought Sisters and nurses should be so trained as to use these remedies. The witness was further questioned by Mr. Collins, and said that the Sisters at Hampstead were regarded as above the nurses, and, coming as paid officers, between nurses and Medical officers, as taking some of the responsibility off the Medical men. He never heard Dr. Grieve order any treatment of the children's heads. He was told by Dr. Grieve that the ordinary diet was considered sufficient for all cases, and that witness had no power to order the full diet. Did not remember having any special directions about bedsores, the use of carbolised oil or precipitate, from Dr. Grieve, for witness was, of course, supposed to be competent.

Cross-examined by Mr. Hammond (in the absence of Mr. M. Williams), he said he always understood that the Sisters were

paid, and believed so from seeing their names in a book with sums attached to each name. He was aware that the Government would not allow of unpaid services in the Hospitals, but he did not know that the money put down to their names went to the Sisterhood at East Grinstead, and not to the Sisters themselves. He never saw delirious small-pox patients until he went to Hampstead. He was aware that patients were restrained at general Hospitals, and that the practice was approved by eminent Physicians. These agreed that there must be manual or other restraint in delirious cases, and manual restraint was as likely to break the pustules in small-pox patients as other restraint, especially if there was much struggling; but sometimes patients could be soothed with quietness. He had no power at Hampstead to order a watcher to watch cases. He never complained, because he was "never told to complain"; and he never asked for and was refused a watcher. He never made any written remark about the want of more assistance in nursing. He considered that a good diet was one of the most essential parts of the treatment of small-pox patients. He ordered "low" diet for acute cases, and "ordinary" for convalescents. He could not remember what constituted these diets. He would not trust himself to say what were the articles in the diet. He ordered the diets, but it was not part of his duty to see that the patients had their diets. Perhaps it was his duty to complain if he saw the diets were short; but he never complained, except to the nurses, because his colleagues complained without redress.

The Chief Commissioner: Did you hear them complain?—No; but it was the common topic of conversation between us of their complaints.

A considerable discussion ensued with regard to the "diets" in the Hospital, and it transpired that the "low diet" was altered twice between December and June. The diets were read over, and he said it was the first time that he knew that children were "on" the same low diet as adults. Questioned on the ordinary diet as given in the dietary, he said it was liberal, but he would not say whether or not it was equal to the full diet of general Hospitals. The dietary tables as put in showed the "ordinary diet" was, for breakfast, one pint of coffee, four ounces of bread, half an ounce of butter; for dinner, eight ounces of uncooked meat, four ounces of bread, twelve ounces of potatoes, half a pint of beer; for tea, one pint of tea, four ounces of bread, half an ounce of butter; convalescents having half a pound extra bread per day and stew or soup for supper. "Low diet" was one pint of tea, one pint of milk, one pint and a half of beef-tea, twelve ounces of bread, one ounce of butter, quarter of an ounce of arrowroot. This had subscribed at the foot, "Approved by the Poor-law Board." The only alterations in the dietary were in "low diet." The first after March 6 gave in the low diet an extra pint of tea a day and an extra half-pint of milk a day. The alteration of June 18 was a reduction of a half-pint in the beef-tea, and the milk allowance each day was increased to three pints.

In answer to Dr. Buchanan, the witness said the "Sisters" at Guy's were promoted nurses of experience, and were thus different from the Sisters of Hampstead.

The Chief Commissioner then informed the witness that his theory that the Sisters and nurses shared the responsibility of the Medical man could not for a moment be admitted. The Medical man was wholly responsible for the care of his patients under his charge.

The witness wished to qualify his statement; but

The Commissioner said the statement was strengthened by the view which the witness took of his duties, in regard to an ointment like white precipitate being left with nurses for use at their discretion. It could not be too widely known that such a view was not warranted by the law governing these Hospitals.

Mr. A. E. Kynaston, one of the three who had signed the letter to the *Times* was then examined. He deposed that he met Dr. Grieve on the Continent during the war, and on his recommendation took the office of Assistant Medical Officer at Hampstead on January 26. He at first had fifty beds, but subsequently, as the Hospital increased with the epidemic, he had 130. In general he paid two visits a day to the wards, sometimes more. With regard to the first charge in the letter in the *Times*, that of the tying down, he had seen this frequently in practice. At first he did not know much about it, not knowing anything of small-pox; but he soon afterwards learnt that the practice was objectionable, and he complained to the nurses, ordering them not to tie down. The answers he obtained from Sisters and nurses were, that they could not go on without it; and he complained to Dr. Grieve of the practice as well as of the insufficient number of nurses. Dr.

Grieve considered the nurses were sufficient in number. No more nurses were obtained as a consequence of the complaints, which on this point were constantly being made. He remembered a man who, in the beginning of July, had the disease very badly, with a most copious eruption, in a rambling but hardly delirious condition, and with a tendency to roll out of bed. This man he found tied down with his wrists fastened to the bedsides with a pocket-handkerchief or bandage, and his ankles the same, both ankles and wrists coming in contact with the iron of the bedstead. Witness unfastened the man, and endeavoured to find out who had tied him, but in vain. The outer skin of the ankles and wrists of the man was rubbed off, and the man died the next morning. The rubbing off was by the bandages. He had, with regard to the second charge in the *Times*, seen strait-waistcoats used, and, with two exceptions, he had always ordered them to be taken off. The nurses when told not to use them said they could not get on without restraining the delirious patients. He was away from the duties of the Hospital from early in April until May 25, having caught scarlet fever in the discharge of his duty, and when he came back he found a practice in vogue of meeting Dr. Grieve officially every morning. At this time he and his colleagues used to make complaints, and Dr. Grieve said he was responsible for the number of nurses. With regard to the third charge in the *Times*, the quantity of milk was generally short. At his first going each patient had an allowance of a pint of milk, but they did not get it. An increase of half a pint was given through the complaints, but the supply was invariably short, and he had complained that even a pint and a half was not sufficient on low diet. He told Dr. Grieve that if he doubled the dietary the mortality would be halved, and though Dr. Grieve said it was sufficient he altered it afterwards—within two hours—and the low diet was certainly improved. Every morning there was some complaint made to Dr. Grieve by the Assistant Medical Officers. He did not like the beef-tea supplied when he had it during his attack of scarlet fever.

Dr. Buchanan: Did you ever find a fever patient who did like beef-tea?—No; I have not found they do as a rule.

The witness went on to speak with regard to the fourth charge made in the *Times*, which charge was—"On making the morning visit we have been informed by the nurse in charge that the patients of her ward on low diet have been kept without food of any kind from 7 a.m. till 3 p.m." He said Nurse Meredith had told him one morning that, and he made her repeat her statement before Mr. Aikman. He then went into the fifth charge in the *Times*, that of the insufficiency and unfitness of food, and in support of this he said that on one occasion when Dr. Grieve had his attention called to the quantity supplied for a ward, he said it was short. The meat looked coarse, and complaints were frequently made by patients, principally of toughness, but once of tainted meat. He did not himself test the statements regarding the insufficiency. He knew nothing about the sixth charge in the *Times*, the finding of dead children in bed, but he supported the seventh, regarding the dead body being kept in the bath-room for several hours, as described by Mr. Aikman. He then proceeded, speaking on general subjects, to say that Dr. Grieve had told the Assistant Medical Officers they were not to report to the Committee, that the Committee would not listen to them.

Dr. Buchanan: Did he really tell you that you were not responsible?

Witness: He did; and I then asked him, if such were the case, who would be responsible if I maltreated a patient and caused death, and who would be hanged for it. He said he did not know. The witness proceeded to state that on this being pressed on Dr. Grieve, as to what the public would think of things of which complaints were made, he laughed, and said that he could defend himself before the public.

An endeavour was then made to enter into the circumstances attending the "dismissal" or "resignation" of the witness and his colleague, Mr. Greaves, and the Commissioners urged that all personal questions should be as far as possible left out of the proceedings.

The inquiry was adjourned till Monday.

FOURTEENTH DAY.

This official inquiry was continued on Monday, October 9, at the offices of the Metropolitan Asylums Board, Norfolk-street, Strand, by Mr. Henley and Dr. Buchanan on behalf of the Local Government Board.

Mr. Kynaston, one of the three Assistant Medical Officers, recalled and examined by Mr. Bucknill, said there was an insufficient supply of milk during the night throughout the time

he was Assistant Medical Officer at Hampstead, even when the low dietary was heightened. In July, No. 4 Ward was for a fortnight without an under-nurse. He also remembered Mr. Greaves telling Dr. Grieve that he had had no under-nurse in No. 9 Ward for a fortnight. Dr. Grieve said he was utterly ignorant of the fact, and he sent one shortly afterwards. This was some time in April. He had noticed the dirty state of the linen—dirt from use and otherwise—and had complained to the nurses about this. It was a general thing for the linen to be in this condition, but in No. 4 Ward the linen was perhaps worse than anywhere else. He could not say whether or not stains on sheets were made by the persons in the beds or by previous occupants.

The Chief Commissioner remarked that he should have thought that such matters would have struck the witness, he being the Medical man visiting the patients and knowing their condition.

The witness said he did not remember any instances of patients in sheets stained by others, but he had known patients being put into beds without the linen being changed. He then proceeded to speak of having told Dr. Grieve that the cording of the beds wanted mending, and Dr. Grieve replied to him that that was not witness's business, for if the patients fell through and died upon the floor he was not responsible.

The witness was then taken over the daily work in the Hospitals described before by other witnesses, and he stated that Mr. Aikman went his night rounds first, witness and Mr. Greaves going later and irregularly, sometimes as late as eleven o'clock, and this was to test the conduct of the night nurses, who, witness considered, should not be allowed to expect the Medical man at one set time. Dr. Grieve complained of this going late, and the object witness had just given was stated as the reason to Dr. Grieve for being late. The assistant Medical men were always accompanied by the night superintendent of the nurses on their visits. Sometimes there was dispensing to be done as well at night, and the Assistant Medical Officers were sometimes called up at night to attend to cases.

Cross-examined by Mr. M. Williams, the witness said he had come straight from Guy's Hospital, where he had held all the appointments, including that of dresser. He had had no experience elsewhere. He was present when Mr. Drake Palmer was examined on Friday, and did not quite agree with that gentleman's views, that the Assistant Medical Officers at Hampstead stood in the same position as visiting Physicians to General Hospitals. He allowed that he should consider it was the duty of the Assistant Medical Officer to see everything was done which could be done to aid the recovery of patients. He knew the Hampstead Hospital was an institution under the Poor-law Board. He had heard of Dr. Bridges, the Medical Inspector for the metropolis of these Hospitals, but he did not know what he was until lately. He knew of the Committee of Management of this Hospital. He remembered seeing Dr. Brewer, M.P., in the wards of the Hospital, but he never spoke to him. He did not think he had seen Surgeon-Major Bostock in the wards; but he had seen that gentleman in the Hospital. He did not remember seeing him visit witness when witness was sick. Witness had seen Mr. Wyatt in the Hospital frequently, and on a few occasions he had conversed with him. He had gone a little way into a ward with Mr. Wyatt once. Asked whether he was treated with kindness by the Hospital authorities when he was ill, and whether he was not then allowed to have champagne, he said he believed the Hospital paid only for a small quantity of what he had had, and he was three days getting a bottle of port wine. He agreed that the object of low diet was to supply nutriment and to slacken thirst, and he agreed that the low diet was equal to six pints of fluid nutriment for twenty-four hours. He was ready to allow that was not a bad diet; but, asked to compare it with other Hospitals, he said he believed others were unlimited—it was so at Guy's. There was a diet table at Guy's, but they "did not stick to it there." He had no experience of any other. He agreed that diet was mainly the treatment in small-pox, but he did not know that certain things were in the dieting. He did not consider it his duty to be present when the dinners were served, so as to see if the patients were treated properly—that was not his duty. He did not inquire whether the people had stew for supper, and he did not remember seeing stew for supper on the dieting tables. He believed the stew must have been for convalescents. He did not know of it being given. The "ordinary diet" he agreed was a good diet, and if the patients got the diets set out it would have been very good for them to have had water to slacken thirst. He never told the nurses not to give water. Could order stimu-

lants without supervision from Dr. Grieve for weak patients; but not eggs at the last without the initialing by Dr. Grieve. Did not know whether this initialing by the superior Medical officer was the custom in other Hospitals. The numbers of diets in each ward at Hampstead were each day put on printed forms made up from the Medical officers' returns, and sent to the steward for transmission to the kitchen to show the quantities and classes of diets required, vouchers being given and taken in each case. The cooks had told him that they had to "work" by the same diet sheets for several days running, and he reported this to Dr. Grieve, who said he would see to it. Would not undertake to say that Dr. Grieve did not attend to it. Did not know that the total supply of milk for the twenty-four hours for any ward was short; he never said it was—he had only said that the night supply was short. Certainly the quantity supplied for the twenty-fours was sufficient. He supposed so; and it would not be injurious if persons who had taken their fluid nutriment supplied for twenty-four hours in a less time slaked their thirst with water, but it would be injurious for patients, in his opinion, to go without nutriment for long periods. As to why he had given strict injunctions to the nurses to apportion out the supply for day and night so that the patients should have quantities in each, he had reported to Dr. Grieve that they did not, but not in writing. He did not report it in writing, because if a verbal complaint did not receive attention, one in writing would not. Witness told the nurses not to give the patients in the day five out of the six pints allowed for the twenty-four hours. He told the nurses constantly not to give the fluid nutriment during the day to the absence of it during the night. The complaints regarding the nurses as not attending to the orders were made respecting all the nurses in his ward. These orders he spoke of as being continuous, and being as continuously disregarded.

The witness here had handed to him the letters and testimonials given by him and his colleagues to nearly all the nurses in the Hospital. He owned that these nurses of whom he had spoken in high commendation were the nurses of whom he now spoke as continually disobeying his instructions to apportion out the milk and fluid nutriment so that the admitted ample supply should have served for day and night. Referring to the tainted meat, of which he spoke as having been served out to patients, he said this occurred in the hot weather. A large proportion of the patients admitted to Hampstead were not in a filthy condition as regards having vermin. Should think that a head in small-pox would be difficult to treat for vermin, owing to the small-pox eruption. The nurses used to cut the hair and treat heads on his instructions, if their time permitted. He directed it to be done, and he knew cases in which this was not done on his order. These "excellent nurses" even did not carry out his orders, because the "excellent nurses" did not have time. Was present when a witness called on his side said the nurses had plenty of time—were three or four hours doing nothing. Heard that sworn to, but did not think it was a fact. One would think a patient in a ward would be capable of saying what a nurse did there as well as a Doctor who was absent. The nurses had enough to do.

Dr. Buchanan: You mean to say, I suppose, they had enough to do if they did their duties?—Yes.

The witness proceeded: There was at times a great pressure of patients for admission to the Hospital. Could not say that there were as many as 300 in one week. Would undertake to say that eight or ten out of every twelve admitted were not filthy with vermin; and though he agreed that it was difficult to get these insects out, it was possible to get them out. It would be necessary to have the assistance of the Assistant Medical Officer to do this. He would not propose to apply white precipitate for small-pox heads; he never prescribed white precipitate, but "stavesacre." He could not say that the use of carbolised oil would stain the sheets.

Dr. Buchanan asked witness what the colour of the carbolised oil was, and he replied he did not know.

Mr. M. Williams asked the Court here to adjourn.

On the re-assembling of the Court, after touching upon the tying down, which practice the witness said he did not believe was approved by eminent Medical men, the witness was taken by Mr. Williams over the subject of the dead body lying in the bath-room all night, and emitting a fearful stench, said to be smelt by the patients in an adjoining ward. He said he was taken to see it; and though he knew that there were means to be taken to prevent unpleasantness, he never suggested anything to be done. It was not his ward. He did not see how long the body continued there, but it was removed, he heard,

shortly after he saw it. With regard to the mortality in the Hospital, he could not say what the average mortality was in vaccinated patients. His memory was faulty. He thought the average mortality was 15 per cent. There was a good deal of difference between the mortality in vaccinated and unvaccinated patients. He did not know Reynolds's "System of Medicine" as a standard handbook in the Profession. He had not read it. Although he had taken a position in a special Hospital, he had not made a special study of small-pox. He had not made himself acquainted with Seaton's "Handbook of Vaccination," although that might be a text-book on the subject of which he had treated. He had not read any special book upon small-pox. He had accepted a special appointment with regard to small-pox, and had given an opinion with regard to mortality—an opinion published in the *Times*—and yet had not read any special books on the subject. The mortality at Hampstead Hospital was something like "19 decimal something," and he should be surprised to hear that this was less than that at the Highgate Hospital in the 1863 epidemic. He did not know that these facts had of late been published in the Medical journals, showing that at Hampstead the mortality was lower than at Highgate.

The following figures were then read:—At Hampstead, during the last epidemic, the mortality was—vaccinated, 9·8; unvaccinated, 45·8. At Highgate Hospital, in the 1863 epidemic, the mortality was—vaccinated, 9·9; unvaccinated, 47.

Witness had heard of Mr. Marson, of Highgate Hospital. Had not referred to any of his works and statistics.

Dr. Buchanan remarked that no lessons were to be gained from going into these figures here.

Mr. M. Williams said he was endeavouring to show standard facts and figures for information.

The Chief Commissioner said the information could not, it was evident, be obtained from the witness.

Witness believed it was necessary to have a dietary for a Poor-law Hospital. Had never read any of Dr. Edward Smith's works on dietary. Witness knew he was an officer under the Poor-law Board when at Hampstead, but had never looked, that he knew, at Glenn's "Poor-law Orders," and never saw the book, as far as he was aware. He acted throughout without responsibility, as he understood from what he asserted Dr. Grieve told him. He did not tell any of the managers anything when he saw them at Hampstead. Patients would be likely to suffer if the responsibility were shifted from the Assistant Medical Officers; but he did not think it was his duty to represent that to the Committee. He believed now Dr. Grieve did not report his complaints to the Committee. Some of the complaints made by the Assistant Medical Officers were of avail, but some were not remedied, and yet he did not think it his duty to report this to the Committee. There was another Medical man on the Committee, Dr. Harvey, and this fact was in witness's knowledge at the time he was in doubt whether Dr. Grieve forwarded the complaints to the Committee. He knew that there were four eminent Medical men on the Committee, still he did not think it his duty to inform them. Knew that the written reports from himself and his colleagues came before the Committee, but he did not think it necessary to report in writing.

The cross-examination was here going into the question whether or not the witness was frequently complained of by Dr. Grieve for neglect of duty, and the Chief Commissioner asked what the purpose of that examination was, and whether it would not be well to drop personal questions.

Mr. Williams said it was his purpose to show that if there had been anything wrong about the treatment of patients these young men who had made the charges were responsible; and to show this he was going to impeach the manner in which they had discharged their duties. He should do this by reference to facts which had come to the knowledge of the managers since these young men had left the Hospital; and he could show that if the things complained of had occurred it was through these Assistant Officers' own neglect.

Mr. Collins disputed the right of the other side to go into these matters after the ruling in regard to the letters of the disputed dismissal or resignation.

Mr. Williams said these young men were making an appeal to the public for sympathy, and he was going to show that they were unworthy of that sympathy.

The Commissioners agreed that Mr. Williams could go into this subject to show animus, but appealed to Mr. Williams to keep to the seven charges in the *Times*.

Mr. Williams bowed to this view, and said he had abundance of testimony to establish what he had said.

The witness was taken in detail over the chief points in his

evidence by the Chief Commissioner and Dr. Buchanan. He was pressed by the latter particularly with regard to his evidence on the supply of milk to the patients, one of the charges which caused much anxiety as implying a neglect of fevered patients. The witness allowed that since June 18 he could not say that the milk had been short in quantity otherwise than owing to the maladministration of the nurses. He admitted that he had not given the nurses special instructions to take precautions for the preservation of a night supply.

Dr. Buchanan read the words in the *Times* as written by the witness and his colleagues, and asked if the witness thought that statement was an ingenuous way of stating the difficulty.

The Witness: I do think so.

Dr. Buchanan: Is it ingenuous, on August 23, the date of your letter to the *Times*, to state matters which you say had not occurred since June 18?—Well, perhaps it would have been better not to have put that in. Don't you think if you had written to the *Times* that what had occurred since the 18th in regard to the short supply of milk at night was owing to the maladministration of the nurses the point would have been taken out of it?—I don't think so.

The Court then adjourned.

FIFTEENTH DAY.

On Tuesday, October 10, Mr. Kynaston's examination was continued.

In answer to questions by Dr. Buchanan, witness said: In my opinion the patients in the Hospital suffered from insufficient nursing. They suffered in the want of general attention. The Assistant Medical Officers used to draw the attention of the nurses to such things as washing, and these complaints were frequent. The nurses always seemed willing to do all they could, and though I found the particular cases to which I had drawn attention looked after, the nurses generally said they had not time. I was able to form some opinion as to the truth of what the nurses said as to want of time. Some of the points on which I formed this opinion that the nurses had too much to do were, that we could not get the hair cut and the heads attended to; and then I have heard the patients calling out for food, and the nurses could not attend to them all at once. I delayed my night visits sometimes, as I said, to see how the nurses acted, but the nurses would, of course, be expecting me. I sometimes "dropped in" after my regular night visits at about twelve o'clock, and generally I then found the nurses at their duty. Sometimes the ward, at this night visit, would be like a Babel, from a lot asking for food at once. That occurred pretty frequently. I have spoken to the nurses, and they have said they could not attend to all at once. I believed these were not mere excuses. It was the duty of one of the Assistant Medical Officers to see in-coming patients; but sometimes they were admitted, through the neglect of the receiving-ward nurse, without being seen by the Medical officer. The Assistant Medical Officer who admitted the patient did not order baths, though that would be a matter requiring Medical judgment. We gave general orders that patients should have their hair cut; but I never, in the receiving-ward, gave particular instruction as to particular patients. When the patients were in the acute stage, they were not habitually washed all over—there were no such appliances as sponges for this. I think, Medically, the patients should have been washed. I should think the tendency in small-pox for the skin to slough would be lessened if the patients were washed. I do think, if this practice of washing patients had been carried out, the tendency to bedsores would also have been lessened. I have told the nurses that the patients should be washed, and they said they had no appliances. I have told Dr. Grieve that the patients should be sponged, and he agreed with me, but it was never done to any extent. I remember giving instructions to nurses to wash particular patients, and I think this has been done as far as possible. Flannel would be of the like use for cleaning the skin as sponge, and I am not certain that I have not seen flannel in the wards. I complained to Dr. Grieve of there being no under-nurse for No. 4 Ward, and he said one should be supplied. One was not given until a fortnight.

The Chief Commissioner read over to the witness the evidence of a patient, who stated that he complained to Mr. Kynaston of not obtaining his stimulants, and that he never had them, even after he complained to Mr. Kynaston. The witness now was asked if he had ever had the parties up before Dr. Grieve and had the matter thoroughly sifted, and he replied that he did not remember having done so. Stavesacre, the remedy he used for vermin in the heads, would be, in his opinion, proper to use at all stages of the small-pox, and he would apply it at all times. He would not think it at all disturbing to a patient

in the acute stage of the disease to have his or her hair cut and the ointment rubbed in.

Dr. Buchanan: Is not stavesacre a very irritating thing?—It is, but I have not seen any ill effects from it.

Having investigated all the cases of erysipelas that have come under your charge, you never had reason to believe that cases of erysipelas had anything to do with this use of stavesacre?—I don't know of any case which arose from this use.

By the Chief Commissioner: He had no reason to believe that tying down was carried on behind his back until he heard the witness say so here.

By Mr. Williams: He could, at any time before June 18, order port, sherry, brandy, whisky, extra bread, and he had ordered extra milk and beef tea. He could also have ordered for any patient *mistura vini gallici*, and did order it—a mixture of brandy and eggs.

By the Chief Commissioner: Dirty bed-linen and such-like want of cleanliness would lead to suffering, and he thought clearly that the patients suffered from this. The dirty linen continued from the beginning to the end of the time he was there. He complained to the nurses, and they said they could not help it. He had complained to Dr. Grieve—not putting it in the form of strong representations that the patients suffered, but he complained verbally. There was not the same necessity for complaints regarding the shirts as the sheets. He never reported or complained in writing of the dirty linen.

In the re-examination by Mr. Collins, who read from the Hospital books a long account of the eggs supplied to staff and patients, in which there was no particular point, the witness stated that he was never questioned by Mr. Wyatt regarding the Hospital. Up to March 6 there was only one pint of milk for the twenty-four hours. The witness was taken in detail over the changes in the diet as already reported, and then Mr. Collins wished to read the statistics of mortality in the Highgate Hospital in contrast with the mortality of Hampstead this year; and the Medical Commissioner expressed an opinion that nothing really would be gained from these contrasts. The witness was then taken over the statistics of mortality at Homerton, Stockwell, and Hampstead. The figures were made up to July 22, and gave the mortality in Hampstead at 19.1, Stockwell 17.6, Homerton 17.1. The witness said these figures gave the mortality in the three sister Hospitals under the Management Board. Respecting the testimonials he had given nurses, he should not have given these if he had known that the practice of tying down was carried out behind his back, as he had heard at that inquiry.

Mr. William Greaves, the third of the complaining Assistant Officers, was then called. He stated that he was the son of a Surgeon, had been in office in a Staffordshire infirmary; entered at Guy's in October, 1866, where he held all the usual appointments.

In answer to the Chief Commissioner, he said he had not been House-Surgeon nor House-Physician. He had been offered the post of House-Surgeon at Guy's, but in consequence of Mr. Kynaston's illness, he did not go up to pass his examination in Surgery. In point of fact, he only held the "Hall" qualification. He considered that the supply of nurses was then insufficient, and he spoke of there being at that time no bed-cords. He spoke to cases of tying down which came under his notice, and he reported one case at this early date to Dr. Grieve, who said it was altogether improper to tie down, and witness believed the Doctor reprimanded the nurse for doing it. In his opinion, the nurse should obtain, in general, the sanction of the Medical officers to the restraining of patients by tying down or strait-jacketing; and he agreed that gentleness should in all cases be first tried, as violent restraint—such as tying down or strait-jacketing—increased the delirium. When patients were dangerous to themselves and others, then it would be necessary; but these cases were very few, scarcely one occurring in 200 small-pox patients. He had told the nurses not to restrain by mechanical means without the Medical officers' orders. He had had fully 1000 patients at Hampstead during his time there, and he had restrained by strait-jackets four males; and he had employed a sheet, opened broadly and tied to the bedstead, to keep females in bed. This tying down occurred in, perhaps, a dozen cases, and he had given these instructions at the first.

By Dr. Buchanan: He had given these instructions to the nurses in the male wards, and this method of restraint was employed in both male and female wards by his permission. He retracted his permission afterwards when convalescents were able to assist. There were only two day nurses at first, and all the cases were then acute, and, in fact, for some time after his first going there the patients were all in the acute

stage. He had told Dr. Grieve that under the condition of things then existing—the small number of nurses to the large number of acute cases—some mechanical means of restraint were required. With regard to the diets, when he first went Dr. Grieve directed his attention to the two diets—the low and the ordinary diet—and Dr. Grieve never told him he might order more. He complained of the inefficiency of the low diet, the quantity of milk more particularly, during the whole time from December to March 6; but Dr. Grieve said the dietary had been drawn up and approved by the Poor-law Board, and it was sufficient. On March 6 witness asked Dr. Grieve if he would increase the low diet by half a pint of milk for each patient, and this increase was given, but the supply was still insufficient. From the time when the morning meetings of the Medical officers with Dr. Grieve commenced, complaints were made of the insufficiency of the milk, of a night more particularly. He also agreed in detail about the milk being sour in the summer months, and he had tested it by the ordinary litmus paper, and frequently found it acid. He had spoken of this to Dr. Grieve, and he said it could not be helped, as the hot weather caused it. Witness allowed that these complaints chiefly referred to the time before June 18, and complaints after that date were not so frequent; but some did occur, and on his telling Dr. Grieve, after June 18, he said that if there was not sufficient milk for the night it must have arisen from the nurses having given too much during the day. The beef-tea was at one time made from shin-beef, at another from "Liebig's Extract." It was weak and exceedingly salt, and the patients greatly complained of it. The witness was taken over many other points, and he was called upon to speak with regard to the eggs not being supplied—matters which have been abundantly gone into before. The witness also spoke of the meat being tough and hard. In regard to the shortness of supply, on some occasions the witness had gone to the cook, and found that all that had been ordered for the wards had been supplied, but witness had not traced who was in fault for the short supply. He then spoke of the dead body being left in the bath-room all night in No. 8 Ward. This was on August 6. He had seen the man whose body this was on the previous night when he was alive. There was a stench from the man when he was alive, and the stench was very bad in death. The nurse Staley reported to witness at eleven o'clock in the morning (Sunday) that the man had died at twelve o'clock the night before, and he had been removed to the bath-room, but had not been removed from there because there was no shirt to put him in. Witness made a written report of this at 11.45, and made a personal report to Dr. Grieve at twelve o'clock, on his coming out of chapel, and the body was forthwith removed.

The Chief Commissioner: Did you not go at eleven o'clock and see for someone at once to remove the body?—No; I sent someone. I was going my rounds at the time.

Dr. Buchanan: When did you commence writing your report, which you date at 11.45?—Well, I commenced it at once, at eleven o'clock; but I finished it afterwards. When did Dr. Grieve get your written report?—After I had met him and told him, I suppose.

Mr. Williams: Dr. Grieve never had it.

The Chief Commissioner: Cannot you tell us whose fault it was that the body was not removed?—No, I cannot. The nurse told me she could not get anyone to remove the body.

The witness went on to say that when complaints were made to Dr. Grieve about the suggested deficiencies in the Hospital, he replied that he alone was responsible. The witness understood by this that, in all things beyond the Medical treatment, the Assistant Medical Officers were not held responsible. Dr. Grieve used sometimes to suggest that less stimulants than witness had ordered were advisable, and he reduced his orders. Pressed on this point by Dr. Buchanan, witness in these particulars deferred his judgment to the Medical judgment of Dr. Grieve, the Medical Superintendent, who, when spoken to as to what the public would think of the Hospital if it were known how overcrowded it was, said he could defend himself against the public. Dr. Grieve never told the Assistant Medical Officers that they could speak to the Committee if they had any complaint to make. He never saw any of the Committee coming to the wards. Dr. Grieve, early in the year, brought some Poor-law rules, threw them down, and said, "Look there! you are not even mentioned; you are nobody; you are nothing." This was in regard to the complaints made.

Dr. Buchanan: Did he really use those words?—Yes; he was angry for the remarks which had been made about packing the Hospital.

The witness further spoke of vermin being in the wards, and

said he used all three remedies—white precipitate, stavesacre, and carbolised oil.

The Court then adjourned.

SIXTEENTH DAY.

The proceedings of Wednesday, October 11, opened by the witness Mr. Greaves being called, and his evidence given on the previous day read over to him. In answer to further questions put to him by the Commissioners he said he believed the beef-tea supplied in the Hospital was made from what is known as "Liebig's Extract," a substance which had been approved by high Medical authorities. What he complained of in the beef-tea that he tasted was that it was weak and was of an unpleasant flavour.

Cross-examined by Mr. Williams, the witness said: I consider myself a judge of Hospital wards, having had some experience, and I consider the Hampstead wards constructed upon an excellent principle for epidemic disease. They have excellent ventilation, with self-acting closets, but I do not know that each closet has separate cross-ventilation. The lavatories are fitted with basins for washing, and water is laid on to each, and there are separate basins to carry into the wards. There is a separate kitchen to each ward, and a general kitchen where the cooking is done by men cooks, and the kitchens are fitted, I believe, with the newest appliances of gas and steam stoves for cooking. There is a separate bath for each ward, and each bath can be detached. The fittings of the laundry and such places are at Hampstead very convenient. I do not know that the Hospital was first intended for only 120 patients; but I know that while I was there the Hospital was run up from 120 beds, which it held when I got there in December, to about 500. Wards 1, 2, and 3 only were opened when I went there, and 4 and 5 wards were opened shortly after. [Mr. Williams read the following figures:—In January the beds were increased from 150 to 190; on February 9 they were increased to 258 beds; on February 12 they were increased to 292 beds; on February 17 they were increased to 326 beds; on February 23 they were increased to 360; on February 25 they were increased to 394; and directly after to 414 beds.] I believe those figures to be about the rate of increase. Islington old workhouse was taken over in April for convalescents, and in May the Hampstead Hospital held 514 patients or thereabout. My belief is that Dr. Grieve said he would defend himself "against" the public when spoken to about "packing" the Hospital, and not "before" the public. I don't know who used the term "packing" in regard to the large numbers in the place, but it was used by the people in the Hospital. I cannot give the least idea of the amount of cubic space given to each patient when the "packing" was at its highest, or at any other time. I cannot say what is the minimum amount of cubic space allowed to each bed by the Poor-law Board's rules. I apply the term "packing" to seeing two persons in one bed. That occurred in January, in Ward No. 1, to persons who were in an acute stage. I saw this very frequently. This (double bedfellowship) lasted from one night till the next day. I have never remonstrated with Dr. Grieve upon this, but I have pointed it out. The cases were in a mild form, but still in the acute stage. I consider the small-pox a very offensive disease, in that the patient often during life emits an offensive stench. The wards, however, were very sweet, and these extra cases were not of the class to lessen the sweetness of the ward in which they occurred. There was a scanty supply of sheets to my wards. I do not know that there were as many as twenty laundry women engaged there at one time, and it would not surprise me to learn that there were twenty. I do not know that 1000 pieces of linen were turned out of the laundry in a day, and it would surprise me to hear it. Although I considered that the patients suffered from the want of linen, I never inquired as to the rules governing the supply of linen, or what were the rules about changes. There should be, in my opinion, no rule as to the supply of linen to small-pox patients. As a matter of fact, I never knew that one of the rules of the Hospital was that certain cases should have an unlimited supply of linen. I commenced writing my report concerning the dead body being in the bath-room before the body was removed, and I finished it afterwards. I don't suppose it came to Dr. Grieve's hands until the next day; but though I did this it did not occur to me to write a complaint about the linen, although that was going on at the same time. The nursing was superintended by benevolent ladies of a Sisterhood, who did their duties ably and kindly. They had under them nurses, helpers, scrubbers, and convalescent helpers. The proportion of nurses at Guy's was throughout the Hos-

pital a nurse to seven patients. When I found the milk sour I did not report it to Dr. Grieve, but I sent the nurse to get a fresh supply. I did not wait to see if a fresh supply were given. I sent the nurse to Dr. Grieve, but I did not wait to see the result. I have inquired on the mornings after the nights on which I have thus sent for a fresh supply if this had been given. I was sometimes told that the supplies were given and sometimes not, because the milk was all sour. It is true that I was told when no milk was given that an extra supply of beef-tea was given in its place. I do not call the use of the sheet to confine the patients, as I gave the nurse directions to use and permission to use, "tying down." I call that restraint, but it is different from the restraint which confines the limbs. I regard the use of the sheet, as I gave permission for its use, as a sort of semi-mechanical restraint, or *semi-demi*. What I meant by one case requiring restraint occurring only in 200 patients on the average referred to cases of violent delirium. Delirium comes on gradually and not suddenly. The case of a man named Wills (a man who had his leg swollen, stated to have arisen through being tied down) was not that of a man suffering from delirium tremens, and I do not remember having described his case to Dr. Grieve as one of a man suffering from the effects of drink. The nurse should send for the Medical officer before restraining a patient; but I should not object to a nurse putting on the strait-waistcoat in extremely violent cases while she sent for me. I always enjoined the nurses not to restrain, but I never told them to keep a record of such cases as they were compelled to restrain. When I have found the patients restrained against my orders I have reprimanded the nurses, and spoken to Dr. Grieve; but I took no other steps to protect my patients. I have found the restraint still used after I had complained, but not so often as before. I cannot name any nurse whom I reprimanded except Nurse Sullivan, who, I know, was dismissed; but I do not know that she was dismissed for drunkenness. Sister Francis was acting as matron to the whole Hospital; but I never reported to her or to Dr. Grieve that I had had to reprimand nurses. Dr. Grieve had offended more than my dignity when he said I was "nothing and nobody." I considered I was "something and somebody." (Asked if he did not consider his position an untenable one for a gentleman to hold, stripped as it was of authority by Dr. Grieve, and if that did not spur him on to complain.) I did not report this to Dr. Brewer. I was not exactly of opinion with Mr. Kynaston that if "the diet was doubled, the mortality would be halved." I don't agree with the literal meaning of those words, but I think that an improved dietary would have assisted to a lower mortality. I never said that or anything else to Dr. Brewer. I did not consider that I was not responsible for anything—I was for the lives of my patients. I was responsible to myself. I did consider myself responsible otherwise to Dr. Grieve as my superior, and not to the authorities. I did advise that strait-jackets should be obtained, because there were no other means of restraint at that time.

By the Chief Commissioner: I remember the case of a patient complaining about Nurse Donaldson drinking his wine. I cannot say positively that she was or was not dismissed at once on my reporting it to Dr. Grieve, who investigated all such things. It is probable that if a man told me he was "nearly starved," I should tell him I had no power to help him. I should not consider it my duty to make any strong representation of this statement to Dr. Grieve to get the man more food. I told Dr. Grieve all these complaints, and I have no doubt I told him this. I do not remember the case. I made no notes of such things. The cases of two persons being in one bed occurred to both sexes, in both male and female wards. The people who were recovering were generally put together in order to allow coming-in patients to have separate beds. I don't know the breadth of the bedsteads; they were the ordinary breadth—I think about 2 ft. 6 in.

The questioning continuing, the witness said: I have remarked upon dead bodies being in my ward for three or four hours. I never had an occasion to report anyone for not removing a body, but upon one occasion I had to go and tell the wardman that if he did not remove it at once I would report him to Dr. Grieve. He at once removed it.

By the Chief Commissioner: The case mentioned in the *Times'* letter was quite an exceptional case.

The Chief Commissioner: I must confess I can hardly see why, instead of going to fetch your colleagues to look at this offensive body, which you say was offensive and injurious to your patients, you did not take means to fetch persons who would have removed it at once.—I did not know where to go to then; it was Sunday morning.

I suppose it would not have been Professional etiquette to

have carried it out yourself for the relief of your patients; but I must say that it strikes me—I speak as a layman—that if I saw my patients suffering from the presence of this body, I should have got assistance and taken it out.

Dr. Buchanan: I must here say that I feel rather compromised, as a member of the Profession to which these gentlemen belong, by the course they adopted on this occasion. I am in the position which one of them regarded himself as being in with respect to Hampstead. I am a visiting Physician to an Hospital, and if I had seen my patients suffering from the presence of a dead body I should have used some means to remove it, even if I had to carry it out, sooner than it should have remained to do mischief.

Witness: But I had not the means.

Dr. Buchanan: You had a sheet, and your two colleagues to help you.

Questioned further by Dr. Buchanan, he said he had permitted—he had told the nurses to give cold water to the patients. He certainly told the nurses to give water. He did not consider cold water was the best thing that could be given to slacken thirst in small-pox patients—not so good as milk—still it might be given. He did not consider beef-tea was a good drink; milk was in his opinion the best drink. He did not know where the nurses got the notion that the giving of water was not allowed by the Medical men—himself and his colleagues. He had heard the evidence given there as to the complaints about want of drink; still he did not think that half of those complaints were due to the misunderstanding which did exist on the part of the nurses respecting the Doctors' objection to giving water. Some of those complaints might certainly have been obviated if water had been given by the nurses. Certainly he agreed with his questioner that the misunderstanding which the nurses had of his and his colleagues' views on this point was a most unhappy one; but he thought this must have been an excuse of the nurses to their patients. He had ordered water to be given when he heard people asking for drink.

Dr. Buchanan: You have told us in your evidence that there was plenty of beef-tea, and you cannot tell us that the supply of milk was short since June 18, and yet in your letter to the *Times* of August 23 you make the charge of there being a "totally inadequate supply of milk and beef-tea." Now, do you not think that calculated to convey a false impression in the minds of the public?

The witness made no direct answer to the question, but said he held different views from those held by his colleagues on the use of beef-tea.

The re-examination then proceeded, and, in answer to Mr. Collins, the witness said he thought the time when he lunched with Dr. Brewer, M.P., the Chairman of the Board, on an occasion when that gentleman came to visit the wards, was before February 14—the date given by that gentleman. Regarding the complaints he made, they were always looked upon as unnecessary—as coming from him on subjects with which he had nothing to do.

Mr. Collins said this was the conclusion of his case, and his clients, who, he said, had sustained the heavy cost of £400 in pushing this inquiry on, could no longer afford legal assistance.

Mr. Williams expressed his deep regret that this course had been resolved upon by the other side, who, he said, had brought grave accusations against a body of gentlemen, who had managed these Hospitals in a time of great difficulty, and against the superintending Medical officer. The withdrawal of the other side at this juncture was very hard upon the managers and Dr. Grieve, who desired to have the evidence they would produce tested in every way for the satisfaction of the public mind as to where any blame rested. He trusted the Commissioners would make such representations to the central authority that the Government would permit the other side to have the advantage of legal assistance.

The Chief Commissioner regretted very much the course which had been adopted by the complainants' side, and said it would be a misfortune if some test were not applied to the evidence the other side was about to bring forward. He and his colleague would make the representation which Mr. Williams had asked for, and he would report the result the next day.

Mr. Williams then opened the case for the managers, and expressed his deep regret that he had been prevented, through the case having been carried on so long on the other side, from sooner giving the answers which the managers had to these libels which had been cast upon them. He then went over the history of the Hospital, traced its gradual rise in December last, ward by ward, to meet the raging epidemic of small-pox,

which increased day by day for months; and he gave the statistics of the Hospital very fully—the admissions, the acute cases, the number of convalescents, and a mass of information of like character, which the managers were anxious should be laid before the public. He desired to give publicity to the fact that there had been, from December, 5578 admissions to Hampstead. The mortality at Hampstead had been 18·8 or 9; Homerton, 18·64; and Stockwell 18·22.

Mr. Williams had not finished his address when the Court rose, and the proceedings were adjourned until the next day.

GENERAL CORRESPONDENCE.

ANÆSTHETIC DISCOVERY.

LETTER FROM DR. ROBERT H. COLLYER.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having in my possession the original publications of May, 1843, wherein I distinctly state that the inhalation of narcotic and stimulating vapours produces an anæsthetic state, prior to which date I had performed various surgical operations during this insensible condition, which enabled me to publish the fact in May, 1843, I cannot now understand how Horace Wells could be named as the originator of modern anæsthesia, when his first essay with nitrous oxide only dates from December, 1844. There can be no objection to raising a subscription for the widow on this side of the Atlantic, on the part of those who are unacquainted with the facts as they occurred at the time. It is, however, most unjust to myself to denominate Horace Wells the original discoverer.

As you have a copy of my work—recently published—wherein I have dispassionately reviewed the whole controversy, there is no occasion to reopen the question at present.

I am, &c., ROBT. H. COLLYER, M.D.

199, Brompton-road, S.W., October 9.

DOMESTIC SANITATION.

LETTER FROM MR. A. G. BROWN.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you allow me the opportunity of replying to your correspondent Mr. Charles Orton, by bringing under the notice of himself and the Profession what seems to me an apparatus for doing the very thing he asks for?—viz., whether "the flushing with disinfectants might be dispensed with if another smaller cistern, or even bottle, holding concentrated disinfectant, could be connected with the pan, and could be made use of easily; for to many persons it is too much trouble to attend to sanitary matters."

For some months past I have been trying to give a practical answer to this very question, and before this reaches the eyes of the Profession a "smaller cistern," under the name "Self-acting Disinfectant for Water-closets," holding one quart of a disinfectant (also a "gallon size"), will be ready for the public. Several things in connexion with it have especially cost me much time and thought—as, for instance, preventing anyone, out of mischief, from running off more than his due share of the disinfectant; and in adapting the disinfectant to every make of closet. Beyond stating that the apparatus is quite self-acting, only requiring to be charged once in from a fortnight to several months, according to its size and the frequency with which the closet is used, and that the disinfectant becomes mixed with the water in passing from the cistern to the closet, it is not for me to say anything further.

I am, &c., A. GARDINER BROWN.

St. Thomas's-street, S.E., October 9.

ON THE FOOD OF THE ARMY DURING THE LATE MANŒUVRES.

[To the Editor of the Medical Times and Gazette.]

SIR,—Whatever may be the shortcomings of those whose business it was to feed the army corps during the recent manœuvres, it is clear that these gentlemen have succeeded in making to themselves friends of the purveyors of intelligence. The Commissariat Department has been several times described as having achieved a comparative success. It is right, however, with a view to future improvement, that points in which it has altogether failed should be put on record.

In the first place, I believe that the fact of our having escaped starvation was due to the continuance of fine weather,

and to nothing else. The stores, which were distributed with such difficulty, would never have reached the forces at all if the rain had made the roads heavy. And be it remembered that the movements were all made in a tract of country about thirty miles by fifteen, in the immediate neighbourhood of Aldershot, and that the place of encampment for each night, and the number of men to be provided for, were known beforehand.

The first half of the time was occupied in movements which did not take the men far away from camp, and short marches. In this period fresh meat and fresh bread were served out. The meat was good, but there was scarcely enough of it. The nominal three-quarters of a pound per man, including bone, was none too much for men in hard work. The bread was burnt black on the outside, and consisted of a clammy mass in the interior which no man could eat with impunity. If "two pudding-ends would choke a dog," certainly one of these loaves would admirably answer the same purpose. It may be true that excellent bread can be turned out with the same portable steam-ovens, and the same materials; why, then, was it necessary after six months' preparation to put men in charge of the ovens who did not know how to use them? The bursting of one of the ovens on the road—which, fortunately, did not result in loss of life—was, probably, also due to the inexperience of its managers.

The detachment to which I belonged as Doctor consisted of about sixty men and officers of an exceptional and highly educated corps, of various birthplaces. The battalion to which we were attached, of which I had the charge during the whole of the movements, was from a southern county, and was composed chiefly of artizans, labourers, tradesmen, and others from the villages and towns. Besides these, there was a detachment of about fifty Londoners. We mustered about 500 altogether. The discipline was excellent; indeed it was so good that the example of perfect obedience and punctuality set by my boys—some of them by no means mere infants—was not needed by the Flichshire lads. I believe the guard-tent remained untenanted the whole time. Physically, my detachment was decidedly the best; the cannon must be fastidious indeed which would be dissatisfied with them as its fodder. After them came the Londoners, and then the countrymen, of whom the dwellers in towns appeared to have the advantage over the agriculturists.

From the battalion so constituted sixty-one cases of diarrhoea, at least, came for treatment in the first week, two of which, on account of loaded tongue and high temperature, were sent to the field Hospital of the division; besides about fifty other cases of slight ailments, sprains, bruises, etc. The diarrhoea was most prevalent among the country lads, nine of whom had to be sent home as unable to march.

Our first camping-ground was apart from the rest of our brigade, and on a worse site than the rest—probably it was feared that our bad discipline would demoralise the regulars if we were put near them—but after a few days' experience of us, it was thought advisable to put us between the regulars and the militia, without taking any extra precautions against us; from which it may be inferred that our camp was not the most disorderly of the three. I think, therefore, that the prevalence of diarrhoea could not be attributed to excesses on the part of the men, and I have no doubt that it was due, in the first place, to bad water near the camp, a defect which was not obviated by the occasional services of a water-cart; secondly, to the extreme irregularity with which the food was served out, and the character of the bread; thirdly, to the absence of a supply of good water on the line of march, which induced the men to drink effervescing saline draughts, or "coolers," offered for sale on the road, and to devour green apples, over-ripe plums, and other like substances.

In the second half of the campaign, the fresh meat and bread were replaced by commissariat biscuit, Yateman's beef sausage, soup in tins, and Australian mutton. The quantity of diarrhoea was very much less on this food.

But I have already occupied too much of your space. I will reserve my further remarks till next week. Perhaps enough has been said to show that the art of keeping men alive, which is the aim and object of the non-combatant departments of an army, has not yet reached absolute perfection amongst ourselves.

I am, &c., MACHAON, jun., M.D.

[N.B.—The printer's devil suggests that our correspondent's name is not in the "Directory"!]

SMALL-POX is making great progress at Belfast, and creating much alarm.

OBITUARY.

CORNELIUS BUTLER, F.R.C.S.,

DIED the other day, from the result of an accident, at the ripe age of 82. The name of Butler in connexion with Practitioners of Medicine has long been associated with Essex. For nearly a century members of that family have been prosperous and successful Practitioners in Brentwood, Ingatestone, and Romford. The subject of the present memoir was the last of this respectable and useful family, and he practised largely and successfully in Brentwood for just upon sixty years. He became a Member of the Royal College of Surgeons in 1811, and was elected a Fellow by nomination in 1852. He was for very many years Surgeon to the Romford Union and to the St. Leonard's (Shoreditch) School, situated near Brentwood. He was remarkably successful in preventing disease in this latter establishment, his last report to the Board of Guardians being most satisfactory. We are not aware that he published any cases or reports on strictly Medical subjects; but he was strongly imbued with poetic powers, and published many very interesting and ably written poems in the local newspapers and in other ways. The only separate work he printed for private circulation was a kind of itinerary in verse, describing with much graphic power the country around his own district, with interesting records of the families who were established in the neighbourhood, together with descriptions of the surrounding churches and mansions. This work was of considerable merit, and deserving of more extensive publication than it received. Mr. Butler was a Surgeon of good abilities and common sense. He had no ideas of a fanciful kind in his practice, and was guided by a large experience and a freedom from theory. He was a kind-hearted, genial, and hospitable man; ever ready to do good. He was wonderfully active even at a very late period, and at 60 could leap a ditch or run a race with an agility worthy of 25. The writer of this short tribute to his memory had an interview and consultation with him nearly twenty years since. The second master of Brentwood Grammar School, an amiable and able clergyman and teacher, had been removed from his office in consequence of some new regulations of the Commissioners. This gentleman removed to an old mansion between Romford and Brentwood—styled "Ditchleys." Here the master had scarcely received his scholars before an epidemic of fever and small-pox broke out, and threatened him with ruin. The scholars were all removed, and "Ditchleys" appeared to be a doomed place. In this emergency, Mr. Butler advised that a Medical survey should be made of the house and grounds by disinterested Medical Practitioners from London. Accordingly, Mr. G. A. Walker ("Graveyard Walker," as he was called) and the writer of this sketch repaired to "Ditchleys," calling on Mr. Butler on our way, and taking him on with us to the "plague-spot." An energetic and careful survey of the premises was made, and the source of the disease prevalent soon became apparent: unemptied cesspools, uncovered drains, and bad water told too plain a tale. Remedies were applied, and in a few days we were able collectively to sign a report which was deemed satisfactory by all parties concerned. The scholars returned, and the school became flourishing. The energy, good-nature, and tact displayed by Mr. Butler on this occasion will not easily be forgotten by the writer.

THOMAS BUSHELL, M.R.C.S., L.S.A.

THE late Thomas Bushell was apprenticed nearly sixty years since to Mr. Coles, a Surgeon near Covent-garden. He was one of the esteemed pupils of the late celebrated Joshua Brookes, and of St. George's Hospital. Passing the Apothecaries' Hall and the College of Surgeons, he commenced practice at 117, Crawford-street, now fifty years ago, where he continued till his death, being highly esteemed by all around. On the commencement of the Royal Botanical Society in Regent's-park, he became one of its earliest members. Being much attached to botany, he was soon elected on the Garden Committee of the Society, to the welfare of which he was much devoted; and, constant in his attendance to making it useful for its scientific as well as for its more agreeable purposes, on the day previous to his death he had been there to meet on the business of the garden. Early on Thursday morning, the 5th inst., he awoke, and ringing for assistance, expired very shortly after, being in the 75th year of his age. He was buried at Highgate Cemetery.

JOHN SAVORY, M. & L.S.A.,

Was born in the year 1800. In 1817 he was apprenticed to his uncle, the late Thomas Field Savory, as an apothecary, and in 1819 he went to Paris, where he was engaged in pharmacy, and the pursuit of Medical studies. Previous to his departure for the Continent, he was a pupil of Mr. Minors, the then celebrated cupper, and was the first to introduce into Paris the English art of cupping. On his return, he became a student at St. George's Hospital, and in 1823 passed his examination as a licentiate of the Society of Apothecaries. At this time he was very anxious to continue his Medical studies and to practise, but many of his Medical friends, including Drs. Baillie, Jenner, and Chambers, urged upon him to turn his attention entirely to pharmacy; he therefore relinquished the idea, and established himself with his uncle in Bond-street, where he eventually became the head of the firm of Savory and Moore. At a future period he was, in conjunction with Messrs. Allen, Bell, Morson, Payne, etc., one of the original founders of the Pharmaceutical Society, and was subsequently President of that Society during the years 1844 to 1848. The passing of the Pharmacy Act compelled him, as a Member of the Society of Apothecaries, to relinquish his connexion with it. Until within the last three or four years he remained at his post in Bond-street; always energetic and punctual in the performance of his duties, he required the same from all in his employ. Genial and hospitable in private life, he formed a large circle of Medical and other friends, by whom he will be deeply regretted.

He was the author of a popular "Compendium of Domestic Medicine, or Companion to the Medicine Chest," which has passed through eight editions; and a treatise on cod-liver oil.

AUGUSTUS G. GREAVES, M.R.C.S., L.A.C.,

DIED last week at the age of 59, the immediate cause of death being thoracic aneurism. He had been in indifferent health for the last two or three years, during which time he had been frequently obliged to give up his Professional duties. He was Surgeon to the Government Diocesan Training College for Governesses, and for many years one of the Surgeons of the Derby Provident Dispensary.

NEW INVENTIONS.

THE "RHODA" INVALID TABLE.

THIS table is adjustable as to weight, so as to fit any bed. It is fitted with candlesticks, which are screwed into sockets, so that they cannot be knocked over by the movements of the invalid. The table has a high reversible rim, to prevent articles from falling off during the night, and this rim can be set up as a book-rest. The great advantage of this table is that it reduces the necessity for attendance, which is generally so great a burden upon a household; and, when it is not in use as a dining- or reading-table, it is ranged along the side of the bed, and the medicines and crockery required are placed on it within easy reach of the invalid. The price asked for the tables brings them within the means of everyone. This useful invention can be inspected at Mr. Robinson's, 173, High Holborn.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received their Certificates to practise, on Thursday, October 5, 1871:—

Addy, Boughton, Southport, Lancashire.
Bradbury, John Batley, Leeds.
Marshall, John, Bolney, Suffolk.
Slater, John Samuel, Bath.
Vores, William Mallam, Great Yarmouth.

The following gentlemen also on the same day passed their first Professional examination:—

Clyma, Handsford Hosking, Guy's Hospital.
Welch, Samuel, London Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ARMSTRONG, JAMES, M.B. Edin.—Honorary Assistant Medical Officer to the Liverpool Infirmary for Children, *vice* Dr. de Touche, resigned.

BUTLER, FRANCIS W., L.S.A.—House-Physician to the Westminster Hospital, *vice* Ferdinand Wallis, M.R.C.S., whose appointment has expired.
CARRUTHERS, THOS., L.R.C.P. and L.R.C.S.—Medical Officer of the No. 1 Tooting District of the Bury Union.
CLARK, ANDREW, M.R.C.S.E.—Assistant-Surgeon at Middlesex Hospital in succession to Geo. Lawson, F.R.C.S.E., etc., appointed Extra-Surgeon.
CORFIELD, W. H., M.A., M.B. Oxon., M.R.C.P. Lond., Professor of Hygiene and Public Health at University College, London—Medical Officer of Health and Analyst for the Parish of Islington.
DUNDERDALE, WILLIAM, M.D., M.R.C.S., L.S.A.—Resident Surgeon-Apothecary to the Warrington Dispensary.
LAWSON, GEORGE, F.R.C.S.E., etc.—Extra-Surgeon at Middlesex Hospital.
TAIT, LAWSON, F.R.C.S. Edin. and Eng., Surgeon to the Birmingham and Midland Hospital for Women—Surgeon to the Birmingham Lying-in Hospital.
WALLIS, ALBERT W., M.R.C.S., L.S.A.—Surgeon to St. Leonard's Schools, Brentwood.

MILITARY APPOINTMENTS.

59TH FOOT.—Staff Assistant-Surgeon Henry Bradford, to be Assistant-Surgeon, *vice* Henry Thomas Brown, M.D., appointed.

MEDICAL DEPARTMENT.—The two undermentioned officers, having completed twenty years' full-pay service, to be Staff Surgeons-Major under Article 342 of the Royal Warrant of December 27, 1870:—Staff Surgeon Herbert Taylor Reade, V.C.; Staff Surgeon George Paul Murchin Woodward, M.D. Assistant-Surgeon Charles Henry Browne, to be Staff Surgeon, *vice* Walter Moses Gibaut, placed on temporary half-pay. Assistant-Surgeon John George Thornley, M.D., from half-pay, to be Staff Assistant-Surgeon, *vice* Charles Backhouse, resigned. Assistant-Surgeon Henry Thomas Brown, M.D., from the 59th Foot, to be Staff Assistant-Surgeon, *vice* Henry Bradford, appointed to the 59th Foot.

BIRTHS.

ADAMS.—On October 7, at Ipswich, the wife of Webster Adams, Surgeon, of a daughter.
CRIBB.—On October 6, at Bishop's Stortford, Herts, the wife of Henry Cribb, L.R.C.P., of a daughter.
FAIRLAND.—On August 26, at Lucknow, Oude, the wife of Dr. Fairland, F.R.G.S., Assistant-Surgeon 21st Hussars, of a daughter.
GLEN.—On August 24, on board the P. and O. ss. *Khedive*, in the Indian Ocean, the wife of the late James Glen, Civil Surgeon, Broach, Bombay, of a son.
GODRICH.—On October 4, at 18, Stamford-villas, Fulham, the wife of Thomas Godrich, M.D., of a son.
MCFALL.—On October 7, at Sandgate, Kent, the wife of D. Chambers McFall, Esq., of the Army Medical Staff, of a son.
ROBERTS.—On the 25th ult., the wife of Charles Roberts, M.R.C.S., etc., Uxbridge, of a son.
ROOSE.—On October 6, at Elmsley House, London-road, Brighton, the wife of E. C. Robson Roose, Surgeon, of a son.
STEELE.—On October 4, at St. Marychurch, Torquay, the wife of W. S. Steele, Surgeon, of a son.
WALL.—On October 7, at 2, Burlington-road, St. Stephen's-square, the wife of Reginald Bligh Wall, M.R.C.S., of a son.

MARRIAGES.

FAGGE—ROBINSON.—On October 5, at Waterloo Church, near Liverpool, Frederick Thomas, second son of Charles Fagge, M.R.C.S., L.S.A., Hythe, Kent, to Emily, youngest daughter of the late Joseph Robinson, Esq., of Litherland House, near Liverpool.
HOSFORD—BUTCHART.—On October 5, at St. Luke's Church, Westbourne-park, Thomas Stroud Hosford, M.R.C.S. Eng., late of the *Dreadnought* Hospital, Greenwich, to Annie Brodie, widow of James Butchart, Esq., of Melbourne, Australia, and daughter of James Ainslie, Esq., formerly of East Lothian.
HUMPHRY—HUNTER.—On October 5, at St. Pancras Church, John Humphry, M.R.C.S.E., of Stone, Aylesbury, to Catherine Jane, niece and adopted daughter of the late C. H. Hunter, Esq., of Edgbaston.
POTTLE—ROTHWELL.—On September 9, at All Saints', Stonebridge, Edgar George Pottle, L.R.C.P., etc., second son of John Rowland Pottle, M.R.C.S., L.S.A., to Sophia, only daughter of T. Rothwell, Esq.
WHITE—BESLY.—On October 5, at the parish church, Kingston-on-Thames, Henry Thomas, elder son of George Peter White, to Mary, second daughter of the late Francis Besly, M.R.C.S., L.S.A.
YOUNG—LAWRENCE.—On October 10, at St. Andrew's, Holborn, Sir George Young, Bart., of Formosa, Cookham, Berks, and of Lincoln's-inn, to Alice Lacy, widow of Sir Alexander Hutchinson Lawrence, Bart., late of the Bengal Civil Service, and daughter of Evory Kennedy, M.D., of Belgard, Clondalkin.

DEATHS.

BUSHELL, THOMAS, M.R.C.S.E., at 117, Crawford-street, Portman-square, on October 5, aged 74.
EVANS, GRIFFITH FRANCIS DORSETT, M.D., of The Crescent, Town Walls, Shrewsbury, Physician to the Shropshire Eye and Ear Hospital, of which he was the originator, at Aberystwith, on September 13, in the 82nd year of his age.
GRAVES, EMMA SPENCER, the beloved wife of J. S. Graves, Deputy Inspector-General of Hospitals, eldest daughter of the late John Curling, Esq., of Offley Holes, Herts, at Westbourne-park, Bayswater, on October 7.
GLEN, JAMES, Civil Surgeon, Broach, Bombay, on board the P. and O. ss. *Khedive*, in the Indian Ocean, on August 20.
GREAVES, AUGUSTUS GORING, Surgeon, at Derby, on October 1, aged 59.
INGOLDBY, SARAH ANNA, the beloved wife of Frederick Ingoldby, Surgeon, at 11, Finsbury-square, on October 7.
MASKEW, JULIA CAROLINE, the wife of J. S. Maskew, M.D., at The Elcombs, Lyndhurst, on September 26.

PEDDIE, THOMAS ANDERSON, student of Medicine, eldest surviving son of Alexander Peddie, M.D., F.R.C.P. Edin., at 15, Rutland-street, Edinburgh, on October 6.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

CHARING-CROSS HOSPITAL.—Assistant-Physician. Must have a Degree from one of the Universities recognised by the General Medical Council, and must be F. or M.R.C.P.L. Residence within three miles of the Hospital is necessary. Applications and testimonials to Mr. H. Woolcott, Secretary, on or before October 24.

CORNWALL COUNTY LUNATIC ASYLUM.—Assistant Medical Officer. Must be duly qualified. Applications and testimonials to Mr. R. Adams, on or before October 14.

DEVON COUNTY LUNATIC ASYLUM.—Assistant Medical Officer. Applications and testimonials to Mr. T. E. Drake, Solicitor, on or before October 26.

DORCHESTER UNION.—Medical Officer for the Workhouse and Dorchester Districts. Candidates must be qualified in accordance with the General Orders of the Local Government Board. Applications and testimonials to Mr. H. Lock, Clerk, on or before October 26. Election the same day.

DUDLEY GUEST HOSPITAL.—Resident Medical Officer. Must have both Medical and Surgical qualifications, and be registered. Applications and testimonials to the Rev. G. Y. Osborne, St. Edmund's Vicarage, Dudley, on or before October 14.

EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK-BRIDGE-ROAD.—Surgeon. Must be M.R.C.S.E., and be registered. Applications and testimonials to the Committee at the Hospital, on or before October 25.

GREAT NORTHERN HOSPITAL.—House-Surgeon. Candidates must be M.R.C.S. Applications and testimonials to the Secretary, Mr. G. Reid, 46, Great Coram-street, W.C., on or before October 30.

LIVERPOOL NORTHERN HOSPITAL.—House-Surgeon. Must possess both Medical and Surgical qualifications. Applications and testimonials to Mr. J. Unsworth, on or before October 16. Election on the 20th.

MARLBOROUGH UNION.—Medical Officer for the Second District. Candidates must possess the qualifications prescribed by the Regulations of the Local Government Board. Applications and testimonials to Mr. E. B. Merriman, on or before October 16. Election on the 18th.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Applications and testimonials to the Secretary, on or before October 24.

NOTTINGHAM GENERAL HOSPITAL.—Resident Surgeon-Apothecary. The qualifications required are as follows:—F. or M.R.C.S. Eng., Edin., Dub., or of the Faculty of Glasgow, and L.S.A. Applications and testimonials to Mr. E. M. Kidd, Secretary, on or before October 24.

POCKLINGTON UNION.—Medical Officer for the Pocklington No. 2 District. Candidates must be duly qualified and registered. Applications and testimonials to Mr. W. Silburn, on or before October 20. Election on the 21st.

PRESTON AND COUNTY OF LANCASTER ROYAL INFIRMARY.—House-Surgeon. Must be legally qualified to practise. Applications and testimonials to Mr. R. F. Easterly, 54, Fishergate, Preston, on or before October 24. The duties will commence on November 9.

ROYAL SURREY COUNTY HOSPITAL.—House-Surgeon. Must be duly qualified in Medicine and Surgery. Applications and testimonials to the Assistant-Secretary, Guildford, on or before November 6.

ST. GEORGE'S, HANOVER-SQUARE, DISPENSARY.—Physician-Accoucheur. Must be M. or F.R.C.P.L. Applications to the Honorary Secretary, 59, Mount-street, on or before October 30. Election the following day.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Medical and Surgical qualifications required. Further particulars of Dr. J. C. Hall, Honorary Secretary, to whom applications and testimonials may be sent on or before October 23.

SWAFFHAM UNION.—Medical Officer for the Saham Toney District. Gentlemen applying for this appointment must be qualified in accordance with the General Regulations of the Local Government Board. Applications and testimonials to Mr. R. Sewell, Clerk, on or before October 21. The duties will commence on the 28th.

TIVERTON UNION.—Medical Officer for the parishes of Silverton and Bickleigh. Candidates must be duly qualified in accordance with the Regulations of the Local Government Board. Applications and testimonials to Mr. C. M. Hole, on or before October 16. Election on the 17th.

YORK COUNTY HOSPITAL.—House-Surgeon. Must be duly qualified. Applications and testimonials to Mr. R. Holtby, on or before October 20.

WARMINSTER UNION.—Medical Officers for the Warminster District and Union Workhouse, and for the Corsley District. Candidates must possess the qualifications prescribed by the Local Government Board. Applications and testimonials to Mr. J. Merrick, Clerk to the Guardians, Warminster, on or before October 16. Election the same day.

WEYMOUTH UNION.—Medical Officer and Public Vaccinator for the Melcombe Regis District. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. R. Hare, Clerk, on or before October 23. Election on the 24th.

UNION AND PAROCHIAL MEDICAL SERVICE.

. The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATION.

Bromford Union.—The Seventh District is vacant; area 2793; population 1220; salary £26 per annum.

APPOINTMENTS.

Devizes Union.—Edward N. Carless, M.B. & M.C. Univ. Aber., L.F.P. & S. Glasg., to the First District.

Orsett Union.—Alfred Thos. Roworth, M.R.C.S. Eng., L.S.A., to the Grays District.

Pocklington Union.—Charles E. B. Danson, M.R.C.S. Eng., L.S.A., to the First Pocklington District.

Settle Union.—Francis Green, M.R.C.S. Eng., L.R.C.P. Edin., to the Workhouse and the Settle, Horton-in-Ribblesdale, and Ingleton Fells Districts.

Towcester Union.—Wm. H. Heygate, M.R.C.S. Eng., L.S.A., to the Towcester District and the Workhouse.

West Derby Union.—James A. Harris, M.B. Univ. Lond., M.R.C.S. Eng., as Assistant Medical Officer at the Workhouse for sick poor.

REGISTRATION OF STUDENTS.—The annual registration of gentlemen pursuing their studies at the eleven metropolitan Schools, which was commenced at the College of Surgeons on the 2nd inst., will not be brought to a close until Monday next. At the hour of going to press we find that the number of new entries registered on Thursday evening was as follows, viz.:—Guy's, 78; St. Bartholomew's, 77; University College, 59; St. Thomas's, 48; King's College, 35; the London, 23; St. Mary's, 20; the Middlesex, 10; the Westminster, 9; St. George's, 8; and the Charing-cross, 8. The total number registered is 1039, including first, second, third, and, when necessary, fourth years' men.

MR. FRANCIS KIERNAN, F.R.S.—This gentleman, who was lately a member of the Council and Court of Examiners of the Royal College of Surgeons, has evinced the great interest he continues to take in the Museum of the College, by presenting the whole of his large anatomical collection, formed during a life of untiring industry. The valuable preparations illustrative of the anatomy and diseases of the liver, for which this distinguished member of the Profession obtained the Fellowship of the Royal Society, will be found most interesting.

ASSOCIATION OF HEALTH OFFICERS.—At the first meeting for the season, on October 21, Mr. Liddle will read a paper "On the Intimate Relation between Defective Ventilation and the Mortality from Tubercular Diseases, Convulsions in Children, Teething, Atrophy, and Debility, with a few Practical Suggestions thereon." The meetings are held at the Scottish Corporation Hall, Fleet-street, at half-past seven.

PRESENTATION TO DR. JAMES SAWYER.—This gentleman, who has lately been appointed Physician to the Queen's Hospital, Birmingham, and Extra Acting-Physician to the Birmingham and Midland Free Hospital for Sick Children, has been presented with an address, a microscope, a timepiece, and the publications of the New Sydenham Society (forty volumes), as a "testimony of the high appreciation of the manner in which, for the last three years, Dr. Sawyer had filled the office of Resident Physician to the Queen's Hospital."

CHOLERA PRECAUTIONS.—The Thames Shipping Inspection Committee have now made arrangements for the immediate engagement of a Medical Officer, with a sufficient Staff under him, for the inspection of all vessels in the river and in the docks, should their services be required. The Metropolitan Asylums Board are about reappointing the Medical staff on board the *Dreadnought*, for cholera cases occurring on the river.

HEALTH OF SCOTLAND.—During the month of September the deaths of 2154 persons were registered in the eight principal towns, of whom 1086 were males and 1068 females. This is the greatest number of deaths recorded for any corresponding month since the Registration Act came into operation in 1855, and, allowance being made for increase of population, is 82 above the September average of the last ten years. A comparison of the deaths registered in the eight principal towns, shows that during September the annual rate of mortality was 17 deaths per 1000 persons in Aberdeen, 22 in Edinburgh and in Leith, 23 in Paisley, 25 in Dundee and in Greenock, and 26 in Glasgow and in Perth. Of the 2154 deaths registered, 1047, or 48 per cent., were of children under 5 years of age. In Perth, 31 per cent. of the persons who died were under 5 years of age; in Edinburgh, 43 per cent.; in Paisley 44; in Aberdeen, 45; in Greenock, 48; in Dundee, 49; in Glasgow and in Leith, 52 per cent.

REFUSAL TO APPOINT A MEDICAL OFFICER.—The local authority for the burgher portion of Fraserburgh, at a meeting last week, resolved, by a majority, that no permanent Medical Officer should be appointed, such not being required by the Public Health Act. One gentleman, however, intimated his intention of bringing the matter under the notice of the Board of Supervision.

MR. CORNELIUS BUTLER has resigned his appointment of Medical Officer of the Brentwood Schools, owing, we regret to say, to severe illness arising from an accident. Mr. Wallis, his partner, is an applicant for the appointment.

A COTTAGE HOSPITAL was opened, on Thursday, at Sudbury. It has been built, furnished, and completely equipped at the cost of Miss Copland, of Sudbury Lodge.

MR. W. H. CORFIELD, M.A., M.B., has been elected Medical Officer of Health of Islington, in the place of Dr. Ballard, resigned.

THE Assistant-Surgeon of Chatham Dockyard will shortly become vacant, the period of the present holder being nearly completed.

LUNATIC ASYLUMS.—A return just issued by order of the House of Commons, shows that in the various borough and county lunatic asylums in England and Wales on July 1 last there were 31,474 inmates.

OF forty-eight Sisters of Charity tending the small-pox patients in the Bieêtre Hospital at Paris, eleven died of the malady. Volunteers from the Sisterhood were called to fill their places, and thirty-three instantly responded.

TWO cases of small-pox have occurred among the women employed in the spinning-loft of the ropery at the Devonport Dockyard, and the Admiral-Superintendent has ordered all the women so employed, as well as the police, to be immediately vaccinated.

SIR JAMES ELPHINSTONE called attention, at the Aberdeen Michaelmas County Meeting, last week, presided over by Lord Kintore, to the desirability of establishing Hospitals throughout the county, on the "cottage" system. The suggestion received the unanimous approval of the meeting, and it was decided that such classified information should be procured as would enable them, at a future meeting, to take action in the establishment of these Hospitals.

THE East London Water Company have notified that "It is their desire and—so far as in them lies—their intention to adopt the system of constant supply in all houses supplied by the Company." A code of regulations for preventing waste, misuse, and undue consumption is being prepared by the Company, and as soon as it is approved by the Board of Trade it will be published for the information of the consumer. Arrangements will then be made for carrying out a constant supply; and the Company intimate that it will be the fault of the public if they have any cause of complaint on this head.

SUGAR IN THE LIVER.—As the result of his numerous experiments, detailed in a paper upon this subject, read at the New York Academy of Medicine, Dr. Dalton comes to the conclusions—1. Sugar exists in the liver at the earliest period at which it is possible to examine the organ after its separation from the body of the living animal. 2. The average quantity existing in the liver at this time is, at least, $2\frac{1}{2}$ parts per 1000. 3. The liver-sugar thus found does not belong to the arterial blood with which the organ is supplied, but is a normal ingredient of the hepatic tissue.—*Boston Journal*, August 31.

PHOSPHORUS IN WAKEFULNESS.—Dr. W. A. Hammond recommends twelve grains of this to be boiled in one ounce of almond oil, and filtered. Half of this is to be mixed with an ounce and a half of gum arabic, adding fifteen drops of some aromatic oil. Of this mixture the dose is fifteen drops, containing one-twenty-fourth of a grain of phosphorus. Three doses are given before bed-time, sleep being generally produced on the second day, if not on the first. The dose may be increased a drop daily until twenty drops are taken, or signs of gastric irritation supervene.—*Boston Journal*, September 7.

CONSUMPTION OF TOBACCO.—A table contained in the recently published reports of the Inspector of the Laboratory of the Inland Revenue, shows that the consumption of tobacco, notwithstanding the proofs to the contrary which may be thought to exist, appears to have been for several years almost stationary. The number of pounds weight of tobacco cleared for consumption in the United Kingdom during the last four years comprised in the table was—in 1866, 40,995,161; in 1867, 41,053,612; in 1868, 41,280,001; and in 1869, 41,719,500, which, estimating the total population of Great Britain and the approximate total population of Ireland according to the percentage increase during the decennial period from 1851 to 1861, would give 1 lb. $5\frac{3}{4}$ ozs. as the weight per head of tobacco so cleared in each of the years just mentioned. One hundred and twenty-five samples of tobacco were examined at the laboratory during the year, and 124 were genuine and twenty-eight adulterated. The adulterants were—sugar, liquorice, and logwood; one sample contained liquorice to the extent of 30 per cent. Of snuff, the report states that twenty-six samples were examined; twelve proved to be adulterated—the adulterants being oxide of iron, alumina, glass, coal, pinewood, fustie, straw, and an excessive amount of sand. Surely these facts disclose a system of adulteration and fraud which calls for the interference of the Board of Trade.

INSANITY IN PARIS IN 1870-71.—M. Le Grand du Saulle, who, from his opportunities, speaks with the greatest authority on the subject, states, in an article in the *Gazette des Hôpitaux* (August 31), on "The Mental Condition of the Inhabitants of Paris during the Events of 1870-71," that it is a popular error to suppose that during or subsequently to any of the French political revolutions the number of cases of insanity have increased. They did not do so after the Revolution of 1848, and on the present occasion there have been actually fewer cases of insanity than usual proportionally to the population. In like manner, the number of suicides during the nine months of trouble was very small.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

I. W., *Chesterfield*.—Try Matthews, Portugal-street, W.C.

Sufferer.—If you cannot afford to pay a fee, go and see a Surgeon at a Hospital. Don't attempt to treat yourself.

A *Naval Surgeon, Plymouth*.—The leading articles on the treatment of naval Surgeons to which you refer, were published in the *Medical Times and Gazette*, vol. xix.

M.D., *Greenwich*.—Mr. Busk formerly practised in your borough. He was admitted a Member of the College on November 19, 1830; an Honorary Fellow, December 11, 1843; a Member of the Council in 1863, of the Court of Examiners in 1868, and President last July. He is a Fellow of the Royal Society. Why not invest one shilling in the Calendar of the College, which will give you the desired information?

A *Provincial Teacher*.—The registration of students now pursuing their studies at the metropolitan Hospitals will not be brought to a close until Monday next; consequently, we are unable to give you the number. We decline troubling the Deans of the respective Schools for a return, preferring the official record.

A *Medical Centenarian*.—Edward Augustus Holyoke, M.D., LL.D., of Salem, Massachusetts, was born August 1, 1728, at Marblehead, Mass., and was the son of the Rev. Edward Holyoke. The extreme age to which he attained—dying March 31, 1829, aged 100 years and 7 months—has been a matter of notoriety at Boston. A memoir of him was prepared, in compliance with a vote of the Essex South District Medical Society, and published at their request—Boston, 1829.

Trinidad.—With the squabble existing between rival Practitioners in Trinidad we wish to have nothing to do. It is a matter of no public importance who is Public Vaccinator so long as he performs his duties properly and efficiently. It matters not what are the real opinions of Dr. Bakewell; all that concerns us in the public interest is, whether, in his report as Vaccinator-General of Trinidad, the following passages appear:—

"The greater portion of the infants under 1 year suffer severely from this cause (fever resulting from vaccination). So much so is this the case, that I vaccinated my youngest child (born in Trinidad) only because I was Vaccinator-General, and felt bound to set an example of obedience to the law. As a private Medical Practitioner, I would have taken my chance of an epidemic of small-pox.

"So far from further compulsory measures being advisable, or even justifiable, vaccination ought to be permissive only, and not enforced by law."

These passages are quoted from a petition now going round for signature in Trinidad, to be presented to the Governor. We reprint the above passages from the petition, which is given in *extenso* in the *Trinidad Telegraph* of August 30. We understand that Dr. Bakewell does not deny that the above are his opinions. We can only say that it is to be regretted that the beneficent influences of vaccination should be so underrated by a gentleman holding so important a position as does Dr. Bakewell.

THE ARMY MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A gentlemanly young fellow, fresh from Netley, called recently to receive a few hints. Perhaps others, or the fond parents of Medicomilitary aspirants, would like to read, mark, learn, and inwardly digest a few observations.

The prospect to a beginner is very good: £180 a year offered to the enthusiastic newly fledged Æsculapius, who, unless he has money or a family opening, must go on a sea voyage, together with a cow—drudge as an assistant; warranted sober, able to ride, photograph enclosed—or, waiting for practice, edit a magazine, criticise the labours of others (*vide* "Lothair"), and live on his friends. To rovers a great opportunity is afforded of seeing foreign countries, besides passing a pleasant, indeed a jolly, life. The shoe pinches after. Dr. Gilmore, aged 37, fourteen years' service, income, in addition to quarters, coals, and candles, as a bachelor, £273 15s. (dem the shillings); as a married man, the cash alone. Now, he made many matrimonial ventures, all progressing swimmingly, until the paternal interview and the following dialogue:—"Do you owe money?"—"Yes."—"Have you any expectations?"—"No."—"Is your life insured?"—"No."—"Would my daughter Ellen have to go abroad?"—"Yes."—"Will she receive a pension if you die next week?"—"I think not."—"Then I think we had better say, Good morning."

Well, my young friends, doing your duty rigidly and conscientiously at all times, avoiding contention, strive to gain the good-will and respect of

your commanding officer. It is of no use attempting to force a position; it will probably be conceded in most instances, if deserving. Avoid extravagance in your dress and habits generally. Above all things, do not sink the Doctor to ape the subaltern. Combatant officers have an entirely different groove of pursuits and ideas compared to a Medical man, who, in his Profession alone, has endless inexhaustible treasures to explore. Take short notes of every interesting case; by-and-by the editors of Medical journals will gladly insert contributions considered worthy. As to recreation—field sports, billiards, literature, music, drawing, or the study of languages or natural history may be indulged in at many stations. Drink and women, as of old, are your "Pearl Rocks." No mercy can be extended to a drunken Doctor—a man entrusted with the lives of others. As to women, God help a poor fellow infatuated!—resembling measles, the later in life the severer the attack. Many men live on their pay—indeed, from India have sent home money to indigent relatives. You cannot marry on less than £500; even then, if children come rapidly, some old father, aunt, or sister has to pinch to keep you afloat. And before taking a delicate girl from the country parsonage, think of the wandering life and hot climates.

We should all like to live our years over again, to spend them differently. How you young gentlemen, strong and hearty, are to be envied! Fresh from the schools and special training at Netley, what is to prevent you making a mark in the world, and reflecting credit on the department to which you have the honour to belong?

However objectionable sounding the *το εγω* may be (a habit that spoils the best literary production), I cannot help saying that, when in health, the only time one feels depressed is when work ceases; and, like Charles Lamb, the dream of home, a wife, and children, changes into the reality of loneliness

Your obedient servant,

A MAGENTA-NOSED BACHELOR.

COMMUNICATIONS have been received from—

J. W.; Mr. R. T. HUNT; Dr. BAKWELL; Dr. LOWE; Mr. LAWSON TAIT; Mr. WOODCOCK; Dr. WHITEHEAD; Dr. SUTHERLAND; Dr. FAYRE; Mr. J. DAVIES; Dr. R. H. COLLYER; Mr. JAYAKAR; Mr. D. C. McFALL; Mr. GASKOIN; Mr. C. H. SAVORY; Mr. F. JORDAN; Mr. BUSHELL; Mr. C. F. MAUNDER; Dr. F. R. HOGG; Mr. J. CHATTO; Mr. A. H. ALLEN; Mr. Wm. CARTER; Dr. WHITMORE; CURIOUS; Mr. F. W. BUTLER; Dr. A. N. KIDD.

BOOKS RECEIVED—

Watson's Lectures on the Principles and Practice of Physic, fifth edition—Day on a Means of Arresting the Spread of Small-pox—Notes on Lying-in Institutions, by Florence Nightingale—Gant on the Science and Practice of Surgery—Biological Science in Relation to Religious Belief: being the Introductory Address delivered at St. Mary's Hospital Medical School, October 2, 1871—Athill on the Diseases of Women—Reports of Dr. Parkes and Dr. Sanderson on the Sanitary Condition of the Borough of Liverpool—Fothergill on Digitalis; its Mode of Action and its Use—The Tobacco Question Physiologically, Chemically, and Botanically Considered—Monthly Report on the Health of the Parish of St. Marylebone.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Practitioner, October—Edinburgh Medical Journal, October—The Port of Spain Telegraph—Griffith and Henfrew's Micrographic Dictionary, parts i. and ii.—Indian Medical Gazette—Pharmaceutical Journal—The Staffordshire Weekly Times—The Philadelphia Evening Bulletin—The Melbourne Argus—The Australian Medical Gazette—Medical Press and Circular.

APPOINTMENTS FOR THE WEEK.

October 14. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 9½ a.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

16. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Casual Communications. Mr. John Gay, F.R.C.S., "On Crural Venosity." Dr. Richardson, "Preliminary Notes of a Research as to the Possibility of destroying Animals intended for Human Consumption without the Infliction of Pain."

17. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. Meeting.

18. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 1½ p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

19. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

20. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, October 7, 1871.

BIRTHS.

Births of Boys, 1069; Girls, 1100; Total, 2169.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29·39 in. The highest was 29·72 in. on Thursday morning, and the lowest 29·17 in. on Tuesday morning.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

ORIGINAL LECTURES.

INTRODUCTORY LECTURE

TO THE

COURSE OF CLINICAL OPHTHALMOLOGY
AT ST. THOMAS'S HOSPITAL.

By Mr. R. LIEBREICH,

Ophthalmic Surgeon and Lecturer to the Hospital.

GENTLEMEN,—Ophthalmology was formerly considered a subordinate branch of Surgery. By its astonishing progress, however, during the last twenty years, it has risen to the rank of a separate science. The most eminent Physiologists, Surgeons, and Physicians have, by persevering studies and attention, developed the science and practice of ophthalmology until they have given it a scientific independence. Special studies and special training have become a necessary consequence of its high development.

The Treasurer, the Governors, and the Medical Staff of this Hospital and Medical School have promptly recognised the importance of the subject. With the greatest care and liberality, the Governors have fitted up a special department for the treatment of the diseases of the eye, and for instruction therein. The completeness of all the arrangements of this institution justly entitles us to indulge the pleasant expectation that it will not turn out inferior to similar departments of other general Hospitals, nor even to any special eye infirmary.

I hope, gentlemen, you will be anxious to derive all possible benefit from those favourable circumstances. For some time, however, there will, no doubt, be some difficulties arising out of my incomplete command over the English language; but I trust they will soon be diminished. Indulgence on your part, and my best intentions, assisted by long experience in teaching, will speedily help us over these difficulties.

The teaching of Ophthalmology aims at two widely different objects. The one is merely to give the student a concise view over this part of Medicine, and to impart to him as much knowledge of the subject as every Practitioner ought to have, whatever branch of Medicine he may take up afterwards; the other purposes to educate Ophthalmologists.

The relation of our department to this Hospital and Medical School requires that our principal attention should be directed to the first object—namely, to impart a general knowledge of the treatment of diseases of the eye. I hope, however, that those who may take special interest in this branch of study, and may intend devoting themselves entirely to it, will have every opportunity of doing so, and will always find me ready to assist them in their pursuits. The laboratory attached to this department will afford them the means for original researches, and my ample pathological collection, which I have brought over from my clinics in Paris, will give them material for microscopical investigations.

A systematic course will be given in the summer session. During the winter I purpose giving clinical lectures twice a week on cases as they present themselves daily in the out-patient department. On Mondays we will analyse cases of more Medical interest, and practise the use of the ophthalmoscope; on Thursdays we will take Surgical cases, and perform the necessary operations.

Now, before I enter into the nature, the course, and the treatment of an individual case, I shall have to draw your attention to the best method of examining your patients. I shall first try to teach you what you ought to learn by looking at a patient before you ask him a single question—how to examine his eyes in ordinary daylight, how to examine them by lateral illumination, and how to use the ophthalmoscope.

In subsequent meetings we shall have to complete this by examination of the refraction, accommodation, acuteness of vision, field of vision, binocular vision, and so forth, for which we require answers from the patient to our questions. I shall bring before you first three patients—one we will examine together by ordinary daylight, a second by lateral illumination, the third by the ophthalmoscope.

In examining a patient in broad daylight I warn you, before all, not to adhere to the widespread practice of taking hold simultaneously of both his eyelids and drawing them asunder, in order to see at once as large a surface as possible. It is, if done by one, sufficiently disagreeable for the patient; and it will certainly be insupportable if done by a larger number of students. But the chief bad consequence is, that the irritation

produced by thus handling an inflamed eye increases the hyperæmia, and gives an erroneous impression of the actual state. In inflamed and irritable eyes a similar mode may even prevent you from a successful examination. I advise you, therefore, first to look at this eye at a distance, and then close to it, without touching it, and then to observe the different parts of the surface of the eye by making the patient move the eyeball in the different directions—namely, above, below, to the left, to the right. During these examinations you may gently draw alternately on the upper and on the lower eyelid; only, after having examined the surface of the eyeball in the way just described, you may then evert the eyelids, if necessary, in order to see their inner surface.

In the second patient you will easily recognise in daylight a cataract of his left eye. But in order to distinctly recognise the nature, the consistency, the maturity of this cataract, it is necessary to examine him by lateral illumination.

In a dark chamber we will, by means of a convex lens of two inches focus, concentrate the luminous rays of a gas-flame, placed at the side of the patient, upon the point which we wish to examine. This method allows us to look through the anterior part of the crystalline lens, even if it be not perfectly transparent, to the nucleus, and even to the posterior surface.

In the third patient you will neither by daylight nor by lateral illumination recognise any cause of his blindness. We must take refuge in the ophthalmoscope. Since you have not as yet acquired the necessary practice in the use of this instrument, I will show you to-day the fundus of the eye with my fixed ophthalmoscope. You will see in the middle of the red fundus formed by the choroid a white round spot—namely, the optic disc—from the centre of which emerge the vessels of the retina. The equally white colour of the disc, and the small diameter of the vessels, will indicate to you that the atrophic state of the optic disc is in this case the reason of the complete blindness of the eye.

After having shown you an instance of each of these three methods, I shall now treat more explicitly of lateral illumination. Long time ago the illumination of eyes by means of a convex lens has been occasionally resorted to. But the idea of introducing it into practice, as a systematic method of examination, was conceived by myself after I had become acquainted with Helmholtz's treatise on "Accommodation." One of his experiments showed so clearly the substance of the cornea and the crystalline lens, that I concluded that it must equally well, if not better, show even the slightest cloudiness in the refracting media. The practical application verified my conclusion, and I then combined this method of illumination with a strong magnifying power, a pocket lens, and even a microscope. I finished the first communication I made, seventeen years ago, on this subject, with the following words:—"Such an intense illumination, directed upon a single point by means of a light which can be freely regulated, allows us the minutest investigations. The most practised observer could only in a very imperfect manner recognise, by the most attentive examination, in daylight, such details as the lateral illumination shows with the greatest facility and clearness."

Yet this very clearness is not without the danger, for an inexperienced observer, of over-estimating the alterations so easily observed. Thus, for instance, one who for the first time sees, by dilated pupil and lateral illumination, a senile crystalline lens, may think it to be a cataract. The somewhat lessened degree of equal transparency which is proper to the crystalline lens of everybody in advanced age is sufficient to make its substance very distinctly appear in a bluish-grey colour, even if it seems absolutely transparent by daylight, and for the ophthalmoscope. To get a correct idea of the effect of lateral illumination, let us compare it with a beam of sunlight entering a dark room through a hole in the shut window-blinds. In the bluish-grey stripe which indicates the passage of the luminous ray we can see even the finest particles of dust, and thereby recognise to what illusions common daylight leads us in regard to the purity of the air which we respire. In an analogous way, and even in analogous colour, the cornea, as well as the crystalline lens of the normal eye, are seen by lateral illumination. It is necessary, therefore, to begin observing normal eyes of the different periods of life before studying any pathological changes.

In observing the cornea, it is easy to combine lateral illumination with a strong magnifying power. Here the slightest changes can be recognised with the greatest certainty. The different kinds of cloudiness which, by common daylight, appear of quite identical nature, are easily distinguished; and we are able to state whether they belong to the superficial or to the deeper layers of the cornea. Very extensive opacities

in the cornea may prevent us from observing the iris and the pupillary region; but we can overcome this obstacle by concentrating the light upon the iris without illuminating the opacities of the cornea. Of the utility of this process I shall show you to-day an example. In one patient, with extensive central cloudiness of both corneae, you will, by concentrating the light upon the crystalline lens, be able to see extensive opacities in the latter, if you look through the non-illuminated part of the cornea. This observation would be impossible by daylight.

In another patient, who, by an injury to his left eye, has got a laceration of the iris and dislocation of the lens, the comparison between his healthy and his injured eye will prove extremely instructive. Whilst in the one eye you see the normal elevation of the iris and the bluish-grey reflex of the substance of the lens, you will see in the other eye the flattened somewhat retracted iris and the perfectly pure black pupil, owing to the absence of the lens. Easier than in the normal eye, you can here look even into the deeper parts of the vitreous body, and there recognise a whitish-grey membrane floating to and fro. By the laceration of the iris the pupil has become so much dilated, that through it, and through the absence of the lens, this case is especially adapted to show how, by lateral illumination of the sclerotic coat, the pupil may be made luminous and the fundus visible without the ophthalmoscope. To these cases I shall add a number of others which will give you opportunity of practising this mode of examination.

Of the two convex lenses usually given with the small ophthalmoscope, you will best use the stronger one to illuminate the eye, the other to regard the illuminated part. You are holding the latter before your eye, and about one inch and a half to two inches before that of the patient. It will be better, however, to begin with simple illumination without any magnifying power. The cornea and pupillary region must be illuminated quite from the side, whilst the observer is looking from the opposite side. The equatorial part of the crystalline lens is also to be illuminated from the side, but it is to be observed nearly in the same direction. For the posterior pole of the crystalline lens and the neighbouring parts of the vitreous body it is necessary to have the light fall a little more from the front. Very different effects of illumination are obtained by somewhat approaching or removing the lens, by shifting it forwards or backwards, and by letting the light fall in a more or less oblique direction. By practice only you can learn how to profit in a special case by the variety of the luminous effects.

LECTURES ON EXPERIMENTAL AND PRACTICAL MEDICINE.

By BENJAMIN W. RICHARDSON, M.D., F.R.S.

ON THE ORGANIC HYDRIDES; WITH AN APPENDIX ON HYDRAMYL AS AN ANÆSTHETIC.

LECTURE II.

(Concluded from page 403.)

CAPROYL HYDRIDE.

Synonyms: Hexyl hydride—Hexylen— $C_6H_{13}H$.

ONE other specimen of the hydrides remains in our hands—the caproyl or hexyl hydride. It has a fluid density of .669, water being 1000; a vapour density of 43, taking hydrogen as unity; and a boiling-point of 154° Fahr. (68° C.). It is insoluble in water. In a previous lecture I showed an experiment with this hydride, and demonstrated its anæsthetic action. I shall be content, therefore, at this moment to offer a brief summary of its action. It is a pleasant vapour to inhale, and it produces sleep when it is inhaled very much as chloroform does. The second degree or stage of narcotism—stage of excitement—is prolonged, and vomiting is not uncommon during this stage; when the third degree of narcotism is reached, there is perfect insensibility. The fourth degree is attended with great muscular prostration, but recovery from the narcotism begins in from three to four minutes, and is usually rapid, no injurious effects being left behind. The temperature of pigeons during the full influence of this anæsthetic falls from two and a half to three degrees Fahr. When a warm-blooded animal, narcotised with the hexyl hydride, is allowed to sleep to death in the vapour, the death, as from chloroform, is almost imperceptible, it is so

gentle; the respiration ceases first, but the heart soon follows in cessation of action. After death the lungs are found to be slightly blanched, but the heart contains blood on both sides. The vapour in no way modifies the coagulation of blood, but the colour of the venous blood is rendered darker than is natural, and the arterial blood is also darkened. The corpuscles are not visibly changed. The voluntary muscles retain their irritability for a long period.

I should consider the hydride of caproyl in the light of a narcotic which acts by reducing the respiratory change of blood rather than by direct influence of its own on the nervous centres. In the absence of chloroform it might be used as a substitute for it, and, had it been tried pure in the early days of anæsthetic research, it would possibly have replaced ether.

In order to render more complete the research with the fluid hydrides, I have administered them by subcutaneous injection in several experiments. Introduced into the body in this manner, they are found to be practically negative in their action—a dose, amply sufficient to produce stupor and death by inhalation, being inactive when the agent is carried into the organism by the hypodermic method. Moreover, the local effects are so exceedingly slight they are unworthy of mention. The insolubility of the fluids in the blood, and their negative chemical action, can only account for these results.

APPENDIX.

ON HYDRAMYL AS A GENERAL ANÆSTHETIC.

IN the course of the present year, 1871, I have made a new investigation of the amyl hydride as an anæsthetic. I was led to this new, or rather renewed, research by some observations on the effect of the compound anæsthetic ether, when it was being used in the form of spray. I have stated that this compound is a mixture of amyl hydride and rectified ether; and the facts I observed in using it for producing local anæsthesia were, that when it was applied for operations on the nose and mouth the patients often passed into a temporary general insensibility whenever the operation was prolonged. In an operation for cleft palate in a youth, Mr. Christopher Heath being the operator, this general anæsthesia was twice fully developed during the operation. In a case where a small but tedious operation was carried out for removing a piece of dead alveolus, the same event occurred, and even in two cases of simple extraction of teeth it was repeated. The sleep in all these cases was so insensibly induced, was so gentle, so deep, and yet so temporary, it could not fail to attract my attention, and as it was clear the insensibility was due to the inhalation either of the vapour of the hydride or of the ether, I began a series of inquiries as to the part played by the hydride. The labour has been useful in that it has led to the application of hydramyl for producing general anæsthesia with great rapidity for short surgical operations. To amyl hydride I have given, for the sake of brevity, the name of *hydramyl*. I am indebted for the suggestion of this abbreviation to Mr. Ernest Chapman.

In recommending the research, I obtained from Mr. Robbins a good specimen of the fluid hydramyl. It had a specific gravity of .625, and it commenced to boil at 86° Fahr. (30° Cent.). It was nearly inodorous, but to some persons it gave the senso of a faint odour. When breathed it created no irritation, and I found, by breathing the vapour of it out of a bag charged with it to the extent of 60 per cent., that I was almost immediately rendered unconscious, the recovery from the inhalation being singularly rapid. I found, also, that by inhaling it again, as I had done originally, from the simple vulcanite inhaler, the same effects could be produced.

On June 6 I administered hydramyl for the first time for a short operation—viz., the extraction of a firm molar tooth from the lower jaw, Mr. Peter Matthews being the operator. The patient was a woman 30 years of age. I poured into a small vulcanite inhaler two fluid drachms of the hydramyl, and, letting the patient hold the inhaler herself, asked her to take a few deep inspirations. She carried out the instructions readily; and at the end of twenty seconds, as there was distinct evidence of an effect, I removed the inhaler, and asked her to open her mouth. She complied, and Mr. Matthews immediately extracted the tooth. The whole proceeding was from twenty-five to thirty seconds. Within the minute the patient had recovered, and was talking to us consciously. She said, immediately after she commenced to inhale she felt as if she were passing into a natural sleep. She remembered being told to open her mouth, and said she obeyed “as well as she could,” but she could recall nothing more relating to the operation; she felt nothing whatever of the extraction. In recovering she had neither vomiting nor nausea, although she had breakfasted a few minutes before; in brief, her recovery was as perfect as it was rapid.

The character of the anæsthetic sleep itself was most satisfactory. It was induced without a movement of any kind; the face retained its natural colour and expression; the pulse underwent no change whatever.

There was in the case this phenomenon, on which I must dwell:—The insensibility to pain occurred before the actual abolition of consciousness. I have observed, with Snow, precisely the same condition from amylene, and have made the fact matter of comment in my reports to the British Association for the Advancement of Science. I have observed the same phenomenon in experimenting with methylic ether, and I do not think there can be a more interesting subject of study.

The metaphysicians, in treating of conscious and unconscious states of mind, have long taught that there may be periods of consciousness with an absence of common sensibility, and the truth of this inference is now sustained by physical facts. In several cases where I administered methylic ether for removing pain in Surgical operations, the patients, when quite insensible to pain, were so conscious they were able to obey every request asked of them; and in some instances were even anxious to reason, stating that they knew what was going on, and arguing that they were not ready for the operation because they were sure they should feel pain. Nevertheless, in this state of mental activity they were operated on, and afterwards, while remembering every incident, were firm in their assertion that they felt no pain whatever during the operation. One patient, who sat for the extraction of two teeth, selected the tooth to be first extracted, putting her finger to it, and afterwards rearranging her position for the second removal. To the looker on it seemed, in fact, as though no change in her life had occurred, yet she affirmed that she was sensible of no pain whatever; and several other less striking, but hardly less singular, examples came before me. We may, then, I think, fairly assume that in course of time we shall discover manageable and certain anæsthetic substances which will paralyse sensation only, leaving the muscular power unaltered, and the mental little disturbed; and we gather from this either that in the cerebral hemisphere there is some distinct and simple centre of common sensation which may be acted upon by certain agents without involving all the cerebral mass, or that the peripheral nervous matter may be influenced without involving the other portions of the nervous system. On the whole, I incline to the view that the action of those agents which destroy pain before they remove consciousness is primarily on the peripheral system; for we know, from the process of local anæsthesia, that it is easy to destroy sensation at the extremities without destroying or even interfering with consciousness, while those who have inhaled the vapours which destroy common sensation before interfering with the mental condition, invariably describe the experience of a numbness and insensibility in the extreme parts of the body.

I offer this theory, wishing, as on all occasions, to enforce the fact only on which it is based. I have said the fact is of importance physiologically; it is of equal importance practically. To have an instrument in our hands by which we can, at will, induce insensibility to pain, with or without destruction of consciousness, as the case before us may demand, means, when it is perfected, an advance second only to the discovery of general anæsthesia itself—a refinement of the art rivalling the art. There are many minor Surgical operations for which consciousness need not be destroyed, although pain ought to be; there are other operations in which the consciousness of the person operated upon is of great service to the operator; and there is a third class of cases in which it is essential to suspend both sensation and consciousness.

What will not, then, be the perfection of our science and of the art that follows it, when we can so master pain at pleasure as to isolate the consciousness from the common sensation, benumb generally, and from within, the periphery of the nervous matter, leaving the grey external matter of the cerebrum undisturbed; or plunge, if need be, consciousness and sensation alike into forgetfulness? Yet this in process of time is certain to be accomplished. It is an advance practically founded at this moment; it waits only for more labour to be made manifest to the world by its daily application.

Returning to the details of practice, I next administered the vapour of hydramyl on June 19 and 24 to three patients for the extraction of teeth, and in both cases with success; but I found a little difficulty, owing to the higher temperature of the air that then prevailed, in retaining the fluid in the inhaler, its lightness and low boiling-point causing it to evaporate with too great rapidity—in fact, a few breathings of the patient emptied the inhaler. I therefore proceeded to an endeavour to meet this difficulty by slightly weighting the fluid with a

heavier body, but one having still a vapour density nearly the same and a low boiling-point.

HYDRAMYL-CHLOR.

In making bichloride of methylene, we place a mixture of alcohol and chloroform in contact with pure zinc. On the application of heat there is set up a brisk action, during which an equivalent of chlorine from the chloroform (CHCl_3) passes to the zinc, and, after a free escape of gases, bichloride of methylene (CH_2Cl_2) distils over. On my request, Mr. Robbins, while manufacturing some bichloride of methylene, added to the materials in the retort prepared for making the bichloride about eight times the volume of amyl hydride. The result was an immediate brisk action without the aid of heat. A copious stream of gases first passed over, and then, the fluid in the receiver having risen in temperature, there began to distil a compound fluid, very light specifically, and of a most agreeable odour. Collecting some of this fluid, I found it had a specific gravity of .699, and that it commenced to boil at 92° Fahr. It was much more manageable for inhalation than the simple hydride; was stable, and acted excellently as an anæsthetic. After carefully testing the vapour of this compound, I administered it fourteen times in cases of extraction of teeth, and with results almost identical with those that followed the administration of simple hydramyl.

Finally, in repeating the process of distillation, the first portion that distilled over was set aside, and none was collected until the temperature had reached 90° , the temperature being sustained between that degree and the degree of temperature of the human body (98°). By this means there was obtained a fluid still very agreeable to breathe and extremely rapid in its action. This fluid has the specific gravity of rectified ether—viz., .725. It boils in the warm hand, and may be considered as containing one part of bichloride of methylene in nine of amyl hydride. I propose to call this fluid “hydramyl-chlor.” I administered the vapour of this fluid for the first time for a Surgical operation on July 3. The patient was a young woman, who wished to have a large firm molar tooth extracted. I placed two fluid drachms of the fluid in an inhaler specially constructed for it, and let the patient take the inhaler in her own hand and administer to herself. There was good anæsthesia in forty seconds, and ten seconds later Mr. Matthews took out the tooth without causing the least pain. The recovery was complete within the minute, and was neither attended with vomiting nor nausea. Since this case I have continued to administer the same form of vapour in short operations, and, so far, have every reason to be satisfied with the results. I have administered it to children as young as 4 years, and to adults of different ages up to 70, and of both sexes. Mr. Matthews has also administered it a great many times for tooth-extraction at the Marylebone Dispensary with success equally good. (a)

Method of Administration.

The method of administration I adopt for the hydramyl-chlor is very simple. Messrs. Krohne and Seseman have made for me an inhaler of leather, on the plan of Randall's inhaler for bichloride of methylene. Instead, however, of having the inhaler perforated at the lower part with a number of holes, it is closed there, and is furnished with a light valve for the admission of air. There is also an escape-valve at the upper part. Inside the inhaler is a lining of domette, covered with an inner fold of muslin.

In application I pour one to one and a half fluid drachms of the anæsthetic solution upon the folds of muslin, and apply the inhaler thus charged gently to the face, covering the nose and mouth. The patient is allowed to inhale until there is a movement of the eyelids—a quick restless movement or twitch of the

(a) While this lecture has lain in proof, Mr. Matthews has been good enough to inform me that his experience of hydramyl-chlor has extended to rather more than one hundred administrations. In all these, two cases only have presented a modification of symptoms from what has been related above. In one of these exceptional cases—that of a girl twelve years of age—there was rigidity of the muscles of the jaw as she became unconscious; the rigidity was, however, overcome at once by gentle traction, the operation was painlessly performed, and recovery was immediate. In the other exceptional case, that of a man 23 years of age, who inhaled the vapour for tooth-extraction directly after breakfast, there occurred, when the operation had been performed, and during the restoration of consciousness, a period of faintness. The faintness did not pass into actual syncope, but there was pallor, coldness of surface, and feebleness. A dose of ammonia given to the patient was swallowed, with the effect of exciting an eructation, followed by vomiting of two mouthfuls of partly digested food. The effort of vomiting was instant, and was over in a few seconds. After reclining for ten minutes, the patient got up and walked away recovered. Mr. Matthews will himself report on his cases at length; but I think it right, having the opportunity, to state the above outline of his experience, as a note to this lecture.

lids, without any turning up or other movement of the ball of the eye. This symptom developed—and it is the first symptom that attracts attention in most cases—the inhalation may cease, presuming the operation to be performed is one of short duration. At this period the patient, however, is not unconscious, and is not insensible to pain. Owing to the insolubility of the vapour in the blood, a short space of time is required for the fluid to diffuse; and so it happens that, in eight or ten seconds after the inhalation has ceased, the patient is in a better state for the operation than he is *instantly* afterwards. To the dentist this occurrence is of importance, because he is not placed in condition of hurry—he can often tell his patient to open the mouth, or give other short directions, and then proceed to extract; and he has no occasion at all to use a gag to keep the mouth open. In every case the phenomenon of prolonged action of the anæsthetic after the inhalation has ceased should be remembered by the administrator, otherwise he may narcotise far more deeply than he intended. It is merely necessary to watch for the first signs of involuntary movement; if the hand of the patient holding the inhaler become unsteady, or if the eyelids begin rapidly to move, it is time to suspend the inhalation—to wait a few seconds—to operate. I have stated the quantity of fluid required to be two drachms; but not half of this is, in reality, used by the patient. It is necessary to have an excess, because there is considerable and unavoidable loss. For dentists' practice I think the loss may be overcome by having constructed a fixed receiver for holding several ounces of the fluid—a receiver so arranged that, on removing a stopper for the admission of air and exit of vapour, the vapour above the surface of the fluid may be inhaled from a simple mouthpiece. Messrs. Krohne and Seseman are at this time carrying out a design for me of this kind.

So far, in speaking of administration, I have referred chiefly to adults. In the cases of children and old people I make no difference as to the quantity of fluid used in an administration. I am rather guided by symptoms and duration of administration. If a child be allowed to hold the inhaler, I notice that in a few seconds the indications of sleep are usually unmistakable; we have only to remove the inhaler and proceed to the operation.

HYDRAMYL-ETHER.

The composition of what is called compound anæsthetic ether for local anæsthesia has already been given. I should add that a compound ether, which I name *hydramyl-ether*, for both local and general anæsthesia, may be made by adding together in equal portions pure hydramyl and absolute ether. The specific gravity of absolute ether (.720), the vapour density (37), and the boiling-point (92° Fahr.) are all conditions so nearly allied to those of hydramyl, that the two fluids, hydramyl and ether, act in combination practically as if they were one. They differ only in the matter of solubility in water and in blood—the ether being soluble in the blood to the extent of eleven parts in the hundred, the hydramyl being insoluble.

In the production of general anæsthesia, the vapour of hydramyl-ether acts differently to the vapours we have previously discussed. It is slower in its action, it produces some sense of suffocation, it causes a little darkening of the face, pulsation of the vessels of the neck, and a series of disagreeable but not dangerous symptoms, from which the hydramyl-chlor is free. Nevertheless, it is a good general anæsthetic, and, though less agreeable, would be found, in a large number of cases, *safer* to inhale. I have no doubt it will receive favour, especially as it supplies the requirement for both local and general anæsthesia.

Conclusion.

The study of the physiological action of the organic hydrides has afforded me much satisfaction, and many months of, I will hope, useful labour. Whether any of the new applications that have sprung out of the study, and that I have ventured to suggest, will find favour with the Profession of Physic, remains to be seen: I do myself no more than submit them for their trial. Knowing how sublime is the folly of assuming that whatever a man may offer is good because it is his to offer, I put forward such results as, by reading from nature, I have gathered, without thought of forcing them on my fellows, or anticipating for them a fraction of unproven general experience. If every other Practitioner cannot use the results with profit, as well as I can, they are useless. If every other Practitioner can use one of them, and no more, with profit, I have done a work—little as it in itself may be—which, by multiplication of hands devoted to it, is sure to be a good work: and this is all the earnest man ever can do, though his ambition devour him, body and soul.

ORIGINAL COMMUNICATIONS.

NOTES ON AN OUTBREAK OF TYPHOID FEVER.

By CHARLES MAYO, M.D.,
Fellow of New College, Oxford.

THE incumbent of one of our College livings at the north end of Oxfordshire told me some days ago that an outbreak of fever had occurred in his parish. I went down at the first opportunity to see the state of things there, and made a few notes, from which the following are extracts:—

The village consists of three hamlets, two of which are on one ridge, about 250 yards distant from one another, and the third on a parallel ridge about 500 yards south. Subsoil, a brown, friable sandstone; water supply abundant, from springs and wells; population 700, entirely agricultural. A colony of Quakers exists in the parish. The population is backward, and there are several idiots; but the Quakers, although they intermarry a great deal, do not appear to have more than their share of these. The cottages are badly constructed of rough stone, and in many cases are packed much too closely together, or are placed against banks. The atmosphere is highly charged with moisture, though the position is high and the wind fresh. My friend, the rector, says that the damp affects everything within doors. Nothing can withstand it—"not even his sermons." He also informs me that the people are accustomed to go to bed in their clothes. Their habits are evidently far from cleanly. There have been about a score of cases, and six or seven deaths. The disease is a severe form of typhoid fever. The worst group of cases occurred in a double cottage with a common entrance, where, in the right-hand house, the mother had died three weeks ago (the father being already dead of phthisis); and in the left-hand house the eldest son, aged 26, died a fortnight ago, the mother at the time of my visit was lying dead, and the father was at the point of death. Moreover, another son, aged 18, had died last year. The mother, in the latter case, was said to have died of exhaustion and delirium, without fever. All the others were undoubted cases of typhoid fever.

In front of this house was a drain of loose stones, carrying the water from the road close to the foundations. At the back, close under the eaves, was a ditch, into which the inhabitants threw all their slops. The ditch was half-full of filthy water. There was plenty of decaying vegetable matter about. The woman lying dead had been in the habit of years of hoarding up old articles of clothing and fragments of woollen stuffs, of which she kept a large stack in her bedroom—the room in which her son died of fever last year.

The drinking-water for this cottage was obtained from a pump opposite. A drain, bringing the slops from two other cottages, passed close to this pump, the distance from the centre of the pump (which stood over its well) to the middle line of the drain being two feet six inches. The drain was made of rough stones.

Such cases as these seem to offer a strong argument in favour of a system of rural sanitary inspection, as advocated by Dr. Acland at the Social Science Congress.

CASE OF INTRA-CAPSULAR FRACTURE OF THE CERVIX FEMORUS, WITH INVERSION OF THE LIMB.

By J. FAYRER, M.D., C.S.I.

S., a Mahomedan woman, of weak and emaciated frame, and about 60 years of age, was admitted into the Medical College Hospital on March 15, 1871, with symptoms of an intra-capsular fracture of the neck of the right femur, caused by a fall on her hip, in consequence of a false step eight days before admission. An abrasion showed that in falling the hip had sustained violence by contact with the ground. She was unable to stand. The limb was shortened about an inch. On extension and rotation crepitus was perceptible. There was eversion of the foot. The limb was extended and placed on the long splint, and opium was given to allay pain and constitutional irritation; but she could not bear the restraint, and, after more than one trial, the splint was discontinued.

On April 2, the double inclined plane was substituted. Her health failed, she became very low, and the foot gradually assumed a completely inverted position; so much so, that attempts to place the limb in the natural position caused so much restlessness and constitutional disturbance that they were relinquished, and she lay with the limb somewhat flexed at the hip and knee, much shortened, and the toes resting against the tendo Achillis of the left leg.

Good food and stimulants were given, but she made no improvement; her appetite and strength gradually failed. Diarrhoea supervened; and at last she sank from exhaustion, on July 12, 1871, four months after the accident.

A post-mortem examination being made, it was found that the neck of the femur had been comminuted, the head only remaining lodged in the cotyloid cavity. The entire neck, from the articular cartilage to the trochanters, had disappeared, a few small detached fragments of bone only remaining.

The capsular ligament was disorganised, especially in front. The femur was drawn up, the fractured surface of its upper end being above the cotyloid cavity. The articular surface of the head of the femur remained lodged in the cavity, but the round ligament was gone. The fractured surface was hollowed out and rough, showing a degenerate and oily state of the cancellated tissue. The fractured surface of the other portion was in a similar state. No effort at repair had been made; indeed, the edge of the acetabulus and the upper surface of the femur between the trochanters were in an incipient condition of necrosis. The thigh was completely inverted, the toes of the affected limb pointing behind the opposite heel. The muscles of the hip and thigh were all much wasted and degenerated. The externals were not, apparently, better nor worse than the internal rotators of the limb.

The chief point of interest in this case, which otherwise presents no remarkable peculiarity to distinguish it from others of a similar nature, is the inversion of the foot, that which gradually came on soon after the accident, when the restraint of the long splint was withdrawn, on account of the intolerance of the patient's constitution of its application.

The natural position assumed by the foot in intra-capsular fractures of the thigh-bone is that of eversion, inversion being very rare, and even yet, I believe, not satisfactorily explained. Why the comparatively feeble action of the internal rotators should have been so predominant in this case does not seem clear. Possibly it may have been due to a changed direction of the fibres of some of the muscles, owing to the drawing up of the shaft of the femur, and the absence of its neck, which, when present, is a mechanical obstacle to internal rotation. There could be no doubt, I think, that in this case inversion was mainly due to muscular action, and not to the mere accident of position as a result of violence; for it is to be remembered that the position of inversion, gradually assumed, became permanent, and that when the limb was adjusted it returned to the inverted position, no other being tolerated by the patient. It is possible that, in the great wasting of all the muscles that rapidly resulted in the patient's feeble and emaciated condition, the external rotators, having suffered in the accident, may have become more degenerate than the other muscles of the thigh; and that thus to the ordinary action of the recognised internal rotators was perhaps added that of the adductors, which thus aided in the inversion of the limb. Such, indeed, seems to correspond with the explanation given by Mr. Erichsen,^(a) and I am much inclined to think that it was so in the case in question.

The explanation of inversion of the limb in such cases given by Mr. C. Hothouse,^(b) in which he concurs with Professor Smith, "that the influence of the muscles in producing inversion is but secondary, the lower fragment being probably thrown, by the violence which produced the fracture, into a position favourable for the action of the internal rotators," is hardly borne out by this case, in which muscular action seemed to play a prominent part in inversion.

Professor Hamilton,^(c) speaking on this subject, says—"But those rare examples of fracture of the neck of the femur, both within and without the capsule, accompanied with a permanent or a temporary inversion of the foot, are of more difficult explanation; and indeed a complete solution of this phenomenon does not yet seem to have been satisfactorily reached." Without venturing to offer an absolute opinion on the subject, I would suggest that the following causes may have been potential in causing inversion in the present case:—Total absence of the cervix femoris; shortening and flexion of the thigh, the femur

being much drawn upwards and forwards; injury and wasting of all the muscles of the thigh, but more especially of the external, which probably suffered more than the internal rotators; increased action of internal rotators, and probably altered direction of the action of other muscles, especially the adductors.

The share due to each of these causes I do not venture to apportion, though I believe that combined they offer the best explanation of the position.

All who have noticed the subject speak of it as one of great rarity. Professor Hamilton^(d) says of it—"In sixty cases of fracture of the neck seen by Cloquet, the foot was never turned in, and Boyer never met with such an example in all of his immense experience; but Lowestoffe, Guthrie, Stanley, and Cruveilhier have each seen one example, and Robert Smith has seen two. I have myself seen one."

I have therefore thought it may be well to place these few notes on record, especially as the case appears to differ in some particulars from others that have been described.

Calcutta.

ON RHEUMATISM.

THE PRINCIPLES OF ITS TREATMENT.

By J. JAMES RIDGE, B.A., B.Sc., B.S., M.D. Lond.

(Continued from page 407.)

In these remarks on the treatment of rheumatism, it is not my intention to discuss statistically the efficacy of the various remedies, nor to decide thus between the rival advocates of mint-water and medicine. Nor am I anxious to prove that alkalies are useless, although they cannot cure by neutralising any noxious acid. Having concluded that we have to deal with a simple catarrhal inflammation of fibrous tissues, I now propose to consider the natural processes for the relief of local inflammation and pyrexia, believing that by such knowledge we shall be best guided to judge of the powers of the remedies which have been employed, and best know when and how to interfere intelligently and efficiently. In the majority of cases there is doubtless no absolute necessity that we should interfere with drugs at all, for in course of time the patient will probably recover alone. If, then, we cannot interfere intelligently, it were surely better to let well alone; but if we can, we are possessed of such influential drugs, and by external means can so powerfully affect the vital processes, that we may legitimately believe that we have shortened or cured the complaint. We shall be able to use our weapons with more precision if we can discover any reason why inflammation often ends in resolution; if we can find out any other way in which inflammation dependent upon the evolution of nerve-energy ceases besides that of simply exhausting the energy in the production of heat and the various associated phenomena. Can the energy cease from manifesting itself as inflammation, and produce some correlated action? If so, can we do anything to bring this desirable alteration about?

That the nerves which preside over arterial muscles, over secretion, and over nutrition can be severally excited by reflex influences, has been abundantly shown by Brown-Séguard and others. But I believe that there is a general law with regard to these nerves which does not seem (as far as I can discover) to have been before recognised and employed to explain pathological processes and guide our treatment, although various approaches to it have been made, and some isolated examples noticed. The law I refer to is this: That an *alternative* or *inverse* relation exists among these various sympathetic fibres, so that, when energy is evolved by the action of ordinary stimuli, it can be successively manifested, and so neutralised or exhausted, either as mechanical work of organic muscles, or as increased tissue-metamorphosis, or as augmented secretion.^(e) Very probable in some cases no actual increase of force occurs, but simply a redistribution of the energy normally expended in these three ways, by which it is concentrated into one form of work at the expense of the others, or into two, at the expense of the third. Further, the stimulus, and so the energy, excited;

(d) "Fractures and Dislocations," page 354.

(e) I refer to the watery part of secretions, which holds a very different position from the solid part. The latter, in the form of salivary corpuscles, mucous corpuscles, and some organic and inorganic compounds, seems to be a distinct production from the former, and not dependent on it, or always varying in the same proportion. For example, the two processes are distinct in the kidney; also in the submaxillary gland, where they can be excited separately by the stimulation of different nerves; and probably in other cases also.

(a) "Surgery," page 271.

(b) Holmes's "System of Surgery," vol. ii., page 854.

(c) "Fractures and Dislocations," page 354.

may sometimes be so great that it may require all three of these channels to exhaust it.

This law will enable us to explain many singular phenomena, both of disease and of the action of drugs. The facts which seem to establish it are numerous, and many will no doubt occur to all who think over the subject in the light of this law, beyond those which I now adduce.

1. *The alternative relation of the vaso-motor and secretory nerves has been long recognised*—so far, at least, that we are told that, when vessels contract, secretion and nutrition diminish. But this has been attributed solely to the deficiency of blood. Retardation of the activity of secretion or tissue-change, however, does not seem to be any more a necessary consequence of diminution of blood than the opposite condition is of the increase of it. No doubt, in a healthy condition, if the power of effecting contraction of vessel is removed by section of the vaso-motor nerves, one of the other sets, and generally the secretory nerves, quietly compensates for its absence by increased activity. Agents, too, which contract bloodvessels also check secretion. Such is the local effect of the application of cold, and probably of quinine. On the other hand, agents which relax the organic muscles increase secretion; as, for example, opium, and the application of warmth and moisture. But secretion does sometimes take place when the vessels are contracted and the blood is diminished in quantity, as in the phenomenon of cold sweat; and, on the other hand, the vessels of a part may be relaxed to their utmost, and the tissue be turgid with blood, while the secretion is diminished, as in the hot stage of intermittents and of the continued fevers generally. These facts show that the act of secretion is not merely mechanical transudation of fluid from distended vessels; and this conclusion is confirmed when we remember that the consequence of simple vascular distension is a form of œdema, and not perspiration or other secretion. We have, therefore, in secretion of fluid a special elective action on the part of the gland-tissues, the result of a definite stimulus; and this stimulus is usually coincident with relaxation of arterial contraction.

2. *Vaso-motor contraction is alternative with tissue-metamorphosis.* If we apply a mild irritant to a tissue, the first effect usually produced is contraction of its vessels. After a time they relax again, and, if the irritation has been sufficiently intense, the usual signs of inflammation begin to appear. Why do the vessels relax? Some have said it is because their contractile power is exhausted; but in some spinal injuries they can remain contracted for days without exhaustion. In my view, it is due to the concentration of the nerve-energy upon the work of tissue proliferation—its transference from the vaso-motor to the trophic nerves. Some other facts tend to prove this. Quinine usually has the effect of causing vessels to contract; but there are some people whose nervous system is so arranged that the stimulus of quinine produces urticaria—that is, an inflammatory action in place of mechanical work. The cases in which there is passive congestion, associated with diminished vital activity and contracted arteries, also illustrate this condition. In such there often occurs a low form of inflammation, which is immediately attended with more or less active congestion and relaxation of the arteries connected with the excited territories, while the deficiency of blood in the whole neighbourhood chiefly accounts for the asthenic character of the inflammation. If there is complete deprivation of blood, or a near approach thereto, gangrene is the result.

It appears to me that when local bloodletting acts beneficially in reducing inflammation it is a result, at least partly, of this law. For, by abstracting blood from an inflamed part we diminish congestion, and thus stimulate the vaso-motor nerves to a certain extent; the nerve-energy being partially diverted into this channel is for the time, as it were, irresolute in which way to exert itself, and we may in favourable cases thus determine a change of action in the part, which may be able to recover itself completely in consequence of our timely aid. The same principle accounts for the beneficial effects of astringents in local inflammations—such as sulphate of zinc in conjunctivitis, nitrate of silver in erysipelas. In these cases, by a gentle stimulus we induce contraction of vessels, and, if the inflammation is not too intense, we may be able to determine the expenditure of the energy in mechanical work; but if we employ too strong an irritant, the tissues themselves are stimulated, and the inflammation is aggravated.

3. *Inflammatory action is alternative with secretion.* An excellent illustration of this occurs in acute catarrh, nasal or bronchial. The first effect on the mucous membrane is to con-

tract its vessels; this contraction is rapidly succeeded by relaxation, with increased heat, tenderness, and irritability, but also for a time with dryness from diminished secretion. This is followed by proliferation of the mucous elements, and formation of very tenacious and viscid secretion, in which the solid or cellular part is almost solely present. The subsidence of the inflammation is attended with a gradual loosening of this phlegm, the gradual substitution of fluid secretion for the gradually diminished proliferation of imperfectly formed mucous elements. Both the secretion of fluid and the epithelium formation may long continue above their normal amount, and so constitute a chronic bronchitis, or, more properly, chronic bronchorrhœa, associated with degeneration of the membrane and congestion of its vessels. Slight exposures to fresh cold may augment this secretion, severer exposure may thicken it for a time, representing an increase of true inflammation; if more severe still, the secretion may be entirely suppressed, the mucus may be too thick for expectoration, and death will ensue unless secretion is restored. The above examples of alternative action are only a few out of many, but sufficient I think, to show that there is some foundation for so regarding them. The same arrangement seems to exist in other directions and among other parts of the nervous system, among the various fibres of the cerebro-spinal system, and between these and sympathetic nerves—indeed, in one sense, nerves which hold an inhibitory relation to each other may be said to be alternative. This field is wider than our present purpose requires, and has not yet been fully surveyed.

The recognition of this law is especially useful in enabling us to understand the action of some of our remedial agents. I can only glance at a few of these.

Thus, the action of emetics, such as ipecacuanha and tartar emetic, is rendered clearer; and they are drugs which can greatly affect catarrhal inflammation. When given in sufficient quantity they evidently depress the cerebro-spinal nerves, and excite the sympathetic, for they produce lassitude and weakness of the voluntary muscles, the cardiac sphincter of the stomach, which contracts under the influence of the pneumogastric nerves, is relaxed, and the œsophagus, though not exactly relaxed, yet contracts antiperistaltically; on the other hand, the pyloric sphincter, set in action through the sympathetic nerves, is firmly contracted, while the stomach expels its contents. These actions are associated with contraction of other muscles under the control of the sympathetic system: thus, the uterus often expels its contents, the ureters and bile-ducts sometimes expel calculi, the pupil dilates, the heart is accelerated, the cutaneous vessels and muscles contract. The energy of the drug having been thus expended to a certain extent in producing these effects, the secretory system is stimulated to action; speedily all the contraction of unstriped muscle disappears, the vessels relax, and perspiration occurs abundantly. If, however, a poisonous dose has been taken, we do not get this beneficial alternation; the increase of secretion is not associated with any cessation of muscular contraction, and may even be accompanied in some cases by inflammatory action: thus, in tartar-emetic poisoning we get increased secretion from the bowels—hypercatharsis, vomiting, pallor, cramps, and cold sweats all occurring together.

If emetics are given to an extent insufficient to excite vomiting and the other extensive muscular contractions, their influence is directed to the secretory system, the action of which they promote. To this extent they may be useful in certain cases of pyrexia, and in local inflammation, especially of secreting surfaces. When emetics are given at the commencement of fevers and local inflammations any beneficial effect is also the result of this principle: the energy is directed to produce muscular contraction and secretion, and in some cases is entirely diverted into this channel, to the relief of the other symptoms; in other cases only partially.

This law also furnishes a rational explanation of the perplexing fact that some remedies in small doses check actions which they produce when taken in larger quantity. Thus drop-doses of ipecacuanha wine given every hour will often stop sickness—not all kinds of sickness, but especially sympathetic or reflex vomiting. Where vomiting is already present there will naturally be greater sensitiveness to anything which tends to excite it; therefore, to produce an alternative effect, very small doses have to be given, and, since the influence of such will be briefer, they must be repeated frequently to maintain it. By this means one correlative may be gradually substituted for another, although the substitution may not be very obvious to the senses—perhaps because it is distributed over a more extensive area. If this new channel for the dissipation of energy becomes thoroughly established, further prompting by

drugs may be no longer required; in other cases the effect only lasts while we actively interfere.

We can thus understand how some drugs having different actions in different doses may apparently exercise reverse influences, from which facts the hasty generalisation *similia similibus curantur* has been made. We can also see the reason of those peculiar results caused by idiosyncrasy. Thus, ipecacuanha in some persons produces all the symptoms of more or less extensive catarrhal inflammation, not by a different kind of influence, but by stimulating the inflammation-exciting nerves instead of secretory. Such an idiosyncrasy may be permanent or only temporary. It is not improbable that special susceptibility to take cold may be correctly expressed thus: that a stimulus which would, as a rule, be safely neutralised, finds the system so situated that it expends its force upon the trophic nerves, or, being only partly expended in producing mechanical work, and unable from some cause or other to excite secretion, is employed in setting up inflammation. In some slight cases of catarrh, however, there may be only that redistribution of energy among the different fibres which I before alluded to.

If we desire to imitate all Nature's plans for shifting morbid action, we must not neglect also the indications afforded us by the alternative relations which exist between different aggregations of tissue-elements. The reciprocal relations of the skin on the one side, and the kidneys, bowels, and lungs on the other, have been long recognised; but the alternation of their secretions has, I think, been too much regarded as a matter of physics. In the case of the kidneys, diuretics act as such by different methods, and are, therefore, not equally efficacious under all circumstances. Abundant imbibition of fluids will generally produce diuresis; but yet mere engorgement of the abdominal vessels is not sufficient to produce it without the normal or an artificial stimulus. This stimulus can be, and probably generally is, conveyed through the nervous system. It is when such is the case that we have the true alternative action. In the process of diuresis, energy is expended, and this channel can be made to take the place of diaphoresis or its correlated actions. By means of certain diuretics we may be able to determine this as the channel in which the energy shall be exerted; and if our drugs are capable of two actions, and the diuresis fails to be established, they may aggravate the disease. Doubly-acting remedies will be found especially among nervine drugs, rather than among mere mechanical irritants; but some remedies which seem to have two actions (as water, which may cause diuresis or diaphoresis) really only indicate to us the direction in which other stimuli are exerting their influence.

Some purgatives, also, take effect either upon the bowels or the kidneys, or can influence both together. Idiosyncrasy, or special tendency for energy to prefer one course to another, is also observable here: thus, gin will purge some people instead of acting as a diuretic. A similar relation exists between the lungs on the one side, and the skin, bowels, and kidneys on the other—in some cases only seen in morbid conditions.

The conclusion to which all these facts point seems to be, that any form of exhibition of energy in one organ (if not too intense) may be replaced by another or the same form in another organ. I must be content with giving a few instances of this out of many which are constantly occurring. Thus, bronchitis may alternate with eczema and the inflammatory eruption of measles, or with diaphoresis and catharsis, or with the effect of cold on the skin. Inflammatory skin affections may alternate with irritations of mucous membranes, whether natural or excited by arsenic, or with gouty inflammation of the stomach or of the joints, or with those neuralgic affections of the stomach and bowels, associated with much spasm, which sometimes characterise retrocedent gout. Hypersecretion from the bowels may relieve some cases of cerebral inflammation if administered at the proper time; a timely emetic may diminish febrile action. Artificially induced inflammation of the skin will diminish spasm of unstriated fibre, and reduce inflammatory action, and will relieve pain, especially that caused by such spasm and inflammation. Lastly, artificially excited diaphoresis or diuresis will often replace or diminish pyrexia and inflammatory action of various kinds.

If this general law holds good in the spontaneous cure of rheumatism, much fresh light is thrown upon its treatment. The greatest success will be obtained by following Nature's indications, and we shall, therefore, be better able to judge of the real value of the therapeutic agents at our disposal, and shall be guided to a less haphazard employment of them.

(To be continued.)

A CASE OF PROGRESSIVE MUSCULAR ATROPHY.

By C. B. MESTERTON.

(Translated from the *Proceedings of the Upsala Medical Society*, vol. vi., part 4, 1871, by J. W. MOORE, M.D., M.Ch. Dub., L.K.Q.C.P.I., Ex-Scholar Trin. Coll. Dublin.)

CAROLINE CHARLOTTE J., aged 18, was admitted to Hospital November 2, 1870. About two years previously the patient had fallen heavily on her right shoulder, and for some time afterwards tenderness persisted in the right supra-clavicular fossa, extending out towards the acromion process. No alteration in the position or aspect of the shoulder could at this period be detected, but gradually, without its being possible to assign a fixed time for the occurrence, the shoulder sank, grew continually weaker, and it became more difficult to raise the right arm. The patient, who was obliged to perform very rough and burdensome work, then began to use the left arm exclusively, so that this limb was consequently often overstrained. In the course of a few months the left shoulder also commenced to sink, and the same difficulty and inability to lift the arm above a horizontal line showed themselves. Simultaneously the tenderness in the right shoulder disappeared; in the left the patient had never experienced anything of the kind. A feeling of numbness or pains down the arms had throughout been wanting. The glands at the sides of the neck and in the supra-clavicular fossa had swollen at intervals, but after a short time the tumefaction disappeared; in other respects the patient had enjoyed perfect health, and did her work as well as she could. She had not yet menstruated. When the patient was viewed in front in the standing posture, with her arms hanging down, both shoulders were observed to be considerably sunken, and, besides, somewhat thrust forward. Both clavicles were directed obliquely downwards, outwards, and forwards, the right more so than the left, so that the acromion on the right side stood about six centimètres lower than the sternal end of the bone. The clavicular portion of the deltoid muscle had altogether vanished on the right side, while on the left it was considerably atrophied, so that the anterior part of the acromial portion seemed to form the anterior border of the muscle. The middle and posterior portions, which were strongly developed, gave to the external part of the shoulder-joint its usual convexity. The pectoralis major was also atrophied, yet much more so on the right side. The characteristic movement induced by the muscle in question, of crossing the arms on the chest, was to a large extent limited, and was attended with difficulty. In the right supra-clavicular fossa some swollen glands were remarked.

If the patient was viewed from behind, the abnormal position of the shoulder-blades at once struck the eye. Instead of resting on the posterior part of the thorax, they appeared to be placed on its lateral aspect, and to be rotated in such a way that their outer edge lay horizontally, with the external and inferior angles on about the same level. The inferior angles stood out from the body like wings, an appearance which was still better seen when the patient was viewed laterally. The scapulæ left the greater part of the back uncovered, and their spinal edges, in consequence of the rotation, were convergent downwards. The distance between the centre of the vertebral column and the spinal edge of the scapula was, at the level of the latter, on the right side fourteen centimètres, and on the left twelve centimètres. The rhomboidei were considerably atrophied on the right side, being scarcely noticeable; on the left side they were present, although attenuated. The supra-spinous fossæ were flattened, the right even somewhat sunken. No obliquity of the spine was remarked.

Of the four principal movements which concern the entire shoulder considered as a whole—namely, elevation, depression, forward and backward motion—the first, or elevation, could in some degree be performed: that is to say, so far as to bring the clavicle into a horizontal position. This limitation in movement was due to weakness in the most superior, or elevator, portion of the trapezius muscle. The action of depression (by means of the pectoralis minor and latissimus dorsi) could be normally effected. The power of movement forwards was diminished by reason of the atrophy of the pectoralis major. The backward motion, or that of approximating the scapulæ to each other, was possible on the left side, since by this movement the border of the rhomboideus major is brought into play. As the inferior portion of the trapezius was atrophied also on the left side, the motion in question could not, however, be performed with full effect. On the right

side this movement was quite impossible, in consequence of the complete atrophy of the rhomboideus and of the inferior portion of the trapezius.

The movements of the arms were also considerably interfered with; the patient could not raise them to an angle of more than forty-five degrees from the trunk. In attempting to raise the arm higher she bent the spinal column. In this movement the above-mentioned rotation of the scapula became more pronounced; the acromion sank still further, the inferior angle rose, and approached the spinal column. At the same time the spinal edge of the scapula and its inferior angle diverged yet further from the thorax, so that the wing-like appearance of that bone increased considerably. The superior and internal angle was also elevated, becoming thus on a higher level than the clavicle. The middle portion of the trapezius and the levator anguli scapulae ran from it like a band along the neck. When it was attempted to compensate the lost action of the rhomboideus and serratus magnus by pressing the scapula against the back, and by bringing the inferior angle outwards and downwards, the patient could lift the arm almost into a perpendicular position. She could bring the left hand up on the right acromion, but not *vice versa*; crossing of the arms in front of the chest was all but impossible. In attempting to execute this movement, it was achieved—at least, on the right side—merely by the biceps and coraco-brachialis. The muscles whose function was checked or enfeebled were thus on both sides the pectoralis major, the clavicular portion of the deltoid, the superior and posterior portions of the trapezius, the serratus magnus, and on the right side the rhomboideus. In addition, wasting and paresis of the radial extensors of the carpus on the right side were noticed. The patient was unable to abduct her hand, and in a state of rest she kept it adducted. The ball of the right thumb, too, was thinner and more relaxed than that of the left. The patient could not abduct or extend the right thumb, which remained bent and drawn into the palm of the hand. Electro-motor contractility had totally disappeared in the right rhomboideus, as well as in the inferior portion of the trapezius, and in the serratus magnus on both sides. It existed in the other muscles already mentioned, although lessened in intensity. Neither anaesthesia nor pain was anywhere present. The condition of muscular sensibility could not be tested, in consequence of the limited intelligence of the patient.

The treatment consisted in the employment of the continuous galvanic current. The sympathetic on both sides was also occasionally galvanised. On December 16, 1870, as the galvanisation seemed to be without effect, local faradisation was tried. This was persevered in daily until February 21, 1871, and under it some reaction began to show itself in the trapezius and serratus magnus. The patient herself thought that the right arm was somewhat stronger; she could now raise it to a right angle with the trunk. The result on the left side was similar. A violent spontaneous pain, which was increased by pressure, along the great saphenous nerve of the right side, now set in, and confined the patient to bed, for which reason the faradisation was intermitted. On the 25th the pain removed to the right lumbar region, running down the sciatic nerve. Cupping, injections of morphia, and blisters were employed against this symptom, and the pains, which were extremely violent, had, when this was written, considerably diminished, so that it was possible to recommence the treatment by electricity.

On one seeing for the first time this very disfiguring form of progressive muscular atrophy, the disease produces a deep impression, and time is required for one to make himself familiar with all the peculiarities of the case. At first sight the case might have been confounded with the so-called paralysis of the serratus magnus, as described, for example, by Niemeyer(a) or by Moritz Meyer.(b) But in this paralysis (which is probably always a peripheral neurosis, and depends on an interruption to the conducting power of the long thoracic nerve) the serratus magnus is usually alone affected, and its antagonistic muscles (the rhomboidei) largely hypertrophied (Meyer). Recollecting the characteristic signs of progressive muscular loss of power, the correctness of the diagnosis in the present case could not be doubted. This form of loss of power, for instance, much more frequently attacks the upper than the lower extremities. It commonly appears diffusely, so that the atrophy engages several muscles or parts of muscles at the same time; the ball of the thumb and the interossei are usually atrophied, and the complaint advances bilaterally, although not strictly symmetrically. Further, the paralysis

and atrophy in this disease do not correspond; for muscles which are to a great extent atrophied react, notwithstanding, both at the will and with an electrical current, while others, which do not as yet exhibit a trace of atrophy, are nevertheless completely paralysed.

It is not so long since we were inclined to regard progressive muscular loss of power as a purely myopathic affection—a paralysis from the alienated nutrition of the muscles, in which the loss of power kept even pace with the muscular atrophy, the latter being looked upon as the primary lesion. To Moritz Benedict, of Vienna, especially belongs the merit of having assigned to this peculiar form of disease its correct place. Already in 1863(c) he had shown that the loss of power did not invariably correspond to the atrophy, that a lessening of or alteration in the electro-motor contractility usually precedes the atrophy or paralysis, that the muscular sensibility is also changed beforehand, and that irritative symptoms in the muscles and in the nerves of sensation often precede the development of the progressive atrophy. He had, in consequence, even then supposed that progressive muscular atrophy was a motor neurosis, and he has since, in his "Electro-Therapeutics" (Vienna, 1868), declared that this was undoubtedly a spinal nerve-lesion, closely allied to tabes, inasmuch as a "new formation of connective tissue and a secondary atrophy, or even a primary atrophy, in the nerve-structures of the medulla spinalis" formed the anatomical basis of the disease. The rapidly progressing atrophy in the attacked muscles, characteristic of the complaint, which may terminate in complete disappearance of the muscular element in a very short time, probably depends on an impaired innervation by the hypothetical trophic nerves, which, perhaps in common with the vaso-motor branches, leave the anterior roots of the spinal cord, to follow the paths of the sympathetic nerves. This view is corroborated by the atrophy of the sympathetic in the neck, which is often observed in long-continued progressive muscular atrophy, and also by the favourable result obtained from galvanisation of the sympathetic, when sometimes in the course of five or six weeks muscles which had quite disappeared are completely reformed. I have myself treated a case, where this method strengthened such muscles in a surprising manner. In the present patient the galvanic treatment of the sympathetic has not produced any result, but it is very well known that in many cases of this affection all treatment is without avail.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ST. THOMAS'S HOSPITAL.

OPERATIONS.

The operations on a recent occasion in the male operating-theatre at this Hospital were interesting, two of them as showing to what risk it is justifiable to put the individual in order to remedy some grave local defect, and the others, on the other hand, as illustrating the propriety of removing an organ or limb to get rid of a serious inconvenience, even when the general condition is such as to forbid any hope of a permanent good result. This latter practice, although well recognised, is occasionally dreaded, and an operation which would furnish the only chance of successful issue is sometimes avoided, because of the possible alternative of the operation causing a more rapid death. We remember seeing, some time ago, a young man suffering from disease of the femur with extensive infiltration of pus amongst the muscles of the thigh, who, when brought into the theatre to be submitted to amputation of the limb, was in such a precarious state that it was discussed whether he should not be sent back to bed unoperated upon. The verdict, however, was ultimately against this, the operation was performed, and, after a somewhat slow recovery, he got quite well. Although it is almost unreasonable to anticipate so good a termination in either of the first two cases, yet the course pursued is one to be imitated, and carries great weight with it, owing to the large experience and skill of the Surgeon who operated upon the cases in question.

By Mr. LE GROS CLARK.

Chronic Disease of Knee-joint—Suppuration, with Ulceration of Cartilages and Articular Ends of Bones—Amputation of Thigh.

A man, aged 26, of small and delicate frame, with sallow complexion, and looking in the last stage of decline, had been suffering for two years from disease of the left knee-joint. The affection had commenced spontaneously with the symptoms of chronic synovitis, which had rendered him unable to work for eighteen months, and gradually went on to suppuration. The joint was tapped two or three times about twelve months ago, and a quantity of thin, flaky sero-pus escaped. About two months ago pus extravasated upwards amongst the muscles of the thigh, and a large quantity of unhealthy discharge had since continued to pass away. The phthisical appearances of the patient were not fallacious—a large cavity had formed at the apex of the left lung, and signs of tubercular deposit existed on the right side also; but the disease of the lungs was, at the time of the operation, quiescent. Mr. Le Gros Clark observed that, in spite of the general health of this patient, and the unfavourable prognosis which he could but entertain, he had considered it the best treatment to relieve the sufferer from such a source of pain and weakening discharge, and thus to give him the chance of improvement after amputation. The operation was performed by means of the double-flap method, the flaps being of nearly equal size, and formed by transfixion. Mr. Clark's dresser was then allowed to take up the vessels and pass the sutures into the flaps.

Epithelioma of the Penis—Amputation of Penis.

The patient was 69 years of age, and the disease had been noticed six months. It had observed the usual course of such cases, and at the time of operation the upper surface of the glans penis presented a red, coarsely granular or warty elevated surface, which extended backwards beneath the prepuce, and produced a rounded prominent swelling, the size of a large cherry, beneath the thinned and purple-coloured skin behind the corona of the glans penis. The glands in each groin were (though slightly) enlarged and indurated; but this, as Mr. Le Gros Clark observed, was probably due to irritation rather than to secondary occurrence of the disease. Mr. Clark could not hold out any great hopes of permanent success, because in his experience the disease almost always recurred after removal by the knife; still, as removal did undoubtedly for the time relieve the patient of a very offensive and loathsome condition, and gave the only chance possible of exemption from death from this cause, he had determined to amputate the organ. The operation was performed with an ordinary curved bistoury, after fixing a phymosis forceps on the penis behind the diseased portion, and grasping the root of the penis between the fore-finger and thumb of the left hand to control hæmorrhage. The amputation was instantaneous; the arteries were taken up individually and ligatured, and the patient removed from the theatre within a very few minutes. Mr. Le Gros Clark remarked upon the tendency to secondary or reactionary hæmorrhage after this operation, to obviate which he had secured all the bleeding vessels; those ligatured were the two dorsal arteries—the artery of the corpus cavernosum on one side, and a small vessel in the corpus spongiosum. The division was made without the presence of a catheter or bougie in the urethra, and the cut through the urethra was made on the same plane as through the rest of the structures, as Mr. Clark does not recognise any advantage in leaving it longer and stitching it over to the skin.

By Mr. MACCORMAC.

Two Cases of Excision of the Knee-joint for Chronic Disease of the Cartilages and Bone.

Mr. MacCormac remarked that these two cases were very similar in many respects. In both the disease had existed about two years, and had resulted in such mischief to the joint as to require excision. Both the patients were boys, and of nearly the same age, and in both he expected to find disease of the cartilages and articular end of one or both bones.

Case 1.—In this little patient the leg was ankylosed at nearly a right angle with the thigh, and the tibia was partially displaced backwards. Caries had taken place, and pieces of bone had been passed at intervals through some sinuses, the scars of which were still apparent around the joint. The knee measured one inch and a quarter in circumference more than the other, and was completely spoiled for all functional purposes. Any effort to correct the malposition would, Mr. MacCormac thought, almost certainly promote a new unhealthy action in the part. The disease was, however, at the time quite quiescent. The joint was excised in the usual manner by means of an oval-shaped incision from condyle to condyle, and the

patella was dissected from out the flap. A small abscess-cavity was found in the inner head of the tibia, and the wall of this was gouged out. Owing to considerable contraction of the hamstring muscles, a second small portion of bone had to be removed from the posterior portion of the end of the femur, and then the surfaces came into excellent adaptation.

Case 2.—The disease in this case had arisen from an accident six years ago. There was some contraction and flexion of the joint, with considerable tenderness and pain over the inner head of the tibia, which was, no doubt, Mr. MacCormac observed, the chief seat of the disease. The operation was performed in the same way as the other (excepting that only the articular surface of the patella was removed), and the cut surfaces of bone came together as accurately as though they had been planed. Besides a small quantity of pus and grumous material in the soft parts in front, the inner head of the tibia contained a sequestrum the size of a hazel-nut, very close beneath the articular cartilage, which was soft, pulpy, and of a dirty-red hue where it covered in the dead bone.

In each instance the operation was performed under the carbolic spray, and the wound was enveloped in carbolic gauze after the edges had been brought together by carbolised sutures. The splint employed in these cases was the same as that in general use at St. Thomas's for knee excisions, and was very admirably adapted for the purpose. It consists of a long, grooved, straight splint of iron, with a foot-board fixed by a screw, and a cross-piece at the lower end to steady it. It is made to reach upwards to the thick part of the thigh, and is interrupted at the position of the knee, where a straight flat piece passes from the under surface of the lower to the under surface of the upper portion. It resembles, in fact, a straight "McIntyre," interrupted at the knee, and without the screw behind. Into this gap, at the situation of the wound, is passed a piece of stout lead-sheeting, cut nearly in the shape of a Maltese cross, having two of its ends long enough to rest in the grooved leg and thigh portions; the other two ends project laterally, and permit of being turned up to keep the dressing in contact with the wound, but at the same time allowing the escape of any discharge at the angles of union of the transverse with the vertical arms of the cross. By this means the dressing can be changed as frequently as desired, without in any way disturbing the limb, by merely removing the lead-sheeting and its pad, or turning down its lateral ends and withdrawing the pad from between it and the popliteal space. But besides this, in order to steady and prevent twisting of the trunk, a vertical piece, about two inches broad, passes from the outside of the thigh portion, to which it is fixed by a screw, upwards nearly to the axilla; this is padded, and to it, by means of a broad chest-belt, the body is kept attached.

CHARING-CROSS HOSPITAL.

CASE OF SYPHILITIC HEMIPLEGIA, WITH CLINICAL REMARKS.

(Under the care of Dr. SILVER.)

E. S., aged 44, twice married, and the mother of nine children, was admitted into Charing-cross Hospital, complaining of loss of power of the left side. During her former husband's lifetime she was healthy, and her children, born at the proper time, were well-nourished and healthy also. But six years ago her former husband died of consumption, and no long time after she married again. About three months after her second marriage she had a sore throat, which remained bad for some weeks; and on examination cicatricial marks are still to be seen at the junction of the soft palate with the hard. Since that date she has had several times what she calls "boils" come out over her body; and though she has been pregnant six times, she has never been able to carry a child to the full period, usually miscarrying about the third or fourth month. Her health has, however, been fairly good, and she seems well-nourished.

Three years ago she had bad eyes. They were, she says, sore inside, and she had drops introduced into them by way of treatment. Since that time her sight has been bad, especially on the left side, the pupil of which is now considerably smaller than is that on the other, and its iris appears to be fixed.

About ten weeks ago (now October 6, 1871) she began to feel a numbness down the left arm and left leg. The feeling went away in a few minutes, leaving behind it a slight sensation of faintness, which caused her to sit down, but speedily passed off. She was never unconscious. Since that time her left arm and leg have never been so strong; but she could use them

up to the time of her admission, a fortnight ago, though they were daily getting weaker. Since her admission she has got rather worse, and now can hardly move either arm or leg. She has felt some tingling on the left side of the face, but she has never squinted, nor has her face been drawn to one side. Asked to protrude her tongue, she does so readily and perfectly evenly. She can feel quite well on the affected side; but the warmth of a bottle is more readily appreciated with the right foot than with the left. She suffers from pain on the top of her head and forehead, and her memory seems a little confused. Asked to get out of bed, she has to lift her left leg; but, once upright, she can throw it forward from the knee (not by swinging the pelvis merely), and can bear some weight on it; so that by the help of a stick she can progress a short distance. There are sores on both legs and thighs, and the marks of old sores on her shins.

Dr. Silver, in pointing out the case to the students, said:—We have here to deal with an imperfect form of paralysis affecting one lateral half of the body—what we term hemiplegia. This much is apparent to all; but though paralysis be no unimportant matter, it is but a symptom, though a symptom rising almost to the dignity of a disease. It is our duty, therefore, to find out the cause of this symptom—the nature and seat of the lesion which gives rise to this paralysis.

But first let us try to bear this in mind: the paralysis does not arise from anything wrong with the muscles—they are capable as ever of responding to the stimulus of the will—it is the stimulus itself which is wanting. We must seek for the lesion in the nervous system; and, in doing so, we must not forget that in nerve lesions the site of the disease is everything—the kind of disease is, comparatively speaking, as nothing. There are not wanting here hints, so to speak, as to the site of the lesion, at all events, within certain limits. First, then, intelligence is not impaired, and sensation is not lost; she even retains in some degree the power of motion. It is probable, therefore, that neither of the great centres, the hemispheres, the optic thalami, nor even the corpora striata, in which reside these powers respectively, are implicated. Other reasons could be given for the same belief; meantime, let these suffice. Let us, therefore, conclude that the nerve-currents are rather intercepted in their course than stopped at their origin.

But, again, it is plain, seeing that one lateral half of the body is affected, that the seat of the lesion is above the level of the nerves supplying the upper extremities; and as there is neither paralysis of the facial nerve, nor of those which preside over the important functions of swallowing, phonation, and respiration, we are fain to conclude that it must be above the level of the medulla oblongata, where are the centres which preside over these. There is, in truth, but one nerve of the face affected—if, indeed, we can say it is affected at all—and of that only one branch. She complains of tingling in the left side of the face. This may mean something, or it may mean nothing; but, concluding that it does mean something, it indicates interference with the middle branch of the trigeminus. Neither the motor root nor branch is affected, that is plain, for she can move her jaws smartly in any direction; nor is the sensory portion of the same interfered with, for her taste is perfect. The function of the middle portion only is interfered with, and that but to a slight extent. That, however, may give us a hint as to the site of the lesion, which would be far enough down the tract connecting the great centres with the smaller ones—the brain proper with the medulla oblongata and spinal cord—to slightly interfere with the sensory root of the trigeminus, but not with its motor portion. Furthermore, in this case motion is more affected than is any form of sensibility (the sense of temperature seems most impaired); are we, therefore, to conclude that the motor tract is interfered with to a greater extent than is the sensory? Most probably; for though in most cases of paralysis sensation goes last and returns first, it is hardly usual to see such a wide difference between the degrees of interference without some corresponding difference in the seat of the lesion.

But the said lesion, what is it? The symptoms we have been considering are merely the symptoms of *pressure* on a portion of the cerebro-spinal nerve tract: we must try to find out what is the cause of the pressure. As far as the paralysis is concerned, any one of half a dozen things might produce it. Practically, however, we are reduced to two things, with a very strong presumption in favour of one of them. These two are, a blood clot or a gummy tumour—in all probability the latter. No one can listen to such a history as has just been read without being struck with the unmistakable evidences of specific disease supplied by it. Here is a healthy woman, who, during her former husband's life, had borne many healthy children,

married to another man not long after the former's death. Within three months she has persistent sorethroat—not a slight quinsy lasting for a day or two, but a sorethroat lasting for weeks, and leaving behind it permanent traces of ulceration. Since that time, though six times pregnant, she has never borne a living child, but has regularly miscarried—she who bore many healthy children before. Furthermore, she has skin eruptions—vaguely called boils—which leave behind them permanent marks. And, as if to crown all, she has had iritis, with adhesion of the iris, and permanent impairment of vision. Such a history cannot but be read in one way: there is but one disease which could produce such a train of symptoms, and that is—*syphilis*. Now, we know that at one particular stage syphilis gives rise to new growths, called gummy tumours or gummata, in various organs. The nervous system is not exempt from—is, indeed, a common seat of—these; and there, in common with other foreign substances, they produce pressure, with its ordinary result—*paralysis*. In this way are produced many of the anomalous forms of paralysis we encounter; but it is not in every instance we have a history so clear as this, which has enabled us unhesitatingly to describe the case as one of *syphilitic hemiplegia*.

And now, what are we to do for the relief of the patient? That, also, if our diagnosis be correct, is clear—at all events, we have acted on it—and here you see the woman is taking thirty grains of iodide of potassium three times a day. This we are accustomed to give with good effect in similar cases, and we hope by its means that in course of time the obstacle will be cleared away, and the nerve-current resume its wonted course. Meantime, we must do something more—we must try to keep the paralysed parts as nearly as possible in a healthy state, so that, when again the nerve-current enters them freely, it may find everything ready to respond to its stimulus. We must try to keep the muscles from degenerating through torpidity; we must try to keep them provided with a due supply of nutriment, and to have their effete particles swept away. This we can only do by exercising them; and to this end we call in the aid of galvanism. By means of the interrupted current we can cause these paralysed muscles to contract at will, and thus we may save them in comparative health to await the hoped-for return of their natural stimulus—the nerve-current set up by the will of the patient. Had we the means, we should prefer to use the constant current; but this for the present must suffice.

HIGHGATE INFIRMARY.

SURGICAL CASES.

(Under the care of Dr. STRETCH DOWSE.)

Chopart's Amputation for Perforating Ulcer of the Foot.

E. D., aged 55, was admitted on February 13, 1871, with an ulcer on the plantar surface of the foot in the metatarsal region. The history was, that some months previously she trod upon a flint stone, which perforated the sole of her boot, and produced an abrasion on the bottom of the foot. For some time she was confined to the house in consequence of the pain it gave her. Ulceration came on, which did not yield to treatment. Upon her admission there was a large irregularly excavated ulcer, extremely painful, discharging a thin, unhealthy, putrescent pus, and accompanied with a general doughy swelling of the fore part of the foot. As there was a decidedly syphilitic history, anti-syphilitic treatment was adopted, with no good result. Upon probing the wound, an extensive sinus was discovered, running backwards and upwards, communicating with the cuboid and cuneiform bones, which were roughened. Finding treatment of no avail, Dr. Dowse removed the foot by Chopart's method. The flaps united readily with the carbolic dressings, and the patient has now a good useful stump.

Removal of Necrosed Fibula.

F. S., aged 10, was admitted on May 13, 1871, suffering from an ulcerated leg, for which she had been under treatment for years. Upon examination, the limb was found generally swollen and tender. On the outer side, about the middle, there were two indurated ulcers, from which a fetid discharge with pieces of dead bone made their escape. Dr. Dowse cut down freely upon the bone from the styloid process to the outer malleolus, and removed the entire shaft between the epiphysal ends. The wound was dressed with lint and carbolic oil. It healed rapidly without a bad symptom. The child, who was greatly emaciated before the operation, is now in good health, and has free use of the limb.

Removal of Breast for Scirrhus.

M. F., aged 50, was admitted on August 7 with cancer of the breast, which was non-adherent to the integument. Dr. Dowse removed the tumour, and perfect union followed by first intention without antiseptic dressing. The patient was up, and said she was quite well, five days after the operation.

SATURDAY, OCTOBER 21, 1871.

ENGLISH AND GERMAN VIEWS OF THE PATHOLOGY OF ADDISON'S DISEASE.

In the year 1855 Dr. Addison first published to the world his paper on the Constitutional and Local Effects of Disease of the Supra-renal Capsules, but several years previously he had read a paper on the subject before the South London Medical Society. In the quarter of a century which has elapsed since the attention of the Profession was arrested by the originality of Addison's observations and deductions, the sands of Medical opinion have been in a shifting state as to the true pathological nature of the disease which bears his name. It is evident from some paragraphs in his original paper that Addison believed that any disease or degeneration of the supra-renal capsules, whether tubercular, cancerous, or otherwise, would be followed by the peculiar train of symptoms which he described. Subsequent observation, however, soon proved that this was a mistake. Cases of cancer of the supra-renal capsules were observed, in which there was no bronzing of the skin; and, on the other hand, cases of discoloured skin were noted, in which, after death, no disease of the supra-renal capsules was detected. On the Continent suspicion was thrown on the whole of Addison's generalisation. German pathologists—and, amongst the latest, Rossbach, of Würzburg—have denied any special connexion between what they are pleased to term Addison's disease and disease of the supra-renal bodies. In this country the labours of Wilks and Greenhow, recorded in the *Transactions of the Pathological Society*, have done much to clear up the difficulties which subsequent observations have grouped round the great English pathologist's discovery; and now, Dr. H. M. Tuckwell has published a masterly paper on the subject in the volume of St. Bartholomew's Hospital Reports which has just appeared. Dr. Tuckwell disposes completely of Rossbach's attempt to relegate the well-defined disease which Addison described to the unsatisfactory group of neuroses—a train of symptoms (*Symptomen complex*) depending on cerebro-spinal disturbance. In the first place he shows that a case described by the German

pathologist was not a case in any real degree resembling Addison's disease, it was a case of scleroderma of the skin, with fatty degeneration of the heart and kidneys; and secondly, he answers the objections—"that the train of constitutional symptoms and the bronzing may be present without capsular disease, and that disease of the capsules has often been found after death, without any general symptoms of bronzing having manifested themselves during life"—by insisting on the fact now pretty firmly established by the labours of Wilks and Greenhow—viz., that it is not every alteration or degeneration of the supra-renal capsules which is associated with bronzed skin and debility ending fatally, but one peculiar pathological condition, which, whether it be termed scrofula or tubercle, he describes as "active hyperplasia of fibrous tissue and cells, followed by caseation." Dr. Greenhow first pointed out that Addison's disease is due, in a hitherto quite unsuspected degree, to the extension of inflammation to the capsules from diseased or injured adjacent parts, in persons of a tubercular diathesis. Enlarged glands are commonly enough found round and about the capsules, and evidence of old inflammation in the abdomen and of miliary tubercle and cheesy deposits in the lungs and elsewhere is frequently to be obtained. But there is still a farther step in the pathology of this disease. Wilks and Habershon have pointed out that the sympathetic plexuses surrounding the diseased capsules are implicated in true cases of Addison's disease, and they are disposed to refer the symptoms rather to the implication of the sympathetic branches than to the diseased condition of the capsule itself. In three cases out of four dissected by Dr. Tuckwell, he found thickening extending from the surface of the capsule to the supra-renal plexus, the semilunar ganglion, and thence up the great splanchnic nerve. In the fourth case, enlargement of the neighbouring glands interfered with a satisfactory dissection of the nerves. The thickening was rather an hypertrophy of the fibrous investment of the nerves than an alteration of the nerve-fibres. The observations of Dr. Tuckwell, therefore, go to confirm the opinion of Drs. Wilks and Habershon, and they have great interest in connexion with the influence which the nervous system seems proved to exert over cell-nutrition, and especially pigmentation. The experiments of Lister, which showed that in frogs the nerves of a limb exert direct influence on the pigment cells of the skin, the observation of sudden pigment-changes in the hair and skin under the influence of mental emotion, and the bronzing of the skin in Addison's disease, where the sympathetic system is profoundly implicated, may perchance be all phenomena governed by the same physiological law, and may perhaps point to a path hitherto unsuspected by both physiologist and pathologist. The interest of Dr. Tuckwell's valuable paper is not lessened by the fact that a national and pardonable feeling is aroused by attempts to detract from the value of the most remarkable generalisation of a great English pathologist.

HOMŒOPATHIC DEFINITIONS.

AGAIN what in Scotland they would call our "kittle"-tempered contemporary, the *Homœopathic Review*, is wroth with us; but really this has happened so often that we begin to think it possible to survive several attacks of the kind. "Well, what is the matter now?" one says; and we reply it is the old cry, "They are misunderstood and they are misrepresented." Some little time ago—on the occasion of a squabble among themselves—we took occasion to remark on a new profession of faith on the part of the apostles of homœopathy. They told us that specific medication and homœopathy were one and the same; we took the liberty of denying the accuracy of the statement. Most of us so-called allopaths have been accustomed to treat certain diseases specifically, and yet we are not quite prepared to accept the homœo-

pathic creed—still less the universal treatment of disease by means of milk-sugar. One remembers giving mercury in syphilis, prescribing sulphur ointment for itch, giving a dose of colchicum for gout, and so on; but, with all due deference to our homœopathic brethren, that was done before Hahnemann was heard of. It is one of their pleasant delusions that nobody knows anything about homœopathy save those who practise it, and that we poor journalists are, above all others, ill-informed on the subject. Does it never strike them that it is possible to study homœopathy and deliberately reject it? People nowadays do read works on alchemy and astrology, and “Moore’s Almanac,” with the prophecies of Zadkiel, without necessarily believing them. So of homœopathy. Homœopathic works are not absolutely convincing, nor, let us add, altogether reliable—witness, as honest homœopaths do admit, Hahnemann’s highly imaginative “Materia Medica Pura.” We have studied these works as far as they deserve study, and we have come to the conclusion that its principles are false—its practice either a delusion or an imposition. We do not deny that the physiological testing of remedies is good; nay, we will say this: their mode of preparing mother tinctures might be usefully adopted for general use—it is better than ours; but if a man talks to us of the wonderful effects of the 800th dilution of anything, be it what it may, we can only look on the individual as an idiot, or something worse. Why, the atmosphere we breathe in town must habitually contain a proportion of almost all mineral substances, including arsenic, infinitely greater than this, and yet its medicinal effects are not particularly striking. The thirtieth dilution contains only an infinitesimal portion of the mother tincture or solid substance, but the 200th or 800th dilution we simply cannot conceive, nor the possibility of making it, still less its effects. When, moreover, the original substance is inert, or nearly so, this subdivision must deprive it of any force it ever possessed—except we suppose that the mechanical work of trituration adds to its efficacy—a superstition we are not inclined to adopt.

They tell us it is the patient that must be considered, not the disease. This to us is no new doctrine, for it is one we have long taught and practised; but when we are told that quinine is homœopathic to ague in some individuals, and not in others, we again beg leave to hint that this is new ground for homœopaths. We are told that Dr. Bayes found quinine homœopathic to the majority of cases of ague in Cambridgeshire: and we are compelled to say that this is not in accordance with homœopathic doctrines. Homœopathy allows a man to acquire a certain expertness in selecting an appropriate remedy for a disease, but it does not permit the acquisition of experience as to the effects of a remedy in diseased states. It is a fundamental doctrine in homœopathy, that, to acquire a knowledge of the effects of any drug, it must be studied in the healthy subject. The totality of its symptoms are noted down, and from them it must be judged whether the drug is *simile*, *similius*, or *simillime* to a given sample of disease. To say, therefore, that experience shows a given substance to be homœopathic to a given disease is clean contrary to Hahnemannian doctrines. True, it may be specific; but it would not suit our friends to admit that it was specific without being also homœopathic. They desire to make use of the remedy, and strive to get it into their system, which, provided they adhere to their original dogmas, they cannot honestly do. This is why they would fain make specific medication and homœopathic medication one and the same thing. This is why they tell us a specific must also be homœopathic; but we could easily point out a dozen remedies which are specific in certain diseases, but which do not produce any symptoms at all resembling that disease in the healthy individual. When homœopathic professors have disproved what has been publicly stated as proved by Jörg, by Rogers, and by Carroll, of New York, we may care to meet them again on this ground; meanwhile it would be a waste of words.

THE WEEK.

TOPICS OF THE DAY.

DR. J. W. OGLE, of St. George’s Hospital, has been appointed Inspector of Anatomy in England and Wales, in place of the late Dr. Cursham.

The article in a Medical contemporary to which reference is made by Dr. Cayley in a letter which we to-day publish, has given rise to a feeling of natural and just indignation amongst the staff and students of the Middlesex Hospital. Dr. Cayley’s letter renders it scarcely necessary for us to say that there is not one word of truth in the insinuation that the Middlesex Hospital has become a mere secondary establishment to University College, or that the former is anxious to receive and provide for the students who overflow from Gower-street. The Middlesex Hospital has an independent and excellent school attached to it, and it has never lacked, and is not likely to lack, pupils to fill its vacant offices.

Professor Balfour, as Dean of the Medical Faculty of the University of Edinburgh, has been under the unpleasant necessity of notifying to the female Medical students, who have recently disturbed the Northern Medical world, that their names and their fees have been received in error for the First Professional Medical Examination, which takes place in the present month. He adds, that the Faculty cannot receive them for such examination without the sanction of the Senatus Academicus. As well-wishers to the University, we can only hope that the sanction of the Senatus Academicus will never be given. If it be given, we shall confidently expect that the male students will migrate, and leave the female to graduate by themselves.

No one can read Mr. Erichsen’s recent letter in the *Times*, on the piracy of his book by the American Government, without indignation. In the American civil war the American Government furnished the Medical staff of the army with 58,074 volumes of Medical works. The two principal items on the list were Mr. Erichsen’s “Principles of Surgery” (5370 copies) and Bumstead on “Venereal Diseases.” These copies of Erichsen’s “Surgery” were not one of them supplied by the publishers of that work in this country; they were, in fact, an American pirated edition, and a robbery of Mr. Erichsen to the amount of from £2800 to £3000. Mr. Erichsen wrote a most courteous letter stating the facts of the case to Mr. Adams, then Minister of the United States in this country, and received a reply, in which the Minister said he had great pleasure in transmitting Mr. Erichsen’s letter to America. He added—“The question of international copyright is one which has been already much discussed in America, but I doubt whether the period for successful negotiation about it has as yet arrived. This is certainly an argument in point.” There the matter has been allowed to remain for the five years that have elapsed since the correspondence. No answer has been returned from the American Government. Meanwhile, Mr. Erichsen has the barren satisfaction of knowing how highly his work on Surgery is esteemed in America.

Several of the papers read at the recent meeting of the Social Science Congress at Leeds have been of special Medical interest. Mr. Dalby, the Aural Surgeon of St. George’s Hospital, communicated one on “The Education of the Deaf and Dumb by means of Lip-reading and Articulation”; and he was followed by Mr. Van Praagh, who has lately introduced the lip-reading system into England, and who was accompanied by Mr. Polano, of Leyden, a deaf and originally dumb gentleman, who readily conversed with anyone who spoke the languages which he had learned. The remarkable success obtained by this method was made a principal topic in Sir John Pakington’s concluding address. Mr. Dalby, in his paper, stated that—

“The education of a child by ‘lip-reading and articulation’ commences at the age of 7, and eight years are required before general conversation can be read from the lips of those who

speaking with no more than ordinary clearness and precision. The time occupied is considerably more than for the ordinary English system; but Mr. Dalby argued that this disadvantage was one to which only small weight should be attached, when it was considered that the pupil was enabled to understand and speak the language of the many, while a deaf-mute who is dependent upon manual signs possesses only the language of other mutes, and of the comparatively few persons who have acquired the art of conversing with them. It appears to be quite impossible to combine the two systems; for it is found that a deaf child who can make himself understood by his fingers will not have perseverance to acquire the art of speaking in the ordinary way. Nearly twice as many teachers are required by the new system; but great experience is only needed from those who undertake the commencement of the instruction."

Mr. Polano's facility in comprehending others and speaking was put to the test by a gentleman named Huth, who spoke German to him in the presence of the meeting. Mr. Huth wore a heavy moustache, but nevertheless Mr. Polano was able to understand with ease and answer intelligibly. Mr. Van Praagh conducts a school for deaf mutes, on the lip-reading system, at 164, Euston-road. Dr. A. P. Stewart read a paper "On the Progressive Degeneracy of Race in the Town Population of Great Britain." He based his conclusions on the returns of the army, which showed an increasing number of rejections of recruits on account of physical unfitness, and on the inferiority of the class of men admitted into the ranks of militia regiments. Increasing dearth of food, intoxicating drinks, indoor employment, and overcrowding and bad house accommodation are the causes which, according to Dr. Stewart, are rapidly sapping the vigour of the English race at home.

Dr. Foster, the new Fellow of Trinity College, Cambridge, is the first Physician elected a Fellow since the passing of the Act for the Abolition of Tests; but for the passing of that statute he would have been ineligible for election. He is a graduate of Medicine in the University of London, but has had the honorary degree of M.A. conferred upon him by the University of Cambridge. He is Prælector in Physiology at Trinity College, and the distinction of the Fellowship has been conferred on him on account of scientific merit.

The post-mortem in the case of the Stockwell murder was conducted by Dr. Rugg, who was sent for when the catastrophe was discovered, Mr. Edward Pope, the divisional Surgeon, and Dr. Samuel Day Goss. They found extensive wounds of the head, fracture of the skull, and extensive extravasation of blood between the convolutions and at the base of the skull. The liver was small and cirrhotic; the stomach contained half a pound of partially digested food; the kidneys were small, flabby, and congested. There were bruises about the body. Dr. Rugg deposed at the inquest that in his opinion the pistol which was found with blood-stains upon it might have produced the wounds.

The fatal cases of small-pox in London last week were 61. In the previous three weeks they had been 89, 51, and 72. There were 69 deaths from diarrhoea, of which 58 were of infants. The deaths from diseases of the zymotic class were 271, against 333 and 288 in the two preceding weeks. Deaths from measles and the various forms of fever had slightly increased, whilst those from small-pox, diarrhoea, scarlet fever, and hooping-cough had declined.

MR. HOLMES COOTE.

THE Profession will hear with deep regret that Mr. Holmes Coote, now Senior Surgeon to St. Bartholomew's Hospital, has, at this early period of the session, been compelled to desist from his labours. His health is in such a critical condition that absolute rest of body and mind are necessary for the time being. This loss will be seriously felt at St. Bartholomew's, and Mr. Coote will have with him the sympathies of all St. Bartholomew's men.

UNION AND PAROCHIAL MEDICAL OFFICERS UNDER THE REGULATIONS OF THE LOCAL GOVERNMENT BOARD.

MUCH doubt often exists as to the qualifications necessary for these officers. Inquiries constantly received show the need for a clear understanding on this subject. The regulations require that to fully qualify a person to be appointed to the office of Medical Officer he shall be qualified by law to practise both Medicine and Surgery; this being established by the production "of a diploma, certificate of a degree, licence, or other instrument granted or issued by competent legal authority in Great Britain or Ireland." As a guide to candidates we give a list of the several Colleges, Societies, and Universities, with the nature of the qualification or qualifications which each bestows—

Name of Authority granting the Qualification.	Nature of Qualification.
The Royal College of Physicians of London	Licence in Medicine and Surgery.
The Royal College of Physicians of Edinburgh	Licence in Medicine.
The King and Queen's College of Physicians in Ireland	Licence in Medicine.
The Royal College of Surgeons of England	Licence in Surgery.
The Royal College of Surgeons of Edinburgh	Licence in Surgery.
The Faculty of Physicians and Surgeons of Glasgow	Licence in Surgery.
The Royal College of Surgeons of Ireland	Licence in Surgery.
The Society of Apothecaries, London	Licence in Medicine.
The Apothecaries' Hall, Dublin	Licence in Medicine.
The Queen's University in Ireland	Degree in Medicine and Surgery
The University of London	Degree in Medicine and Surgery.
The University of Edinburgh	Degree in Medicine and Surgery.
The University of Dublin	Degree in Medicine and Surgery.
The University of Oxford	Degree in Medicine.
The University of Cambridge	Degree in Medicine and Surgery.
The University of Glasgow	Degree in Medicine. Degree or Licence in Surgery.
The University of Durham	Licence in Medicine and Surgery.
The University of St. Andrews	Degree in Medicine.
The University and King's College, Aberdeen	Degree in Medicine.
The Marischal College and University, Aberdeen	Degree in Medicine and Surgery.

This list, we believe, includes all the qualifications at present recognised by the Local Government Board. Should we, however, have omitted any which that Board or the Poor-law Board have recognised, we shall be glad to rectify the omission.

MEDICAL CLERGYMEN.

SOME weeks since we stated that the Bishop of Kingston, Jamaica, had determined, on the presentation of a memorial numerously signed, to ordain Mr. Hugh Croskery, M.R.C.S. Ireland, to the order of Deacon. Accordingly, on Sunday, September 17 last, this determination was carried into effect with some ceremony. The morning prayer was said at 7 a.m. The ordination service commenced at 11 a.m., with a sermon from the Bishop. The text was well chosen—"Preaching the Gospel of the kingdom, and healing all manner of sickness and all manner of disease among the people." The sermon was most eloquent and interesting, and the preacher dwelt at considerable length on the compatibility of the duties of a Physician with those of a clergyman. The ordination has excited much interest in Jamaica and the other West India Islands, and it is rumoured that other Physicians may possibly be ordained. Without disputing the compati-

bility of the duties of Physician and clergyman, we doubt the policy of this combination. In China and some other places Medical missionaries have undoubtedly effected much benefit amongst their patients. The Chinese and others could see and appreciate the value of medicines judiciously employed, or the relief afforded by a well-performed Surgical operation. But the religious labours of these Medical missionaries have hitherto not been so well rewarded as was anticipated. We can readily believe that the influence of the successful Physician may pave the way for the teacher of religion, and procure him a more favourable hearing.

NEW CORONER'S COURT, DUBLIN.

A BOON has been conferred on the citizens of the Irish metropolis by the recent opening of a Coroner's Court and offices. The situation of the building—a substantial stone edifice—in which they are located is most convenient, being in close proximity to the river Liffey, and almost in the centre of the city. On passing through the main entrance, the visitor finds himself in a lofty hall, with a tiled pavement. To the left are the coroner's private room and the post-mortem chamber. The latter is well supplied with the necessary fittings; but in the matter of both lighting and ventilation there is room for improvement. The operating-table consists of a massive slab of black marble, which is hollowed gradually from all sides towards the centre, where a small grating allows fluid to pass into a syphon-pipe communicating with a sewer. Turning to the right of the entrance, we reach the morgue, which is intended for the reception of three corpses. With the situation of this chamber some fault is to be found. It is on the ground-floor, in the south-western, and consequently the warmest, corner of the building, and the ventilation is not all that can be desired, there being windows on but two sides of the room. The dimensions of the morgue, too, are comparatively small. The fittings are, however, very good. Three tables of black marble, supported on granite blocks, are intended for the reception of the dead. At the head of each is a water-spray. Unfortunately, the tables are not, as that in the post-mortem room, hollowed towards the centre, nor fitted with a grating and drainage-pipe. In consequence, the water must drip from the sides of the tables on to the floor, and thence escape by a single gutter at some distance off. Besides the rooms already described, there are urinals and water-closets on the same floor. The Coroner's Court is reached by several flights of stairs. It is nicely fitted up, well-lighted, and has a good, though a one-sided, system of ventilation.

PURE CARBOLIC ACID FOR MEDICINAL USE.

MR. CHURCH, the well-known chemist, calls attention to a method of preparing pure carbolic acid by a method laid by him before the Odontological Society eleven years ago. The best preparations of the acid of commerce are so seldom free from a disagreeable gas-like odour, entirely foreign to carbolic acid itself, as to render the use of the acid in dentistry, and as an application to the throat, objectionable. Mr. Church's method of depriving the commercial article of all naphthalic odour is so simple, and can be so readily employed by the country Practitioner, that we gladly give it greater publicity than it has in the pages of the *Chemical News*. One pound of the best carbolic acid of commerce (the white crystallised acid) is poured into two gallons of cold distilled water, taking care not to permit the *whole* of the acid to enter into solution. With a good sample, if, after shaking repeatedly at intervals, between two and three ounces of the acid remain at the bottom of the vessel used, this will be a sufficient residue to hold and contain all the impurities; with bad samples, less water must be used, or more acid. The watery solution is to be syphoned off and filtered, if necessary, through fine filter-paper till perfectly clear. It is then placed in a tall cylinder, and pure powdered

common salt added, with constant agitation, till it no longer dissolves. On standing, the greater part of the carbolic acid will be found floating as a yellow oily layer on the top of the saline liquor, and merely requires to be removed to be ready for use. As it contains 5 per cent. or more of water, it does not generally crystallise, but it may be made to do so by distilling it from a little lime. The portion collected up to about 365° Fahr. has at ordinary temperatures scarcely any odour, save a faint one resembling that of geranium leaves; and advantage may be taken of this curious resemblance still further to mask the slight odour proper to absolutely pure carbolic acid, by the addition to it of four drops per fluid ounce of the French oil of geranium. This addition has the advantage of liquefying the pure crystallised product. The pure acid may be dissolved in 230 parts of water, and used as a gargle; or in 25 parts of water for painting the throat, or in 50 parts for the carbolic spray. We are sure that the Profession will thank Mr. Church for the introduction of such a simple method of depriving this invaluable agent of its disagreeable odour.

MEDICAL BURSARIES.

COMPARED with the Church, Medicine is lamentably deficient in the aids she receives from bursaries. With one or two exceptions, the English universities have no "exhibitions" for Medical students. Scotland is not in a better position in this respect. It is satisfactory to record that at the half-yearly meeting of the General Council of the University of Aberdeen the subject of bursaries was discussed. Mr. C. C. Brown, in giving in the report of the special committee appointed at the last meeting, relative to Medical bursaries, said the committee was of opinion that the best method of proceeding would be to have a statement drawn up setting forth the great want of bursaries in the Medical as compared with the other faculties in the University, and at the same time indicating the conditions under which such bursaries would be most likely to prove useful. With respect to the latter point, the committee was of opinion that any such bursaries should be open to all, and given by competition; the competition, while embracing the parts of general education, should give prominence to natural science. The committee further recommended that after two years the tenure of such bursaries, for the remaining two years of Medical study, should depend on a satisfactory examination being passed in the earlier branches of the Medical curriculum. The report was unanimously adopted. If the recommendations of the committee be carried out they cannot fail to be of considerable service to the Profession.

THE PATHOLOGICAL SOCIETY.

THIS Society met for the first time this session on Tuesday last, with a goodly attendance of members. In the absence of Mr. Hilton, the chair was taken by Mr. Holmes, and Dr. Murchison did duty for Dr. Dickinson as Medical Secretary. Some very interesting specimens were exhibited, especially one by Dr. Green, of interstitial inflammation of the liver in a child; aneurism of the heart, by Drs. Peacock and Murchison; enlarged lymphatic glands, by Dr. Payne; and certain specimens of hydatids of the peritoneum, which had been removed by Mr. Spencer Wells from the patient's abdomen, with apparently good results. We hope the Society will have a successful session.

THE CLINICAL SOCIETY.

THE Clinical Society resumed its sittings on Friday, the 13th, the President, Dr. Gull, in the chair, when the proceedings partook somewhat of that undue solemnity which has of late characterised its meetings. On taking the chair, the President made some remarks on the work of the Society, which, if somewhat paradoxical, were nevertheless good. He pointed out how useful isolated bits of clinical work might be made, even if not necessarily tied to the history of one or more cases.

Three interesting papers followed—the last, by Mr. George Lawson, exceedingly practical, though giving rise to a theoretic discussion on the local or constitutional origin of cancers. The text was, the use of zinc chloride after the removal of cancerous or malignant growths, especially of the eyeball. Mr. De Morgan pointed out that the practice, though good, was liable to be followed by epileptiform convulsions. For the sake of those members who do attend, we hope that the meetings of this Society will be characterised by a little more vitality and vivacity.

THE LATE DR. BABINGTON, OF DERRY.

Soon after the lamented death of the late Thomas Henderson Babington, M.D., the Medical Practitioners of the city and neighbourhood of Derry resolved to testify in some tangible form the affectionate regard and respect in which Dr. Babington was held by members of his own Profession; and this resolution they have now, after some unavoidable delay, carried out in a manner highly creditable to all parties concerned. A handsome tablet has just been placed in Derry Cathedral to his memory. It is placed in the north aisle, is in the Gothic style, and is formed of richly carved Caen stone, with Sicilian marble panel and serpentine marble columns. It bears the following inscription in early English characters, surmounted by the arms of the Babington family:—

“In memory of Thomas Henderson Babington, M.D., F.R.C.S.I., M.R.I.A., Surgeon of the County Londonderry Infirmary, Mayor of Derry, who died August 2, 1869, aged 56 years. His Medical brethren in this city and neighbourhood have erected this tablet in testimony of their affectionate regard for him as a friend, and as a record of their appreciation of his distinguished Professional attainments and eminent public services.”

TAXATION OF HOSPITALS.

THIS important question has been brought to something like an issue—at all events, as far as those Hospitals which are incorporated are concerned. The magistrates have decided against the rating of the Queen's Hospital, Birmingham. It appears from a statement made at a meeting of the Committee of the Hospital, held last week, that if a distress were made for rates a few goods might be seized in the Secretary's office, and the only thing which remained would be to take the beds from under the patients, which was a contingency the law did not contemplate, and would not be put in force. It is believed that the authorities of the General Hospital are about taking steps to place that institution in a like position to that of the Queen's Hospital.

MEDICINE IN THE PUNJAUB.

MEDICINE has made rapid strides of late in the region of the “Five Rivers.” We are pleased to observe, from the yearly Report of the Punjaub University, or University College, just published, that the institution is in a most flourishing condition. The Report states that the College is engaged in issuing scientific works in Hindustani, including vernacular treatises on Medicine, and a Medical journal, which has an extensive circulation. Twenty hakeems, or native Physicians, attend its classes. The Report, altogether, is a satisfactory document, and gives information on the progress of the College as remarkable as it was probably unexpected.

FROM ABROAD.—SYMMETRICAL ERYSIPELAS—GLYCERINED VACCINE LYMPH.

THE following is an abstract of some clinical observations recently delivered at the Hôtel-Dieu, by M. Noel Guéneau de Mussy, on symmetrical cutaneous affections, in relation to a case of symmetrical erysipelas:—

“The symmetry which prevails as a law in normal organic evolution (he observed) is not infrequently met with in the pathological condition, as manifested by the repetition of the

morbid process in homologous parts of the two sides of the body. Thus, caries of a tooth is often followed by caries of the corresponding tooth, affections of the eye are often double, and in gout and rheumatism, when one joint is affected, we not infrequently find the congenerous articulation suffers likewise, or is soon invaded in its turn. In many cutaneous affections the same symmetry is observed. It seems more easy of explanation in organs to which are distributed the cerebro-spinal nerves, having their symmetrical distribution on each side of the body, and being under the dependence of the strongly centralised innervation having its source in the encephalon. It is, perhaps, here more apparent, but it is also exhibited within the domain of the great sympathetic. Here, too, is found the pathological consensus—sympathies, in the proper sense of the word—between the two halves of simple organs, or between double organs, such as the kidneys or the ovaries. Graves has pointed out one of the most striking examples of pathological symmetry in median erysipelas; and he has laid down the rule, that when erysipelas commences at the median line, it becomes developed symmetrically on the two sides. A case which has come under my notice at the Hôtel-Dieu furnishes so striking and curious a confirmation of the law enounced by Graves, that I feel I ought to relate it.

“In June, 1871, a man entered my service affected with erysipelas of the face, this having commenced on the bridge of the nose and extended symmetrically on both sides. On the third day it occupied the forehead; but external to and below the frontal protuberances there existed two triangular spaces, having sides of two centimètres and a half, within which the skin, pale and depressed, remained perfectly healthy, its normal colour contrasting with the carmine-red of the surrounding parts. The borders which limited the portion of skin unattacked by the erysipelas formed prominent elevations, indicating (as Chomel has observed) that the morbid process was not arrested, and that this portion of the integuments would also be afterwards invaded. On the left side, the external boundary of this triangle exactly corresponded to a linear cicatrix remaining after an old wound of the forehead which had divided the skin throughout its thickness. The right half of the forehead had undergone no lesion, and yet the portion of the integuments unaffected by the erysipelas presented exactly the same form, seat, and dimensions as that which on the left side was contiguous to the cicatrix. The two triangles were of a perfect geometrical regularity, their positions and directions being absolutely alike. On the left side it might be supposed that the interruption of the vessels by the cicatrix may have retarded the erysipelatous fluxion; but on the right side this exemption could only be explained by the law of symmetry. The anomaly, however, was only temporary; for at the end of twenty-four hours the erysipelas had passed the obstacle, and the whole forehead was of an uniform redness, the white line of the cicatrix on the left side alone indicating the place which had been occupied by the triangle the day before.”

We have repeatedly called attention to the remarkable success which has attended Geh.-Med. Rath Müller's employment of glycerine as a vehicle for the prolonged preservation of vaccine lymph, and for the almost indefinite extension of its employment during the period of epidemic visitation. During the late epidemic much of the inconvenience arising from the short supply of reliable lymph, so often complained of, would have been avoided had these results received in this country the attention they deserved.

In a recent communication upon the subject (*Berlin. K. Woch.*, September 25), Dr. Müller points out that the purity of the glycerine employed is of great importance; and that those Practitioners who have complained that the preservative power is only of short duration, have probably employed an impure article. In his hands, lymph, after being kept two years, has produced normal pocks; and in this way he has been able to store up, in the Berlin Vaccine Establishment, of which he is Director, supplies of reliable lymph sufficient for vaccinating thousands of subjects. The demand made for the German soldiers and the French prisoners during the late war could never have been supplied by the means ordinarily in use. Besides this valuable preservative power, Dr. Müller considers that glycerine facilitates the operation of vaccination, dilution of the lymph by its aid producing a far more efficacious, and much more intimate and easily employed, mixture than when water

is employed for this purpose. Nay, according to his own experience and that of many official vaccinators, glycerine lymph acts more certainly and more completely than when unmixed fresh lymph is employed. This he supposes may arise from the coagulability of the blood being diminished by contact with the glycerine, and the lymph thus rendered more easily absorbable.

As already stated, the purity of the glycerine is of the greatest consequence when employed for this purpose, and Dr. Müller's object in the present communication is to point out the means recommended by Dr. Burgemeister, in his recently published monograph on Glycerine, for distinguishing between the mild article suitable for medicinal uses and one of a more irritating kind, not infrequently met with in the shops. Dr. Burgemeister states that if we mix in a test-glass equal volumes of rectified sulphuric acid of a specific gravity of 1.83 and pure glycerine, an elevation of temperature takes place, the mixture in some rare instances becoming of a very pale brown. It is quite clear, and at the very most a few air-bubbles are observed as a consequence of stirring it up. Glycerine which so comports itself is fit for medicinal use. On the other hand, objectionable glycerine, immediately on its being mixed with the acid, gives rise to a development of gas, resembling carbonic acid gas in a clear fluid; and after the gas has been removed and the mixture has been left at rest, a renewed development is produced by stirring the fluid, and this several times in succession—some kinds of glycerine giving rise to the production of more gas than others. From 100 grammes of glycerine, Hager extracted about 6 cubic centimètres of gas, which, on examination, proved to consist of carbonic acid gas and carbonic oxide. Oxalic acid and some formic acid were also found. For medicinal use only glycerine which has undergone purification by distillation should be employed.

From these investigations, as well as from others conducted at his request by the well-known chemist, Schädler, Dr. Müller draws the following conclusions:—1. Glycerine should be colourless, of a pure sweet taste, completely fluid, and miscible in any proportion with water or spirit of wine. 2. Turbidity, or a gelatinous separation, induced by the addition of strong spirit of wine, indicates the presence of gum. 3. Concentrated sulphuric acid should not induce a brown colour or the development of gas; and a further addition of spirit of wine should be followed by no turbidity or deposit indicative of the presence of chalk or lead. 4. No brown discoloration should ensue on heating it with a solution of potass, nor should any smell of ammonia be perceptible.

In mixing glycerine with lymph, an equal portion of distilled water has to be added; but when the lymph has to be preserved for a long period, it may be mixed with the undiluted glycerine, as this will probably preserve it still longer from decomposition, and the water may be then added when the lymph is employed. Dr. Müller, however, in his trials, has not perceived any difference in the lymph treated in these two different ways.

THE APPOINTMENT OF MEDICAL OFFICER OF HEALTH FOR LAMBETH.

(From a Correspondent.)

THE opinions of the vestrymen are about equally divided as to the necessity for the future Medical Officer of Health holding the above appointment to devote the whole of his time to the duties of the office. The parish of Lambeth has a population of over 208,000, covers an area of 4615 statute acres, and is about six miles in length. Although it has not been the practice hitherto in the metropolis to restrict the Medical Officer of Health from private practice, doubtless the present vacancy in Lambeth presents an opportunity for the introduction of a wise principle, and one which, to our minds, would prove alike

satisfactory and economical to the ratepayers. In such an extensive parish an active practical man would find sufficient work to occupy his time in devising every means for preventing disease; and the policy of paying the Health Officer liberally, so as to enable him to devote his time exclusively to the work, would prove but a small expense to save a greater one. Nor if, as suggested by the Social Science Association, the Poor-law Medical Officers are to be utilised as Health Officers, do we see less necessity for the Medical Officer of Health-in-Chief giving his whole time to the work, for such an arrangement would vastly increase his duties. It would be wise for the Vestry to consult their late Medical Officer as to the necessity for such an arrangement. We should be glad to hear his reply.

THE LEGAL LIABILITY OF PERSONS UNDER AGE FOR NECESSARY MEDICAL ATTENDANCE.

MEDICAL Practitioners, who so readily bestow their services in the cause of humanity, frequently without any other reward than that of an approving conscience, deserve, at least, the full meed of protection which the law can afford, and in this respect they are not forgotten. We allude to the ease of patients who in the eye of the law are infants, though perhaps infants of a full growth. In the matter of children residing with their parents or at school, there is no difficulty in recovering charges for Medical attendance upon such, because the contract, as a rule, is made with the parents or tutor; and, indeed, the infant, if living with and properly maintained by, the parent, cannot bind himself to a stranger for even what otherwise might be allowed as necessaries (2 Black. Rep., 1325). But there is a large class of young persons under age living apart from any parental protection—such as officers in the army and navy, young men at the universities, and young persons of both sexes obtaining their own living, and whose exact age it might be difficult to guess. In all such cases the contracts are made with them individually, and can be enforced if for what in the eye of the law are necessaries. Charges for medicine and attendance are very properly in law deemed necessaries, as, indeed, they are in fact, for which an infant is liable (*see* Co. Litt., 172A; Pal., 528; and Cam. Dig., 172A.) Indeed, this principle is well-nigh as old as the hills. Neither does it matter of what nature may have been the complaint under which the patient was labouring. A complaint contracted through immoral courses or vicious propensities requires necessary treatment for its cure equally with one of a purely natural or constitutional character. A tradesman, it is true, cannot recover for goods supplied to a prostitute to enable her to pursue an immoral career, although he may not have looked expressly to the proceeds of her prostitution for repayment (*see* Pearce *v.* Brooks, Law Rep., 1 Excheq., 213; Taylor *v.* Chester, Law Rep., 4 Q. B., 309); but a Medical man can recover for Medical attendance upon her for a complaint resulting from immorality. The law cannot disregard the health of any, but it can, and does, endeavour to check immoral courses, and will lend no assistance to anyone aiding and abetting. Such is the broad distinction, and a Medical man may rely upon every assistance in recovering all fair and reasonable charges in both such cases. An infant husband is also liable for necessaries supplied to his wife (*see* Turner *v.* Trisby, 1 Str., 168) or for infant children (Bazeley *v.* Forder, Law Rep., 3 Q. B., 559; and Bacon's Max., p. 86, edit. 1741). In a judgment delivered in Chapple *v.* Cooper, 13 M. & W., 252, 258 (A.D. 1844), by Baron Alderson, it is stated that "the medicines" which would be deemed necessaries for an infant would "depend on the illness with which he is afflicted, and the extent of his probable means when of age." And even "contracts for charitable assistance to others, though highly to be praised, cannot be allowed to be binding, because they do not relate to his own personal advantage." Medical attendance upon another at the request of the infant—as, for instance, upon an infant officer's servant at his master's request—would not be allowed, because, as Baron Alderson observed—"In all these cases there must be a personal advantage from the contract derived to the infant himself." It might also become a question whether supernumerary Medical attendances at the request of an infant patient, or expensive medicines, beneficial, though not absolutely essential, or expensive appliances which, though conducing greatly to

the patient's comfort, might have found a more economical and equally efficacious substitute, would be considered "necessaries" to an infant of but limited means. But an admission of existing liability, or a promise in writing signed by the debtor upon attaining majority, and before action brought, would in any case amount to a ratification (*see Thrupp v. Fidler*, 2 Esp., 628; *Reeve v. Hopwood*, Law Rep., 4 Q. B., 1). The admission must, however, be voluntary (*Harmer v. Killing*, 5 Esp., 102), and no particular form is necessary. The paper need have neither date nor address, nor need the amount be stated (*Hartley v. Wharton*, 1 Ad. and Ell., 934). Any letter or writing which in effect amounts to the adoption by a principal of the act of an agent will be sufficient in the case of the ratification of a contract made by an infant (*Harris v. Wall*, 1 Exch., 122; and *Mawson v. Blane*, 10 Exch., 206).

THE HAMPSTEAD HOSPITAL INQUIRY.

SEVENTEENTH DAY.

On Thursday, October 12, this inquiry was continued before Mr. Henley and Dr. Buchanan, the Commissioners appointed by the Local Government Board. The case for the defence—*i.e.*, the Management of the Hospital—which had been opened on the previous day by Mr. Montagu Williams, was continued.

The Management Board was represented by Mr. Montagu Williams and Mr. John Humphreys; but there was no legal attendance on the other side.

The Chief Commissioner, referring to the application which Mr. Williams made on behalf of the managers on the previous evening, that the Local Government Board would devise means for continuing the legal assistance to the other side, stated that as yet no answer had been received from the central authority. The Commissioners had considered the inconvenience arising from the course adopted by the complaining persons in withdrawing now, and, in order to secure the attendance of a representative, a summons had been issued to Mr. Kynaston, so as to secure his attendance during the remaining days of the inquiry.

Mr. Williams then continued his speech, commenced on the previous evening, and he again expressed his deep regret that the evidence he was about to produce would not be exposed to the searching and able cross-examination of the counsel who had hitherto appeared on the opposite side. In the course of a very able speech, which occupied about two hours in delivery, Mr. Williams reviewed the voluminous evidence given. He said that beyond all doubt the very men who had brought these charges had proved one of two things—either that they wantonly and negligently stood by and had seen their fellow-creatures greatly suffering without doing their duty by them, or they were actuated by pique in sending these charges to the *Times*. In regard to the first and second charges—those of restraining, the speaker pointed out that not one case of improper tying down had been shown; and, indeed, these men had sanctioned the practice, and had shown the nurses how to carry it out. He commented upon the character of the evidence, as shown by Hunter, the man Palmer, and the woman Haynes, and he concluded by declaring that the public, when his side was heard, would, so far from holding Dr. Grieve or the managers to blame, consider that they merited the gratitude and thanks of the community at large for their beneficent and devoted labours.

Mr. William Henry Wyatt, of 88, Regent's-park-road, was then called and sworn. Examined by Mr. Williams he said: I am a Middlesex magistrate, and, by the nomination of the Local Government Board, a Manager of the Metropolitan Asylums. By the Asylums Board I was elected Chairman of the Committee elected to manage the Hampstead Hospital. In the Asylums and at Hampstead in June we had 2200 beds for small-pox. These were wholly for pauper patients, for our powers went only to provide for paupers received through the relieving officers, and, strictly speaking, no one ought to have been admitted except through relieving officers; but some persons came to the gate, and in the emergency we took them in, regarding this as a public good. Other persons than the pauper class were admitted on relieving officers' orders. The cost for maintenance is thrown upon the parishes; the cost of establishment is a charge upon the metropolis as a whole. In no case has any payment been made to the Hospital; but all charges made for maintenance have been made by the parishes and received by them. In 1869 the Hampstead Hospital was put up in six weeks—so much of it as at first existed; three wards and an administrative block were opened in January, 1870, for

the relapsing fever epidemic which arose in London, and in June, 1870, the Hospital was closed and its staff dispersed. In November, 1870, on a letter from the Poor-law Board, we put the Hospital into order for the expected small-pox epidemic, to which our attention was first brought by Dr. Bridges, the Medical Inspector of the Poor-law Board. The Hospital was opened on December 1 for 120 patients. The staff was approved by the Poor-law Board, and augmented as time went on and exigencies arose by the need of fresh wards being opened. The staff only entered the Hospital on November 28, Dr. Grieve, Mr. Drake (the steward), and the Sisters from East Grinstead being the first who on that day took possession of the Hospital, Sister Frances to be matron, and the other Sisters as superintending nurses. The 120 beds thus opened on December 1 were filled in three or four days, and from that time until the middle of May the demands for admission were most pressing from the parishes, both messengers and telegrams coming hour by hour. The first thing we did was to take Wards 4 and 5, which the year before had been fitted up on the grounds of the London Fever Hospital in the Liverpool-road, at the expense of the Asylums Board, and transfer them to Hampstead, adding them to the other wards there. These were opened on January 1 for seventy beds. Between December 1 and March 1 we had increased the accommodation by 300 beds. Later still we erected huts in the grounds for convalescents, and on May 24 we had 509 patients under treatment. I must add that in all this building it was very difficult to get workmen to come in, there being a great dread of the disease; and no sooner were the workmen out at night from finishing a ward, than beds were put in and filled with patients, so great was the pressure. Each ward had two nurses and a convalescent help for day, and at night one nurse with a convalescent help, and there was a night superintendent. The night superintendent was a superior paid nurse, and should never have been out of a ward for more than two hours at a time—such were her instructions. She came about Easter, and left on August 26. As each ward was opened this proportion of nurses was supplied. We had the greatest possible difficulty in getting suitable nurses, even though we were offering the most liberal wages. That difficulty first induced us to place male convalescent wards under male wardsmen, and the wards so placed were 4 and 5, until the huts were opened, when these wards were made for acute cases. The kitchen and laundry, originally built for 180 patients, were found, as the Hospital increased, to be totally inadequate to the demands, and in February new kitchens, with all the most convenient scientific appliances, were completed for 600 patients. The new laundry was delayed owing to the want of workmen and the delay in the machinery. There was the greatest possible difficulty in getting the linen washed in the old laundry; and as we could not send off linen to be washed outside, our difficulties were greatly increased by the want of laundrywomen. The Committee were:—Dr. Brewer, M.P., Mr. Suter, Surgeon-Major Bostock, C.B., Mr. P. Duff, Mr. R. Furniss, Mr. W. Harvey, J.P., Dr. Jervis, J.P., Mr. J. Marshall, J.P., Mr. A. H. Ross (Chairman of the Middlesex Hospital), Mr. J. B. Sedgwick, Mr. J. C. Swail, Mr. Tavener, and Mr. J. A. Shaw Stewart, J.P. (Treasurer of St. George's Hospital). On the pressure of the small-pox increasing beyond our space, we met and discussed whether we should refuse admissions beyond our space, or whether we should still take patients in, and we were continually obliged to give the parishes notice that they were not to send more, at particular times, until some had left, but they did send, and I have told Dr. Grieve that he should not take patients in thus sent when the Hospital was full, but he rejoined that a second journey would, perhaps, be fatal. It was no benefit to Dr. Grieve to take fresh patients in, for each admission gave him additional trouble, and his only reason for so acting was on the score of humanity. I have seen four or five ambulances, with three or four patients in each, in the Hospital grounds at one time, showing the pressure we were under. We have received at Hampstead more than 5700 cases since December 1, without speaking of Islington. The Committee often met, usually at the Hospital, and went frequently through the wards. Until I went into the country, in August, I used to go into the Hospital three times a week, and stayed there about two hours each time. I used to speak to the patients, and I have spoken to at least 100, and I always went over some of the acute wards. No one ever made a complaint to me of any kind—the only thing approaching one was that a convalescent man in the grounds said the wheeling of a barrow made his back ache. I was often in the "huts," and at least half a dozen times I was there when the patients were at dinner, and no complaints were made as to the food. The

meat contractors at first were Game and Sons, of Cannon-street, and afterwards Baker, of the Meat-market. (The form of meat tender was here put in.) I frequently went into the kitchen where the meat was cooking, and I never saw anything to complain of. We had two male cooks, with assistants, and all the newest appliances. In going over the Hospital I frequently saw the Assistant Medical Officers, and I believe I spoke to them all; but I certainly have spoken, and frequently, to Mr. Greaves and Mr. Kynaston. They never made the slightest complaint to me of anything, and I beg to say most emphatically that any complaint from the most subordinate officer, if in respectful language, and coming through the proper channel, or in any other way, would have received most earnest attention from us. The Hospital was always clean and sweet when I saw it, and proved to be wonderfully well ventilated. I am sure that everything which could be done under the pressure was done; but I should have liked to have had a larger laundry to commence with; that was our only weak point. Reports were made every fortnight to the Board. When I went up to Hampstead I used to see Dr. Grieve, and we talked unreservedly of the Hospital, and I am sure, from all I saw and all I know, that the public are under a deep debt of gratitude to him. I was Chairman of the Committee on July 24, and I can tell you what occurred then in regard to the dismissals. It came to my knowledge that these young men went out of the Hospital without notice, and I told Dr. Grieve that if they did it again he was to suspend them. He gave them notice of this. This was six days before the 24th. At the meeting of the 24th, from what I observed, I recommended the Committee to dispense with the services of these two gentlemen—Mr. Greaves and Mr. Kynaston. There was a discussion as to the form this should take, and the Committee agreed to let the matter go as if the two were to leave because of the decrease of the disease. There was no difference of opinion among the Committee as to dispensing with the services of these young men, but it was decided that, as they were young, and entering on their Professional career, a simple notice should be given. They (Mr. Greaves and Mr. Kynaston) were called into the Board-room and notice given them to leave. They referred to a letter they had sent asking to be heard on charges which they understood Dr. Grieve had made against them, but they were told the Medical Superintendent had forbore to make charges against them, and, therefore, no charges could be entered into. The Medical members of the Committee conversed with them, and told the two young men that they had acted wrongly in leaving the Hospital, as they had done. They made no complaints of these charges even then; not one word. We never told them they might resign, but we dismissed them; and when Mr. Aikman sent in his resignation afterwards it was accepted, and notice given to him of this acceptance the next morning. I never gave authority to ask Mr. Aikman to withdraw his resignation. I produce the prices paid for the goods consumed or used in the Hospital, and from my experience I can say the prices are fair and the contracts fair. We did not go upon the principle of taking the lowest tender. The Committee have held forty-four meetings in the year up to this time, twenty-five of which were held in the Hospital itself. The conduct and devotion of the Sisters were beyond all the praise I could give. I don't like singling out any, but I must say that, being much in the children's wards, I have seen Sister Agnes taking the deepest interest in her charges. Throughout, everything which could be done was done to meet the emergency of the case; and the only thing I would add, after all my experience, if I had to begin all over again, would be to improve the laundry.

The Chief Commissioner: I think I am right in saying that after November 19 last full powers were given to the managers by the Poor-law Board in dealing with the epidemic?

Witness: The Committee said that if they had to apply to the Poor-law Board for leave to appoint every officer they could not do the work so as to meet the emergency, and the Poor-law Board gave us power to go on without an order until June 16, but I think we had a caution that we were not to be extravagant. Dr. Grieve was not responsible for the whole of the servants, for the female staff was put under the Sisterhood, but Dr. Grieve was responsible for the male staff except for the steward's department. Subsequently we provided Dr. Grieve with a clerk for book-keeping purposes; but he had nothing to do with the stores, beyond reporting to the Committee anything he might see, as a Medical man, in those stores affecting the patients. Dr. Grieve never made any application to the Committee for help which was refused, and the same remark applies to the matron. He never, that I remember, said that the staff was overworked, but we knew that the staff were hard-worked,

and that he worked exceedingly hard. If any such application had been made to the Committee, it would certainly appear on the minutes. Sister Frances applied to the steward for all linen, and the steward applied to us. I do not think there was any want of linen; whatever difficulty in respect to linen arose, was caused by the trouble in getting the dirty linen washed. We never refused any application from the steward for fresh linen. The dietaries in the Hospital were made by Dr. Grieve and shown to Dr. Bridges, of the Poor-law Board. The low dietary was not fixed at all under any considerations of economy, and Dr. Grieve's recommendations that extra supplies should be given were at once approved. The meat supplied was quite equal to any meat supplied to the sick in other public institutions, and the best proof that the meat was fit to be eaten is that it was eaten, and, as some have said, more was asked for. The cooks said the meat was good; but once or twice it turned during the very hot weather, and to meet such emergencies we had in store supplies of Australian preserved meat. The milk was contracted for at 1s. a gallon of four quarts. The Committee examined the porter's book to see what the conduct of the Assistant Medical Officers was in respect to out- and in-coming, and have informed their own minds upon these points. Many of the men in Wards 4 and 5 who were quite able to go out, were kept in solely from consideration for the safety of the outside public; they were kept in a sort of quarantine. I never had any complaints from patients about the seventh charge in the *Times*, and I can say, as I have been present at all the committee meetings except two, that no complaints of this were made to them. No request by any officer for stores or anything, I clearly say, was ever refused. We had great difficulty in getting servants.

By Dr. Buchanan: I should not have considered it an act of insubordination if a junior officer had come to the Committee with a complaint the subject of which he had pointed out to his superior. If the subjects of these complaints had existed I think I must have heard of them, for I have frequently seen persons who have been inmates, and they have never complained to me, even though when I saw them they were free from Hospital control. I knew persons were restrained by sheets, and I thought it the kindest thing which could be done for them in their then condition. I never on any occasion had the least complaint of the treatment or food in the Hospital. The books of the steward as to the quantities of things were checked by the clerks of this Board, and by the numbers of patients in the wards. With regard to the responsibility in the Hospital, we consider the Assistant Medical Officers were responsible for the Medical treatment in the wards, and they were to take Dr. Grieve's opinion upon a case. Dr. Grieve would have been held responsible to a great extent, if he had allowed any neglect to go on by the Assistant Medical Officers. In the case of the girl Stokes we should have thrown upon him the chief responsibility for any neglect occurring after the time when his attention was called to the case. As to whether he took proper means of control over the Assistant Medical Officers, I must say I think the Committee had too much responsibility on their hands in taking Islington Workhouse, where Dr. Grieve had to be every day for three hours, away from Hampstead, and, besides that, he had to answer an immense number of letters from patients' friends and from parishes. I did tell Dr. Grieve, after Islington Workhouse was in our hands, that I did not think the Assistant Medical Officers were supervised enough—not from any fault of his, but because we had too much on our hands—and that I would not have the same arrangement again if ever occasion required the Hospital to be used.

The Commissioner: Did you hear of any of these matters of complaint before you saw them in the *Times*?—To the best of my belief we never had any complaints at any time from anyone, except some regarding persons whose clothes were destroyed.

EIGHTEENTH DAY.

On Friday, October 13, the Chief Commissioner, Mr. Henley, stated that the Local Government Board were about to make arrangements by which the complaints—not the complainants—would be represented at the inquiry, and proposed an adjournment till Monday. The inquiry was accordingly adjourned.

NINETEENTH DAY.

On Monday, October 15, the inquiry was resumed, the managers being represented by Mr. Montagu Williams and Mr. John Humphreys, and the complaints by Mr. Collins and Mr. Bucknill.

Mr. Wyatt was recalled, and questioned by the Chief Com-

missioner. He said, with a view to preventing any future complaints in regard to restraint, the Committee have ordered that a record shall be kept of every case in which it may be necessary to restrain a patient mechanically.

Examined by Mr. Collins: Dr. Grieve had had experience of Hospital management. He superintended the Princess Alice's Hospital at Darmstadt during the late war; he was House-Surgeon at Glasgow; he had been a navy Surgeon; and had had private practice in Yorkshire. He was a man of good experience. This I gather from his testimonials, which were very satisfactory to the Committee. He had a salary of £30 a month at first, and he slept in the room afterwards allotted to the Assistant Medical Officers. I do not think £30 a large salary, and I think he should have had more for the hard work he did. We paid his predecessor at Hampstead, in the enteric fever epidemic, a salary of £35 a month, and this I considered fair. I know he was overworked, and the reason why we threw more responsibility upon him, and more work when he was thus over-worked, was because we could not help it. The pressure came, and no other Committee of the Board could be formed to undertake the duty of superintending Islington Workhouse; so when this was thrown upon us, we gave Dr. Grieve another Assistant Medical Officer, and £10 additional salary. Islington Workhouse took about three hours a day of Dr. Grieve's time. The Medical Assistant Officers were paid £12 a month, subject to notice of a fortnight, coming at the end of the month. I was aware of the want of harmony between the Assistant Medical Officers and Dr. Grieve in May or June, and in the latter month the Assistant Medical Officers, I knew, were directed to make their complaints in writing. The reports were laid upon the table, but the Committee never examined them, for they relied upon Dr. Grieve to bring any special matters before the Committee. I have no doubt he would have done so, but there was never anything of the slightest importance in those reports. I never spoke to these young men, although I considered the want of harmony prejudicial to the Hospital. I did not, for a reason which I will tell. I recommended Dr. Grieve to report them, and have the matter investigated. He told me that he had spoken to them, and they had promised things should be amended. I was weak enough to agree to this.

Mr. Collins: We are all wise after the event.

Witness: Yes; this inquiry has opened my eyes in many things as to the conduct of some persons. I asked Dr. Grieve how matters had altered, about a week after, and he said that Mr. Greaves had gone on better, but that Mr. Kynaston had not. There was no complaint, I should mention, of Mr. Aikman. I did not deal with Mr. Kynaston even then, for he had just recovered from his illness, and I thought it would be better to give him a little more time. I did not speak to him, for I have found by experience that it is not advisable to interfere between superior and inferior Medical officers. I often spoke to Mr. Kynaston as to his own general welfare during and after his illness. The Assistant Medical Officers did order eggs for the patients until June 18, when the Medical Superintendent's initials were required to the orders, because an unheard-of quantity had been ordered and consumed the week before; that was the reason that course was adopted. On July 24, when Mr. Kynaston and Mr. Greaves were dismissed, it is likely that I spoke to Dr. Grieve before the Committee met. I am not certain, but I think I was told that these two Assistant Medical Officers were about to ask for an investigation. We did not look into this, for we thought we were doing these young men the greatest kindness in not entering upon any such matters in their position; and if it had rested upon me, I should have dismissed them in a very different manner. They were dismissed because their conduct was insubordinate, and they showed no zeal in their duty. I did not consider them fit for their posts, and I am strengthened in my views by what I have heard here. I now consider they were bad Assistant Medical Officers. The reference in the Committee's report addressed to the "chief officers" in regard to the zeal of the staff did certainly not refer in any way to these Assistant Medical Officers, for I penned it myself, and I can distinctly say this. In regard to the Committee's report as to the reduction of staff, and giving that as a reason for dispensing with the services of those young men, I do not concur in it, and it is not a fact, and was placed on that issue to serve the young men themselves. In a second letter to the *Times* they stated that I had requested Dr. Grieve to express the highest satisfaction with their services, and I must here say that a greater falsehood was never penned. We did not go into any investigation when we dismissed Mr. Kynaston and Mr. Greaves. They had made no complaints, but they asked that charges of insubordination and

disobedience which they understood were to be preferred against them should be investigated in their presence. We told them the charges were not made, and could not therefore be investigated. We dismissed the young men because of what we knew of them.

Dr. Brewer, M.P. for Colchester, Doctor of Medicine, and Chairman of the Asylums Board, was then called and sworn. Examined by Mr. J. Humphreys, he stated that he was at one time chairman of this Hospital Committee, that he generally agreed with the evidence given by Mr. Wyatt as to the arrangements of the Hospital, and that, having gone there very frequently, he could bear witness to it being clean and well ventilated. He deposed to speaking to patients and hearing no complaints of any kind from them regarding the food and treatment in the Hospital. Among those he saw there was Mrs. Fowle (the person who gave evidence on the other side), and he stated that she made no complaint to him. He described her baby as an unvaccinated one (16 months old), and she told him that it had not been vaccinated because the "father did not agree with vaccination." Witness told her the baby could not live, and he described it as having a most fearful attack of the disease. The woman and her infant were in a clean condition, and she had a very light attack of the disease. If the woman had made any complaints they would have been instantly seen to.

Cross-examined by Mr. Collins: I was occupied about twenty minutes with the woman, who was not in physical suffering, but was in mental distress. I examined the child, and found it a mass of disease, and quite unable to swallow. I saw by the bed-card that the Medical treatment was quite unobjectionable. I spoke to Dr. Grieve about the case, and he gave me such answers as to show me that he knew about the case. I did not speak to the Assistant Medical Officer in charge of the case, because I considered it the proper course to speak to Dr. Grieve, who was in the ward, and who was the superintendent. I should not have thought it a breach of etiquette to speak to the Assistant Medical Officer, but in the threatened loss of life I considered it a duty to speak to Dr. Grieve, as the head. I always presided at the meetings of the Board, and always have, with the exception of when I was taken with fever, caught in the Board's duty. I was at Hampstead twenty-seven times, but you will not find my attendances entered as twenty-seven, as I preferred to go at other times than at the committee meetings, and without the Medical officers, so as to hear if patients had any complaints to make. While at Hampstead I tasted the beef-tea made from beef and that made from Liebig's extract, and though I did not like the "extract" tea so well as the other, yet I believe it is better than the meat-made tea. I also saw the meat used, and it appeared good. Taking into consideration the great difficulties under which the Hampstead Hospital was made ready and carried on, I do consider that everything which could be done was done for the patients.

Dr. Jarvis, 32, Connaught-square, a magistrate of Middlesex, a visitor of Hanwell Lunatic Asylum, a manager of the Asylums Board by nomination of the Poor-law Board, Doctor of Medicine, Member of the Royal College of Physicians, M.R.C.S., etc., stated that he entered practice in 1824. He deposed: I heard Mr. Wyatt examined, and I agree with all he stated in reference to the time since April 24 last, when I first visited the Hampstead Hospital. When I visited on April 24 there were about 440 patients. I visited it twice in May, four times in June, and three times in July. On those occasions I went through some of the wards and conversed with several patients. No complaints were ever made to me about the Hospital, or in regard to the seven charges in the *Times*. I have been in the Hospital at the time when the convalescents have been at dinner, once when the dinner was being brought in. I looked at the meat, potatoes, and bread generally whenever I went, and the meat I considered good—as good as I saw anywhere else, and the quantity on the plates ample. The wards were ever clean when I saw them, capitally ventilated, and quite free from the sickening odour of small-pox. The appearance of the patients was quite in keeping with their proper treatment. In the case of the child's head described by Mr. Aikman, it would have been the duty of the Medical man to attend to it. It was essentially a Medical treatment which was required in attendance upon the "crusts" forming in small-pox. Restraint must be adopted for delirious small-pox cases, and mechanical restraint was the kindest treatment which could be adopted. Manual restraint would be most offensive to a patient, and by "tying down," as it is called, or the use of the strait-jacket, ophthalmia and severe-pitting are prevented. Blindness is one of the evils of small-pox. From my own experience, seeing the exigencies of the

situation, I think everything was done which could have been done at Hampstead. I gave no notice of the times when I was going to visit Hampstead.

Examined by Mr. Collins: I have a strong opinion that delirious small-pox patients should be mechanically restrained. I don't say I would do so in lunatic asylums, for padded rooms are better there, but in small-pox the end is to secure the patients from doing themselves an injury. It would be quite right for a nurse to restrain a person at once, but she should report it afterwards to the Medical officer. It would be quite right to restrain a delirious person with a twisted sheet, and I should prefer that to a strait-jacket, and so would anyone of experience. I have used a twisted sheet myself, and I prefer a sheet to a nice silk handkerchief, which would cut into the flesh when tight. The mere "tying down" at four corners would be no restraint at all. Dr. Abernethy used to say that there was more sense in a jack-towel than in a nurse, and he advised a towel to tie the feet. There should be a record-book kept of restraints, but it was not done at Hampstead, for you must remember the hurry everything was done in up there. The pressure was exceedingly great, and I was astonished to see the organisation there was there with the heavy pressure—for they were receiving there three times as many patients every day as any large London Hospital receives on given days only, and with due time for selection and preparation for them. I consider two nurses were sufficient to thirty-four patients where there were convalescents to assist, but not without; and one night nurse would be sufficient with aid from an assistant. In the condition of the wards at that time, with convalescent patients, that number would be quite adequate. It would not certainly be advisable to bathe people at all stages of the disease. It would be better to treat people without bathing them, even though they were admitted covered with vermin; for of two evils I should choose the lesser, and it would be less evil to treat them with vermin than to bathe them. A lunatic and a delirious small-pox patient cannot be compared, for a lunatic would come to little harm by getting out of bed, while a small-pox patient would take most serious harm. I have seen the sheets stained, but that would occur immediately after a person was put into them. I spoke to the patients by themselves, but not one ever complained to me of anything, even though I spoke very encouragingly to them. I am quite sure that the food supplied at Hampstead, and which I saw, was quite equal to that supplied to other Hospitals.

Re-examined by Mr. Williams: I had certainly every reason to be satisfied with Dr. Grieve, whom from my observation I considered a very able and zealous officer.

TWENTIETH DAY.

Surgeon-Major John Ashton Bostock, of 54, Chester-square, sworn and examined by Mr. M. Williams, stated:—I am Surgeon-Major of the Fusilier Guards, and Honorary Surgeon to her Majesty. I have had much Hospital experience. I went through the Indian campaign of 1843, and was in the campaign in the Crimea. Since I have been home I have had charge of the Regimental Hospital of the Fusiliers, containing 100 beds. I never went into the Hospital at Hampstead (and I went there frequently) without going into some of the wards. I took up Dr. Gordon, Deputy Inspector of Hospitals in the Army, as well as some of my brother Medical officers and colleagues. This shows I was not ashamed of the Hospital, and I consider it was one of the best I ever saw. I went into the wards and examined them to ascertain how far they were perfect in sweetness, cleanliness, and purity of atmosphere. They were as perfect as possible, and the lavatories, latrines, and baths were in general in good order. I never heard any word of complaint from anyone. I saw no dirty sheets on the beds, but I saw a heap of sheets as removed from the beds once in a bath-room. The patients were then coming in very rapidly, and I did not think this a surprising occurrence. Once I found a latrine stopped up, which I have found even in military Hospitals. I reported this to Dr. Grieve, who told me it was to be rectified at once, and he knew of it. I examined the bedding and sheets when I was there, and found, as might be expected, that the sheets were soiled by the patients, even though, as I have reason to believe, those sheets were put on half an hour before. The sheets are quickly stained in these Hospitals, and I have heard of as many as five sheets being used in a day to a patient in Stockwell Hospital. I consider it the duty of a Medical officer having charge of a ward to superintend the dressing of bedsores every morning, and, in case of danger to life, to dress such sores with his own hands. That is the custom

in my regimental Hospital (I believe it is the same throughout the army), and was so at St. Bartholomew's. This is the duty of the ward Medical officer. I should not hesitate to employ restraint to delirious patients by means of a strait-jacket or a folded sheet. It is perfectly possible that there were vermin in the Hospital, but I never saw them. I have had experience in vermin, for there were "Crimean donkeys" as well as "Hampstead donkeys"; and I can say that, when patients of the class afflicted with these "things" are once admitted to an Hospital, it is very hard indeed to eradicate them. It might be dangerous to the patients to try to eradicate the vermin.

Dr. Buchanan read from one of the standard text-books of Medicine an opinion that in cases of delirium generally good nurses were required, but that mechanical restraint judiciously applied was of still greater importance, and asked the witness if he agreed with that opinion, and he replied in the affirmative.

In reply to questions put by Dr. Buchanan, the witness said: Holding this opinion with regard to delirious patients generally, there is, in my opinion, a greater reason for the application of mechanical restraints to small-pox patients, considering the state of the skin in that disease, and I think there will not be two opinions about this among persons who have had to do with delirious small-pox patients. A folded sheet is the best means of restraint to use. I would prefer to have a nurse controlling a patient by what is known as "moral means," if the patient is amenable to reason; but I should prefer to have a person who is not amenable to reason restrained by a sheet. A delirious patient could not be restrained by one nurse; it takes three or four men to restrain one man, and these would likewise have to wait upon the patient as well in the intervals of the attack. If there were three or four patients with delirium at one time, it would be impossible to attend to them without mechanical restraint, for the effect of manual restraint in such a case would be to excite all in the ward, and so would injure the patients generally. Manual restraint would not soothe a patient, but would be likely to act contrariwise. It would be nothing surprising for a Doctor to find a patient quiet and in a strait-jacket asking to have it off, and there would be nothing inconsistent in that with the fact that the man might have been in dangerous delirium a few hours before. In all cases a nurse, after restraining a delirious patient, should send for the Medical officer, night or day, for the nurse should not be saddled with a responsibility of this character. I never saw a patient tied down at Hampstead. I prefer a sheet being folded, but a twisted sheet would not be improper, for it could not do much harm. Stains from blood and other things in small-pox Hospitals on sheets cannot be removed even with a dozen washings if the stains are once allowed to dry. (The deposition of Mr. Aikman was here read as to finding the bed sore on the child Stokes.) I cannot well understand a Medical officer finding out a large bed sore of that character on the sacrum without knowing something of its previous history and character. I do not think the Medical officer in charge of a ward absolved from responsibility on account of such a bed sore because the nurse had not reported it; he should have looked out for it, and anticipated its formation. In the then condition of the child (when the sores were formed) mechanical means to prevent contraction of the limbs would have been worse than useless. The Medical Superintendent could not have seen the case as he passed the wards. I do not see how the Medical Superintendent could have seen the case, or have known of it, unless his attention had been specially drawn to it, which should have been done at the period before the bed sores had formed. Mr. Aikman should have reported the case to Dr. Grieve, even if he had only reason to have anticipated a bed sore. Mr. Aikman should have found out the bed sores earlier, and their tendency to form on the sacrum. It is the practice in Hospitals for the Medical attendant—the officer treating the patient—to inspect the skin over the sacrum, and to make applications to prevent bed sores, for this is a most important part of the Medical treatment, as the formation of a bed sore lessens the patient's chance of recovery. I certainly am opposed to the leaving of a pot of white precipitate ointment in the care of the nurses, to be used at their discretion. As a rule, I should leave nothing to the discretion of the nurses. I do not know what stavesacre is, but I should not so leave that or carbolic oil, although this oil would be less likely to do mischief. We do not keep such things in the Guards, for we have none of these things among our men in the Guards.

Dr. Buchanan: But you did have when you were in the Crimea?—Well, we all had them then. And what did you do then?—Well, we didn't write to the *Times* abusing the Commander-in-Chief. We could do nothing. We hadn't shirts to put on, and I never slept in a house for nine months.

By the Chief Commissioner: The diet at Hampstead is a most liberal diet, for I give only six ounces of uncooked meat to a soldier recovering from fever. I think eight ounces of uncooked meat, as on the ordinary diet at Hampstead, quite sufficient for men who were detained there until they were discharged. I saw the meat used in the wards at Hampstead frequently, and inspected it, and can say it was equal in every respect to what the Guards eat in London. The invalids' meat in the Guards is exactly the same as the other rations. I tasted the beef-tea made from the meat at the first opening of the Hospital, and I found it as good as any in London. (It was made from a pound and a half of meat to a pint.) That made from the extract was quite as good medically, though not so palatable as the other. No written reports from the Assistant Medical Officers were ever presented to the Committee. If I had been aware that they were ordered to send in such reports, I should have considered it my duty to look over them. As a rule, I should have one nurse to seven beds, as the proportion for the whole Hospital—that is a liberal proportion. In a large ward of sixty-four children I should have more nurses than in a ward with thirty-four convalescents; but I did not inquire as to the number in each ward. The result of my inquiries about the nursing showed me that with Sisters, nurses, and convalescent help there was fully the proportion of one nurse to every seven beds.

Mr. Williams said all the Committee were there, and Mr. Collins might, if he chose, call any of them and cross-examine them; or if the Commissioners wished to have them called, or any of them, they should be called.

The Commissioners said they did not wish to examine any of the gentlemen; and Mr. Collins said he left his friend Mr. Williams to conduct his case as he thought proper.

Mr. Williams then said he would mention the names of the gentlemen who were ready to be examined as the other members of the Committee:—Mr. William Harvey, the Chairman of the Islington Guardian Board; Mr. A. H. Ross, the Chairman of Middlesex Hospital; Mr. J. A. Shaw Stewart, Treasurer of St. George's Hospital and Chairman of Stockwell Asylums; Mr. Bell Sedgwick, Mr. Suter, Mr. Tavener, and Mr. Marshall. With giving in these names he thought he had carried his case far enough as regarded the Committee of the Hospital.

Elizabeth Meredith, who was one of the nurses at Hampstead, was then called and sworn. She had not found the diet insufficient. The patients never complained of insufficiency, and when she had served the ordinary diet, it was her habit to ask the patients if any wanted more (a second "helping"). Sufficient was sent up for the full quantity for each, and there was always some left for those who could eat more than others. The potatoes were generally good, and the beef-tea was always good. The meat was generally good, but she had once to notice in the hot weather a leg of mutton being a little tainted in the vein, and she told Dr. Grieve in Mr. Kynaston's presence of it. She deposed that Mr. Kynaston had been in the ward where she was when a delirious patient was restrained by being "tied down," and yet did not interfere in the case. She had not made any complaint that her ward was insufficiently nursed, and if she had required assistance she should have reported the fact, and obtained assistance. Witness had received testimonials from Mr. Greaves and Mr. Kynaston. In regard to the fourth charge in the *Times*—"On making the morning visit, we have been informed by the nurse in charge that the patients of her ward on low diet have been kept without food of any kind from 7 a.m. until 3 p.m.," the witness said she never made a complaint to Mr. Kynaston, as he had stated she had, to form this charge. The only foundation he had for saying this was his hearing her talking to the nurse about there being no milk, owing to its having turned sour.

The inquiry was then adjourned.

TWENTY-FIRST DAY.

On Wednesday, October 18, the witnesses examined were the nurses, Elizabeth Meredith and Mary Manning, and Thos. Rose, the under-cook of the Hospital. Their evidence went to prove that the food, in quantity and quality, was good; that there was a sufficient supply of milk; that there was no unnecessary tying down of patients; and that the charges with respect to damp and dirty linen were untrue, that the linen was plentiful and clean. Nurse Meredith acknowledged that on one or two occasions she had not been able to get eggs for patients; and Nurse Manning allowed that two convalescent boys were occasionally put in one bed.

REVIEWS.

A System of Medicine. Edited by J. RUSSELL REYNOLDS, M.D., F.R.S., etc.; Professor of the Principles and Practice of Medicine in University College, London; Physician to University College Hospital. Vol. III.—Local Diseases (continued). London: Macmillan. Pp. 995.

In his preface the editor says—"The delay which has occurred in the appearance of the present volume is due to the fact that the editor did not receive, many months after he expected to do so, the manuscript of those articles which were necessary to complete the section on 'Diseases of the Circulatory System,' several of the papers on which subjects had been for a long time in print." With his woes we duly sympathise, the more so as, doubtless, we are thus deprived for some time to come of the use of several valuable essays on a most interesting subject. The editor also tells us he has resolved to extend the work to four volumes instead of three. Such a course was necessary from the long delay already referred to, and, in point of fact, has long been foreseen if each separate subject was to receive the space justly due to its importance.

The present volume accordingly deals with Diseases of the Digestive System, and Diseases of the Respiratory System:—We have diseases of the mouth, diseases of the fauces, pharynx, and œsophagus, diseases of the intestines, diseases of the peritoneum, diseases of the liver, and diseases of the pancreas. Diseases of the respiratory system are subdivided into those affecting the larynx and those affecting the thoracic organs.

The authors and their works are thus arranged:—Dr. Squarey, formerly Resident Medical Officer at University College Hospital, deals with diseases of the mouth, pharynx, and œsophagus; Dr. Wardell, of Tunbridge Wells, treats of enteralgia; Dr. Bristowe, of St. Thomas's Hospital, takes enteritis, obstruction of the bowels, ulceration of the bowels, cancerous and other growths of the intestines, and diseases of the cæcum and its appendix; Dr. Warburton Begbie, of Edinburgh, takes colic, colitis, and dysentery; Mr. Curling, diseases of the rectum and anus; the next subject, intestinal worms, being treated by Dr. Ransom, of Nottingham. Diseases of the peritoneum follow—peritonitis being handled by Dr. Wardell; whilst Dr. Bristowe takes tubercle and carcinoma of the peritoneum, affections of the abdominal lymphatic glands, and ascites. Of the several diseases of the liver, the following allotment has been made:—Hepatalgia, to Dr. Anstie; congestion of the liver, to Dr. Maclean, of Netley; jaundice, to Dr. Goodeve, of Calcutta; biliary calculi, to the same; suppurative inflammation of the liver, and gangrenous inflammation of the same, to Dr. Maclean; whilst Dr. Goodeve treats of chronic atrophy or cirrhosis, and acute or yellow atrophy of the organ; Dr. Warburton Begbie taking up the other diseases—namely, fatty liver, cancer of the liver, hydatids, and waxy disease of the liver. Dr. Wardell discusses diseases of the pancreas, and Dr. Morell-Mackenzie diseases of the larynx. Diseases of the thoracic organs are divided into emphysema of the lungs, by Sir William Jenner; asthma, by the late Dr. Hyde Salter; phthisis pulmonalis, by Dr. Hughes Bennett; cancer of the lung, by Dr. Hermann Beigel; pneumonia, syphilitic affections of the lung, and brown induration of the lung, by Dr. Wilson Fox; cirrhosis of the lung, by Dr. Bastian; apneumatosi, by Dr. Graily Hewitt; bronchitis, by Dr. F. Roberts; the remaining articles—pleurodynia, pleurisy, hydrothorax, and pneumothorax—being from the pen of Dr. Anstie.

The preceding volumes of this System have, like most such works, been made up of articles of varying quality—good, bad, and indifferent—but neither of them contained such a proportion of poor and mediocre articles as does this. After a careful survey of the present volume, we are constrained to ask ourselves, Does this volume fairly represent the Medicine of Great Britain in 1871?—and we are fain to answer, No. Have the articles been written by the men best fitted to handle each separate subject?—and again we answer, No. We know not whether Dr. Russell Reynolds has endeavoured to secure the services of the men best qualified to treat of each particular malady: if he has done so, we must regret that he has failed, for he has not obtained them. But, in justice to the accomplished editor, we must excuse him in a certain way for the inequalities of the articles—it is so long ago since some were written. For the tardiness of his contributors he is not to blame; for his selection of them we can say nothing, except that we wish it had been more satisfactory. It would be invidious to say which we esteem the best, or which we esteem the worst treatise in this volume, though neither task would be difficult; but we

are at liberty to point out certain of the styles which vary so much in the volume before us. Thus, there is the cold catalogue *raisonné* of symptoms culled from the ordinary textbooks, without even passing through the crucible of experience; there is the article dealing with its subject from the clinical, and the article dealing with its subject from the pathological standpoint; there is the writer who relies entirely on his own experience, and the writer who relies upon everybody's experience except his own; there is the intensely practical article, and the purely theoretical article, all combined in various proportions, and here offered to the public. Perhaps the best type of article is afforded by Dr. Wilson Fox's treatise on Pneumonia, although it must be confessed its length is out of proportion to the rest in the volume, occupying 186 out of a total of 968 available pages. Nevertheless, we say it is an admirable paper, because it contains the results of much reading and other kinds of hard work, carefully collated with the results obtained by personal experience. The article is not of the kind called erudite—an *omnium gatherum* of the opinions of every man who has written on the subject, from Hippocrates downwards—nor of the absolute, dogmatic kind, which, though infinitely superior to the former, and best suited to students, is not that most to be commended for Practitioners—the men who mainly use this book. On the other hand, there are articles in the present volume little better than stop-gaps, for whose existence it is difficult to account: certain of them are really little more than commentaries on recognised authorities on the same subjects. Now, the article we are about to cite is not the worst in the book, nor would we cite it but for the great importance of the subject and acknowledged position of the author. The article we allude to is "Phtthisis Pulmonalis," by Dr. Hughes Bennett, of Edinburgh—in one respect, perhaps the most important treatise in the volume; it occupies but fifty-three pages, and what little there is is sadly behind the time. We have no hesitation in pronouncing that part of the article which deals with the histology, chemistry, and general pathology of tubercle as an anachronism—or worse, seeing it may by some be accepted as accurate. What says anyone acquainted with recent researches on tuberculosis to the following?—"With regard to its mode of production, tubercular matter is first separated from the bloodvessels as a fluid exudation, forming by its coagulation a molecular blastema. . . . There (*i.e.* in the lung) all observation demonstrates that it originates in a molecular exudation, which, in consequence of diminished vital powers, seldom passes beyond the nuclear stage of growth." Is this 1871; and is Rip Van Winkle, in the shape of the Professor of Physiology and Clinical Medicine in the University of Edinburgh, once more among us?

Finally, we notice in this volume a considerable number of words, proper names and others, persistently wrongly spelled. This is not creditable. Let us hope the editor will be speedily enabled to remedy these blots in a new edition.

Organic Philosophy. Vol. III.—*Outlines of Biology: Body—Soul—Mind—Spirit.* By HUGH DOHERTY, M.D. London: Trübner and Co., Paternoster-row. 1871.

THE preface of this work performs the remarkable part of "medium" for the advertisement of the writings of the same author published at long intervals, the present volume being No. 3 of the series. The first treats of Epicosmology ("the three kingdoms of nature on our globe, *epi-cosmos*); the second is a general outline of Ontology (Eternal Forces, Laws, and Principles); the third is an outline of Systematic Biology (Body, Soul, Mind, and Spirit); the fourth will be an outline of Systematic Sociology; the fifth a treatise on Dialectics, or Biological Methods in parallel with Mathematics as a Science of Method—each of which (past, present, and future) may be procured for the ridiculously small sum of 10s.!

We have looked over Vol. III., the last-issued number of the series—we do not pretend to have read it; but we have seen enough of it to convince us that, notwithstanding its philosophic title, it contains a defence of the doctrine of spiritualism—or "spiritism," as it is called by the author, and explained by him as meaning "communications received from departed spirits"—of which he states he has himself witnessed the phenomena, or he should not vouch for them. We are told not only that the experience and knowledge of spirits are not equal in spirit-land any more than on earth, but that there are lying as well as truthful spirits; and that the action of evil among them is pretty much the same as on earth. Notwithstanding such defects, however, we are informed that many

people have through spiritism been consoled by a belief in life after death, which they could not realise before. A spirit whose revelations are published in the *Medium* for April, 1871, announces that children who are full-grown and born alive are immortal; but that, in cases where the fœtus died before maturity, the child had no spiritual existence. It can easily be imagined how such a doctrine might be applied to criminal purposes by a spiritist who might happen to combine the professions of medium and abortionist. It is some satisfaction to learn that spirits do not agree on this point, nor do we care to enter into vain speculations as to the moment at which the human embryo becomes the seat of a living soul—suffice it for us to know that the whole period of embryonic life, from the moment of conception to that of complete delivery, is protected from interference not only by the dictates of morality and religion, but by the laws of this country. No revelations by either "spirit of health or goblin damned" capable of being applied to the diminution of the sacredness of the simple physical life of the embryo, on the grounds of its spiritual non-existence, can have any other than the most immoral tendency.

Dr. Doherty does not hesitate to enlist "spiritism" in support of the truth of the miracles narrated in the New Testament. He asks on what other grounds can we imagine the reality of Christ walking on the water, the body of a person being carried through the air to a distance, or the multiplication of the loaves and fishes, if modern spiritualism did not give us some reliable experience of analogous phenomena—such as the levitation of mediums, table-moving, and the transference of fruit, flowers, and sea-shells, even dripping with salt water, from great distances into rooms with closed doors and windows, where no such objects were known to be a minute or an hour before? For the explanation of such phenomena we have only to suppose, he tells us, that spirits can use some form of electricity or magnetism so rapidly and mutably as to render solid bodies liquid or fluid for an instant, without change of place, or mechanical disturbance, so as to allow other solid bodies to pass through them as through vapour. It is much easier, in Dr. Doherty's opinion, to conceive this possible velocity in physical modes of motion and mutation than to disbelieve the evidence of men and women in the perfect enjoyment of all their senses and their reason, who affirm the truth of facts which they have seen and felt, and know to be real. Further on in the work we find that, although we do not know on what evidence Socrates may have founded his belief, that disembodied spirits can live in "the burning lake of Tartarus, situated in the centre of the globe," spiritists in our day have abundant evidence that even mediums in the flesh, entranced and possessed by spirits, can handle burning coals without being injured in the least, and that paper can by spirit mesmerism be rendered incombustible. Hence, of course, those who choose, may derive an argument in support of the comforting doctrine of the real physical existence of the figuratively described lake burning with brimstone and fire.

The main purpose of the work, so far as we can make it out, is to establish an analogy or parallelism between the bodily organs and mental functions of man and the physical conditions of the globe on which he lives. The style is loose and inconsequent, and abounds with big words, with tortuous terminations which render them not only puzzling, but, in many cases, quite unintelligible to the ordinary mind. From the specimens we have given of the "Organic Philosophy" of Dr. Hugh Doherty, our readers can judge for themselves whether their libraries would be enriched by having on their shelves the collected works of the same author, at the price announced in the preface to his third volume.

NEW BOOKS, WITH SHORT CRITIQUES.

The Micrographic Dictionary. By J. W. GRIFFITH, M.D., etc., and ARTHUR HENFREY, F.R.S., etc. Third Edition by J. W. GRIFFITH, M.D., assisted by the Rev. M. J. BERKELEY, M.A., F.L.S., and T. RUPERT JONES, F.G.S., Professor of Geology and Mineralogy, Royal Military College, Sandhurst, etc. Parts I. and II. London: Van Voorst.

*** It is with much pleasure we welcome a new edition of this well-known and well-tried naturalists' companion. Poor Henfrey is now no more, but Dr. Griffith has secured able assistance, and we hope great things of the book. As for the work itself, it is superfluous to praise it, as most men will say who have ever used it: good as it was, we trust it may now be better. The plan of publishing it in monthly parts, adopted in this edition by Mr. Van Voorst, will put it within the range of all. It is above all books useful to the private investigator.

Spiritualism and Animal Magnetism. By PROFESSOR G. G. ZERFFI. Hardwicke.

*** An interesting little work on interesting subjects, and written in a charming style. We do not agree with all the conclusions and statements contained in it; but it is well worthy of perusal, and will attract much attention at a time like the present, when the subjects to which it relates are discussed with so much ardour and antagonism.

GENERAL CORRESPONDENCE.

THE LANCET AND MIDDLESEX HOSPITAL.

LETTER FROM DR. W. CAYLEY.

[To the Editor of the Medical Times and Gazette.]

SIR,—With reference to an article in the *Lancet* of October 14, headed "University College Hospital," I beg leave to state that students of University College are only admitted to the Medical and Surgical practice of the Middlesex Hospital on exactly the same terms, with regard both to fees and privileges, as other occasional students who may enter for Hospital practice, no preference whatever being given to students from University College over such other occasional students with respect to clinical appointments, for which they are only eligible in event of no general pupil of the Middlesex Hospital Medical College offering himself.

The notice in the prospectus of University College, of which mention is made, refers to matters of private arrangement between the authorities and students of University College itself, with which the staff of the Middlesex Hospital are in no way concerned, and of which they had not even been made cognisant.

With regard to the advantages which the writer of the article intimates this Hospital would derive from the supposed agreement, by being thereby enabled to fill up its clinical appointments, I may be permitted to state that for these appointments the wide field for practical study afforded by the Middlesex Hospital has never yet failed to secure an ample supply of eligible candidates.

I am, &c., W. CAYLEY, M.D., Dean of
October 16. the Middlesex Hospital Medical College.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 13, 1871.

DR. W. W. GULL, F.R.S., President, in the Chair.

THE PRESIDENT, on taking the chair, congratulated the Society on beginning its work again—for it was a work we were always beginning. He thought we could not be over-critical in such a Society; he might say that at its doors we ceased to be Practitioners, to become critics. The past history of Medicine was full of wrong theories—most experience was fallacious; yet everybody appealed to it. Their great difficulty was to avoid fallacies, and, therefore, they required great acumen to insure that their facts might never be disputed. They were all striving here to throw light on their daily work, and he would be glad to hear brought before the Society the value of a symptom clinically or its fallacies, or, again, the natural history of a disease, the use of a drug, or of any one mode of investigating a disease. The future of Medicine rested on accurate diagnosis, and they ought, therefore, to encourage any accurate inquiry into clinical Medicine. He concluded with welcome and encouragement to all.

DR. BAÜMLER read a paper on "Partial and General Idiopathic Pericarditis," in which he endeavoured to prove that the white or milky spot on the surface of the heart frequently met with at post-mortem examinations has a clinical history of very transient acute pericarditis. He adduced in support of this proposition two cases, in which an acute illness, coming on with dyspnoea, with pain behind the sternum, radiating upwards to the larynx, the left shoulder, and towards the left ear, and with slight febrile disturbance, was accompanied by a characteristic pericardial friction-sound, lasting, like the other symptoms, only for two or three days. In a third case, where the onset had been more gradual, the friction-sound was heard over a larger area; and there was also some distension of the

pericardium by fluid; yet the whole attack was mild, and lasted only a fortnight. Such intermediate forms link the very slight cases to the more serious ones, which more generally come under observation. Cases of idiopathic pericarditis being of rare occurrence, Dr. Baümler appended the history of three other cases of this kind which had come under his observation. The three patients had been little girls from 8 to 10 years of age, and the pericarditis had come on in so insidious a manner that they had walked about with the pericardium full of effusion. One of them died; the two others recovered—one entirely, the other with valvular disease remaining. With regard to treatment, Dr. Baümler particularly recommended the application of ice to the cardiac region, especially for its influence in reducing the number of the heart's contractions, and in relieving pain.

Some discussion arose with regard to the length of this paper, and it was generally understood that in future the ten minutes rule should be adhered to as closely as possible.

THE PRESIDENT said it had been denied by great Physicians that pericarditis ever, *per se*, causes pain: in these cases there was much. Was it certain they were cases of pericarditis?—for pleurisy would give some of the symptoms. If this disease—pericarditis—was idiopathic, what conditions set it up? The friction-sound was fallacious; in many instances he had seen it to be so, for it might be simulated by pleurisy outside the pericardium. Some of the patients alluded to were adults and some were children, yet the conditions of the pericardium in these were different.

DR. POWELL asked how the author reconciled the action of the ice-bag with mustard and blisters. In other forms of acute disease with high temperature—astuberculosis—he had heard a pericardial râle come on and pass away again in a few hours. Perhaps it might arise from a kind of dryness in the pericardium.

DR. C. T. WILLIAMS asked the exact effects of the ice-bag on the heart and temperature.

DR. BAÜMLER, in reply, said the ice-bag reduced the number of beats per minute, and also the general temperature. In one case he had kept on the ice-bag for four days, with great comfort to the patient. He thought ice relieved pain as well as the fever. Empirically both ice and blisters did relieve pain.

MR. NUNN read a paper on "Lupus Erythematosus." This disease, known also as superficial lupus, was believed by Mr. Nunn to be essentially an inflammatory atrophy of the cutis, limiting itself to that structure, and thus distinguished from lupus exedens, which was capable apparently of destroying indiscriminately every structure. Two cases of lupus erythematosus were reported, in which the family history afforded no clue to the nature of the disease; and, in contrast, one case of lupus exedens, in which an hereditary syphilitic taint was with almost complete certainty to be traced. The first two cases had been treated for years before coming under Mr. Nunn's care with mercury, iodine, arsenic, etc. The first patient, a male, aged 34, had (October, 1870) suffered during thirty-two years, the second during twenty-one years, with lupus erythematosus of the cheek. The bromo-iodine waters of the Woodhall Spa, in doses of a wineglassful three times a day, were given, and a tablespoonful of lemon-juice in a tumblerful of milk every morning. In the first case, the gums being spongy, a solution of chloride of zinc (one grain to the ounce of water) was ordered to be applied to them. This case was to all appearances cured at the end of six months. The second patient was still continuing the treatment with advantage, having only commenced it in May last. The case of lupus exedens had been in the Middlesex Hospital, under the care of the late Mr. Moore, and was now an inmate of the Hospital for Incurables at Putney.

DR. ALTHAUS said he had no experience of the Woodhall Spa waters, but they resembled those of Kreuznach, which in such cases did good. Their beneficial effects raise the question—Do we not give too much iodine in some cases? In many mineral waters patients only took the equivalent of one grain per diem.

DR. GULL said the disease was one of the opprobria of Medicine, and constantly resisted all treatment—Kreuznach and all. The name lupus was as good as any other.

MR. G. LAWSON related the particulars of a case of large Melanotic Tumour of the Eye, which had burst through the sclerotic and had extended into the orbit. He first excised the globe and then freely applied the chloride of zinc paste for the purpose of destroying all the tissues within the orbital cavity, and thus effectually to get rid of all the cancer-germs with which those structures are in such cases generally infiltrated. The operation was performed in July of this year, and the patient was now progressing favourably towards recovery. All the tissues within the orbit sloughed, and large portions

of the bony cavity had exfoliated. Mr. Lawson remarked, that when the diagnosis of melanotic tumour within the eye is made at a very early stage of the disease, the simple removal of the eye is frequently sufficient. He quoted the case of a patient in whom he had been able to recognise the tumour by the ophthalmoscope when it was scarcely of the size of a pea. He removed the eye, and now nearly three years have elapsed and there has been no recurrence of the disease in the orbit.

Mr. DE MORGAN said the application of caustics after the removal of an eye for early disease was a good plan. In many eyes excised the elements of cancer were found in the optic nerve, at such a point as to indicate their implication of the structures beyond the point of section. Were zinc applied the patient would probably live longer. He would warn gentlemen attempting the practice that severe epileptiform attacks may follow the operation in a few hours. In one case he remembered they recurred every twenty minutes. With each attack the pulse went down; again, it gradually recovered up to a certain point, when the patient went off again. Ultimately he did very well. In reply to Dr. Buzzard, he said there was no tendency to the recurrence of the epilepsy.

The PRESIDENT said there were two great points to be considered here—Was cancer a local malady? and could a patient attacked by cancer be saved? He wished cancer always began in the eye, for then an early and accurate diagnosis could be made. He saw the other day a man who, nine years ago, had his eye removed for cancer. He had been well since, but it was now recurring in the liver. He believed the disease was always local; he did not know where the constitution lay. Malignant diseases began in a particular place in a particular way. Generally we saw them when too far advanced.

Mr. G. LAWSON said whilst such tumours were growing in the eye they were black. When they burst the sclerotic, they grew much more rapidly, and were white, becoming encephaloid.

Mr. T. NUNN said that, in about one case in thirteen, cancer would last ten or twenty years. This was a fair sample of fallacious experience.

Mr. H. LEE said his views were different. The other day he removed a breast, not with a view to cure the disease, but to prevent a disagreeable ulcer. He thought the same perverted nutrition which had caused the original disease would set it up elsewhere.

The PRESIDENT asked what evidence there was that the glands stopped the disease.

Mr. LEE thought the experiments with gunpowder showed that.

Mr. DE MORGAN was entirely at variance with Mr. Lee. He considered cancer to be a local disease, and that one gland communicated it to another. Gunpowder reaches one, and stays there. In no single instance did the part most prone to cancer take it on secondarily—as, for instance, one breast from another.

Mr. LAWSON said the Middlesex Hospital statistics showed a family history of cancer to be rare.

Mr. ARNOTT had constantly seen a whole chain of glands affected, from the part primarily to the part secondarily attacked. Later figures hardly bore out Mr. De Morgan's statement; for cancer might affect both breasts, or breast and uterus.

OBITUARY.

FRASER THOMSON, M.D., L.R.C.S.E., AND F.R.S.E., WAS born in Perth. His father, Dr. W. A. Thomson, and his uncle, Dr. Andrew Thomson, of Edinburgh, were well-known clergymen of great ability. He studied Medicine at the University of Edinburgh, where he graduated in 1828, having the year previously become a Licentiate of the Royal College of Surgeons of Edinburgh. After further pursuing his studies in Paris and elsewhere on the Continent, he married and settled in his native city, and soon acquired one of the most extensive general practices. He also became one of the Surgeons of the Perth City and County Infirmary in 1838, and he held this responsible position till failing health necessitated a curtailment of his labours, and then he was made Honorary Consulting-Surgeon. His dexterity as an operative Surgeon was great, and he was invariably consulted in all difficult cases in the county. For many years before retiring from active practice (which he did at the end of 1865), he was the chief Practitioner in the county, and he maintained the same position in consulting practice subsequently. His cultivation,

sagacity, genial yet dignified urbanity, and his commanding presence, peculiarly fitted him for such a position. Even in his student-days (and as member of the old and now extinct Plinian Society of Edinburgh) he was devoted to scientific and, especially, zoological pursuits, and he was an able microscopist; indeed, his fine collection of valuable microscopes, his cabinets of beautifully mounted preparations, and his great knowledge of the subject, used to surprise even Professor Quekett. His observations on the structure of many marine animals would have given him a name in the department if he had made them known, but he avoided this, having only recorded some of his remarkable Medical cases in the *Edinburgh Medical Journal*. He was distinguished by his concise and clear diction as a lecturer and speaker. In 1861 he became the first President of the Perthshire Medical Association, and afterwards Chairman of the Directors of James Murray's Royal Asylum for Lunatics, positions in which his great acquirements, sound judgment, and practical sagacity were invaluable. Much of his time was lately devoted to the museum of the Literary and Antiquarian Society of Perth. He was a Fellow of the Royal Society of Edinburgh, and a Justice of Peace of the county of Perth. He was a keen golfer, angler, and sportsman, even in his declining years. His loss makes a great blank not only in his wide circle of private friends, and in the public institutions of the city and county with which he was connected, but in the community in general.

HENRY S. ILLINGWORTH, F.R.C.S., ETC.,

DIED on the 16th, 62 years of age. Mr. Illingworth practised for many years at the corner of Arlington-street, Piccadilly. He joined Mr. Moore in partnership upwards of thirty years since. The practice was a very old one, and for nearly a century had been associated with Royalty. Mr. Illingworth was Apothecary to the late Queen Dowager, the Duke of Cambridge, and the Duchesses of Gloucester and Kent; he was also Visiting Apothecary to St. George's Hospital. His contributions to Medicine appeared in the old *Medical Gazette*—the first "On a Case of Poisoning by Corrosive Sublimate"; the second "On Œdema of the Glottis." Mr. Illingworth was a quiet, unobtrusive gentleman, and well informed in his Profession.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an extraordinary meeting of the College on Monday last, Edward John Waring, M.D. St. And., 49, Clifton-gardens, Maida-vale, was admitted Fellow; and the following gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, were granted Licences to practise Physic, including therein the practice of Medicine, Surgery, and Midwifery:—

Biddle, Cornelius, M.R.C.S., 26, Queen's-road, Dalston.
 Davies, Henry, M.R.C.S., Pentrepoth, Morrison, Swansea.
 Eager, Wilson, M.R.C.S., Bethlehem Hospital, S.E.
 Edmonds, Frederic H., M.R.C.S., University College Hospital.
 Hobley, Simon Halford, M.R.C.S., 20, Queen's-crescent, Haverstock-hill, N.W.
 Newington, Frank E., M.R.C.S., 1, Evering-villas, Amherst-road, Hackney.
 Scully, John, M.R.C.S., Middlesex Hospital.
 Stamford, William, M.R.C.S., Tunbridge.
 Thomas, John Howell, London Hospital.
 Wall, William Barrow, University College Hospital.
 West, John G. U., M.R.C.S., University College Hospital.
 Wilby, John Burdett, M.R.C.S., Leicester.

The following candidates, having passed in Medicine and Midwifery, will receive the College Licence on their obtaining Qualifications in Surgery recognised by the College:—

Bland, George, St. Bartholomew's Hospital.
 Harries, Thomas Davies, Guy's Hospital.

APOTHECARIES' HALL.—The following gentleman passed his Examination in the Science and Practice of Medicine, and received a Certificate to practise, on Thursday, October 12, 1871:—

Masterman, George Frederick, Croydon.

The following gentlemen also on the same day passed their first Professional examination:—

Bowkett, William David, London Hospital.
 Grogono, Walter Atkins, London Hospital.

THE Surgeoncy to the Metropolitan Dispensary, Fore-street, is vacant through the resignation of Mr. Sydney Chater. Ill-health, we regret to say, has obliged him to withdraw from the office.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- CARNEGIE, JOHN, M.A., M.D., C.M.—Surgeon to the Chesterfield and North Derbyshire Hospital and Dispensary.
 DONOVAN, H. J., A.B., M.D.—Medical Officer for the Emlagh Dispensary District of the Cahereiveen Union, co. Kerry.
 DORAN, ALBAN H. G., M.R.C.S., L.S.A.—House-Surgeon to St. Bartholomew's Hospital, *vice* A. J. Hogg.
 FLOWER, THOMAS, M.R.C.S.E., L.S.A.L.—Medical Officer and Public Vaccinator for the Warminster District Union Workhouse, and Corsley District of the Warminster Union, *vice* P. Grubb, resigned.
 MACCALL, WM. N., M.D.—Assistant Medical Officer to the Clinical Hospital and Dispensary for Children, Manchester.
 NORTON, ROBERT, M.R.C.S.E. (1836), L.S.A.L. (1836)—Medical Officer for District No. 2 in the Bristol Incorporation of the Poor.
 THORPE, G. E. K., M.R.C.S.E.—House-Surgeon to the Public Hospital and Dispensary, Sheffield, *vice* Algernon Taylor, M.R.C.S.E., resigned.

MILITARY APPOINTMENTS.

- 10TH FOOT.—Staff Assistant-Surgeon James McNamara, M.D., to be Assistant-Surgeon, *vice* Theobald Andrew Purcell, appointed to the Staff.
 MEDICAL DEPARTMENT.—Assistant-Surgeon Theobald Andrew Purcell, from the 10th Foot, to be Staff Assistant-Surgeon, *vice* James McNamara, M.D., appointed to the 10th Foot.

BIRTHS.

- RANGER.—On October 17, at Westfield Villa, Peckham-rye, the wife of W. G. Ranger, M.R.C.S.E., of a daughter.
 FARR.—On Wednesday, October 17, the wife of Dr. Archer Farr, 88, Waterlog-road, of a daughter.
 PRICE.—On October 13, at Margate, the wife of William Price, M.D., of a son.
 WARD.—On October 13, at Northbourne, Chobham, the wife of Dr. Ward, of a daughter.

MARRIAGES.

- DALY—STONE.—On October 11, at the parish church, Longworth, Farringdon, Joseph Harding Daly, M.R.C.S.I., L.R.C.P.L., of Kingston-Bagpuize, to Caroline Mary, only surviving daughter of Mark Stone, Esq., Longworth, Berks.
 GAY—THIMBLEBY.—On October 12, at the parish church, Spilsby, Lincolnshire, John Henry Gay, Surgeon, Spilsby, only son of William Gay, solicitor, Wisbeach, to Alice, elder daughter of Dr. Thimbleby, of Spilsby.
 LANGLEY—LEE.—On October 10, at Dawlish, Albert Gordon Langley, Esq., of Lincoln's-inn and Blackheath, barrister-at-law, to Isabella, widow of the late Captain Seymour, R.M.L.I., second daughter of Dr. Robert Lee, of 4, Savile-row.
 POWIS—STEWART.—On October 12, at St. Giles's, Camberwell, H. S. Powis, M.D., Castle-hill, Maidenhead, to Mary, second daughter of Ramsay Stewart, Esq., formerly of Edinburgh.
 PRICHARD—BATEMAN.—On October 14, at the New Church College Chapel, Devonshire-street, Edward Ellison, son of Henry Prichard, Esq., of Stanley-gardens, Kensington-park, to Helen Maria, daughter of Henry Bateman, F.R.C.S.E., of Compton-terrace, Highbury.
 THORP—BURFORD.—On October 14, at St. Mark's, Hamilton-terrace, T. E. Thorp, of Whitley, Berks, to Emma Champion, eldest daughter of H. B. Burford, M.R.C.S.E., of Hamilton-terrace, St. John's-wood.
 WRIGHT—TOLLER.—On October 12, at Kettering, J. Brampton Wright, M.D., of Wellingborough, to Caroline Addison, second daughter of W. Toller, Esq., Rockingham-road, Kettering.

DEATHS.

- FAITHORN, GEORGE, Surgeon, at Chesham, Bucks, of typhus fever, on October 12, aged 64.
 FAWCUS, JAMES, M.D., Surgeon in the Bengal Army, Inspector-General of Gaols in Bengal, at his mother's house, Etal Villa, North Shields, of fever caught in Calcutta, on October 11.
 ILLINGWORTH, HENRY STANHOPE, F.R.C.S. and L.S.A., of Arlington-street, Piccadilly, W., at 43, Curzon-street, Mayfair, on October 16, aged 62.
 JONES, KATE, the dearly beloved child of Dr. David Jones, of Bolton House, Clapham-road, and 15, Welbeck-street, Cavendish-square, on October 12, suddenly, by a fall from the baluster of a staircase, aged 7 years and three days.
 THOMSON, FRASER, M.D., L.R.C.S.E., etc., at Perth, very suddenly, on October 10, aged 68.
 WATTS, ANN, relict of William Watts, Esq., of Bucklebury, near Newbury, Berks, and the dearly beloved mother of William Henry Watts, M.R.C.S.E., at the residence of friends, 21, Hampton-place, Brighton, of gangræna senilis, on October 12, aged 77.

VACANCIES.

- In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
 DEVON COUNTY LUNATIC ASYLUM.—Assistant Medical Officer. Applications and testimonials to Mr. T. E. Drake, Solicitor, on or before October 26.
 DORCHESTER UNION.—Medical Officer for the Workhouse and Dorchester Districts. Candidates must be qualified in accordance with the General Orders of the Local Government Board. Applications and testimonials to Mr. H. Lock, Clerk, on or before October 26. Election the same day.

- EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHVARK-BRIDGE-ROAD.—Surgeon. Must be M.R.C.S.E., and be registered. Applications and testimonials to the Committee at the Hospital, on or before October 25.
 GREAT NORTHERN HOSPITAL.—House-Surgeon. Candidates must be M.R.C.S. Applications and testimonials to the Secretary, Mr. G. Reid, 46, Great Coram-street, W.C., on or before October 30.
 GREAT OUSEBURN UNION.—Medical Officer and Public Vaccinator for the Workhouse and the Ouseburn District. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to H. H. Capes, Esq., Solicitor, Knarborough, Yorkshire, on or before October 28. Election on the 30th.
 HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, S.W.—Resident Clinical Assistant. Applications and testimonials to the Secretary on or before November 4. Further information may be obtained at the Hospital.
 LONDON FEVER HOSPITAL.—Physician. The necessary qualifications are—F. or M.R.C.P.L. Applications and testimonials to the Secretary, at the Hospital, on or before November 7. Election on the 10th.
 MALE LOCK HOSPITAL.—Resident House-Surgeon. Applications and testimonials to the Secretary, on or before October 27. Further information may be obtained upon application at the office, 91, Dean-street, Soho, on Monday, Wednesday, or Friday at 12 o'clock.
 NORTH DEVON INFIRMARY.—House-Surgeon. Must be M.R.C.S.E., and be registered. Applications and testimonials to Mr. John Bridgman at the Infirmary, Barnstaple, on or before November 4. Election on the 14th.
 NOTTINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Applications and testimonials to the Secretary, on or before October 24.
 NOTTINGHAM GENERAL HOSPITAL.—Resident Surgeon-Apothecary. The qualifications required are as follows:—F. or M.R.C.S. Eng., Edin., Dub., or of the Faculty of Glasgow, and L.S.A. Applications and testimonials to Mr. E. M. Kidd, Secretary, on or before October 24.
 PRESTON AND COUNTY OF LANCASTER ROYAL INFIRMARY.—House-Surgeon. Must be legally qualified to practise. Applications and testimonials to Mr. R. F. Easterly, 54, Fishergate, Preston, on or before October 24. The duties will commence on November 9.
 ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD.—Operating Surgeon. The qualifications required are—For M.R.C.S.E. not practising midwifery or pharmacy. Applications and testimonials to Mr. C. L. Kemp, on or before November 7. Election on the 21st.
 ROYAL SURREY COUNTY HOSPITAL.—House-Surgeon. Must be duly qualified in Medicine and Surgery. Applications and testimonials to the Assistant-Secretary, Guildford, on or before November 6.
 ST. GEORGE'S, HANOVER-SQUARE, DISPENSARY.—Physician-Accoucheur. Must be M. or F.R.C.P.L. Applications to the Honorary Secretary, 59, Mount-street, on or before October 30. Election the following day.
 SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Medical and Surgical qualifications required. Further particulars of Dr. J. C. Hall, Honorary Secretary, to whom applications and testimonials may be sent on or before October 23.
 SWAFFHAM UNION.—Medical Officer for the Saham Toney District. Gentlemen applying for this appointment must be qualified in accordance with the General Regulations of the Local Government Board. Applications and testimonials to Mr. R. Sewell, Clerk, on or before October 21. The duties will commence on the 28th.
 WESTHAMPTON UNION, SUSSEX.—Medical Officer for the Rumboldwhyke District. Candidates must have both Medical and Surgical qualifications and be registered. Applications and testimonials to Mr. R. G. Raper, Chichester, on or before October 21. Election on the 23rd.
 WESTMINSTER HOSPITAL.—House-Surgeon. Must be qualified to practise under the Medical Registration Act, 1858. Further particulars of Mr. F. J. Wilson, Secretary, on or before October 25.
 WEYMOUTH UNION.—Medical Officer and Public Vaccinator for the Melcombe Regis District. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. R. Hare, Clerk, on or before October 23. Election on the 24th.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

- Ellesmere Union.*—Mr. Wm. Davies has resigned the Overton and Penley District; area 5915; population 1780; salary £30 per annum.
Fulham Union.—Mr. Fredk. W. Spurgin has resigned the Fifth District; area 1650; salary £50 per annum.
Glendale Union.—Mr. Thomas Hunter has resigned the Lowiek District; area 12,875; population 1946; salary £10 per annum.
Great Ouseburn Union.—Mr. J. P. Hunt has resigned the Great Ouseburn District; area 9458; population 1994; salary £20 per annum; and the Workhouse; salary £30 per annum.
Walsall Union.—Dr. Burton has resigned the Workhouse; salary £100 per annum.

APPOINTMENTS.

- Gower Union.*—Henry V. Ellis, B.M. and M.C. Univ. Aber., to the Western District and the Workhouse.
Harwarden Union.—Wm. Roberts, M.R.C.S. Eng., L.S.A., L.R.C.P. Edin., to the Second District.
St. George's Union.—George Fenton, M.R.C.S.E., L.S.A., to the D District.
Whitchurch (Hants) Union.—Sydney Hayward, M.D., M.R.C.S., L.S.A., to the Overton District.

UNIVERSITY OF CAMBRIDGE.—Dr. Michael Foster, the recently appointed Praelector on Physiology at Trinity College, Cambridge, has been elected a Fellow of the College. Professor Wood (of King's College), Dr. Herbert Davies (of the London Hospital), Dr. J. W. Ogle and Dr. Barclay (of St. George's Hospital), and Mr. Callender (of St. Bartholomew's) are among the Examiners for Medical and Surgical Degrees nominated by the Board of Medical Studies and appointed by the Senate.

ROYAL COLLEGE OF SURGEONS.—At a meeting of the Council on the 19th inst., Mr. Robert Boyle Travers, of Ros-tellan, co. Cork, was admitted a Fellow of the College; and Mr. Richard Bowes, of Richmond, Yorkshire, was also elected a Fellow, and will be admitted as such at an early meeting of the Council. The gentlemen are both Members of the College, their diplomas bearing date respectively May 21, 1841, and November 4, 1831. The first examination for the present session for Membership of the College will take place on the 4th proximo for the primary, and on the 10th for the pass.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the annual stated meeting of the College, held on Wednesday, the 18th inst. (St. Luke's-day), the following Fellows were elected as officers for the forthcoming year:—*President*: Dr. Alfred Hudson. *Censors*: Dr. Ringland, Dr. Gordon, Dr. James Little, Dr. Grimshaw. *Vice-President*: Dr. Gordon. *Treasurer*: Dr. Dwyer. *Registrar*: Dr. Finny. *Representative on General Medical Council*: Dr. Aquilla Smith. *Professor of Medical Jurisprudence*: Dr. Travers. *Examiners in Midwifery*: Dr. Johnston, Dr. Atthill.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the first meeting of the session, to be held at the Scottish Corporation-hall, Crane-court, Fleet-street (Robert Druiitt, F.R.C.P. Lond., F.R.C.S., President), on Saturday, October 21, at 7.30 p.m., Dr. T. O. Dudfield, Medical Officer of Health for Kensington, will be balloted for as an ordinary member; Mr. Gardiner Brown, F.R.C.S., will exhibit his patent self-acting deodoriser, for water closets, etc.; and Mr. Liddle will read a paper on "The Relation between Defective Ventilation and the Mortality from Tubercular Diseases, Convulsions in Children, Teething, Atrophy, and Debility, with a few Practical Suggestions thereon."

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this Society, on Friday, October 13 (Prior Purvis, M.D., in the chair), the following gentlemen were elected officers for the ensuing session:—*President*: J. M. Burton, F.R.C.S. *Vice-Presidents*: Edward Clapton, M.D.; A. Roper, M.R.C.S. *Council*: John Anderson, M.D.; William Carr, M.D.; Samuel Giles, B.A., M.D.; Ralph Gooding, B.A., M.D.; William Lockhart, F.R.C.S.; Charles Nind, M.R.C.S.; John C. Thorowgood, M.D. *Treasurer*: Prior Purvis, M.D. *Secretary*: John Prior Purvis, M.R.C.S. *Librarian*: G. G. Bothwell, L.R.C.P.E., M.R.C.S. The newly-elected President, J. M. Burton, Esq., delivered an inaugural address. The night of meeting was altered from the second to the first Friday in the month.

REGISTRATION OF STUDENTS.—The annual return of the number of gentlemen pursuing their Professional studies at the eleven recognised metropolitan Hospitals, which has just been prepared for Mr. Charles Hawkins, F.R.C.S., the Government Inspector of Anatomical Schools in London, exhibits an increase of 175 over the number of last year, and an increase in the number of new entries or freshmen of thirty-five. This increase is the more remarkable, owing to the large number of rejections during the present year at the University of London, the College of Surgeons, and Society of Apothecaries, to which allusion has been made on several occasions in the *Medical Times and Gazette*. The following represents the number at each of the Hospitals; but there are, of course, several students pursuing their Professional studies for the Fellowship of the College of Surgeons at each of these institutions who are not required to register:—

1. Guy's Hospital	328	including 86 freshmen.
2. University College Hospital	271	" 88 "
3. St. Bartholomew's	256	" 81 "
4. St. Thomas's	145	" 58 "
5. King's College	121	" 43 "
6. The London	99	" 29 "
7. St. George's	85	" 22 "
8. St. Mary's	61	" 21 "
9. The Middlesex	46	" 19 "
10. The Charing-cross	40	" 11 "
11. The Westminster	23	" 10 "
Total	1475	" 468 "

It will be seen from this analysis that University College has the largest number of new entries—for the first time displacing St. Bartholomew's in numerical strength, and running Guy's very hard.

OPHTHALMIA AT PLASHET SCHOOLS.—We are glad to find that the patients suffering from ophthalmia are nearly convalescent, and that four only of the number would receive permanent injury to their vision.

THE fifth Italian Medical Congress was opened at Rome on the 15th inst., at the Lyceum. Numerous delegates attended.

OUR contemporary, the *American Medical Times*, has changed its name to the *Philadelphia Medical Times*.

THE Smethwick Local Board have decided to appoint a Medical Officer of Health for that district.

DR. G. W. DAVIDSON has been chosen Professor of Comparative Anatomy in the Royal Veterinary College, Edinburgh; and Dr. Robert Brown has been appointed to deliver the annual course of lectures on Geology, Physical Geography, and Palæontology in the Glasgow Institution.

MR. EBSWORTH, one of the late Medical Officers of Newington, not considering £19, which the St. Saviour's Board of Guardians had awarded to him for loss of office, consequent upon the amalgamation of the parish of Newington, as sufficient compensation, has given them notice that he intends to take counsel's opinion, with a view of testing the question in a court of law.

THE session 1871-72 of the Liverpool Medical Institution was opened by an introductory address from Edward R. Bickersteth, F.R.C.S. Ed., President, on Thursday, the 12th instant. There was an unusually large attendance of members present.

THE Medical Officers of four East London parishes have found, on an examination of the Regent's Canal, that the bad state of the water arises from the quantity of mud at the bottom of the canal, and they have called upon the directors of the Company to remove the cause of the nuisance by taking away the offensive accumulation.

WOMEN-STUDENTS OF CHEMISTRY.—At the conclusion of his inaugural address, the Professor of Chemistry at Newcastle, Mr. A. Friere-Marreco, stated, on behalf of himself and Professor Herschell, that they were prepared to receive lady-students on exactly the same footing as other students. Who shall say "The age of chivalry is gone"?

LIBERAL GUARDIANS.—At the meeting of the Guardians of the City of London Union on Tuesday, the Amalgamation Committee reported that they had considered the amount of compensation (£61) awarded by the Local Government Board to Dr. Robert Fowler for the loss of his office as District Medical Officer in the East London Union, and had no remarks to make upon it further than they did not think it excessive. Wonderful liberality indeed! Generous conduct to a man who for many years was their able, indefatigable, and faithful servant!

QUEEN'S UNIVERSITY IN IRELAND.—The Annual meeting of the University for the purpose of conferring degrees was held in St. Patrick's Hall, Dublin Castle, on Thursday week, the 12th inst. The Most Honourable the Marquis of Kildare, Chancellor of the University, presided, and amongst the members of the Senate present were—Sir Dominic J. Corrigan, Bart., M.P., M.D., Vice-Chancellor of the University; the Rev. P. Shulldham Henry, D.D., President Queen's College, Belfast; Edward Berwick, B.A., President Queen's College, Galway; and Sir Robert Kane, LL.D., President Queen's College, Cork. In the course of his address the Chancellor announced that the degree of Doctor in Science had been conferred on Dr. Wyville Thompson, formerly Professor in the Queen's University, and now Professor in the University of Edinburgh. He also mentioned that at the first examination in the Faculty of Medicine 119 candidates had presented themselves, of whom 86 had come up to the standard required by the examiners. Seventy-two gentlemen had been examined for the degree of M.D., of whom 52 proved successful, and the candidates for the Mastership in Surgery had numbered 48, of whom 41 had passed. A further allusion by the Chancellor to Mr. Joseph P. Pye, who received the degree of Doctor in Medicine with honours of the first-class, as having been highly complimented by the examiners on his answering, was greeted with applause. At the conclusion of the Chancellor's remarks, the following degrees in Medicine and Surgery were conferred:—M.D.—First-class: Joseph Patrick Pye, Galway. Second-class: James Magill, B.A., Cork. Third-class: Andrew Lang Browne, Belfast. Passed: Samuel Agnew, B.A., Belfast; Hazlett Allison, Belfast; Thomas Bennett, Cork; Robert A. Bernal, Cork; Robert Blood, Galway; David Graham Browne, B.A., Belfast; William R. Browne, Belfast; Moses Black, Belfast; John King Brigham, Belfast; Thomas Clarke, Belfast; William Burke Cuppage, Belfast; James Dawson, Cork; Benjamin Derham, Cork; Thomas Derham, Cork; Thomas J. Donnelly, Belfast; Bernard Doyle, Belfast; William Fleming, Galway; Anderson Forsythe, B.A., Belfast; A. M'Leod S. Hamilton, Belfast; Alexander Harbinson, Belfast;

Richard Henry, Belfast; Geo. Johnstone, Belfast; John Johnstone, Belfast; Leslie Jones, Cork; James King Kerr, Belfast; John Knox, Belfast; James Lawrence, Belfast; Charles Little, Belfast; Robert M'Bride, Belfast; James M'Carthy, Galway; John P. M'Carthy, Cork; John M'Conaghey, Galway; William M'Gowan, B.A., Belfast; Christopher J. M'Nally, Galway; George H. M'Swinney, Galway; James Martin, M.A., Belfast; Joseph Mark, Belfast; William Augustus Maybury, Galway; John Morrow, Belfast; W. Kirkpatrick Murphy, B.A., Belfast; Patrick C. O'Brien, Cork; Sutherland Rees-Phillips, Belfast; Robert Riddell, Belfast; William Rutherford, Galway; Richard Ryan, Cork; Ebenezer Sloane, Belfast; James E. Smith, Galway; Samuel J. Smith, Belfast; William Skelly, B.A., Belfast; J. Wilson Steele, Belfast; Francis J. Tuohy, Cork; George Vickery, Cork; John Woodrow Watson, Belfast; Alexander Weir, Belfast; John Wilson, M.A., Belfast; J. Bower Wilson, Galway; Joseph Wilson B.A., Cork; Alexander Young, Belfast. M.Ch.—Hazlett Allison, Belfast; Thomas Bennett, Cork; Robert A. Bernal, Cork; Robert Blood, Galway; Andrew Lang Browne, Belfast; David Grahame Browne, B.A., Belfast; William R. Browne, Belfast; John King Brigham, Belfast; William Burke Cuppage, M.D., Belfast; Benjamin Derham, M.D., Cork; Thomas Derham, M.D., Cork; George Johnstone, Belfast; John Johnstone, Belfast; Leslie Jones, C.E., Cork; James King Kerr, Belfast; John Knox, Belfast; James Lawrence, Belfast; Charles Little, Belfast; Robert M'Bride, Belfast; James M'Carthy, Galway; John M'Conaghey, Galway; William M'Gowan, B.A., Belfast; Christopher J. M'Nally, Galway; George H. M'Swinney, Galway; James Magill, B.A., Cork; James Martin, M.A., Belfast; William Augustus Maybury, Galway; William Kirkpatrick Murphy, B.A., Belfast; Patrick C. O'Brien, Cork; Walter W. J. O'Reilly, M.D., Galway; Joseph P. Pyc, Galway; Sutherland Rees-Phillips, Belfast; Robert Riddell, Belfast; William Rutherford, Galway; Richard Ryan, Cork; James E. Smith, Galway; John Wilson Steele, Belfast; Francis J. Tuohy, Cork; George Vickery, Cork; John Woodrow Watson, Belfast; Joseph Wilson, B.A., Belfast; Alexander Young, Cork. Among the prizes and exhibitions awarded on the same occasion were the following:—*Prize in Composition*, limited to the competition of undergraduates in Medicine, awarded for the essay signed "Salus populi suprema lex," to William Thomson, B.A., Galway. *Exhibition*, awarded at the First University Examination in Medicine—Louis R. Dawson, Belfast, first in the non-Professional subjects of the course; two instalments of £20 each.

PROFESSIONAL ADVERTISING.—The following resolution, passed at the annual meeting of the Middlesex Medical Society, Massachusetts, may convey a useful hint to members of the Profession in the Middlesex and other counties of the mother-country:—"Whereas the Medical Profession is not a trade, in the common acceptance of that term, and whatever tends to reduce it to that level is derogatory to its true dignity, and antagonistic to the usefulness of its members: Resolved,—1. That publication of petty accidents in local newspapers, accompanied by the name of the Medical attendant, at his instigation or by his connivance, is an infringement of both the letter and the spirit of the Code of Ethics. 2. That it is the duty of the members whose names may appear in such paragraphs to take all necessary steps to prevent the same occurrence in future, by notifying local publishers not to insert their names in notices of accidents. 3. That the above resolutions apply to all publications of Medical matters in secular journals, accompanied by the name of the Physician interested, when such publication is made at the instigation or with the connivance of a member of this Society."

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Rue Bayard, Pau.—Letters received with thanks. Dr. Hammond's book sent by post; delay from unavoidable causes.

Podophyllum.—In all probability there will be; but no official notice has yet been given.

Humanitas.—The subject has been frequently discussed, and will again most likely engage the attention of those interested in the treatment of insanity. No doubt there is some difficulty at present in providing accommodation for pauper lunatics in the metropolis and Middlesex. We cannot agree in the proposition of establishing a lunatic Hospital in the way suggested.

C.—We learn that Dr. Griffiths has returned to Hyères, and Dr. Marceet to Nice for the winter. Invalids may be sure of being welcomed by the southern French population.

Dr. de H.—Gout is considered to be connected with excess of uric acid, to arise from mal-assimilation and excess, to attack the smaller joints, to affect the middle-aged, and to lead to deposits of lithate or urate of soda. Rheumatism is connected theoretically with lactic acid, is considered to arise from cold, and attacks the larger joints and heart in young persons. Rheumatic gout is an ill-defined term, more popular than scientific. Sometimes it is used for true gout in the young, or for rheumatism in the smaller joints, or for chronic rheumatic arthritis with enlargement of heads of bones from bony deposit.

NITRITE OF AMYL IN CHOLERA COLLAPSE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Permit me to suggest a trial of the inhalation of the vapour of the nitrite of amyl in the collapse stage of cholera. The physiological action of the nitrite appears to be a lowering or paralyzing of the inhibitory function of the sympathetic nerve; and the collapse of cholera is, in my opinion, due to an exalted and perverted state of this inhibitory power.

I am, &c.,

J. DAVIS,

Assistant-Surgeon 39th Regiment.

Ferozepore, Punjab, September 13.

Glasgow.—Sir Hans Sloane, thirty years before his death, presented to the Company of the Apothecaries his botanical gardens at Chelsea, and a statue of the founder is erected in front of the greenhouse. The foundation of the British Museum was the immediate result of his will, in which he directs that after his decease—in 1753—the whole of his museum of natural and artificial curiosities, which had cost him £50,000, should be offered to Parliament for the moderate sum of £20,000, to be paid to his family. Such was the origin of the British Museum, which was opened in 1759.

Newcastle.—The *Staffordshire Weekly Times* of the 14th inst. contains a well-written article on the frightful death-rate of the above town, in which the writer shows with much force that 43 per 1000 is a mortality which could be lessened if proper preventive measures were employed, and concludes with the following apposite quotation from the *Home Nurse*:—

"At the present day few would hesitate to admit that in its origin infection depends on the existence of unsanitary social condition, and that if cleanliness, ventilation, and good habits were universally observed, and efficient drainage, plenty of wholesome water, and abundance of nutritious food enjoyed by all, its ravages among mankind would cease, or become excessively rare."

INFANTILE THRUSH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The "Soldaten Lied" just over, the married ladies have their cards full; the hopes of pretty wallflower maidens, who began to think that men may come and men may go, have been raised by the advent of a bachelor with half a lung and a glass eye, tacked on to £5000 a year.

Mrs. Hyde Parker, in great form, splendidly dressed, is surrounded by the *crème de la crème* of cavalry exquisites. The apoplectic family Practitioner, too fat to dance, leans against a pillar in the room—*Eheu fuimus!* His thoughts travel back to work, especially to Mrs. Hyde Parker's child, suffering from thrush, and not so well to-night.

The Registrar-General reports, in 1869, the deaths of 571 males—552 under 1 year, one man over 65; also, 459 females—430 under twelve months, one over 55, and an old lady over 75.

Hot weather, bad milk, a dirty bottle, a close unwholesome nursery, the slops unemptied, windows never opened, damp linen drying by the fire—the nurse young and flighty, or old and coddling, possibly overworked in a family crowded in a small house—the mother averse to giving up dinner parties or spoil her figure by nursing, possibly inclined either to study "Sartor Resartus," stop at country houses, or go to balls. Including a weakly constitution, stuffing, or improper food, here are the conditions to induce disease.

A fair number of officers' families come under treatment, but the larger proportion of patients are poor, consequently exacting. Yet thrush in squalor and misery becomes very amenable to treatment, for a very good reason—the child has breast-milk. The mother invests a few pence in borax and honey, gives internally chlorate of potash, takes castor-oil herself, so ends the matter. But read this extract of a letter written by a lady who has been Chevassing a week without Medical assistance:—"My baby seemed to be getting on, but the thrush has never left him; his hot and inflamed mouth is coated with plaster of Paris; the glands of the neck are enlarged; he is terribly chafed below; the secretions are all wrong. Yesterday he began to vomit every time he took nourishment. I gave him arrowroot and brandy, but that, too, returned. The diarrhoea continues; he looks very bad, and I am thinking of trying a wet-nurse, but with your advice first." Of course one goes to find treatment too late; the mother is spared a coroner's inquest; the obloquy falls on—Yours truly.

Unattended to, this deceptive complaint becomes dangerous: the neglected patient, put in its crib to-night, may be dead and cold before the morning. Too much space would be taken up giving full details. From that masterpiece, "The Wasting Diseases of Children," by Eustace Smith, we learn that the concretions are due to a cryptogamic vegetation, the sporules of which, increasing with great rapidity, form tubular fibrils. Mr. John Jorrocks realised the pain when he blistered his mouth with the hot kidney. The excoriations about the nates depend on acrid secretions.

In treatment, our object is to destroy the parasite with hyposulphite of soda, to apply borax and glycerine, convert the drawing-room into a nursery, procure a wet-nurse, correct secretions. Some people, using nitrate of silver or sulphate of copper to remove the curdy coating, disbelieve the idea of honey under fermentation increasing irritation. All concur in recommending the universal panacea, cod-liver oil, and change of air subsequently.

The band strikes up the "Night-bell" galop; Mrs. Currie is sleepy and snappish; my daughter Decima, having hooked a moon-faced militiaman (addicted to the *trois temps*), naturally refuses to come home. Poor child! why not enjoy herself for once? Already the champagne has started a twinge of gout, and accursed be the Cheltenham, October, 1871.

NIGHT-BELL.

Foot and Mouth Disease in Children.—Mr. Wyman, the chairman of the Chamber of Agriculture at a late meeting at Hertford, said that the "foot and mouth disease" was very prevalent in his own neighbourhood amongst children. We shall be obliged to any of our subscribers, who have seen such cases, for some information respecting them.

A Governor of the Bedford Infirmary.—Next week we shall go somewhat into detail with respect to the subject of increasing the accommodation at the Infirmary. There cannot be a doubt that such accommodation is required, and should and will be afforded. Our correspondent may rely on the valuable statistical tables furnished by the sub-committee. The further information promised by "A Governor" will be acceptable, and should be forwarded at his earliest convenience.

Plympton.—We had hoped that discussion on the small-pox case in this village had ceased, but we regret to find that it has not. At the meeting of the Board of Guardians on the 13th, the subject was again brought before the meeting. It appears that Mr. Miles had written to the Poor-law Board, giving a detailed account of the transaction, and requesting to be informed "whether the course he pursued in the matter was right or wrong, and whether any of the authorities of the Union House had the power to refuse the admission of the case sent there. This communication was sent to the Board of Guardians, in order that they might furnish the Local Board with any observations which they might desire to make on Mr. Miles's letter. After some discussion, the following resolution was carried "unanimously, amidst much applause":—"That this Board is of opinion that Mr. Miles was not justified in sending the patient into the house, he not being a pauper, and Mr. Miles not having previously consulted the Medical Officer of the Union on the subject." Now, it would be much more creditable to the Guardians of the Plympton Union to erect a proper place for the reception of persons suffering from infectious disease than to pass impertinent resolutions like the above. It is in the highest degree reprehensible that in a union containing a population of 20,489 there was not a single ward in the workhouse fitted to receive a small-pox patient—and this, too, at a time when the disease was epidemic in most parts of England. A vote of censure on the Guardians for their laxity in this respect would be far more justifiable than the vote they have passed on Mr. Miles. With respect to the question of Medical etiquette involved, that is of little moment when compared with the public interests.

SOME CURIOUS ECCENTRICITIES IN MEDICAL ETIQUETTE.
TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Would you permit me to point out what I feel sure must appear some of the inexplicable peculiarities of Medical practice to an impartial outsider.

Medical men often complain of the sale of Church livings—a system by which an inferior man with money will too often easily beat a superior man without that appendage. Again, promotion by purchase in the army does not appear to please most of my Medical friends; yet Doctors sell their practices most unscrupulously, praising to the very sky any fellow, however ignorant, who will give the largest sum for their disinterested introduction.

Medical men do not hesitate to protest against the vicious abuse of patronage common enough in the other professions; but will anyone who knows the way in which Medical men exert their own influence in getting appointments of a Professional character filled up think them more virtuous? One has but to take up the advertising columns of a Medical paper to find that countless appointments are openly offered for sale to the man who will pay most for them.

Do not Medical men object to curates without degrees, and did not a good many think it an evil precedent when a bishop was recently appointed to a Welsh see who was not a University man? but how many Doctors, I wonder, seriously object to unqualified and untrained assistants? Yet, mark, the latter may be absolutely ignorant of all Medical knowledge, but the curate must have passed the bishop's tests before he could be licensed.

Again, what outcries there are about Doctors underselling one another! but are not some Medical men worth fifty times as much as others? All Royal Academicians do not charge the same price for their paintings. In a large town the youngest Physician is often expected to charge the same fee as the most experienced and accomplished man in the town—if the young man charges less, he is said to be underselling; yet, if all the Physicians charge the same, are not the seniors in reality very greatly underselling their comparatively unknown and relatively inexperienced juniors?

The Medical men who will loudly complain of abuses at the Horse-guards, where many lucrative posts too often are held by one general, see no blame in the conduct of eminent Medical men who cling to all their appointments like grim death, and resolutely keep down their ablest juniors by retaining posts, both honorary and paid, of which they cannot or will not execute the duties.

Is it not notorious, too, that men who will scout their juniors for having an uniform charge of one shilling or eightpence a visit, will hold clubs and snap at parish appointments not producing twopence a visit?

Is it not strange that Medical opinion should tolerate the wonderful elasticity of the charges of some well-established Surgeons in certain large towns? Is there rhyme or reason in a man who charges two guineas for going four or five miles to see a rich patient and yet eagerly grasps clubs at three shillings or half-a-crown a year? Is it right, again, that many "highly respectable" Surgeons in our very large towns should systematically ignore a most able and talented Hospital staff, resolutely refusing to meet them in consultation, and never voluntarily calling them in, but should select old college friends when a second opinion is needed—men at the bottom of the tree, among the humblest of the general Practitioners there, of indifferent character, and too often very far from being good Physicians or Surgeons? These "able amateur consultants," in return for the guineas they have received (but not earned), do the same kind office for the friends who have kindly assisted them.

An impartial observer would be struck, one fancies, by these peculiarities of Medical etiquette and Medical practice.

I am, &c.,

October 3.

AN OXFORD MAN.

The late Dr. Symonds.—The *Worcester Herald*, in a review of "Miscellanies," by Dr. J. A. Symonds, says:—

"The late John Addington Symonds was born at Oxford in 1807. His immediate ancestors had been settled for about a century in Kidderminster, whither they had removed from Shrewsbury. They claimed a common descent with the family of Symons or Symeon, of Pyrton, the heiress of which branch married John Hampden. Dr. Symonds' life was not sensational, for at a very early age his future was foreshadowed. Adopting Medicine as a profession, he soon displayed a strong inclination for the study not only of subjects closely associated with Medicine, but of those connected with general literature also. He was eminently gifted by nature with soundness of judgment and logical precision, and when settled into successful practice at Bristol, Dr. Symonds became a marked man in the worlds of classic literature and practical science."

Precedence in India.—The *Indian Medical Gazette* for September 1 has an able leading article on the injustice practised towards certain members of our Profession in respect to "precedence," and concludes an eloquent denunciation of the injustice as follows:—

"While, as a matter of justice and right to the Profession, thus asserting a claim to consideration not accorded, we can nevertheless afford to do without it; as, if we recollect right (except the substitution of one word), Milton wrote, 'None sure will claim in *Styx* precedence,' so many among us are indifferent to the manner in which the matter is settled in Indian life. They would rather 'stand not on the order of their going,' than be respected for their place rather than for themselves. For they recollect the old saying—'The top rooms of tall houses are often badly furnished, and are, therefore, "contented to sit below.'" Neither is the fable of the 'Fox and the Grapes' in the least applicable, for the fox had no right to his grapes, while we have every right to ours."

MORTALITY OF SOLDIERS IN INDIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A great many statements have been made of late with respect to the effect of the climate of India on European soldiers serving there. It has been stated that young soldiers die like flies, that the death-rate increases with every year of age, or, at any rate, that the death-rate is higher with each advancing five years of life; and while we have been told, on the one hand, that the older a man is the more unfit he is for the country, it has been argued, on the other, that men should not be sent out till they had passed a certain age, in order to enable them to withstand the depressing effects of the climate. So probably there is some happy medium of years during which the death-rate would be lowest; and if we could enlist men all at about the proper age, and keep them in India for the right number of years, we should have done the best thing, as far as saving life goes, that we possibly could do. The last Blue-book publishes, at pages 194 and 275, the usual mortality tables according to age, where, as usual, the death-rate is lowest under 20, and goes on increasing every five years afterwards. Then we are told that these tables prove what they ought not to prove, and that though, according to statistics, the death-rate is lowest of all under 20, it ought not to be so. Somehow or other, tables not proving what they seem to prove are very unsatisfactory statistical tables; and if some others could be contrived which would not mislead ordinary readers it would be an improvement. According to these tables, the death-rate in Bengal per 1000 of strength for the years 1862-66, and in Bombay and Madras for 1861-66, was 7'68 under 20, 16'11 from 20 to 25, 24'64 from 25 to 30, 32'18 from 30 to 35, 41'94 from 35 to 40, and 56'01 from 40 upwards. The ratio of deaths per 1000 of strength in Madras and Bombay for 1861-68 seems to have been, for different ages, as follows:—5'62 under 20, 14'47 from 20 to 25, 21'60 from 25 to 30, 30'21 from 30 to 35, 39'75 from 35 to 40, and 53'79 for over 40. Of course, these tables, if they prove anything, seem to prove that the death-rate under 20 is lower than at any other period, equally as they prove that the mortality is higher with advancing age; and if the latter is to be accepted as true, and the former rejected as false, it is surely fair to ask if some statistical tables could not be framed which would be true throughout. Allusion has been made to what might be proved by carefully comparing statistics according to age among men who have been the same length of time in India, and some most valuable statistical tables could, without doubt, be constructed. Why should we not have some carefully drawn-up tables showing whether the death-rate increases year by year among men who, from 18 to 20, have been serving continuously in India, or whether it increases simply with the age at which men are landed for the first time in India, or what is the proportionate increase for long tropical continuous service, and late arrival for the first time in India? It is easy to imagine that there would be a high mortality per 1000 among a number of men, all with ten or twelve years' service, many of them with damaged constitutions, who for the first time were landed in a tropical climate; and with statistics being brought forward regarding an increase of mortality, with each quinquennial period of life in India, it is allowable to ask whether quinquennial periods of continuous Indian service are meant, or whether it is only meant that the later a man or a soldier comes to India the more likely he is to die. If the latter is meant, it points pretty strongly against sending men over a certain age to India. Why should old soldiers be killed off any more than young ones? Of course every regiment coming out to India under present arrangements must bring out men with very different amounts of service, and at very different ages. Surely some tables could be formed showing the death-rate of British soldiers per 1000 for each advancing quinquennial period of continuous Indian service, or for each advancing year of continuous Indian service, and also the results of arrivals in India for the first time at different ages. Some tables might also be constructed showing the total number of days absent from duty of men at the different ages, and also with respect to the time during which they had continuously served in India. Perhaps some such tables would prove to demonstration that very little actual service could be got out of mere boys of 18 or 19; and it would be a more satisfactory thing to have tables proving what would be acknowledged universally to be true than to have tables proving one thing, and then attempts made to explain them away till they are made not at all to prove what any ordinary reader would suppose they proved. If tables showing the loss of service at different ages were ever compiled, it would be well if all days during which men were merely detained in Hospital were counted against them equally with those days during which they were on Hospital diet. Looking at the constitution of British regiments coming out to India with men at several different periods of life, it would involve the expenditure of a good deal of time and trouble to draw up statistical tables showing the death-rate and loss of service, both with respect to age and with respect to time

actually served continuously in India; but it is a very different thing whether you form tables of mortality and loss of service, constructing your statistics from the returns of a mixed multitude who arrived in India with their constitutions in very different states, at all ages from 18 to 45, for the first time, or carefully separate all men into classes according to the ages at which they arrived for the first time in India, and according to the time continuously served there. Thus, all men arriving in India at 18 could belong to one class, and the ratio of deaths and loss of service could be recorded against the class year by year for the entire period of their Indian service. Those arriving at 19 in India could form another class; those arriving at 20 another; those arriving at 30 another; and so on. We would soon find out the death-rate and loss of service for each year of continuous Indian service—with respect, also, to the time of life at which Indian service was begun. As at present formed, it cannot be learned from the Blue-book statistical tables whether it is continuous Indian service or the arrival in India at a late period of life that has most to do with the increasing mortality for each advancing quinquennial period. In conclusion, it may be remarked that if such statistical tables as proposed above were compiled for India, they could also be framed for all our other possessions.

I am, &c., SCRUTATOR.

COMMUNICATIONS have been received from—

Mr. J. DAVIS; Mr. UNSWORTH; SCRUTATOR; Mr. T. C. WHITE; Mr. R. G. WHITFIELD; Dr. CARNEGIE; Dr. W. CAYLEY; Mr. H. W. SHARPIN; Mr. W. READ; Mr. DOGGETT; Mr. T. FLOWER; Mr. R. ELLERY; Mr. G. University College Calendar, Session 1871-72—Report of the Sewage Inquiry Committee, Parish of Birmingham—Statistical Tables of the Patients under Treatment in the Wards of St. Bartholomew's Hospital during 1870—A Lecture on Diarrhoea and Cholera, by John Dixon, M.D.—Cases of Diarrhoea and Cholera treated Successfully through the Agency of the Nervous System, by Dr. John Chapman—St. Bartholomew's Hospital Reports, vol. vii.—Smith on the Preservation of Sight—The Annual Oration delivered before the Medical Society of London on May 1, 1871—Dr. Henry Adams on Intermittent Malaise—Anstie on Neuralgia and the Diseases that Resemble it.

PERIODICALS AND NEWSPAPERS RECEIVED—

Philadelphia Medical Times—Western Daily Mercury—The Staffordshire Weekly Times—The Perthshire Constitutional and Journal—Medical Press and Circular—Boston Medical and Surgical Journal—Nature—The Jamaica Gleaner—Pharmaceutical Journal—Londonderry Sentinel.

APPOINTMENTS FOR THE WEEK.

October 21. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, 7½ p.m. Meeting.

23. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Adjourned Discussion on Mr. Gay's Paper on "Crural Venosity." Communications by Mr. Spencer Watson—"1. Traumatic Dislocation of the Crystalline Lens; 2. Congenital Displacement of both Crystalline Lenses; 3. A convenient Method of applying Cold to Inflamed Parts." Mr. John Pennefather, "On the Physiology of Sound" (with illustrations).

24. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. J. W. Haward, "On Ether and Chloroform as Anæsthetics." Mr. Le Gros Clark, "Case of large Biliary Concretion in the Ileum."

25. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

26. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

27. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Dr. C. T. Williams, "Cases illustrating the Contraction of Cavities in Phthisis." Dr. John Murray, "On a Case of Paracentesis Thoracis." Dr. Anstie, "The Continuation of a Case previously reported." And other Papers.

QUEKETT MICROSCOPICAL CLUB, 8 p.m. Mr. T. Charters White, "On the Microscopical Structure of the (so-called) 'Nerve' of a Tooth."

VITAL STATISTICS OF LONDON.

Week ending Saturday, October 14, 1871.

BIRTHS.

Births of Boys, 1097; Girls, 1157; Total, 2254.

Average of 10 corresponding weeks, 1861-70, 1996.7.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 30.11 in. The highest was 30.33 in. on Friday morning, and the lowest 29.59 in. at the beginning of the week.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

Fox's "Palatable" Castor Oil

USED BY THE LONDON HOSPITALS FOR ITS CHEAPNESS, FLAVOUR, AND NUTRITIVE QUALITIES.

WHITEHEAD'S SOLID ESSENCE OF BEEF,

The only Pure Solid Extract of Beef, 1 lb. equalling 42 lbs. of Butchers' Meat.

SOLIDIFIED SOUP SQUARES

No house should be without, as they are one-fourth the cost of ordinary-made Soups. 16 Squares (each make 1½ pint) occupy only the same space and are the same weight as One Pint Tin of Preserved Soup.

Wholesale of Copland & Co., Travers & Sons, Crosse & Blackwell, E. Lazenby & Sons, and of the Manufacturers, at 8 and 9, Lime-street-square, London.

MELBOURNE MEAT-PRESERVING COMPANY (LIMITED).

COOKED BEEF AND MUTTON, IN TINS,

With full Instructions for use.

PRIME QUALITIES AND FREE FROM BONE.

Sold Retail by Grocers and Provision Dealers throughout the Kingdom. Wholesale by

JOHN McCALL & CO., 137, HOUNDSDITCH, London.

SYR. FERRI PHOSPH. CO. (AMERICAN).

PARRISH'S CHEMICAL FOOD,

PREPARED BY PARRISH, OF PHILADELPHIA,

and imported by his **SOLE AGENTS,**

P. AND P. W. SQUIRE, 277, OXFORD-STREET, LONDON, W.

For convenience and security, this preparation is supplied in 4 oz., 8 oz., and 1 lb. bottles.

Each Bottle bears the name **SQUIRE** on the Seal and Label.

PEPSINA PORCI.

Messrs. **BULLOCK & REYNOLDS**

Beg to direct the attention of the Profession to the experiments upon Medicinal Pepsin by Professor Tuson, recorded in the "Lancet," Aug. 13th, 1870, which incontestably prove the very great superiority of their preparation in point of digestive power over every other Pepsin, British or Foreign. Dose—Two to four grains.

Messrs. **BULLOCK** and **REYNOLDS** will be happy to forward a Reprint of Professor Tuson's Paper on application.

3, HANOVER-STREET, HANOVER-SQUARE, W.

WESTERTON'S PATENT ZYMOTIC DISINFECTING FLUID

Prevents the spread of infection; protects the nurse and those about the sick-room. Sponging over the body with the Fluid disinfects the emanations from the skin and (being volatile) exhalations from the lungs of the sufferer. Destroys the noxious properties of the excretions, and purifies the atmosphere.

PREPARED BY

W. C. WESTERTON, 85, Abingdon-villas, Kensington, London

and may be had of all Chemists, in bottles, 1s., 1s. 9d., and 3s. 6d.; 10s. per gall.

NEPENTHE.

PREPARED EXCLUSIVELY FROM OPIUM. (Dose the same as Tinctura Opii.) Price 8s. per lb.

From the "Lancet," Dec. 18, 1869.

NEPENTHE, OR ANODYNE TINCTURE (PREPARED BY MESSRS. FERRIS AND CO., BRISTOL).

This preparation really consists, as stated, solely of opium, resembling somewhat the liquid extract of the British Pharmacopœia. It is claimed for it that it does not produce headache, stupor, giddiness, depression of spirits, diminution of nervous energy, prostration of strength, nor constipation; it is doubtless less stimulating than those preparations of opium made with the solid and crude drug; and a further commendation of Nepenthe is its uniformity of strength. The Nepenthe intended for subcutaneous injection is of double the ordinary strength; and that it is really so we have verified by analysis.

May be procured direct from the Sole Manufacturers,

FERRIS, BOORNE, TOWNSEND, and BOUCHER,
Wholesale Druggists, Bristol,

And through all leading Wholesale and Retail Chemists in Great Britain and the Colonies.

NOTICE.—Notwithstanding the enormous and increasing advance in Opium, the price of Nepenthe remains the same, and it is now the cheapest as well as the best preparation of this important drug.

N.B. Two Pounds **NEPENTHE**, or One Pound **NEPENTHE** and Two Pounds Ferris and Co.'s **SYRUP** of **CHLORAL**, will be sent, Carriage Paid, to any Railway-station on receipt of P.O.O. for 16s.

ORIGINAL LECTURES.

CLINICAL
LECTURES ON OPHTHALMOLOGY,

DELIVERED AT

St. Thomas's Hospital,

By R. LIEBREICH,

Ophthalmic Surgeon and Lecturer to the Hospital.

LECTURE II.

EXAMINATION OF THE EYE WITH THE
OPHTHALMOSCOPE.

GENTLEMEN,—The plan which I at first proposed to follow leads us to-day to the examination by means of the ophthalmoscope. I defer, however, speaking of theory to a special course on this subject. I will just tell you as much as will enable you to use that instrument in practice.

I begin with its most simple application—namely, with the mere illumination of the eye for the examination of the refracting media. Hitherto you have not as yet to consider dioptrical conditions, but only to illuminate the eye with the mirror. The light of a flame placed at the side of a patient is reflected into his eyes by means of a concave mirror; and, by looking through the centre of that mirror, you will be able to observe his pupil luminous with a red light. This red light comes from the fundus, and passes through the refracting media of the observed eye, before it reaches the observer. If there be any opacities within the refracting media, they will interrupt the course of the red light, and appear as black spots in the red pupil.

The first question which you have to ask yourselves, on seeing those black spots, is—In what part or parts of the refracting media are they situated? for opacities in the cornea, crystalline lens, and vitreous body may at first sight appear perfectly alike. You can most conveniently arrive at a differential diagnosis, if you attend to the following points, which I will illustrate by an example:—Supposing there be opacities in the centre of the cornea as well as in the anterior and posterior surface of the crystalline lens, and in the centre of the vitreous body, and that they cover each other, then those opacities will appear as one single black spot in the fundus, if the eye is observed in the axis of the pupil. But if their respective positions are changed, either by the movement of the head of the observer or by making the patient roll his eye, the opacities which were before seen coinciding in one part now appear isolated. To understand the way of localising those opacities from the change of their mutual position, you will have to consider the following principle:—

The centre of rotation of the eyeball remains unchanged in these movements. Everything situated in front of it is turned in the direction in which the eye moves; but everything situated behind it is turned in the opposite direction. Since the posterior pole of the crystalline lens is situated so very close to the centre of rotation of the eye, its displacement, during the movements of the eye, will be almost *nil*. Consequently, an opacity at the posterior pole of the crystalline lens will remain during the movements of the eyeball almost fixed. For similar and obvious reasons, an opacity in the anterior pole of the crystalline lens moves only a little, and remains in the centre of the pupil; that in the cornea turns more considerably to the side to which the eyeball has been rolled, and passes over the margin of the pupil; whilst that of the vitreous body moves in the opposite direction.

As regards the movements of the opacities of the vitreous body, you will have to distinguish the apparent from the real ones which are a consequence of its partial or total softening. This change of position I consider a most useful and practical diagnostic sign. Other means, as the use of the various concave and convex glasses, require more careful investigations into the optical conditions.

After the refracting media have been examined by the mere illumination by the ophthalmoscope, and after the result of the examination by lateral illumination has been controlled so as not to over-estimate the easily observed opacities, you may now begin with the examination of the very fundus of the eye, and first with the observation of an inverted image. For that purpose you have to stand about twelve to fifteen inches from your patient, and, after having illuminated his eye in the same manner as before, hold a lens of two and

a half inches about two inches before the eye of the patient. This lens collects all the luminous rays coming from the illuminated fundus into an inverted image, which is thrown from two to three inches in front of the lens, in a direction between it and the observer. This fact is especially to be noted, lest you involuntarily arrange your accommodation for the distance of the lens, whilst the image situated in front of the lens has to be considered.

The patients whom I am going to show you to-day have naturally or artificially dilated pupils. But I sincerely hope that in a short time you will have acquired practice enough in the use of the ophthalmoscope to enable you to examine accurately the fundus of an eye even with a contracted pupil. Let me here warn you not to abuse atropine for a mere ophthalmoscopic examination. I am sorry to say that I have frequently seen *strong* solutions of atropine used for the sole purpose of facilitating ophthalmoscopic examination. By its means patients have been prevented from attending to their work for a week or so, which, especially as regards the poor, is an injustice. Many Medical men have the wrong notion that, for the ophthalmoscopic examination of the eye, atropine is absolutely necessary; and often patients have been brought to me by their Medical attendant, who had had their pupils previously dilated by atropine in order that I might have no difficulty in examination. This was as disagreeable to me as to the patients, for I could not test the accommodation of their patients.

There are, however, cases of amaurotic or highly amblyopic eyes, in which the instillation of a drop or two of a *weak* solution of atropine will do no harm. If the pupil is very contracted, and if there are opacities of the refracting media, even the most practised observer would be obliged to have recourse to atropine. To-day's cases will not offer you any of these difficulties. On the contrary, by correctly adjusting mirror and lens, you will immediately recognise the red surface of the fundus. The aspect of this fundus is very variable in different individuals, as to colour and drawing. If we wish to understand the signification of these variations, we should first study the effect which is produced by the different elements of the deeper eye-membranes upon the general ophthalmoscopic aspect of the fundus.

The retina, being almost transparent, has only a small effect on this aspect, which we will pass by for the moment and speak of later.

On the contrary, the choroid has the greatest influence upon it, its different layers taking part in this influence in different proportions. We have to distinguish between the effect of the following layers:—*First*, the most anterior—that is, the layer of pigmentary epithelial cells; *second*, the layer called *chorio-capillaris*; *third*, the strongest posterior layer, which is composed of a very close network of vessels and pigmentary tissue supporting these vessels. The different degrees of pigmentation in the anterior and posterior layer give the principal reason for the great variations in the aspect of the fundus. The anterior part of the choroid is composed of a simple layer of pigmented hexagonal epithelial cells. If the pigmentation of these cells is very dark, as is the case in persons with black hair and dark eyes, this layer is capable of covering almost completely the other parts of the choroid, and then the fundus appears brown instead of red. If, on the contrary, the pigmentation of epithelial cells is very weak, as is the case in persons with fair hair and blue eyes, this layer permits us to distinguish the posterior parts of the choroid. The tissue supporting the vessels, being of weak pigmentation, also enables us to recognise the network of choroidal vessels, even to the smallest branches. These latter are covered, and the largest vessels only are visible, if the epithelial cells are of weak pigmentation, but the tissue rather dark. In such cases the aspect of the fundus is a singular one, and has often occasioned erroneous diagnosis of pathological alterations. All or part of the fundus seems to be covered with irregular grey spots, separated by a network of more or less well-defined little red bands. A more attentive examination teaches us that these little bands are the principal branches of choroidal vessels, and that the grey spots are formed by the pigmented interstices, in which the smallest vessels are covered by the pigmented connective tissue.

We did not mention the effect of the second layer (the *chorio-capillaris*), because we believe that this layer has no effect at all on the ophthalmoscopic appearance of the fundus of the eye. This (which I expressed many years ago) was, at first, energetically contested by other observers, who attributed to this layer the principal effect of the more or less intense red colour, and of the granulated aspect of the fundus.

This question had the greater importance, as conclusions for pathological alterations could be drawn from the colour of the fundus; if, for instance any hyperæmia of the *chorio-capillaris* could change the colour and appearance of the fundus.

If you examine anatomical preparations of the choroid injected with a substance coloured with cinnabar, for instance, you will see that the *chorio-capillaris* forms so close a network of vessels that it alone determines the microscopical aspect of the preparation. But such is not the appearance in the living eye. Here the vessels are not filled with an opaque substance like cinnabar, but with blood, a transparent liquid which appears red if it has a certain thickness—equal, for instance, to the diameter of the smallest bloodvessels which are visible to our naked eye. But if the blood only forms columns of as fine diameter as the capillaries of the choroid, it does not appear at all red, but only of a very light yellow colour.

A drawing, made in lines as delicate, and of an equally pale colour, would be nearly invisible, even under the enlargement given by the ophthalmoscope, though made on an entirely white fundus. It is utterly impossible to see it in the red-brown fundus formed by the posterior parts of the choroid, the more so as it is not denuded on the anterior surface, but covered by a layer of epithelial cells, which, even in the lowest degree of pigmentation, suffice to efface any effect of this fine second choroidal layer; and so it is not at all the *chorio-capillaris*, but, on the contrary, the layer of epithelial cells, which forms the characteristic granulations of the fundus, the very exact observation of which had so great importance for the diagnosis.

This opinion, so vigorously contested when first advanced by me, is now generally adopted, and I hope you will all be convinced that it is possible to recognise even the isolated cells as I have described them. The cases most appropriate for this study are those of a moderate degree of pigmentation, like Figures 4 and 5, Plate II., of my "Atlas." In such cases you can really count the cells, and there is no possible doubt but that they really are the epithelial cells which produce the characteristic granulated aspect of the fundus. In order to recognise this, it is well to examine the upright image, and it is indispensable to be very exactly adjusted to the distance, not only of the fundus in general, but exactly to the anterior surface of the choroid. For the same reason the observation of the cells can help you to control the exactness of your adjustment.

For pathological observations it is also very important to direct our attention to the cells; firstly, because they are themselves the seat of important changes visible by the ophthalmoscope; and also because they furnish us with the best means of recognising the place of other changes—to distinguish, for instance, between different white spots produced by alterations either in the retina or in the choroid.

THE
DISCUSSION ON PURULENT INFECTION
AT THE
PARIS ACADEMY OF MEDICINE.

By Professor VERNEUIL.

(Continued from page 404.)

I HAVE no idea of here describing septicæmia, but I shall be obliged to recall a few of its principal characters essential to my argument:

1. The mediate or immediate contact with sepsine.
2. The mixture of this latter with the blood.

Although sepsine produces itself wherever animal matter becomes putrified, it is well to mention the circumstances under which it enters into conflict with our organs. Putrid decomposition comes on inevitably after death of the individual; but it can also invade parts still adherent to the living organism. This is frequently observed in gangrene, at the surface or in the depths of wounds, when the anatomical elements are exposed to a prolonged action of the air; or to altered secretions, when the decomposition invades the normal or pathological humours, blood, urine, pus, etc., yet contained in the natural or accidental cavities. Violent inflammations, whether superficial or profound, when arrived at a degree close to mortification, also generate products very similar to, if not identical with, sepsine. I shall cite, as example, the diffuse phlegmon, osteomyelitis, and osteoperiostitis, which cause such a suite of symptoms that M. Chassaignac has given it the characteristic name of "typhus of the extremities."

Certain parenchymatous inflammations—nephritis and hepatitis among others—bring about a general state quite comparable to septicæmia. The septic focus may, therefore, be fixed to the body or be more or less distant; how, then, does the sepsine mix with the blood? The penetration in the first case can be easily understood, only a feeble barrier intervening between the poison and the absorbents. The veins, and especially the lymphatics, are on one side, the sepsine on the other. The transfer is, unfortunately, very easy. However, we must not forget that this absorption does not take place necessarily; for, as I have already observed, a wound or an inflamed part may conceal a good deal of septic matter without the general state of the patient (*septifère*) being modified.

In order to appreciate the greater or less chances of *auto-infection*, we must take into consideration the general conditions which are opposed to or favour absorption: the smooth or ragged form of the focus, wound, abscess, or cavity; the composition and anatomical state of the surface of this focus; the retention, the stagnation, or the easy flow of the putrid matter; the condition of the peripheral circulation of the blood or the lymphatics, and the circulation in general; the period of the primary lesion, or the health of the subject, etc. All these are conditions which the Surgeon must examine, and which help to explain nearly all individual variations.

It is also well to remember that the production of sepsine varies from one day to another in the same individual. It is almost constantly developed on the surface of recent wounds, or a few days after the opening of a cavity; but it often disappears in a short time, ready to come again in case of a bad dressing, a local irritation, some imprudence in the diet, or on account of the development of some intermittent disease. The changes in the aspect of the exposed surfaces and of their secretions give sufficient warning of these caprices; but we yet wait for chemists to give us a reactive agent, of easy use, by which to recognise and estimate approximatively the putrid poison.

The same variability exists in the absorption—a subject which, quasi-apyretic this morning, may to-morrow, or even this evening, absorb a certain dose of the poison, and become feverish. The thermometer gives these daily oscillations better than any other sign. Lastly, we often find the products of normal and pathological secretions mixed with the ordinary products of putrefaction of the general tissues and the nutritive liquids. From the mixture of sepsine with the urine, the bile, the intestinal matters, the synovia, the pus, result chemical combinations, badly known, but which impart particular types and characters to septicæmia. We can, consequently, admit a urinous, a stercoral, a bilious septicæmia, and so on. The most common of these complex forms is the septic-pyohæmia.

Another point to be taken into consideration, aside from the preceding causes which are capable of influencing the progress of septicæmia, is the power which the economy possesses of ridding herself of the poison by the natural outlets. Sepsine escapes with the excretions of the skin, with the pulmonary exhalations, and especially with the intestinal secretions. The ordinary expulsion takes place spontaneously; but it is well to favour this elimination. Unfortunately, it is not rare to see the poison remain and accumulate in the blood; and in that case the danger is great, for this concentration may be counted among the most certain and most irremediable causes of death. (The wounded of last winter, mowed down by septicæmia and pyohæmia, were for the most part constipated.)

This much of the pathogeny of septicæmia originating from the patient himself. Let us now study the case when the septic focus is extrinsic—that is to say, placed away from the patient. At the time of the perilous contact, the future septicæmic individual is well, or, at least, is merely the bearer of a local lesion, without any appreciable reaction. In what way will the sepsine invade that organism? How will this form of septicæmia be developed? It is here where the difficulties commence and the different interpretations prevail, though the fact itself is undeniable.

Sepsine is a fixed poison which attaches itself to any solid body—to pieces of dressing, sponges, linen, charpie, instruments, or the Surgeon's clothes—dissolves itself in the fluids of the wound, and which, also, easily spreads through the atmosphere, owing to the dried *débris* or particles of dust which the air is charged with, and in which epidemic or pus cells, filaments of linen, etc., can be easily recognised. A septic miasma, in the latter case, can be admitted without inconvenience—that is to say, a mixture of air and toxic matter, in indefinite proportions. If this definition of miasma

does not suit my colleagues, I shall be pleased to accept a better. I may here remark that the terms of miasma and virus are by no means contradictory, and can be applied to one and the same poison: of this we find a proof in variola.

Sepsine, whatever may be its molecular state, envelopes its victim, and looks for an opening by which to enter. The skin of the mucous membrane of the digestive canal, as long as the epithelium is intact, is proof against admission. The cutaneous surface, among others, only yields to violence, and the poison can only traverse it in case of direct inoculation or the previous existence of a wound. The efficacy of inoculation is sufficiently demonstrated by the innumerable experiments made upon animals, and by the lamentable history of dissecting-wounds. As to recent wounds, their aptness for reception is not doubted, though this varies according to the state of the surface and the period of the accident. A recent wound represents all the conditions of inoculation, and will admit of all the forms of contagion. A chronic wound, covered with healthy granulations, is more refractory, except, consequent upon some accident—and which is infinitely more frequent than we think—it becomes the seat of a new wound, occasioned by an exploration, a movement of the patient, a muscular contraction, or the tearing away of a piece of dressing, etc.

Be this as it may, it is impossible to deny that the contagion is effected by the wound, whether the agent is brought by the dressings, the instruments, the fingers of the Surgeon, or by the surrounding air which has become miasmatic; but it is more difficult to know if this same air, introduced by the respiratory channels, can carry with it into the circulation the sepsine with which it is charged—if, to quote Marshal, "*le principe de mort peut se glisser avec le principe de vie.*"

No doubt but that the inspiration of putrid emanations is dangerous, and may even cause death. The experiments of Magendie, the accounts of fatal accidents observed after certain autopsies or late exhumations, the well-proven effects of overcrowding, have long since rendered all hesitation on this point impossible. I will add that the general state observed in these circumstances presents the greatest similitude of symptoms with septicæmia. If, therefore, by crowding patients not wounded, and even persons in health, a poisoning takes place, how then can we admit that wounded assembled in too large a number escape the well-known influence of adulterated air?

In order to avoid the dangers of induction, I began, in my wards at the Lariboisière, direct researches, to know if persons not wounded could with impunity support the surroundings of patients suffering from traumatic septicæmia. These researches are not yet terminated, but I can affirm that, in certain very evident cases, this proximity provoked a nosocomial fever in individuals who had entered the Hospital for a contusion, an insignificant subcutaneous fracture, and even in those who were merely awaiting a Surgical operation. I speak of these cases with complaisance, for when in the presence of a more or less tardy case of septicæmia, we may well ask if the disease depends upon an auto-infection, an hetero-infection (both having their origin in the wound), or if it depends upon an infection through the respiratory channels, and only due to overcrowding.

(To be continued.)

ORIGINAL COMMUNICATIONS.

CEREBRAL AND GANGLIONIC DISORDERS OF MENTATION.

By METCALFE JOHNSON, M.R.C.S.E., L.S.A.

PART I.

THE author of a book called the "Pilgrim and the Shrine"—a comprehensive thinker of our day—has put into words what has passed through the thoughts of many of us when he says, "the constant repetition has utterly destroyed the meaning of words for me." This is so much the case in general language that Dr. Oliver Wendell Holmes speaks of words becoming "polarised." I offer these remarks as an apology for using the word "mentation," which seems to me to convey the whole process resulting from the combined action of all the organs concerned in the generation, conveyance, and reception of thought more correctly than any one or more of the old words in common use among us.

During the last four years I have endeavoured to direct attention to the subject of Mind, from several aspects of import-

ance (theoretical and practical), in a series of papers published in the *Lancet* and the *Medical Times and Gazette*. In the *Lancet*, September 26, 1868, the relation of the sympathetic nerve to the operations of the mind was pointed out; September 18, 1869, the various conditions of perception, as anæsthesia, dysæsthesia, enæsthesia, and hyperæsthesia, were alluded to; and March 19, 1870, the question of responsibility was considered. In the *Medical Times and Gazette*, April, 1871, under the term "Hedonism," individual peculiarity was discussed; and September 30, 1871, the relation of certain mappings of the frontal convolutions to sane and insane mentation was laid before your readers; and it is now proposed to draw attention to these and other cases of a similar nature by entering into further details respecting them, with a view to show not only that there are two distinct phases of aberration from healthy mentation (one due to abnormality in the cerebro-spina, the other traceable to disordered function of the ganglionic system of the great sympathetic nerve), but to enforce more earnestly the consideration that the process, which is here called by the collective term "mentation," is not solely the result of the physiological action of the brain alone, nor even with the assistance of the continuous network of spinal nerves of which the cerebrum is the collecting centre, nor yet with the addition of the great sympathetic, with its ganglia (resembling the receiving offices of a great postal or telegraphic system), but every bone, muscle, tendon, ligament, fascia, fibre, or cell of the whole body is required in its entirety to make up what Professor Owen, in his pregnant words, calls the spiritual "sum of the force centres termed body."

In the following cases we have examples of various conditions of brain—brain in which parts are deficient from arrest of development; brain in which disease is superadded to deficient substance; brain in which infantile disease has impaired the efficiency of otherwise powerful substance; brain in which function has been impaired by deranged ganglionic nerve; and healthy brain doing good and sane service as the principal centre whence is evolved the function of mentation.

In the following table of head-measurements the centre is taken at the tragus of the external ear on either side, the temporal over the eyebrows, frontal over the forehead, parietal over the crown of the head, occipital over the occiput (midway between coronal suture and occipital protuberance), cervical below the protuberance, and oblique from the tragus to the middle of the eyebrows round the occiput.

A. B., No. 1, is a macrocephalous female, aged 40 years, of very weak intellect. The only history of parents is that the mother had macrocephalous offspring as well. The cause of her macrocephaly unknown, as well as of B. B., No. 2, her brother. These two are very striking instances of small heads with more intelligence than the size of the head would lead to expect.

A. B. was able to tell pence from shillings, and before she came to the workhouse would buy and pay for her own food. She was of a kind and gentle disposition, could understand much that was said to her, and expressed her wants in very fair words. She slavered slightly, and stooped in her gait, which was very ungainly. Her health (except asthma) was good; catamenia regular; showed no signs of genital desire. Was very fond of ribbons, and of a doll. Appetite very large; would eat till she vomited. Would eat uncooked food or dough. She died of carbuncle. A post-mortem examination of her head revealed the following particulars:—

On removing the scalp, the distance between the origin of the two temporal muscles measured three inches. Beneath the calvarium, dura mater not adherent; the falx a quarter of an inch deep; fibrous texture very visible. Arachnoid perfectly transparent in all parts; vessels large, and full of blood.

Weight: Cerebrum 14 oz. 6 drachms.
Cerebellum 4 oz. 6

Total 19 oz. 4 drachms.

Shape of brain oval, corresponding with the skull, which was not thick, but firmly ossified.

The posterior lobes just covered the cerebellum. The anterior lobes much less developed than usual. The sulci all over very shallow, in some parts being mere indentations, the most developed varying from half an inch to three-quarters of an inch in depth. The frontal fissures on the left side were both absent, while the superior frontal on the right side was so slightly developed that the gyri which they isolate were little more than rudimentary. The fissure of Sylvius very shallow, straight, and terminating in the middle outer side of middle lobe. Fissure of Rolando not very well marked. The callosomarginal of right side terminates in a cul-de-sac at the middle of corpus callosum; on left side runs parallel to the end. The horizontal depth from surface of brain to anterior commissure of corpus callosum, one inch and a quarter; perpendicular, three-quarters of an inch; to posterior commissure, perpendicular, one inch and a quarter. Olfactory bulbs and nerves very large, especially the external root. Substantia perforata and locus niger very distinct. Centrum ovale minus showed the sulci very shallow. Grey matter very distinct, dark, one-eighth of an inch to three-sixteenths of an inch thick; equally thick in anterior and posterior lobes. Corpus striatum very distinct and large compared with the whole brain. (a) Choroid plexus light in colour. Fluid in ventricles healthy, and normal in quantity. Grey matter of corpus striatum easily separable from the white fibres surrounding it; on the outer side separates almost like a nut. Pons Varolii small, and rather soft. General substance of brain very firm. Here we have an apparently healthy brain, whose development has probably been arrested between the sixth and seventh months of intra-uterine life.

No. 2 is the head-measurement of B. B., brother to A. B., aged 45, still living; earns three or four shillings a week at a coal-yard. His intelligence is very limited—does not know how many pence in a shilling. I gave him 2d., and asked him, "What will you do with it?" He replied, "I can get hæfe an ounce o' 'bacca wi' it, and git a ho'penny out." His actions and gait are ungainly; he does not slaver much; plays marbles with boys; is very good-tempered; has a large appetite; but takes no notice of women. On the whole, his intelligence is superior to that of A. B.

No. 3 is the measurement of A. C., aged 16, an idiot of lower mental power, who laughs at everything said to him. He knows money when it is given to him, but answers no questions. All his measurements, except the temporal, are larger than the two B.'s.

No. 4.—A. D., aged 50; weak intellect; always was strange in manner; children shout at her in the street. She is, however, sharp enough to do some work as a servant.

March 20, 1870.—I was called to her and found her taciturn, eyes shut, skin cool, conjunctivæ clear, pulse quiet slow, 65; attempted suicide with a hair-pin by making a hole in her throat.

22nd.—Still silent; pulse 70; tongue blistered; after two turpentine enemata, bowels open; no scybalæ; takes no food.

27th.—Silent; eyes quiet closed.

29th.—Pulse 74; temperature 98°40'.

April 7.—Pulse 96; takes more notice; tongue clean; bowels open; temperature 96°60'; has eaten some food.

13th.—Sits up in bed, and eats more.

28th.—Sits up out of bed; speaks reluctantly; eats more.

After this she recovered, and returned to her place.

No. 5.—B. E., female, aged 42, factory operative, insane; has been depressed in spirits six months; delusions about stealing; sleeps badly; hears noises; speaks slowly, and stammers; tongue white; skin cold; pulse 72; eyes restless. Sent to asylum.

No. 6.—A. F., female, aged 40, servant, insane.

October 13, 1869.—Skin cool; pulse 74; tongue clean; continually moaning "Lord have mercy on me; let me stop here,

I don't want to go;" delusions about something inside her which eats her food. Was in workhouse two months, always the same, moaning and talking almost incessantly night and day. No account of any catamenia.

Here was an instance apparently of cerebral insanity in a slightly macrocephalous female, possibly superinduced by ganglionic derangement through the genital organs (ovaries).

One point worthy of notice in the history of the case is, that November 16 and 19, when she was less depressed, the pulse rose to 84 and 85.

No. 7, C. G., female, aged 45, factory operative; feeble mind, very tidy, and virtuous. The parietal measurement is better than the others.

No. 8, A. H., aged 36, an "army lawyer." A very interesting case, having, whilst in the workhouse, resisted all law. He died of asthma. Post-mortem examination of his head revealed—frontal sinuses very large, so as to render fallacious the measurement called temporal, which is large; his parietal was good, but occipital very small; calvarium separated easily; veins of dura mater large and full of black blood; arachnoid full of vessels, very thick and opaque over middle third, very opaque over right anterior third, more like a fold of dura mater than arachnoid; pia mater very dark, and not easily detached from the convolutions. The whole brain very soft; bloody points numerous. Ventricles healthy; fluid natural; outer wall of right lateral ventricle very much softened. Grey matter very distinct, three-sixteenths of an inch thick over the general surface, but posteriorly much paler and less distinct. Middle lobes both very soft; olivary body perfect, and spinal columns well defined; cerebellum healthy; optic nerves distinct and full-sized (he had opacity of both corneæ and lippitudo for some years); olfactory bulb small and very soft. Here was a man whose development of cerebro-spina was not only at fault, but had been at the same time the subject of disease, while the ganglionic instincts were abnormal, or had become so, as evidenced by craving for drink when at liberty. His intelligence was small, not being able, even by the assistance of pen and paper, to discover how many pence were in a sovereign.

No. 9, J. K., aged 68, is an example of a man of considerable ability—very taciturn; a great drunkard in early life; what you might call a good common-sense reasoner. His occipital measurement, compared with No 8, is very large; it is larger than the average. He was sensible to within a few hours before his death.

Post-mortem examination showed results as follows:—

Weight: Cerebrum 48 oz. 4 drachms.
Cerebellum and pons Varolii 7 oz.

Total 55 oz. 4 drachms.

The whole brain very soft; meninges healthy; no opacity; vessels of pia mater large and full; olfactory bulbs large; optic nerve large; pineal gland gritty; infundibulum strong; grey matter distinct, equal throughout, one-eighth of an inch thick; sulci deep—perpendicular depth from surface of convolutions to anterior commissure of corpus callosum one inch and a half, to posterior commissure two inches and a quarter—(compare this with A. B.); fissures of Sylvius and Rolando natural; superior frontal fissure of right side longer and extending more into the front than that of the left; bloody points few; no fluid in the ventricles.

The following case (No. 10, C. L., aged 56) presents many points of interest as a brain deficient from early life in some parts of its fibrous structure. Two of the measurements are omitted, but the circular, the cervical, and oblique are above the average:—

He was born of a clever industrious father, and a mother of rather weak intellect. Had several brothers—all clever—one a very prosperous man with a large head, who died of apoplexy. No history of fits or brain disease to be heard of. C. L. was a stupid boy at school, a very difficult child to manage; was severely chastised as a lad, but to no purpose. He was always strange, and in after years was treated as a "half-wit." As a man, very cunning. Like his brothers, he had woolly-curly hair and a rather negrine cast of face.

Post-mortem examination of his brain revealed—skin of scalp very thin; bones of calvarium very thick and soft; weight of cerebrum and cerebellum fifty-four ounces; arachnoid opaque over middle lobes. At the insertion of the veins on the left side the membrane was firm and very tough. A slight opacity and adhesion of the left middle lobe in the cavity of the sphenoid bone. The lobes of the two hemispheres adherent by the arachnoid in front. The fissure of Sylvius—left passes far into the posterior lobe; the right terminates in the middle

(a) It is worthy of remark that the angle formed between the brow, the tragus, and the horizontal line proceeding from the tragus is very constant, and corresponds with the base of the skull and its contents, the corpus striatum, and thalamus opticus.

lebe. The superior frontal fissure—right passes lower to the front than the left. The fissures of Rolando equal on either side. The intra-parietal and parallel fissures well marked; the parieto-occipital less so. Right lateral ventricle natural in size; fluid rather in excess of natural quantity; grey matter of convolutions distinct, but thin; corpus striatum healthy; striæ very distinct. Left lateral ventricle very much enlarged, measuring when opened six inches antero-posterior diameter, and five inches lateral, giving twenty-two square inches of surface in the interior of the ventricle. Substance of brain around very firm; grey matter equally distinct with that of right side. Thalamus opticus rough, but grey matter very distinct. The calloso-marginal fissure of the right side was very straight, extending from one end of the hemisphere to the other. That on the left very tortuous, commencing at the upper surface of posterior third, and terminating in front of the anterior commissure of corpus callosum.

Nos. 11 and 12 are the measurements of two persons of very feeble intelligence, whose size and shape of head resembled those of the very intelligent. In both cases the gait is very awkward, but the appearance of the face alone is in both cases remarkably pleasing. The manner and speech are, of course, indicative of low intelligence. Possibly (as, I think, was the case with C. L., No. 10) they may have only *narrowly escaped* being very clever men. The relatives of No. 12 are (in one instance especially) very clever as a family.

Nos. 13 and 14 are two remarkably clever men, but diametrically opposed in the nature and development of their talents.

No. 15, H. M., aged 47, is the measurement of a man whose hedonism is certainly disordered, but whether the result of cerebral or ganglionic derangement it is difficult to diagnose. I have been told that, some years ago, he was found walking in the streets of the town perfectly naked. He was afterwards sent to an asylum, and there the diagnosis was found puzzling. He is very taciturn at times, and generally seemed desponding. He will not work, but sits idling all day in his ward.

No. 16, E. N., aged 21, whose head-measurements are not complete, was a case of pure hysterical insanity, brought on by menorrhagia. Her excitement was severe, but of a very cheerful character.

Cases of this kind are of such frequent occurrence that a reference to them is all that is necessary. In such and such-like we should look in vain for cerebral lesion, and the pathology of the ganglionic nerve is not yet sufficiently advanced to admit of demonstration in the nerve itself; but the following case, though not one of insanity of mentation purely, will serve, together with some very interesting cases reported by Dr. Wilks, in a paper on the "Functional Diseases of the Nervous System," in Guy's Hospital Reports, to demonstrate the bearing of this subject on the general question of ganglionism:—

No. 17, O. P., aged 25, a servant, well developed, with convergent strabismus. Mother is an intelligent but rather eccentric woman; father clever, but intemperate.

Mother says she was always well till puberty, at 17; a very great "romp"; after 20, catamenia very irregular. She never cared for the society of men. Twelve months since had severe vomiting, with hysterical symptoms.

January 1, 1869.—Has been ill a month; emaciated, especially in face; pain in pit of stomach; vomits blood (coffee-grounds); she is asthmatic. Mother says she has taken no food for five weeks. Voice completely gone. Pulse 72; tongue clean.

3rd.—Passed three large scybalæ.

8th.—Pulse 72; skin cool; tongue clean; vomit black; milk by enema returns black in five hours; hypodermic morphia does not produce sleep.

9th.—Pulse 72.

10th.—Tongue clean; skin cool. Parted with a lump of blood per anum. Eats onions, vomits them, and passes them per anum.

12th.—A fæcal evacuation; skin cool; pulse 72; tongue dry; vomiting much slime and blood.

23rd.—Pulse 72; tongue clean; skin cool; bowels act of their own accord; vomits, as before, onions; voice still mute, but occasionally returns slightly.

February 19.—After having some ease by morphia taken by mouth, she gradually became weaker, and died yesterday.

To-day I made a post-mortem examination of the abdomen:—Stomach perfectly healthy; empty. Bowels healthy; empty so far as sigmoid flexure of the colon; at the commencement of the colon there were minute granular masses of fæcal matter, increasing in size all along the bowel to the rectum, which was full of large masses of hardened fæces. Uterus and ovaries healthy, except a small cyst at the end of left Fallopian tube. Spleen healthy; bladder empty; kidneys healthy. The rest

of the body was not examined, but, from the symptoms, I am inclined to believe that death resulted from injury to the sympathetic nerve—whether caused by the pressure of the scybalæ, or the scybalæ caused by the disordered nerve, I cannot tell; but in the course of her history I had often occasion to notice that she was decidedly eccentric in her manner, at times almost amounting to insanity. She was very intelligent, and very truthful, and her case was one of great interest.

(To be continued.)

WELL-MARKED APHASIA WITHOUT PARALYSIS—RECOVERY.

By WILLIAM VAWDREY LUSH, M.D. Lond.

ON May 4, 1871, I was called to Mrs. S., a lady past 60 years of age, whom I had attended on several occasions, generally for attacks of acute or subacute rheumatism, without cardiac complications. The account given me was, that she had been confined to her bed for four days with rheumatism, principally affecting the right foot and occiput; that she had got better and been up for two days; that she went to bed fairly well. About 11.30 p.m. her daughter noticed her mother sitting up in bed, with flushed face, falling from side to side, and not able to speak as usual. There was no loss of consciousness. Her daughter gave her some brandy-and-water. She became "herself," and went to sleep again. About 5.20 a.m. her daughter woke up, and found her mother again sitting up in bed, and apparently recovering from another attack; her speech affected, but not so much as in the first attack. Some brandy-and-water was again administered, and the patient appeared relieved. Subsequently she ate a mutton-chop for breakfast.

On my arrival I found the patient downstairs, reclining on a couch or sofa. Her face was pale. No loss of consciousness, but a want of her usual readiness of speech, she now and then forgetting a word, or hesitating in the word she wished to say. Pulse somewhat feeble, 70 to 80. Heart sounds—no murmur; now and then diastolic. R. Potassæ bicarb. ʒij., sp. ammoniæ aromat. ʒiss., tinct. cardamomi comp. ʒij., aq. distill. ad. ʒvi.—ʒss. c. aquæ ʒss. statim et secundis horis. On the occurrence of an attack, an ether and ammonia draught to be given. Beef-tea, milk, brandy-and-water. 7—8 p.m.: In bed. In much the same state. Pulse 80.

May 5.—Passed a quiet night. Remains in bed. To-day (12—1, noon) appears decidedly more aphasic. Could not tell me the names of a watch, a ring, or a bottle when the articles were shown her. Pulse 66, with tendency to intermission. No cardiac murmur. Rept. mistura c. potassæ bicarb. ʒij., et liquor cinchonæ ʒj.

6th.—Has passed a quiet night. Still very aphasic. Could not tell me the name of a watch when shown it. Was much distressed at not being able to do so. Tried to relate some circumstance, but could not convey her meaning. Tried to write it. Wrote with a pencil "Regenbys theren," and relinquished the effort. (It was subsequently ascertained that she wished to state that she had at her second attack been frightened by the running down of an alarm clock.) Countenance pale. No inequality of pupils. Pulse 72; hands cool; tongue clean. I could detect no paralysis. I could not get the patient to inflate her cheeks; but her daughter states that she can eat and drink, neither food nor drink escaping from the mouth. Has eaten a kidney for breakfast. Starts at sounds. Continue mixture. Tranquillity enjoined. Cotton-wool to be placed in ears.

7th.—Patient was restless in the night. Pulse 72. Daughter has had her first mixture repeated. To take it every three hours.

8th.—Has passed a good night. Face flushed from stimulus. Pulse 72. R. Mist. quartâ quâque horâ.

9th.—Patient more restless in the night. Was found awake by her daughter, who has slept with her throughout, and deemed by her to be suffering from indigestion from the medicine. Pulse 68, with tendency to intermission. Takes her food well. Told me the name "ring," but failed to tell me the names of watch or bottle. R. Liquor cinchonæ (Battley's) ʒij., pot. bicarb. ʒij., sp. ammoniæ aromat. ʒij., tinct. cardamomi comp. ʒij., aq. camphoræ ad. ʒvj. Misce. Sumat ʒss. c. aquæ ʒss., quartâ quâquo horâ.

10th.—Has passed a good night. Pulse 72. Enjoys her food.

17th.—During my absence has been attended by Dr. Griffin, who continued my treatment. Converses much better. old

me the names of "watch," "ring," and "phial" on being shown the articles. Pulse 72. Allowed to get up. To take an aperient pill (ext. colchici acetici, etc.) to-night.

June 5th.—Patient has had some rheumatic pains. Bears riding in a bath-chair well. Has written a letter.

7th.—Pulse intermittent at times. I suggested good sherry (three glasses per diem) instead of brandy.

On the 12th, 13th, and 14th patient had slight bleeding from nose. On the 14th I received a note from the patient quite correctly expressed and spelt. Subsequently she left Weymouth for Derby.

On August 10 I received from my patient a well-expressed letter occupying two sheets and a half of paper. She had received no Medical treatment. Her principal complaint was of weakness and a severe cold in the head, accompanied with dryness of the throat, etc., on account of which she had discontinued her sherry. Previously to the aphasic attack she had had much mental strain.

Weymouth.

ANALYSIS OF ONE HUNDRED AND EIGHTY-TWO CASES

TREATED IN THE LOCK WARDS OF THE ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.

By JOHN WARD COUSINS, M.D. Lond., F.R.C.S.,
Surgeon to the Royal Portsmouth Hospital.

(Concluded from page 470.)

MANY of the patients referred to in the table (page 469) had been previously under treatment, labouring under chronic vaginal discharge, and some of them have been inmates of the Lock Hospital over and over again. After a few weeks' rest and cleanliness, in a large majority of cases, the external organs and vaginal secretion appear to the eye healthy, but soon neglect and dissipation bring back all the old symptoms. It is true that the vaginal mucous membrane is in some cases red, patchy, and granular, and that in others the morbid action clearly extends to the uterine cavity; still, in very many, little local change can be detected beyond a pale and relaxed condition of the mucous surface, accompanied with excessive discharge. Now, the daily mode of existence of this class of women must render them prone to unhealthy secretion; and this, I believe, is dangerously modified by the chronic and often latent cachexia which many of them possess, and that it is sometimes the inoculating fluid by which syphilis is communicated to the male.

I now wish to draw attention to a very important practical question, which has probably very often occurred to many of my Professional brethren who have been engaged like myself in this department of practice. The Contagious Diseases Act provides, by the 31st clause, that prostitutes who are labouring under chronic disease, and who have been detained some months under treatment, can be discharged by the Medical officer with a certificate stating that "they are still affected with a contagious disease"; but if they are found in any place for the purpose of prostitution, before they have received another certificate showing that they have been entirely cured, they are liable to imprisonment. Now, I affirm that there is often great difficulty in declaring when the period of danger is safely passed over, and when women who have laboured under a constitutional taint may safely be permitted to return to their loathsome and unnatural vocation.

Syphilis in a large number of cases is undoubtedly a curable disease; but is it not a long time in running its course? and does it not often crop up in some new form, even after a long period of latency? When does the dangerous power of communicating the disease cease in the female? At what period in her history is a prostitute clean who has been infected with syphilis? Some would say, "When the external organs are free from disease; for constitutional syphilis is not communicable."

Well, if this is a correct opinion the matter is easily settled. My experience, however, leads me to a very different conclusion, and I believe that in many cases of this class it is impossible to draw the line, with safety, where cleanness begins and uncleanness terminates. Prostitutes are not only dangerous because they labour under local disease and constitutional diseases in progress, but also because they have recently laboured under a syphilitic taint. Even when scars and stains have died out, the system often eliminates the specific poison in the secretions, and the vaginal surface, especially from frequent and unnatural irritation, pours out unhealthy mucus, which may be the vehicle of communicating the dis-

ease. All must admit that the pathology of syphilis is still in many respects surrounded with mystery. We know not the nature of the poison we are contending against, and the laws which regulate its peculiar manifestations are still but partially defined.

It is not really more remarkable that the vaginal membrane should be capable of excreting a specific mucus in some cases, long after the disease has apparently run its course, than that the seminal fluid of the male should impart a mysterious taint to the ovum, or that the saliva of a syphilitic child should infect a healthy nurse.

I believe that the effectual working of the Contagious Diseases Act depends greatly upon the application of the clause to which reference has been made.

The pathology of syphilis points out the necessity of a very stringent application of it, and, if it were possible, all prostitutes ought to be considered dangerous and still affected with a contagious disease for a certain period after they have laboured under genuine syphilis. It is only a severe application of the law, in my opinion, that can effectually control the disease in any locality. Its ravages may be mitigated by milder means, but its progress will never be successfully subdued.

It is true that the theory, as to its propagation by the vaginal secretion of prostitutes labouring under syphilitic cachexia, is by no means actually proved. This question could only be settled by experimental inoculation. Still, if the object of this Act of Parliament is to stamp out the malady, we ought (scientifically speaking) to take every means to avert the dreadful scourge, and act, for the sake of safety, as if all disputed questions were really settled. Small-pox can only be controlled by isolating as far as possible persons affected with the disease, and by protecting the healthy from those capable of infecting them. It is just so with syphilis. The disease is mainly disseminated by prostitutes; and the only way to prevent its spread throughout any community is by a stringent inspection of this unfortunate class of society. The clean must be separated from the unclean, and none labouring under any kind of constitutional or local affection must be permitted to follow their degrading occupation.

But here arise a multitude of moral and social questions, and these—rightly, I think—will ever prevent the practical operation of such stringent regulations. Without them the disease may be partially checked, but it can never be effectually subdued.

One word as regards the treatment of the cases referred to in my table. In the large majority of patients who laboured under local disease, rest and cleanliness were the only necessary remedies. When the uterine cavity was involved, astringent applications were injected, and sometimes strong iodine tincture applied freely to the cervix appeared to be very serviceable. Syphilis in its early stages was not treated with mercury, but in obstinate cases mercurial frictions and vapour-baths were often employed with great benefit. Several chronic cases of a severe form were much benefited, after combinations of quinine and iron and cod-liver oil had failed, with large doses of compound decoction of sarsaparilla. Two cases of relapsing iritis seemed to be much relieved by this simple treatment.

REPORTS OF HOSPITAL PRACTICE

IN
MEDICINE AND SURGERY.

ST. GEORGE'S HOSPITAL.

THE carbolic acid treatment is being freely employed in this Hospital. We lately had the opportunity of seeing Mr. Rouse perform Symes's operation on strictly antiseptic principles. The patient was a young woman, who had for some time been in the Hospital under the care of Mr. Hewitt. The operation had been deferred on account of the low condition of her general health, with the hope that by generous diet and tonic medicines she would improve; but as this was not the case, and as suppuration took place into the joint, her health became worse and worse, and suppurative fever set in. Mr. Rouse would no longer leave her, and therefore decided upon removing the foot at the ankle. The limb having been previously rubbed with carbolic oil, and all the instruments steeped in carbolic water, the operation was done in the ordinary way, with this.

exception, that as the foot was somewhat distorted, the dissection had to be made further back than usual to get clear of the os calcis. The foot being removed, the malleoli were taken off by means of Pollock's claw-forceps, a much more expedite method than the saw. Carbolic water was then poured over the flaps, carbolic sutures used, and the whole covered by gauze and lac-plaster.

Mr. Rouse showed to us a patient in whom he had performed Chopart's operation, two weeks previously, for disease of the carpal joints. He used the same antiseptic means as in the other case, and kept in the bed bags of McDougall's carbolic powder. This case had done remarkably well; the wound had nearly all healed by first intention, and as the girl was very ill at the time the operation was performed, and much suppuration and a tedious recovery expected, Mr. Rouse attributes the good result to the influence of the antiseptic dressings.

Vesico-Vaginal Fistula, by Mr. Rouse.

This was an opening about the size of a shilling, very high up in the vaginal wall, which was caused by sloughing following a protracted labour. From its position it was very difficult to reach, but by the aid of a duck-bill speculum the edges were vivified, and three wire sutures were passed from side to side, and then secured by twisting. Mr. Rouse alluded to the want of success which often attends such operations when the fistula is so situated, and said that if unsuccessful in this particular case he should suggest to the patient the advisability of paring the surfaces of the vagina, and sewing them together. Some years ago Mr. Pollock did this with a good result; and, as the patient was a single woman, there was less objection to the practice than otherwise would be the case.

The notes of the following cases, which were under the care of Mr. Rouse, have been obtained through the courtesy of Mr. G. E. Walker, the House-Surgeon. Cases 2 and 3 are alluded to above.

Case 1.—J. A., aged 34, a clerk, in stepping down from an omnibus, fell forwards and struck the right knee, probably on a sharp stone on the road. He was unable to rise, and was at once brought to St. George's Hospital, a distance of about a quarter of a mile. On admission, was slightly stupid, and apparently under the influence of liquor. There was a contused wound, which would admit the finger, on the outer side of the right patella, which was comminuted. The upper fragment (about one-third of the bone) was drawn upwards about a quarter of an inch. The lower two-thirds was broken into several irregular fragments, one of which was tilted edgewise. The joint was evidently opened. He said he was accustomed to drink whisky, but not in large quantities, and enjoyed good health. His aspect corresponded with this account. Pulse 78; temperature 100.2°; respiration 19.

The wound was sponged freely with carbolic acid lotion (one in twenty), but not injected. It was then covered with Lister's antiseptic gauze, and outside that, lac-plaster. The limb was placed in a M'Intyre's splint, on an inclined plane, and ice-bags kept on joint. Diet: Beef-tea Oij., milk Oij.

September 10.—Tinct. opii mx., ft. potas. citratis 6tis horis.

11th.—Joint very little swollen or painful. Inj. morph. gr. ¼ omni nocte. 10 a.m.: Temperature 99.2°; pulse 76; respiration 18. 10 p.m.: Temperature 101.6°; pulse 88; respiration 18.

12th.—Joint very little swollen. Tongue white. 10 a.m.: Temperature 100°; pulse 80; respiration 20. 10 p.m.: Temperature 101.2°; pulse 80; respiration 20. Hyd. subchlor. gr. v. st., haust. sennæ post horis quatuor

13th.—Dressing changed; moderate suppuration, principally around the joint. Joint not tense; discharge rather foul. Tongue white. 10 a.m.: Temperature 102.2°; pulse 104; respiration 21. 10 p.m.: Temperature 99.2°; pulse 100; respiration 20. Perstat. e. inj.

14th.—Not much pain or swelling about joint. Temperature 100.2°; pulse 98; respiration 20. Perstat. c. inj.

15th.—10 a.m.: Temperature 102.6°; pulse 96; respiration 20. In the evening he became restless and talkative. 10 p.m.: Temperature 102.2°.

16th.—Passed a sleepless night; is very restless and talkative. Talks nonsense; fancies he sees non-existing people and things. Tongue white, tremulous and moist. 10 a.m.: Pulse 110; temperature 103.4°. A free incision was made into the joint, at the outer side; some sanious fluid evacuated. Joint injected with carbolic lotion, and dressed with lac-plaster. P. c. inj. 4tis horis; omit mist.; whisky ʒvj. 10 p.m.: Temperature 101.8°.

17th.—Slept an hour last night. Still in same state of delirium. A blush of cryspelas on outer side of thigh.

Tongue moist. Temperature 101.2°; pulse 110. Whisky ʒviij. Was placed in a separate room; allowed to smoke.

18th.—Erysipelas fading. He is inclined to shiver. Slept a little at intervals. Small amount of discharge from knee-joint. Pain in the left shoulder. Temperature 103°; pulse 140, small. Sherry ʒxij.; tinct. opii mxxv. 6tis horis.

19th.—Tongue creamy. Remains in same state of delirium. Is getting weaker. Temperature 102.8°; pulse 148. Rep. vin.

20th.—Remains in same state, but pulse weaker. Left shoulder slightly swollen. Died in the evening, without change of symptoms.

On making a post-mortem examination, all the organs were found congested, but otherwise healthy. The left shoulder contained a large collection of pus, and the knee-joint was disorganised.

Case 2.—Mary Ann T., aged 18, admitted April 19, 1871. On admission there was disease of the tarsal joints—with a good deal of thickening of the structures of the left foot, which was painful and tender to the touch. Was quite unable to walk on it. The ankle-joint seemed unaffected. She was also suffering from an abscess in the axilla. Ordered steel wine (ʒij.) twice a day.

June 10.—The abscess in the axilla has nearly healed, but the foot is more swollen and painful. Her general health has by no means improved, and her appetite fails her. Is taking six ounces of port daily. Lin. belladonnæ applied to the foot.

20th.—Foot more painful, and there is fluctuation on the dorsum. Has a good deal of constitutional disturbance.

July 8.—The abscess in the foot, which is less painful, has burst, and there is a great deal of purulent discharge. No improvement in her general health.

August 1.—The foot is a good deal inflamed, and the sinus continues to discharge freely. The pain is continuous, and her health much worse.

24th.—As her health seems to be quite failing her, Mr. Rouse determined to remove the foot. This he did to-day, under chloroform, by Chopart's operation. The vessels were secured with pure silk, the ligatures being cut off short and left in the wounds. The sutures were of the same material. The wound was syringed out with carbolic lotion, and dressed with Lister's gauze, and outside this with lac-plaster.

25th.—Temperature 100.4°; pulse 140. Seems no worse after the operation. Complains of pain in the foot, but not more severe than before the operation.

27th.—The foot was dressed to-day for the first time since the operation. The wound was looking very quiet, and there was scarcely any discharge. Dressed in the same manner as before. Is more cheerful, and her health greatly improved. Very little pain in the stump. Temperature 97.8°; pulse 102.

29th.—Wound dressed again to-day. No signs of any inflammation. Very little discharge. Temperature 99.1°; pulse 101.

31st.—Complains of pain in outer angle of wound, which is slightly swollen and inflamed. Three of the sutures were removed, and a director passed in, but no matter was found. Rest of the wound looking healthy, and in great part united. Temperature 99.3°; pulse 110.

September 2.—Inflammation subsiding, and scarcely any pain. The rest of the sutures were removed, and the gauze only applied.

6th.—Wound nearly united; no discharge; painful only on pressure. Is looking much better; appetite improved.

13th.—Wound quite united, except at outer angle. Brown dressing (calamine cerate) only applied. Allowed to dress and lie outside her bed.

20th.—Quite well. Walks about with a crutch.

27th.—Sent to Wimbledon Convalescent Hospital.

Case 3.—J. K., aged 24, admitted December 14, 1870, has had pain and stiffness about left ankle for three years. Two years ago she was under treatment in this Hospital, and was able to walk for a time; but during the last year numerous sinuses have formed, and it has become steadily worse. No injury. Has cough and weak health. Since her admission each successive month has seen no improvement in the state of the foot, and her health has become decidedly worse. Her treatment has consisted principally in iron and quinine, cod-liver oil, and a free supply of stimulants. Poultices to the foot.

September 6.—The foot has become much more painful, and the swelling has increased. There is also more discharge. As her general health seems to be failing her, it has been decided to remove the foot.

14th.—Under ether Mr. Rouse amputated at ankle by Syme's method, except that only the malleoli were removed, and articular surface of tibia left. The vessels were tied with pure

silk, cut off short and left in the wound. The sutures were of the same material. Dressed with Lister's gauze, and outside with lac-plaster. Wound syringed with carbolic lotion (one in twenty).

15th.—Complains of a good deal of pain in the stump. Shock from the operation less than might have been expected. Pulse 96.

17th.—Dressings changed to-day for the first time. Stump looking quiet, but very painful. There is very little discharge. General health much the same. Tongue clean. Pulse 92.

18th.—Stump very painful; dressings consequently changed. There is a good deal of puffiness, and the wound is looking somewhat inflamed. A good deal of semi-purulent discharge. To be dressed daily.

20th.—Stump looking much the same; and as the wound was very tense, three of the sutures were removed. Complains of a great deal of pain, especially at inner angle of wound. Ordered haust. acid. phosph. c. strych. ter die s.

22nd.—Is much better in her general health. Tongue rather white. The stump is looking much quieter; but at about an inch above the inner angle of the wound a small abscess has formed and burst. There has been a great deal of discharge. The rest of the sutures removed.

24th.—Discharge still copious; the wound gapes a good deal; edges brought together with white strapping. Gauze left off, and lac-plaster only used. Bowels constipated. Tongue foul. Ordered pil. col. c. hyos. gr. x. statim.

26th.—Is much better; stump looking quieter; inflammation subsiding; discharge less; complains of very little pain. Bowels have acted freely. Tongue clean.

29th.—The inflammation has quite subsided; outer half of wound beginning to unite; ceased to discharge. Says she feels better than she has done for months past. Allowed to lie outside her bed. Her appetite has greatly improved.

October 2.—Outer half of wound has quite healed; the inner half looks healthy and is healing rapidly. Complains of no pain.

6th.—Stump nearly healed. Will be sent to the Convalescent Hospital on Wednesday next.

ST. GEORGE'S (HANOVER-SQUARE) DISPENSARY.

CASE OF MORBUS CÆRULEUS.

(Under the care of Dr. SUTHERLAND.)

E. N., a girl, aged 13, an unusually intelligent and clever child, whose extreme blueness of skin at once suggested the idea of some cardiac derangement, was first seen on August 5, 1871. The history of the case was peculiar, as the patient herself had never suffered from rheumatism, although her father was a martyr to this disease some years previous to her birth; but it could not be ascertained whether his heart was affected or not. She had two brothers and three sisters, all younger than herself, but healthy up to the present time in every way. Nothing unusual was noticed in the child till she was about 7 years old, when she began to suffer from intensely acute pain in the left side whenever she ran any distance, walked fast, or went upstairs. About two years ago the blueness of the skin first began to make its appearance, and this discoloration was at times increased paroxysmally, when she used to turn almost black at the lips and extremities. She was not weaker during these attacks than at other times, as she was able to walk out when they came on, but was obliged to wear a thick veil to avoid exciting the attention of the passers-by, as the blueness was so intense on these occasions. During the last fortnight she has several times vomited black semi-coagulated blood.

On August 5, the day she was first under observation, she became so feeble that she was unable to sit up, and was put to bed. She was then seen to be very emaciated; tall for her age; had dark-brown hair, greenish eyes—pupils equal and active. The tips of the fingers and toes were bulbous, and the nails much incurvated. The discoloration was unevenly distributed over the body, the forehead being tolerably white, the nose and chin of a slightly purple tinge, and the lips bluish-black, as if from eating black-currant jelly. This blackness extended irregularly beyond the mucous membrane of the lips. The tongue was very dark in colour, its papillæ prominent, somewhat resembling the tongue of scarlatina. The superficial veins of the hands, and the jugular veins were much distended, and the carotids were seen throbbing beneath the skin. Pulse 156; respiration 46; temperature in axilla 99° Fahr. There was much difficulty in breathing, amounting to orthopnoea, and the sterno-eleido-mastoids were acting to assist respiration. The chest was

slightly dull on percussion both in front and behind, as low as the third rib, and below that quite dull, rendering it impossible to define the præcordial dulness. There was prolonged expiration and occasional creaking at both apices of the lungs. There was no cardiac murmur, but the first sound of the heart had a very peculiar metallic twang. In the left axilla a distinct friction-sound of pericarditis was audible. Both sounds of the heart were unnaturally sharp and clear, and the impulse was much increased. The patient had a troublesome cough, which caused headache and loss of sleep. The abdomen was normal; the appetite good; the bowels regular; the urine high-coloured. She was treated with mild tonics, and an occasional linctus for the cough, and a belladonna plaster was applied to the cardiac region.

August 21.—No alteration. Pulse 144; respiration 42; temperature 100°.

22nd.—Pulse 136; respiration 40. Last night she had an alarming attack of syncope. Tongue coated.

23rd.—Pulse 136; respiration 40; temperature 98°.

24th.—Pulse 156; respiration 44; temperature 98·7°.

26th.—Pulse 144; respiration 40; temperature 99°. A petechial eruption has appeared on the arms and chest. Last night had a severe attack of dyspnoea.

28th.—Pulse 156; respiration 50. Face very pale. Great dyspnoea. Ordered carbonate of ammonia, squills, and ether.

30th.—Breathing less embarrassed. Was able to sleep lying down last night, for the first time since she came under observation. Decubitus on the left side only.

September 1.—Slept well. Complexion less dusky. Able to lie down in the daytime as well as at night.

17th.—Appears weaker. Œdema of the legs has appeared.

21st.—Dyspnoea much increased. Cannot lie down at night.

28th.—The skin became much darker than usual, the face and tongue being especially dark. There was absence of breathing and complete dulness over the middle lobe of the right lung.

On the 29th she appeared much more feeble, and became gradually unable to recognise those around her, and at last she had several attacks of syncope, and expired at eight o'clock, p.m.

Post-mortem Examination, October 2, sixty-eight hours after death.—Body much emaciated. Signs of putrefaction commencing on the abdomen, which was much distended with fluid. The legs were also cedematous. Sugillation of depending parts. Large petechial patches covered the thighs, body, right arm, and forearm, which were absent on the legs and left forearm. This redness became deeper in colour from the waist up to the neck and ear, which were of a deep purple colour. The genitals were also of a deep colour, the clitoris long (three-quarters of an inch in length). Rigor mortis slightly marked. On opening the chest, the skin was noticed to be unusually thin, and the thorax contained much fluid. The pericardium contained four ounces of fluid, and a coating of velvety lymph covered the whole of the anterior surface of the heart and corresponding pericardium. The lungs were universally adherent and much congested: the liver was also much congested, and on cutting into it was found to be very soft, and to contain dark bilious blood in a semi-coagulated condition. The heart was misplaced, the right auricle being very low down, and the apex tilted upwards and forwards. This auricle had the shape of a short horn or Phrygian cap, and was much dilated. The right auricular appendix was also much enlarged, the left appendix being smaller than usual. Between the two auricles the foramen ovale was seen to remain open, and was large enough to admit the middle finger without tearing. This aperture in front was made up of two or three muscoli pectinati crossing each other, giving a plaited appearance, and behind was formed by a free margin of endocardium. The heart was unusually round, there being no distinct apex, and the ventricles were enormously hypertrophied and dilated, the whole organ weighing eighteen ounces. It is remarkable that with such an abnormal condition of the circulatory apparatus the child should have lived to be 13 years old.

BIRMINGHAM GENERAL HOSPITAL.

ACUTE PULMONARY CONSUMPTION—TEMPERATURE NOTES.

(Under the care of Dr. RUSSELL.)

THE term "pulmonary consumption," adopted from Niemeyer, is a convenient one to those who, like myself, await a decision by our teachers as to the proper limitation of the word

"tubercle." Whatever be the view entertained on this subject, the pneumonic process was doubtless the active agent in effecting the morbid changes observed in this case. The following sentence from Niemeyer well describes the nature of the disease:—"It may be said with perfect truth that all forms of pneumonia may end in caseous infiltration under certain conditions, and that there is no form of pneumonia of which caseous infiltration is a sole and constant termination. It is true that the difference is very great in the frequency with which the inflammatory products undergo cheesy transformation instead of liquefaction and absorption. In croupous pneumonia such a result is rare; in acute catarrhal pneumonia it is somewhat more frequent; while in the chronic catarrhal form it is almost the rule." My present case was one of "croupous" pneumonia. I have used the appellation "acute," though the duration of the case exceeded the usual length in acute phthisis.

I did not witness the post-mortem examination; but our Pathologist, Mr. Rickards, reported that the central part of the right lung was occupied by a large cavity containing yellowish puriform fetid fluid. The walls of the cavity were thick, like Gloucester cheese in colour and consistence. The apex of this lung was solidified by masses of white cheesy matter, the intermediate tissue exhibiting the ordinary red pneumonia. Some smaller cavities existed in the base, and a few granular knots. The whole left lung was in a state of pneumonic engorgement; the apex was consolidated, and contained a small cavity. A few granular knots, from the size of a pea to that of an acorn, were scattered through the lung. The bronchial glands were enlarged and cheesy; the mesenteric glands were healthy; but there were numerous ulcers in the ileum. The liver was fatty, and the vocal cords were somewhat thickened.

The patient was aged 35; intemperate; had been out of health for a year, but never had more than a slight cough. Six years ago, however, he spat a little blood. His father was said to have died consumptive. His illness had an acute commencement; he had "some shivering," and a bad cough, but no pain. He at once laid by. The case occupied just fifteen weeks, thirteen of which were spent in the Hospital. The symptoms were remarkable, from the absence of any active reaction, strikingly contrasting, in this respect, with the elevated temperature. The most prominent characteristic of his condition was great languor, increasing at an early period to marked prostration. The patient lay quietly on his back, hardly noticing what went on around him, yet perfectly alive to any questions put to him. His intellect, though torpid, was perfectly clear to the last. His face was quite pale, the pallor proceeding to complete anæmia. He had constant tremors. In the early period there was some tendency to rigor. At first his appetite was very bad, his aversion to food becoming so great that three weeks after admission nutritive enemata were prescribed; subsequently, however, he took liquid nourishment in moderate quantity. The tongue was perfectly natural to the last, and there was entire absence of diarrhoea. The urine was abundant, specific gravity 1015 to 1025, free from albumen, and contained abundant chlorides throughout; it was generally free from deposit, of deep yellow colour. Emaciation steadily progressed, but was not extreme. Perspiration was a very prominent symptom through the entire illness, being frequently of the most profuse character; it was general. As regards the chest symptoms, though cough was constant, expectoration was practically *absent entirely*, the smallest quantity of greenish mucus being all that was voided, and this only occasionally. He was quite free from pain.

At admission the evidence of consolidation existed only at the root of the right lung; thence it gradually extended, so as to include, by the fourteenth day after admission, the greater part of the lower lobe, but was not complete; the base, however, at this time, presented only coarse crepitation. On the left side the physical signs were limited to crepitation over the region of the lower lobe, the respiratory sound varying remarkably at different times from vesicular to blowing breathing. It was not till the end of the first month after admission that consolidation was noticed at the right apex; and the earliest sign of softening was observed in the right interscapular space at the end of the fifth week (the seventh of the illness).

The temperature illustrated in a remarkable manner the violent perturbations which disturb the course of pyrexia in this class of cases. It was regularly recorded by our Clinical Assistant, Mr. Bateman, from the day of admission (the fourteenth day) to the ninety-eighth day (within nine days of death). During the first ten days the temperature generally had the character of

ordinary pneumonia, by maintaining a persistently rather light temperature, excepting that it exhibited a variation from 104° to 102° by one gradual decline, rising again as gradually to the original marking. On the eleventh and twelfth days successively it attained 105° in the morning, falling in the evening, and on the second occasion continuing to fall until, on the following evening, it was at 99°, whence it again attained its former elevation, within a degree, by the next morning. Thenceforward the markings presented considerable variation in the height attained, and often considerable remissions. Thus, the temperature several times scored 104° or 104.5°, more frequently 103° or 103.5°; on fewer occasions 102°, or even a degree lower. On the other hand, it descended many times to 99° and lower, on one occasion registering a fall of collapse from 104° in the evening to 93° next morning; on two other occasions marking 95° from 102° and 100° respectively. The general range of remissions was from 2° to 3°, but several occasions happened in which the variation in twenty-four hours equalled 5° or even 6°, and on two occasions even 7°. I should add that, with one or two exceptions, the elevated or depressed temperature was not maintained beyond a single observation. These "isolated brusque elevations and intercurrent falls of temperature," noticed by Wunderlich as sometimes occurring in the fever of ordinary pneumonia, are here exhibited in a protracted form. Wunderlich also notices that in protracted pneumonia "the daily maximum generally occurs about noon. In the evening there is a remission, which has a great tendency to collapse, and this is succeeded by a second though slight exacerbation about midnight." In my present case the evening remissions were observed on fifteen out of the eighty-four days.

ACUTE PURULENT PLEURISY—TEMPERATURE NOTES.

(Under the care of Dr. RUSSELL.)

A fine robust-looking man, aged 28, with traces upon his trunk of an eruption, probably syphilitic, of uncertain date, and admitted primary symptoms, was admitted with acute pleuro-pneumonia, apparently of the ordinary type, of three days' standing. In two days the physical signs indicated commencing resolution; but three days afterwards it was discovered that the pleuritic fluid, which had hitherto been very moderate in quantity, had suddenly occupied the entire right chest. Some albumen previously present in the urine had disappeared, and never returned, but the chlorides were not restored to the urine, nor did they regain their normal proportion till nine days afterwards. Profuse perspiration was present for a time. I did not see the case for five weeks after this time; but on my return home I found that, a month after the pleuritic aggravation, an abscess was opened over the mamma, with copious discharge, which continued for three weeks, when it lessened by degrees, but at the present time has not perfectly ceased. During this time the patient became extremely emaciated, but regained flesh with the diminution of the discharge, and is now in a fair state of health, though far below his original standard. The right side of the chest is falling in; the ribs are closely approximated; the right side has lost more than an inch in circumference; the right shoulder is two inches below its fellow; and the vertebral column exhibits the usual double curve. A fair amount of respiratory sound is heard over the upper lobe, but the chest is dull below the level of the seventh dorsal spine. The opposite lung is passing behind the sternum.

The temperature taken by Mr. Bateman for sixty-three days exhibited a permanent tendency to elevation of 102.5° to 103°, with moderate morning and evening variations, but divided into different periods of gradual rise and gradual fall. From 103° on the day after admission, it underwent through the succeeding eight days a steady decline of three degrees; then occurred in five days a gradual return to 103°, with little diurnal oscillation. Then a period of eleven days began and ended with an evening temperature of 102°, the intermediate term being occupied by gradual depressions followed by gradual rise to a less height; this period ended in a rather sudden fall to normal temperature, followed immediately by a spring in the evening, to 101°, and a further rise of a degree and a half through the following two evenings, with a drop of three degrees in the mornings. During the next fifteen days the score varied between 100.5° and 99°; but three times rose to 101°, and three times fell to normal. At this time the abscess was opened, and thence occurred a gradual rise of temperature again to 102° in four days, continuing high in the evening through fourteen days, even to 102.5°, with some diurnal variations of four degrees; the last of these diurnal remissions introduced a permanently normal temperature on the sixty-second day.

SATURDAY, OCTOBER 28, 1871.

THE LONDON DIALECTICAL SOCIETY ON "SPIRITUALISM."

It will doubtless be remembered by some of our readers, that many months ago, so far back as January, 1869, the London Dialectical Society, on the motion of Dr. Edmunds, appointed a Committee "to investigate the phenomena alleged to be spiritual manifestations, and to report thereon." The Committee cannot be accused of undue haste over their important work, for they did not present their report to the Society till July 20 last, and their labours are now given to the public in a large octavo volume of some 400 pages. We cannot say whether or no any enthusiastic spiritualists, or non-spiritualists, expected any solid result from the inquiry; but it seems to us that the whole question remains just where it was. Believers will certainly be believers still; and unbelievers will be fully justified in shrugging their shoulders and going on their ways undisturbed. As a scientific inquiry into the "phenomena alleged to be spiritual manifestations," the report is of no value whatever. Nevertheless, the volume is a very curious one, and deserving of attention for several reasons.

It is noteworthy that, though the Council of the London Dialectical Society received the report, and ordered it to be entered on their minutes, they declined to accede to the request of the Committee that it should be printed under the authority of the Society; and it has been published on the responsibility of the Committee only. Then we find that the Chairman of the Committee—the gentleman who proposed the inquiry—states that "the passing of the report, and the selection, publication, and reviewing of the evidence, has practically drifted into the hands of devoted and zealous spiritualists, who are led by skilled and successful writers." An editorial note to this statement affirms that, "of the five acting members of the editing Sub-committee, only one is a spiritualist;" to which Dr. Edmunds replies, that by "spiritualists," he means "not only such persons as have avowed a defined theory of causation by spirits, but also such as believe in the genuineness of 'mediums,' and of those more extraordinary phenomena which cannot be accounted for upon recognised hypotheses."

Again, the Committee state in their Report that the reports of the six Sub-committees into which the Grand Committee was divided, "substantially corroborate each other, and would appear to establish" various propositions which they put forth, the most important being—that sounds of a very varied character occur without being produced by muscular action or

mechanical contrivance; that movements of heavy bodies take place without mechanical contrivance of any kind or adequate exertion of muscular force by the persons present; and that these sounds and movements, by means of a simple code of signals, answer questions, and spell out coherent communications. But when we turn to the reports of the Sub-committees, what do we find? Sub-committee No. 1, which worked very hard, and held no less than forty meetings, saw heavy bodies moved without contact with any human being. Sub-committee No. 2 reports that it witnessed all these manifestations, and in very startling forms, and "presumably established occasional communication with a number of spirits, or intelligences—announced to be such by themselves—many of whom stated they were connected in various degrees of relationship to certain members of the party, for whom they professed a friendly regard." Sub-committee No. 3 was almost entirely occupied in watching and testing the tilting of tables, but believe that "the phenomena witnessed, though comparatively unimportant, do, nevertheless, raise some most important questions in science and philosophy," and deserve full examination. Sub-committee No. 4 simply reports that, "Nothing occurred in the presence of this Sub-committee worth recording." Sub-committee No. 5 was considered, we suppose, the most important of these bodies, for it was honoured by the attendance of Mr. Home, and of two noblemen whose names, if we mistake not, have occurred frequently in reports of spirit "communications"; but the *séances* were productive of but very few and very trifling phenomena. The report says that "Mr. Home afforded every facility for examination, and appeared to be anxious to further the object which the Committee had in view," but "nothing occurred at any of the meetings which could be attributed to supernatural causes. The members had fully expected that they would have witnessed some of the alleged extraordinary levitations of Mr. Home; but he explained at the opening of the inquiry that the phenomena produced through his agency were of uncertain manifestation, and that he had no power whatever to produce them at will. The *séances* were held in a fully lighted room." Sub-committee No. 6 sends in a short and very significant report—"The Committee met four times, but failed to obtain any phenomena that deserve to be recorded. On one occasion a lady visitor brought with her two little girls, aged, apparently, about 8 and 10 years respectively, whom she declared to be mediums. The children were placed at a small chess-table, which they proceeded deliberately to rock to and fro, to their own intense delight and the amusement of the company. At no other meeting was there even the pretence of any spiritual phenomena."

It appears, then, that of the six Sub-committees half saw really nothing whatever, and only one, No. 2, was favoured with any of the communications, "presumably spiritualistic," by signals; and yet the Committee coolly states that "a large majority of the members of your Committee have become actual witnesses to several phases of the phenomena without the aid or presence of any professional medium," and that the reports "substantially corroborate each other." We venture to think that less corroboration, as the term is ordinarily used, can hardly be imagined; but we are not members of the London Dialectical Society, and on referring to our English dictionary, as is our wont when expressions puzzle us, we find that the term "dialectical" is "applied more generally to any peculiar style or manner of expression, speech, or language," so we cease to wonder at what appears to us an extraordinary use, by the Committee of the London Dialectical Society, of the expression "substantially corroborate."

It is to be remarked that none of the Sub-committees succeeded "in ascertaining any specific conditions that would command the production of the phenomena," but that Sub-committee No. 2 states that "a somewhat moderate supply of light appeared to aid the manifestations," that their few trials by daylight invariably resulted in failure, and that "we

invariably failed to obtain manifestations without the presence of the two ladies in our party ;” and that Sub-committee No. 3 says that “it was only when certain persons were present that any evidence of this (peculiar) force and intelligence were presented. Two friends were particularly noticed as indispensable.” These are candid avowals ; and it must be allowed that the Committee has not hesitated to publish very hostile criticism and evidence. The volume contains the report, “the evidence oral and written, and a selection from the correspondence” ; and the editing Sub-committee has frankly published communications of a by no means complimentary or corroborative character.

Mr. G. H. Lewes writes—“In my experience—and it has been large—the *means* (of producing the so-called spiritualistic phenomena) have always been proved to be either deliberate imposture, aided by the unconscious assistance of spectators, or the well-known effects of expectant attention.” Professor Tyndall’s reply to an invitation from the Committee is amusing and significant. He states that, more than a year previously, he had been favoured by a visit from Mr. Cromwell Varley, “one of the greatest of modern spiritualists,” who told him that his presence at a *séance* resembled that of a great magnet among a number of small ones—he threw all into confusion. “A comparison which,” observes the Professor, “though flattering to my spiritual strength, seems to mark me out as unfit for spiritual investigations.” Mr. Varley, however, hoped that arrangements might be made to show him the phenomena, and he expressed his willingness to witness them. “But,” he adds, “I have not since been favoured by a visit from Mr. Varley.” And Professor Huxley declines to act on the Committee in a letter which must have made that body grieve much for his mental attitude. He says—“In the first place, I have no time for such an inquiry, which would involve much trouble and (unless it were unlike all the inquiries of the kind I have known) much annoyance. In the second place, I take no interest in the subject. The only case of ‘spiritualism’ I have had the opportunity of examining into for myself was as gross an imposture as ever came under my notice. But, supposing the phenomena to be genuine, they do not interest me. If anybody would endow me with the faculty of listening to the chatter of old women and curates in the nearest cathedral town, I should decline the privilege, having better things to do ; and if the folk in the spiritual world do not talk more wisely and sensibly than their friends report them to do, I put them in the same category.” And then, remembering probably the remark made by an ex-Lord Chancellor, that a noble biographer of departed Lord Chancellors had added a new terror to death, the Professor goes on to say, “The only good I can see in the demonstration of the truth of ‘spiritualism,’ is to furnish an additional argument against suicide. Better live a crossing-sweeper than die and be made to talk twaddle by a ‘medium,’ hired at a guinea a *séance*.”

The Committee—even the believers on it—must, on the whole, have felt grievously disappointed with the very meagre and limited experience of the various Sub-committees. With the exception of Sub-committee No. 2, the spirit-world neglected them to a degree that in worldly matters would indicate absolute indifference, if not contempt. No scientific spirit seized the opportunity of enlightening the world ; no tender and compassionate spirit was moved to reward weary waitings for manifestations ; no “lying spirit” even cared to utilise such unusual chances of finding human minds in a beautiful state of receptivity ; nor any “vagabond spirit” to take advantage of so many openings for fun and larking. Of course we are speaking of the spirit-world of the “spiritualists,” and using terms used by them, or we should hardly venture to class spirits in this way. Sub-committee No. 2 was visited by some very merry and convivial spirits, and the spirits informed this Committee that “disputation amongst ourselves at a *séance*

was a disturbing element, but that they liked fun and joking occasionally.” The visits of scientific spirits appear to be very rare. The reason of this, according to Mr. Varley, is, that spirits of high intelligence require mediums of high intelligence ; and he “has failed at present to find a medium acquainted with science, and therefore capable of translating into intelligible language ideas of a scientific nature.” He was himself, however, once in communication with the spirit of Dr. Franklin, and does not appear to have gained any new scientific knowledge.

We must defer, however, to our next impression what remarks we have to make on the copious and remarkable “communications” published by the Committee.

PHYSICAL DEGENERACY OF THE PRESENT GENERATION.

In the Health Department of the Social Science Association, a paper by Dr. Rumsey, “On the Progressive Degeneracy of Race in the Town Populations of Britain,” was read by Dr. A. P. Stewart. The author quoted evidence from leading journals in support of the assertion that the average physical type of Englishmen had degenerated of late years, that broad chests and powerful limbs were no longer common among labourers and artisans, and that Medical examiners of recruits rejected a larger proportion every year ; while those admitted into the ranks, especially of Militia regiments, were very inferior in height, bone, and muscle to their elder comrades. The author also referred to the researches of Dr. Beddoe, respecting the stature and bulk of men in these islands, and to the Army Recruiting Returns, which concurred in showing that the rejection of recruits on account of bodily unfitness had increased from 6 to 10 per cent. during the last thirty years ; and that this degeneracy is fairly attributable, in great degree, to the growing concentration of the working-classes in towns, to the depressing circumstances of town life, and to the large number of those engaged in indoor employment.

Now, as we are of those who think that there is sufficient reason, if it were merely in the increased average length of life of the population of the British Islands, for doubting that a progressive physical degeneration of race is gradually at work among us, we have been induced to examine for ourselves into such facts as the Returns of Recruiting for the Army may contain. We have therefore consulted the Report of the Commission presided over by Sidney Herbert in 1857, to inquire into the sanitary condition of the Army, and the Statistical Reports of the Army Medical Department from 1860 till 1869. We find in the former authority, at page 493, a Report prepared, we believe, by Dr. Balfour, F.R.S., the present head of the Statistical Branch of the Office of the Director-General of the Army Medical Department, who acted as Secretary to Lord Herbert’s Commission. We find in the preliminary observations that the Returns subsequently given do not show the total number of recruits inspected for the Army, but merely the numbers at the head-quarters of the different recruiting districts, and, unfortunately, do not distinguish between primary and secondary inspections, men enlisted at head-quarters, and those previously inspected at out-stations. In attempting, therefore, to compare the results given in these tables with those of later date in the Statistical Reports of the Army Medical Department, this observation must be borne in mind, otherwise we shall not be comparing like with like, as in the latter Returns—at least, from 1864 till 1869—the distinction between primary and secondary is observed, and strikingly modifies the results. It is obvious that the total number of men primarily inspected is the correct basis on which to calculate the proportion of rejections ; because the number of men secondarily inspected represents a class from which a considerable number has been already eliminated by the primary inspection, and therefore, if added to the number primarily

inspected, would very materially modify the composition of the whole.

From the returns given in the Report of Sidney Herbert's Commission, we learn that from April, 1832, till March, 1841, in a total number of primary and secondary inspections amounting to 134,621, there were 40,076 rejections; and from April, 1842, till March, 1851, in a similar total of 171,276, the number of rejections was 57,381; or in the whole period of twenty years, in a total of 205,897, there were 97,457 rejections, being in the proportion of 318.60 per 1000. In the tables given in the appendices of the several Statistical Reports of the Army Medical Department, are abstracts showing the number of recruits and the numbers found unfit for service at the headquarters of the recruiting districts during each year, from which it is easy to find the total of primary and secondary inspections, thus assimilating the basis of comparison with that given in Sidney Herbert's Report. We thus find that from 1860 till 1869, from a total of 145,396 primary and secondary inspections, there were 47,666 rejections, being in the proportion of 327.84 per 1000, or 9.24 per 1000 (or less than 1 per cent.) more than the proportion rejected between 1832 and 1851; and this very slight difference would be fully accounted for by the fact that during 1838, in consequence of the disturbances in Canada, there was a sudden demand for 10,000 recruits, to obtain whom a considerable relaxation in the practice of rejections was necessary. No such extra demand existed during the period from 1860 till 1869.

Having made these deductions from the facts represented by the figures given in the official returns from which we have quoted, and which we believe furnish the most reliable information on the subject, and not having had the opportunity of examining the data on which Dr. Rumsey founds his statement that the proportion of rejections of recruits during the last thirty years has increased from 6 to 10 per cent., we are at a loss as to the authority on which he makes his statement. We believe, at the same time, that we are correct in stating that there are no reliable statistics of the results of recruiting for the Army during any period earlier than that referred to in the returns from which we have quoted. During that period it should also be borne in mind that the recruiting sergeant first commenced to feel the presence of competition in the labour market, from the increased demand for both skilled and unskilled labour in the construction of railways, from the increase of emigration, and of the general improvement in the material prosperity of the population. We think, therefore, that we have shown that—so far, at least, as recruiting is concerned—there is foundation for the opinion that in the physical condition of our race we have as a nation, at least, not lost ground during the last few generations.

THE BEDFORD INFIRMARY—DEFECTIVE HOSPITAL ACCOMMODATION.

For some time past an important section of the Governors of this Infirmary have been desirous of improving and enlarging it. A Committee which had been appointed on the subject had carried the following resolutions:—

1. "That it is the opinion of this Committee that the present accommodation of this Infirmary is inadequate for the number of beds now in the Infirmary; and to give the minimum space of 1200 cubic feet to each patient, the number of beds should be reduced to fifty-seven."

2. "That this Committee, having fully examined the question of accommodation in the Infirmary, with reference to the average number of in-patients during the last few years, and in comparison with the space provided per patient in the last Hospitals of modern construction, consider that the building should be so enlarged as to provide a minimum of 1200 cubic feet for at least eighty beds."

At the quarterly meeting of the governors of the institution, held on the 9th inst., these resolutions were read, and Lieutenant-

Colonel Stuart, on behalf of the Committee to whom the subject had been referred, entered into some details and figures to show the importance and necessity of carrying out their recommendations. He stated that in the Bedford Infirmary the number of cubic feet for each bed averaged $736\frac{1}{2}$, and the superficial area 64 feet. He showed that in Addenbrooke's Hospital, Cambridge, a space was allowed of 1800 feet for Medical, and 1900 feet for Surgical cases, with 100 feet superficial area for bed; that in the new St. Thomas's Hospital, London, the number of cubic feet for each bed was 1800, the space for each bed 120 feet; in Bury St. Edmunds Hospital, 1500 cubic feet and 100 feet respectively; in Northampton, 1139 cubic feet and 81 feet; and in Leicester 1600 cubic feet and 100 feet. The gallant gentleman showed conclusively that the wards of the Bedford Infirmary were most inadequate in the two points referred to in the report of the Committee, and urged upon the Governors the importance of making the improvements suggested. Having formally moved that the report of the Committee be adopted, Mr. Howard said that, with the corridors, instead of the average of sixty-five patients having 1050 cubic feet, they must add 150 feet for each patient. Dr. Shaw said corridors were most objectionable in Hospitals. Mr. Sharman remarked that in other Hospitals corridors were not calculated. If the air in the Bedford Infirmary were so healthy as asserted, it was strange that all the nurses should have had erysipelas. It was not fair to take the average number of patients as the basis of testing the amount of cubic space per patient, because on the men's side they would find that the beds were filled, when on the women's side there were but few patients. A few days ago the men's wards were much too full, and in one ward the patients had something like 600 cubic feet each. There was a general impression that the health on that side was good, but his own impression was quite the reverse. It was his opinion that the Hospital was calculated to hold only fifty-seven patients. Mr. Tucker seconded Colonel Stuart's proposition, and enforced its necessity in an able speech. Mr. Sharman opposed the adoption of the report, and had failed to see from the letters addressed to the different Hospitals by the Committee that they have referred to the corridors. The letter briefly asked, "How many cubic feet are allowed in your wards for each patient and bed; whether any deduction is made for bedding, furniture, etc., contained in the wards?" Now, he (Mr. Sharman) had a letter from Dr. Edward Smith, who said—"Our rule is as follows: Wards 20 feet wide for two rows of beds, 10 to 12 feet in height, and 6 feet 9 inches wall-space to each bed—say 10 by 6 feet—equals 60 feet floor-space by 11 feet, equal 660 cubic feet each bed." So, continued Mr. Sharman, they had actually more space for the highest number in that Hospital than Dr. Smith thought necessary. The enlargement would cost £4000 or £5000, which must be taken from the funded property, and would, with other outlays, diminish their income by about £400 a year. An amendment was proposed and seconded, that the "report be received and entered on the minutes." This was carried by twenty-six against seven. Another resolution was proposed by Col. Higgins and seconded by Col. Stuart—"That it is the opinion of this meeting that the present accommodation of this Infirmary, as to cubic space, is inadequate to the number of beds." This was opposed by Mr. Chapman, a gentleman, who, thirty years before, had been House-Surgeon to the institution, but since then has taken little interest in the Infirmary. He said his experience of the Infirmary convinced him that the ventilation was so good, that even if the number of cubic feet was comparatively small, the result would not be felt as it would be if the ventilation were less. This superior ventilation was the cause that so few cases arose in the Hospital from a vitiated atmosphere. Besides, the Hospital was so constructed that, if necessary, arrangements could be speedily made to convert the women's into men's wards. Eventually an amend-

ment was carried, by twenty-three against sixteen, to the following effect:—

“That there is no evidence before us sufficient to enable us to come to a proper decision on the subject.”

We have referred to the above proceedings at some length, because they are of importance to other institutions than the Bedford Infirmary, and because they show what fallacious arguments are occasionally made use of on the score of “inexpedience” and “economy.” There can be no question, all quibbles set aside, that the Infirmary is deficient in proper accommodation; and the Senior Surgeon, a man of sagacity and experience, declares that in his opinion the healthiest of its wards are not healthy, and that every nurse in the institution has suffered from erysipelas. In reference to the statement of Dr. Edward Smith, that 660 cubic feet are deemed sufficient in workhouse infirmaries, it must be remembered that it is imagined these do not constantly contain cases of serious accidents, and that it is particularly provided, in the construction of these infirmaries, that the ventilation should be effected by special means, apart from the usual means of doors, windows, and fire-places, and that the wards have windows on opposite sides. The plea of poverty cannot be sustained by the Governors of the Infirmary, which, in addition to a handsome yearly subscription, has £40,000 in the funds. With all due deference to the opinion of the majority, we think that a few thousands of this sum spent in enlarging the Hospital would be an “expedient” and “economical” proceeding.

We regret that the Governors of the Bedford Infirmary should have ignored the report of their own Committee—always an invidious, if not an unjust, proceeding—considering that it was drawn up with great care, and after much inquiry and mature consideration; that they should, moreover, set at defiance the result arrived at by a vast majority of the Profession, and by competent architects and surveyors. The question cannot rest where it now is. The majority, we venture to say, on some future occasion, not far distant, will be reversed. That majority must eventually be in favour of progression, and of the prevention as well as the cure of disease.

THE WEEK.

TOPICS OF THE DAY.

At the last meeting of the Council of the Royal College of Surgeons, a decision was arrived at as to the partition of the fees to be paid by students who shall present themselves for the Conjoint Examinations of the two Colleges of Physicians and Surgeons. As the proposed Conjoint Board is only a partial one, and will fail to secure a uniform examination and licence for the general Practitioner of Medicine, Surgery, and Midwifery, it will be neither satisfactory to the Profession nor to the public. We cannot but think that the Council of the Royal College of Surgeons would not fulfil the trust they have received if they imperilled their revenues for the sake of a scheme which has failed to secure the adhesion of all even of the English Examining Bodies, and which will certainly not diminish the competition between the Examining Bodies of England, Scotland, and Ireland. We need not say that that competition will not be one which is likely to raise the standard of Medical Education.

An important subject has been brought before the Council of the College of Surgeons by Mr. Gay. It is the number of rejections at the Preliminary Examination for the Membership. We believe that the number of rejections at the Preliminary Examinations both at the Royal College of Surgeons and at Apothecaries' Hall has been recently very large. This is certainly a matter for inquiry, and is much to be deplored; but, at the same time, we are not prepared to admit that the standard imposed by the Examiners of these two institutions is at all too high. The fact, however, reveals either the great shortcomings of the English process of education or the fact that a large minority of English boys of 17 are not capable of

acquiring a fair knowledge of their own language, a moderate knowledge of two other languages, and of learning history and elementary mathematics and arithmetic. It must be remembered that previously to the present system of Examinations there was no test of the attainments of the average English schoolboy. A boy left school because he had reached a certain age, not because he had reached a certain standard of knowledge. The stupid boy might, in after years, when his brain-power was more developed, make up for early failure, or he might get into some walk of life where book-knowledge was not necessary. But under the present system of examinational tests at the threshold of every gentlemanly occupation, what is to become of the stupid boys? We are far from maintaining that they should be admitted into such a Profession as the Medical, but we think it may be safely asserted that the admission into the rank and file of the Medical Profession should be open to the average of the youth of the upper middle-class of society. We have yet, however, to learn that this standard has been exceeded by the institutions we have named. Facts, however, have proved that this standard has been exceeded—and, we think, very unwarrantably exceeded—in the case of the Matriculation Examination of the University of London. A few weeks ago we published a letter from a correspondent which placed the matter in a very just light. At the last Matriculation Examination of the University about 600 candidates presented themselves, and of these nearly 400 were rejected. It must be remembered that all these candidates had prepared themselves, at least to a certain extent, for the ordeal, and that the subjects of the Examination were perfectly well known. The University is supported by the State for the promotion of education amongst the people, and for the very lowest step in graduation it sets up a standard which four out of six educated English lads cannot pass. It cannot, therefore, be said to fulfil its national purpose. The fact is, that the lads are examined in ten subjects, failure in any one of which rejects the candidate. Amongst these subjects are Natural Philosophy and Chemistry; and it is no secret that the greatest dissatisfaction has been produced by the character of the papers set in the former subject. The system of requiring a certain standard in all subjects of examination, and of allowing nothing for high proficiency in any, if a smattering of all have not been obtained, may be useful in the production of respectable mediocrities, but it is fatal to the development of special talent. We need not say that it is not by this system that Oxford and Cambridge have earned their laurels.

In the case of murder at Stockwell, the plea of insanity has been advanced, and it is supported by the opinion of Dr. Rugg, the Medical man who first saw the Rev. Mr. Watson. He says that on his visit to Mr. Watson the prisoner showed him an oyster-shell, and made some trivial remark about it; and he considers this to have showed that Mr. Watson was oblivious of the awful position in which he was placed. The analysis of the fluid taken by Mr. Watson proved that it contained prussic acid, and a large number of blood-stains were found upon his clothes, and on the pistol found were portions of human skin, and hairs on a sponge. The analyst was Dr. John Mater, Director of the South London School of Chemistry and Pharmacy. It is to be hoped, in the interests of society, that sufficient evidence of the insanity of the prisoner will be collected to warrant his acquittal on that ground. The murder was evidently purposeless; and although a Latin sentence found written on a slip of paper on his study table seemed to show that he was not happy with his wife, there is not a scrap of evidence to prove that the crime was premeditated.

A letter from a “Would-be Indian Surgeon,” in a recent number of the *Times*, points out that there has been no examination for the Indian Medical Service for nearly two years, and complains that so short a notice of an examination is given by the Government authorities. It is not yet announced whether there is to be an examination in February next.

The Senatus Academicus of the University of Edinburgh, after a long discussion, has adopted a resolution to the effect that no further difficulties are to be placed in the way of women-students as regards either Matriculation or Preliminary Examination. The Senatus will probably succeed in ruining the University of Edinburgh as a Medical School for male students.

The deaths in London from small-pox, which were 61 in the previous week, fell to 53 last week. There were 237 deaths from the seven principal diseases of the zymotic class, against 288 and 271 in the two preceding weeks.

The English must look to their laurels. The Germans are developing into sailors, as well as soldiers and philosophers. A telegram from Gotha, dated October 20, announces that Dr. Petermann has received detailed accounts from the North Pole explorers, Herren Payor and Weiprecht. These dispatches fully confirm their discovery of an ice-free North Pole sea, which swarms with whales.

H.M.S. "MEGERA."

THE account of the loss of this ship, by being beached in an unseaworthy condition at the Island of St. Paul, on June 19 last, has been received at the Admiralty from her commanding officer, Captain Arthur T. Thrupp. It will afford much relief throughout the country to learn that up to July 9 the shipwrecked party had experienced fewer sufferings than might have been expected. They had not only succeeded in taking ashore with them four months' provisions, including a supply of rum and wine, but had also found 3000 lbs. of rice on the island. Fish were to be had in abundance, 100 lbs. to 150 lbs. being caught daily during fair weather, but much less when the weather was unfavourable. There were also about a hundred wild goats, a large quantity of mushrooms, and some few cabbages and potatoes. But still, after having been three weeks on shore without having had an opportunity of sending information as to their condition, the Captain thought it advisable to reduce the allowance of provisions, and each man was getting only four ounces of biscuit and half a pound of salt or preserved meat a day, half an allowance of tea every other day, and a quarter-allowance only of sugar; but, there being plenty of cocoa, the men had that every second night instead of tea. Lime-juice without sugar was being served out every other day; no flour was being issued. The charts reporting no water on the island, three tanks were hoisted out from the vessel to use as boilers for condensing; a supply of coals was also landed; and it was calculated that with coals 300 gallons, and with turf 150 gallons, could be made daily. But rain-water was found in abundance in cavities among the cliffs, at a distance of 860 feet from the ship, to which it was conveyed through hose; and rain being very frequent at that season, there was no uneasiness felt as to the supply of water. Hot fresh-water springs, strongly impregnated with sulphur, so as to be unsuitable for drinking, furnished a plentiful supply for washing, and the clay around them, being found to lather well, served as a substitute for soap. There were several sheds and houses on shore, so that, with tents constructed of new sails landed from the ship, men and stores were got under cover. The weather was very severe—high winds, haily squalls, and rain, the higher parts of the island near the signal-staff being covered with snow, and the temperature below 42° at night. The climate, however, appeared healthy. On June 20 only five men were on the sick-list from wounds and sores. On July 9 some of the men and officers were suffering from diarrhoea and slight dysentery, and there was one severe case of acute rheumatism; but there were, however, only eight on the sick-list, owing to the great care of the Medical officers in inspecting the tents, and seeing that they were kept clean and dry. Parties had been sent out to collect different grasses, with herbs, dandelions, and other sub-

stitutes for ordinary vegetables that could be found, to prevent the men suffering from scurvy, as there was very little lime-juice left, and they succeeded in cooking some tolerable vegetables. The island appears to have been not entirely uninhabited, as Captain Thrupp mentions having procured the services of a "Frenchman here," to assist in the selection of a berth for the ship. Captain Thrupp's dispatch is a characteristic specimen of the noblest qualities of the British sailor. It is simple, straightforward, and manly, and is full of instances of the willing and cheerful endurance of hardships by all ranks, and of the readiness of resource under difficulties, which have at all times distinguished our race, and which, notwithstanding the disparaging conclusions of social science philosophers as to our physical degeneracy in the present day, continue to do so in all climes and under all circumstances in which such qualities are put to the test. We find by the Navy List of April last that the Medical officers on board the *Megara* were Surgeon William H. Adam and Acting Assistant-Surgeon William F. Sweetman, on voyage to join H.M.S. *Blanche*, and Surgeon James L. Whitney, about to join H.M.S. *Rosario*.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE first meeting of this Society for the present session was held on Tuesday at the Society's rooms. Formerly these meetings did not begin till November, but this year it was determined to commence a month earlier, and the first meeting would have been held a fortnight ago had it not been for the alterations going on in the premises of the Society. These are now very nearly completed—sufficiently so, at all events, to admit of the meetings of the Society—and promise to be exceedingly convenient to the Fellows. The new room built at the back of the old meeting-room is not yet ready for use, but will be exceedingly useful for those who desire merely a look at the Medical papers, whilst arrangements will be made in the great hall for the accommodation of those who do not desire to take books from the library, but merely to consult them on the spot. A new staircase has been made, improving the access to the store of books in the floor above; whilst at the same time the communication between the ante-rooms and hall has been improved. Meanwhile the meeting-room looks brighter and smarter for its renovation.

The subjects discussed on Tuesday were—a curious case of biliary calculus producing fatal obstruction of the bowels, by Mr. Le Gros Clark; and some observations on the relative merits of chloroform and ether as anaesthetics, by Mr. Warrington Haward. An important question, as far as the calculi were concerned, was, whether they had reached the gut by the ductus communis, or by ulceration. Of the latter there was no trace, and there had never been jaundice. Altogether the case was one of much interest. Mr. Haward made some observations on the use of ether as an anaesthetic. He had tried it a good many times—among others, in certain cases where chloroform would have been dangerous—and had invented a plan for giving it satisfactorily and comfortably. A good deal of discussion followed.

A NEW ENGLISH HOSPITAL IN PARIS.

IN addition to his many other gifts to charities, and his labours with the Ambulance Committee during the late war, Sir Richard Wallace has established, entirely at his own expense, a Hospital for the English at Paris. Until a proper building be erected it will be conducted temporarily in spacious premises in the Rue de la Révolte. The situation of the new building will be in the neighbourhood of Passy, and will be extensive enough to contain thirty beds, to be divided equally between the sexes. The first committee of management will consist of the founder, Mr. Atlee, the British Consul, and Drs. Rose Cormack and Herbert, who will also be Physicians to the institution.

MEDICAL CLERGYMEN.

THE combination of the offices, if not of the active duties, of Physician and clergyman is an idea of no mere recent realisation. The ordination of Mr. Hugh Croskery, M.R.C.S., to the office of Deacon by the Bishop of Jamaica was only so far an innovation upon established practice that he seems to have been ordained without the usual appointment to a curacy. But such an exception is by no means singular. It is always made in favour of Fellows of Colleges; sometimes, also, in favour of Masters of Arts actually resident at the university, and others at the Bishop's discretion. The late Professor Clark, of Cambridge, to whom the present anatomical museum at that University is so much indebted, both for valuable additions and scientific arrangement, and who was also the accomplished translator and editor of Van der Hoeven's "Zoology," was at one and the same time Professor of Anatomy, M.D., F.R.C.S. Lond., a clergyman of the Church of England, and rector of a parish in Yorkshire. The present Bishop of Ripon having formerly practised as a Medical man, though subsequently ordained, was, not many years since, and after his elevation to the Episcopal Bench, created a F.R.C.S. The same was the case with Bishop M'Dougall, the retired Bishop of Labuan. There are also scattered throughout the country many clergymen who were originally Medical men, some of them possessing, and of course in such cases retaining, M.D. degrees, upon which degrees, in fact, they have satisfied the Bishop's requirement of having received an academical education. With the exception of Professor Clark—who, however, did not pursue private practice after obtaining clerical preferment—these gentlemen have virtually withdrawn from the active duties of the Medical Profession. The converse, however, seems to be the intention of Mr. Croskery, who, it is stated, will continue his Medical practice without undertaking any spiritual charge. In such case it is somewhat difficult to perceive the object of the combination, except that there may be a paucity of clergymen in some of the outlying districts of Jamaica, and a Medical man thus authorised to administer spiritual consolation may occasionally, if not frequently, supply the pressing need. Such a combination has in bygone times been somewhat abused. In the middle ages clerical Physicians were the rule, and a canon of the Church directed them to postpone the cure of the body until the more important cure of the soul had first been effected. It is needless to say that this gave these clerical Physicians an immense spiritual power over their patients, and also an undue advantage over their lay competitors.

THE GUARDIANS OF THE SOUTHAMPTON INCORPORATION AND HOMŒOPATHY.

MR. EDWARD J. ARCHER, whose appointment by the Guardians of the Southampton Incorporation as one of their District Medical Officers has been much objected to, on account of his adoption of the system of homœopathy in the treatment of his patients, appears to have entered on the active discharge of the duties of the office. In this Incorporation the Guardians undertake to supply at their own cost the necessary medicines and drugs for the use of the sick poor; and at their meeting held on the 5th inst., a letter was read from Mr. Archer which contained the following passage:—

"I beg to inform you that, in order to do justice to the patients of the district, and to facilitate their early recovery, I am desirous of being furnished with a few of the most important homœopathic medicines. They are not included in the British Pharmacopœia, and there is nothing mentioned in it which can at all take their places. They are comparatively inexpensive, and will last a considerable time. I enclose a list."

A resolution was proposed and carried, to the effect that Mr. Archer's application be acceded to. We believe that this is the first instance in which homœopathic medicines have been provided at the cost of the ratepayers for the use of a Medical officer. As Mr. Archer possesses the prescribed Medical and

Surgical qualifications, we do not know whether the Local Government Board will refuse their assent to the appointment; but we shall be anxious to learn what action is taken in the matter by the central authority if, as is very probable, the poor become dissatisfied with this (to them) novel treatment. We have no hesitation, however, in expressing our opinion that the Local Government Board will not do their duty if they sanction the treatment of the sick poor by homœopathy.

THE EXTINCTION OF THE UNFIT.

MORE than once there has been shadowed forth, during the discussion of the evolutionary hypothesis, an idea or a suggestion that our Profession was in reality an opposing force to the natural course of things in uncivilised society. The law of evolution proclaims—The fittest shall live; the unfit die. But what is our work if it is not to neutralise the latter portion of this law? Dr. Richardson, of Philadelphia, in his lecture introductory to the Course of Pathological Anatomy in the University of Pennsylvania (*Philadelphia Medical Times*), has formulated this portion of the law: he terms it the "extinction of the unfit." It is a theory we would do well to recognise (this tendency to extinction), as in many instances we have it in our power to so modify the course of events that the unfit shall become fit, and leave behind him a still fitter progeny. If we are to succeed in our endeavour, however, we must act as nearly as possible after the fashion of nature; to make a weakly individual strong, we must make ourselves acquainted with any hereditary taint, and seek to neutralise it (or more than neutralise it) by careful sanitation, the selection of the most suitable climatic conditions, and the most appropriate kinds of food. Thereby we may hope not only to combat the law of the extinction of the unfit, but to do something more. A lifelong invalid existence is not, perhaps, a pleasant thing to which to look forward, but viewed in this light it is not without hope. A steady observance of the rules of health may be rewarded with an increasing measure of that blessing. Not only so, but it may in time justify a man in forming family ties he would otherwise shrink from, and he may hope to beget a fitter family than that of which he was a member.

THE ST. PANCRAS GUARDIANS AGAIN!

AS usual, the St. Pancras Guardians are opposed to any scheme which seems to offer reasonable hopes of preventing disease by sanitary measures. They are already at war with the new Local Government Board. They have entered a protest against the proposal of the Board to issue an order to enable the Metropolitan Asylums Board to provide Hospital accommodation for cholera patients. The Guardians express a hope that the Government will not carry out the Board's intentions, which would "entail an outlay of £150,000 at the cost of the ratepayers of the metropolis." They further assert that an epidemic of cholera can be satisfactorily met by the local authorities. It will therefore, they say, be the business of the ratepayers to obtain the maximum amount of protection, secured at a minimum cost. No doubt, an epidemic of cholera could be satisfactorily met by the local authorities, provided these authorities did their duty satisfactorily, which is not always the case. It was to enforce upon "local authorities" this execution of their duty that the Local Government Act was passed.

ILL-GOTTEN REVENUE.

It is a disgrace to the Government of this country that it still derives some income from the sale of patent medicines. For the paltry sum of £68,000 odd, the Government allies itself with quacks and quackery, and gives the "authority" of its name to the "genuineness" of the trash sold under the name of patent medicine. The amount of mischief inflicted by secret "remedies" is out of all proportion to the advantage which the stamp duty gives the State.

UTILISATION OF SEWAGE—A NOVEL PURCHASE.

WHILST the important question of the utilisation of sewage is being discussed, a private company in Glasgow has been formed for the purpose (as the *Glasgow Herald* says) of "relieving the city of a public nuisance." The company has purchased that part of the sewage at present collected in the various urinals throughout the city. The company is to pay £1000 a year for twelve years for the daily collection for the same period. During the night the daily collection is to be removed to the company's works, where, after an ingenious mechanical and chemical process, the liquid will be resolved into sulphate of ammonia. The example thus set by our "canny" neighbours might, we believe, be followed with advantage in our own metropolis.

SMALL-POX IN WOLVERHAMPTON—NEGLECT OF SANITARY MEASURES.

THE epidemic of small-pox continues its ravages in various districts. Wolverhampton is now the locality chiefly infected. There are upwards of 200 cases in the borough, and the number is daily increasing. The epidemic has broken out in the police-barracks. One policeman was removed thence to die in the Workhouse Infirmary. On Thursday last these barracks were abandoned for a new building, and extemporised into a Small-pox Hospital for Wolverhampton. The town is in "a shocking condition as to its sanitary aspect." The Sanitary Committee urge the necessity of the appointment of a Medical Officer, and other remedial measures are declared to be necessary. The death-rate is 33 in the 1000. Application is about to be made to the Home Office to interfere and compel prompt action by the local authorities.

MEDICAL METEOROLOGY.

ASSISTANT-SURGEON VERCHERE, of the Indian Army, has suggested that some experiments should be made with reference to meteorological influences on sickness and health. Medical meteorology in India is still all but an unknown science, and, as at present studied, is useless to Medical Practitioners. The long range of "readings" tell us nothing; but a register of the effects of meteorological conditions on the men selected for the purpose, with all conditions of exposure, etc., taken into account, and compared with the average sickness of a corps for the same period, would teach us more in a few months than yards of meteorological tables. We understand that the Sanitary Commissioners of India are favourable to the proposal of Mr. Verchere, and it will therefore, probably, be carried out.

MR. HOLMES COOTE.

WE are very glad to learn that the announcement of the retirement of this eminent Surgeon was premature. He had been suffering from the effects of overwork, but is now sufficiently recovered to resume his usual duties.

CRIMINAL ABORTION IN AMERICA.

THE *Journal of the Boston Gynecological Society* for May and October contains some interesting facts relating to criminal abortion, by Dr. Warker, of Syracuse, New York. The former paper dealt with instrumental abortion; that in the present issue deals with abortion by medication. The exceeding commonness of the crime in America is well known, especially owing to recent exposures of the doings of professional abortionists; but these trust as a rule to the use of instruments, and to them few apply who have not already done their best to remove the "obstruction," as it is euphemistically termed, by means of drugs. Drugs for this purpose are not only openly sold and prescribed in almost every druggist's shop, but advertisements are spread abroad over all the land, of pills "which pregnant females are warned against taking, as they infallibly produce abortion"—this thin

cloak of disguise being the scant tribute of wickedness to morality. These pills, and other remedies of the same kind, are to be obtained not only at drug stores, but at the stores of country merchants. The use of these dangerous drugs is common among all classes. The wealthy and fashionable seek to confine their families to fashionable proportions; the poor, from motives of economy, also desire to limit the number of their offspring. There can be no doubt that the evil is eating into the vitals of the country; and men of right feeling and sound morality are seeking for the means of checking its prevalence. In the paper just alluded to, some interesting observations are made on two abortives—ergot of rye and extract of cottonwood—the latter unknown in this country. As is well known, ergot exercises its peculiar powers over unstriped muscle—not in the uterus alone, but also on all unstriped muscle—notably over that in the walls of the smaller arteries. The condition of the arteries affected by ergot reacts on the heart, and the circulation is considerably interfered with; but its two most notable effects are diminution of bodily temperature and alteration in the pulse as shown by a sphygmographic tracing. The use of ergot will speedily reduce the temperature nearly to 96° Fahr.; and the pulse-wave, modified by the tension of the artery, and its tracing with a curiously flat apex, is unlike anything which does not betoken serious disease. These facts may be made useful in cases of criminal abortion coming under Medical investigation. The extract of cottonwood, introduced into practice in the Southern States as an emmenagogue, is very extensively used as an abortifacient. The degree of its efficacy is uncertain, but it has the reputation of exercising great power over the uterus in a singularly gentle manner. The only other unusual effect it seems to produce is great drowsiness. We commend the American press for fairly facing what is now the most crying evil in their country, and the greatest blot on their national escutcheon.

FROM ABROAD.—INQUIRY CONCERNING THE ALLEGED MISDEEDS OF GERMAN MILITARY SURGEONS—PHILADELPHIA MORTALITY RETURNS FOR 1870.

THE Société de Médecine du Département de la Seine has undertaken the somewhat delicate task of investigating the complaints made against the German Military Surgeons for their conduct during the late war. This it believes to be but a reasonable step before taking into consideration the proposition that has been laid before it, of expelling all its German Members and Correspondents on account of the conduct in question. It has therefore named a Committee of seven members, which now—

"Makes a pressing appeal to all who are in a position to furnish it with exact and precise information concerning the conduct of the German Surgeons during the war, in the triple point of view of science, patients, and French Practitioners. The Committee, as the interpreter of the wishes of the Society, is desirous of acting only with the most loyal impartiality, and will therefore receive and employ for the purposes of its report all documents sent to it, whether these be favourable or unfavourable to the German Surgeons. The sole condition which it exacts is, that such documents shall be sincere and authentic, and be accompanied as far as possible by proofs and testimony, so that they may be sheltered from all contestation."

This sounds fair enough, but the difficulty of obtaining impartial statements from interested persons is proverbial; and when we consider the sufferings and indignities to which the French have been subjected, we can scarcely expect to find them in a frame of mind suitable for the pronouncing of judicial decisions on a matter in which they have so much personal feeling and interest. There can be no doubt that if any of the Surgeons attached to any of the invading armies have been really guilty of the base actions so freely attributed to them in the French journals, their names should receive an European publicity, in order that they may be visited by an indignation and contempt that certainly await them, not only in foreign countries, but also in their own. Amidst such a

large number of persons, it is possible that some individuals may have betrayed the honour of the Profession; but we feel convinced that, under a really searching investigation, they will be found few in number. But while we should quite approve of the Society stigmatising individuals who may have disgraced themselves and their Profession, surely it is on the wrong track altogether in searching out such evidence in order to furnish it with a seeming justification for the expulsion of its German members, who have had nothing whatever to do with the actions in question, and who, as men holding high and honourable positions, as proved by their very election, would doubtless be among the first to decry them.

As the accused are absent, they cannot be heard in self-defence, and mere uncontradicted and untested assertions will not carry weight unless supported by the most irrefragable testimony and received with cautious calmness. It is somewhat ominous, as respects this latter feature, that all communications upon the subject are requested to be sent to the office of the *Union Médicale*, the editor of which suffered much during the war, and has expressed himself in no doubting manner as to the iniquities of the German Surgeons. The terms in which he recommends the investigation, and the very enlarged scope he seeks to attribute to it, are, we fear, but indications of what he considers should be the verdict delivered.

"We most sincerely desire," he says, "that for the dignity of our science and the honour of our Profession this inquiry may terminate in negative results. Yes, it would be desirable that these shameful facts, of which vague reports are in circulation, may not prove true—depredations committed by Surgeons on public and private libraries and collections, the pillage of ambulances, the subtraction of apparatus, instruments, and pocket-cases, to the detriment of French Surgeons, bad treatment of and exactions practised on patients—of all those acts, in fact, which would for ever tarnish German Medicine. Yes, it would be desirable to learn that the German Universities and Medical Societies had protested against the barbarous warfare which has been carried on against us—the bombardment of our Hospitals, the expulsion by main force of the wretched patients from our asylums and hospices, the burning of our towns, and the contempt of men and things protected by the Geneva cross and banner. On these conditions alone can French Surgeons, the compatriots of the pure and humane glories of Military Medicine, the compatriots of Paré, of Larrey, of Desgenettes, and of Percy, say to the Surgeons of Germany, 'You have not disgraced either science, humanity, or the Profession. You are still our *confrères*. Welcome again to our hospitable hearths, and resume your places in our scientific societies.' If not, no."

In a recent paper on "Bills of Mortality," in the *New York Medical Record*, Professor Dickson, of Philadelphia, after some interesting observations upon the advantages and defects of registration returns, gives some account of those for Philadelphia (which he says are among the most complete of any American city) for 1870. In that year the deaths amounted to 16,750 in a population of 670,000—*i.e.*, 1 in 40—being 1964, or 13.20 per cent., in excess of those returned for 1869. The average of the last ten years has been 15,706. The excess of births over deaths was only 444, while in 1861 it was 2803, the only explanation which is suggested for this enormous difference being remissness in registering births. As almost everywhere else, the proportion of *infantile mortality* was frightful, 7432 (or nearly one-half) of the death-taking place under 5 years of age. The great bulk of this excess took place during the hot months, *cholera infantum* carrying off 1002. A curious fact is recorded respecting *relapsing fever*—*viz.*, its very great fatality in the coloured races. Of 490 cases admitted into the Municipal Hospital, 246 were whites, of whom only 4, or 1 in 60½, died; while 244 were coloured, of whom 62, or 1 in 3½, died. "It is not easy to explain this prodigious difference. Negroes do not die thus of yellow fever, scarlatina, or diphtheria." At first the disease was supposed to exist only from importation, but Dr. Parry has succeeded in showing that it has an independent origin in Philadelphia. He also proves that it does not arise from desti-

tution, as it has been assumed to do in Europe. Dr. Goodman "is confident that no less than 5000 cases occurred in Philadelphia during the year ending September, 1870, with 200 deaths—*i.e.*, 1 in 25. The prevalence of such an epidemic involves untold misery, suffering, and destitution among a class little able to bear them." *Phthisis pulmonalis*, as in all other places, heads the mortality list; and Dr. Dickson observes that it is remarkable how little the ratio, either to population or to absolute number of deaths, varies from year to year, whatever capricious changes may occur in the various seasons. For the last ten years its average proportion to population has been about 1 in 335. The average proportion to absolute number of deaths, during the decennium, has been one in 7½. "Phthisis had been increasingly fatal for a considerable course of years up to 1864; thence, until 1870, we mark a slight decrease. I have before me the records of consumption in an unbroken series from 1848 inclusive. These statistics do not accord with the general belief that the disease has become either less frequent or more curable than in times past. It is to be feared that the Profession has indulged too sanguine expectations, on the one hand, from certain supposed specifics, and, on the other, from the unduly eulogised improvements in our general therapeutics." Of *scarlatina* 956 died, this being, as Dr. Dickson well observes, "foremost among the *opprobria medicorum*. Thirty deaths from cholera have given rise to more panic, and afforded occasion for more fine writing and ingenious special pleading than the hundreds carried off every year by our more familiar and tenacious disorders. To these we submit with true Mahomedan passiveness and acquiescence." Usually, *pneumonia* is second on the list after phthisis. In 1870 it stands first, owing to the great prevalence of *cholera infantum* and scarlatina, and caused 811 deaths. The average number of deaths during fourteen years has been 715.

"It is curious to observe," Dr. Dickson says, "how little special notice is taken of this large mortality. In the comments upon the detailed tables which always accompany them, we shall never fail to find remarks made upon items comparatively unimportant and insignificant—apoplexy, croup, hooping-cough, measles, hernia, etc.—but not a word of this constant cause of the greatest number of deaths next to consumption.

"I have elsewhere endeavoured to attract the attention of my brother Practitioners to this not unimportant topic. In all our systematic works on Medicine, pneumonia is treated of as one of the most curable and, indeed, self-subsiding of maladies. It is, indeed, the chosen theme of the Homœopathist, Expectant Medicine, and the 'Restorative System.' On the contrary, taking a wide view of its prevalence and danger in all temperate climes, I have found it to be among the most fatal of human diseases, giving rise to a mortality of not less than 1 in 5 of the sick, as is shown by most extensive statistics gathered from all accessible and authentic sources, to the amount of fully 100,000 examples, in tables quoted. This is the average result of the details communicated from Hospitals and private practice, in war and in peace, among soldiers and civilians, rich and poor, in cities, country places, barracks, and field service."

THE HAMPSTEAD HOSPITAL INQUIRY.

TWENTY-SECOND DAY.

THIS inquiry was resumed on Thursday, October 19. The Local Government Boards Commissioners, Mr. Henley and Dr. Buchanan, presided. Mr. Montagu Williams and Mr. John Humphreys represented the managers; and Mr. Collins, with whom was Mr. Bucknill, represented "the complaints" in the *Times*.

It was announced by Mr. Williams that the late night superintendent, Mrs. Winstanley, and the under-nurse Haynes had disappeared from their lodgings, and could not be found.

Thomas Rose, the under-cook, was cross-examined. He deposed to the excellency and sufficiency of the food. But he said the best joints were served to the acute wards by the order of Dr. Grieve. Sometimes "clods" and "stickings" were served up on "beef days" to the convalescents, and

this occurred about once a month. There was no mention of "clods" and "stickings" in the tenders, and the witness was questioned at some length as to how these pieces came in; but he could give no explanation. The Australian meat, he said, was made into a stew, and was served up to the general staff of the Hospital.

Sarah Daly, a nurse, contradicted the statements made on the other side as to insufficiency of drink and the bad quality of food. Only delirious patients, she said, were tied down. She contradicted the statements as to the scant supply of linen, the filth and vermin, and the want of nurses.

Mr. Rutherglen, the second clerk, was here recalled, and cross-examined by Mr. Collins on the minute-book of the Hospital Committee. The witness was particularly questioned respecting the occurrences when the two senior Assistant Medical Officers, Mr. Greaves and Mr. Kynaston, received notice of dismissal, and he maintained that the account given by Mr. Wyatt as to the notice being given to the two seniors for particular reasons in respect to their conduct, and laid to the reduction of the staff at the desire of some on the Committee, was in strict fact.

Re-examined by Mr. Humphreys, the witness said that the dismissed Assistant Medical Officers made no complaint whatever to the Committee; all the inquiry they desired to have was as to the charges they thought Dr. Grieve had preferred against them.

The next witness was John Matthews, the chief cook. He asserted the excellent sufficiency of the provisions, and said that "clods" and "stickings" were not received, and that the inferior parts of beef were only used to make beef-tea. He said that the meat was often cooked so soon after killing that there was not time for it to become tender.

TWENTY-THIRD DAY.

On Friday, October 20, the Chief Commissioner said that he trusted the inquiry might be concluded by the following Friday.

Sarah Ettery, a nurse, was examined. She deposed to the goodness of the food and the sufficiency of supplies. She gave evidence regarding the dead body left in the bath-room, and she said it remained there longer than it would have done, because, from, its being Sunday morning, the man who should have supplied the shroud was rather late. She declared that she had not stopped the patients' stimulants at any time, and the patients got all they were ordered. Everything she had applied for to Dr. Grieve she obtained, and she certainly never knew of Dr. Grieve treating any patient with harshness. One patient had shown her a damp sheet he had got, and she gave him a dry one for it, and she might have said it was "scandalous"; but the patients sometimes helped themselves to sheets while she was absent, and she supposed this one was thus obtained. The witness declared that she always had arrowroot and a sufficiency of stores; and having regard to the numbers admitted, and the pressure on the resources of the Hospital, everything that could be done was done for the benefit of the patients.

Emma Weaver and Susan Shufflebotham, nurses, gave similar testimony. The latter said it was in her ward that the man died whose body was left in the bath-room, and she said it was so left because there was not a shroud. She removed the body from the ward to the bath-room herself, and laid it in the bath-room on the bed on which the man had slept. When patients died in the night, the beds were screened, and the bodies removed early in the morning.

By Dr. Buchanan: She took the dead body out of the ward because it smelt so strongly; and, though it was not her duty to remove it, she took it out for the comfort of the patients.

Manoah Walker, who had been a patient and was now coachman to the institution, was examined. He stated that the treatment he had received was kind and considerate.

TWENTY-FOURTH DAY.

On Monday the evidence of patients in favour of the management of the Hospital was commenced. We give the evidence of one witness *in extenso* as a sample.

James Salmon, a cabman, of Drummond-street, Euston-square, who stated that he had been a butcher before following his present calling, was called, and examined by Mr. Humphreys. He said he went into the Hospital on May 9, and was discharged on June 2. He was tied down when he first went, but he was not hurt by that, and it was necessary in his case, for he got out of bed and raced about the ward. He deposed to there being sufficient of good food, both when he was in the acute stage and in the convalescent stage. The beef was once in the way a little tough, but in general the meat was good. The bread and butter were excellent. The linen was clean in all

parts of the Hospital, as he saw by going in various wards; and every morning the nurse used to ask if anyone wanted a clean shirt or sheet. There was no cause whatever for complaining of anything.

In reply to the Commissioners, the witness (who was a respectable man of his class, and seemed in excellent health) said the beef given was sometimes one part of the animal and sometimes another. He had had "chuck," a piece of the "sticking part," a piece of sirloin, or a piece of the "clod" part. He had about five or six ounces of cooked meat, at least.

Questioned by Dr. Buchanan, the witness said he was not delirious in the daytime, but only in the night. He said that he saw no one who complained of suffering from thirst unattended to. He acted as a convalescent help, and sat up nine nights, and there were then quite sufficient supplies of milk and beef-tea; and very often milk and beef-tea were left over in the morning. There were generally not many acute cases in a ward at a time—some ten or twelve—and the other patients, though not quite well enough to go to the dormitories (convalescent wards), were able to help themselves. He was not a "nurse's favourite"; he gave no "tips." Regarding the changing of the beds, he said a fresh bed was always served out in lieu of one on which a patient had died, and he could say that clean sheets were on the beds for fresh patients; and the same course was adopted when a patient came into the convalescent wards from other wards. The towels, he said, he knew were changed every morning, for he changed them himself. He described some of the convalescents as being most unwilling to wash themselves, and as being disinclined to bathe even when ordered. In respect to the towels having vermin, the witness said he had seen them on one or two occasions, and the towels were then at once removed. This was in the convalescent ward; and then at once a search was made among the patients to discover who were the patients so afflicted. When they were found, means were at once taken to cleanse them. The potatoes were generally good, and the patients were told that if they had a bad "tatur," they could have a good one for it.

The witness was cross-examined by Mr. Bucknill, who, in reference to the boy Croake, a patient called early in the inquiry, wished to elicit the facts connected with that youth sleeping in his clothes in the convalescent ward, to which he said he was necessitated by there being no clothes for him. The witness said the boy did get into bed with his clothes on, and cover himself with the bed-clothes; but he was not necessitated to do that, for he had served out to him a white suit. In regard to the bath-room being sometimes in a "sloppy state," whenever this was the case it was caused by the dirty habits of the patients themselves. He had heard no complaints of any sort in the Hospital in regard to the treatment, food, and nursing. Asked how he had been searched out to give evidence, he said he had read the complaints in the newspapers, and he drove there in his cab. The only person he saw was one of the wardsmen, who said to him—"Well, we have not killed you," and witness said—"No, just the reverse;" and then told the officer that he was desirous of bearing testimony to the excellent treatment he had seen in the Hospital. Questioned as to his experience as a butcher, he was shown the tender for meat, and asked if a butcher would be justified in sending in "clods" or "stickings" under that tender, and the witness, while candidly owning that neither "clods" nor "stickings" would come in under the tender, yet a butcher, he said, would, under the contract, "try to shove one in now and then."

By the Commissioner: He only once saw "clods" and "stickings" brought into the Hospital by the butcher. There was not the least difficulty in the way of men drying the floor of the bath-room if they had felt so disposed, and the bath could have been emptied at once by anyone who felt inclined to empty it, even if the pipes were out of order.

Re-examined by Mr. Hammond, in the absence of counsel (who were at the Old Bailey), the witness said that when he was delirious he got up at night and washed his bedstead, as if he had been washing his cab, and he used the sheets as reins, as if driving. It was because he knew the statements made at the opening of the inquiry were false that he had come to give his evidence.

John Thomas Slater, railway waggon examiner; Henry Ripsher, of the goods department of the London and North-Western Railway Company; John Peake, a butcher; Stephen Wakefield, a bricklayer's labourer; Harriet Boyce, who went into the Hospital to watch over her three children who were there; Charles Alderson, an artizan; James Dix, a packer; and A. F. Gible, a tailor, all gave evidence as to the general excellence of the arrangements and of the treatment they received in the Hospital.

TWENTY-FIFTH DAY.

Similar evidence was given by Ellen Glanders; W. J. Ansell, a packer; Flowers Allpress, a saddler; Charles Cripps, a publican, who had sent his five children to the Hospital; Ellen Cripps, a girl of 10; Elizabeth Bowen, a cook; Mr. C. H. Good, a surveyor; Mrs. Swann, the mother of a child who was in the Hospital, which child she said had come out with a "corporation," which was "pure fat"; George Tate, an archery maker; and James Bray, a butcher. These all gave evidence as to having had sufficient food and drink of good quality, of the general cleanliness of the linen, of the sufficiency of nurses and attendants, and of the general good character of the arrangements. At the conclusion of the day the Chief Commissioner said that he and his colleague did not require any more evidence of this character.

TWENTY-SIXTH DAY.

Messrs. George Edward Douglas, Governor of St. Marylebone Workhouse; Mr. George Soper, a relieving officer of St. Saviour's District, St. Marylebone; Mr. Metchin, a relieving officer of the Second District of St. Mary's, Islington; Mr. Fussell and Mr. Judge, relieving officers of Shoreditch, were examined in behalf of the Management. They deposed to the large numbers of patients sent to the Hospital during the epidemic, to the filthy condition in which many of them were, their bodies and clothes being infested with vermin, and to the miserable overcrowded and dirty houses whence they were taken. Mr. Douglas gave some evidence with regard to the tenders and contracts of the Hospital. He said he had had considerable experience in regard to contracts, and the prices put for the articles in these contracts were for the best articles. At St. Marylebone the guardians were in the habit of looking more to the character of the persons tendering than to the lowest prices, and thus paid higher prices than many parishes might pay; but the prices paid at Hampstead were in many cases higher than those given by his guardians. The meat in summer would be hard from being fresh killed.

By the Chief Commissioner: The breast of mutton should not have been sent in under the tender, nor "stickings" of beef. "Clods" formed a good part of meat, but "stickings" were only fit for making beef-tea. The average waste from boiling mutton, taking the whole carcase, was 37 to 40 percent., including freeing from bone, cooking, and serving out.

Questioned by Dr. Buchanan in reference to the prevalence of vermin in the Hospital, he said: Some of the persons taken into the workhouse were in a most fearful condition in regard to vermin. Some had led a wandering life in the parks, and it was then most difficult to cleanse them when the heads were sore. The first thought was always given to the Medical treatment of the patient, and from his experience he should hesitate before interfering with a head with a small-pox eruption out, whatever might be the condition of the head in regard to vermin. No nurse would apply anything to a sore head to kill vermin without the orders of a Medical officer. It was most difficult to keep wards free from these things when they once gained admittance. Some good specimens of the creatures could be seen any night in the casual wards.

Mr. Collinson Hall, milk contractor to the Hospital, was called and examined. He stated he served Guy's Hospital, St. Mary's Hospital, the Brompton Consumption Hospital, Caledonian Asylum, London Hospital, Bartholomew's, Christ's Hospital, the Foundling Hospital, Charing-cross Hospital, Deaf and Dumb Hospital, the Langham Hotel, and various other large hotels and many clubs. Only on one occasion had the milk been returned from Hampstead, and that was when it "turned off," owing to a thunderstorm, and fresh was immediately sent. It was tested generally before being sent out, and it was sent as received from the country.

The other witnesses called on this occasion were Mr. Autrey, a relieving officer of Paddington; Mr. F. Moon, a relieving officer of St. Pancras (from which parish 2000 small-pox patients were sent); Mr. T. A. Lester, a relieving officer of Islington; Mr. Richard Ody, a relieving officer of St. George's, Hanover-square; and Mr. Overton, a relieving officer of St. Marylebone. All these gave like testimony regarding the reported good treatment of the patients; and even those sent from the rich districts—some of them gentleman's servants, "used to good living"—had made no complaint of having suffered in the Hospital from anything.

The contractors for butter, eggs, and potatoes were called and gave evidence showing that they had been called upon by their contracts to supply good food at fair prices, and they declared they had done so.

John Jones, the wardsman, was then examined, and the Court adjourned.

THE VACCINATION ACT, 1871.

THE following circular letter has been issued by the Local Government Board in reference to certain portions of the Vaccination Act, 1871:—

Local Government Board, Whitehall, London, S.W.,
October 17, 1871.

Sir,—1. I am directed by the Local Government Board to forward for the consideration of the guardians a copy of the Act 34 and 35 Vic., c. 98, which was passed in the last session of Parliament to amend the Vaccination Act of 1867.

2. The Board desire me to direct the attention of the guardians to the 5th Section of the Act, which requires them to appoint and pay one or more Vaccination Officers. This provision will not come into compulsory operation until January 1 next (see Section 2 of the Act); but, as the duties of those officers should commence from that date, and as the guardians have at present the power to make such appointments, under Section 28 of the Act of 1867, it is desirable that the matter should be proceeded with at once.

3. The new Act will not interfere with any appointments of paid Vaccination Officers which have already been made by the guardians, under the provisions of the Act of 1867, and those appointments will remain in force until the guardians put an end to them. In view, however, of the new duties imposed on Vaccination Officers by the Act of 1871, the terms and conditions of their appointments will require reconsideration; and in some instances it will be necessary for the guardians to consider whether any and what further appointments may be required for carrying into effect the intentions of the present Act. On the other hand, where the guardians have not already made any such appointments, they will be called upon to consider the question anew, with reference to the fresh obligations now imposed upon them.

4. The first question for the consideration of the guardians will be, whether one officer should act for the whole of the area within the jurisdiction of the guardians, or whether that area should be divided into districts, and an officer appointed for each district. In the latter case, the guardians will observe that any such district which they may form must (unless the Local Government Board otherwise direct) coincide either with a vaccination district or districts formed under the Act of 1867, or with a district or districts of a registrar of births and deaths.

5. It will be the duty of every Vaccination Officer so appointed to see to the execution of the Vaccination Acts, with the view of securing the vaccination of every child who is not unfit for it, or is not insusceptible of it. For this purpose it is provided by Section 8 of the Act, that every Registrar of Births and Deaths shall transmit to the Vaccination Officer a monthly return of births and of the deaths of infants under twelve months of age. The obligation to furnish these returns will not arise until after January 1 next (see Section 2 of the Act); and in the meanwhile the registrars will receive the necessary forms for making the returns, with such instructions as may be given them by the Registrar-General of Births and Deaths in England, with the approval of the Local Government Board.

6. When the new Act shall have come into full operation, the registrars will no longer be required to submit to the guardians the half-yearly lists referred to in Section 27 of the Act of 1867; and the only duties which it will then be incumbent on them to discharge under the Vaccination Acts will be—(1) to give to the parents or other persons the notices contemplated by Section 15 of the Act of 1867; (2) to keep the record of such notices, which is required by Section 24 of that Act; and (3) to transmit to the Vaccination Officers the monthly returns above referred to. For the performance of these duties, each registrar will be entitled to receive the following remuneration:—namely, under Section 24 of the Act of 1867, a fee of one penny in respect of every child whose birth he shall have registered, and in respect of whom he shall have given the required notice; and under Section 8 of the Act of 1871, a fee of twopence for every birth or death entered in the return referred to in that Section, which fee is to be paid to him whether he is or is not also the Vaccination Officer. These fees will be payable to him by the guardians in the same manner as the fees were formerly payable under Section 25 of the Act of 1867.

7. As Section 27 of the Act of 1867 will be repealed on January 1 next, it will devolve upon the Vaccination Officer, acting under the instructions which will be issued by the Local Government Board, and under the directions of the guardians, to examine the lists of births and deaths supplied to him by the registrar, and in those cases in which, at the expiration of the time allowed by the law, certificates of successful vaccination or of postponement of vaccination, or of insusceptibility to vaccination, or information of the death of the child shall not have been received, to take such steps as his instructions shall point out for insuring compliance with the law. The Vaccination Officer will be required to keep such registers, and other records of his proceedings, as the Local Government Board shall direct; and the Board will shortly issue forms for this purpose, under Section 5 of the new Act.

8. Under Sections 16 and 29 of the Act of 1867, the parent or other person is liable to a penalty, who shall neglect to have the child vaccinated within three months after its birth, or after receiving its custody, or in certain cases within the further period limited by Section 12 of the Act, and shall not render a reasonable excuse for such neglect. This offence is complete at the end of the three months or other period, and as, therefore, it can only be committed once, only one penalty can be inflicted on account of it. (See *Pilcher v. Stafford*, 33 L. J., new series M. C. 113; 9 L. T., new series 759.) Under Section 31 of the same Act, however, an order for the vaccination of a child under 14 years of age may be made by a Justice of the Peace if he see fit, upon the application of the Vaccination Officer, and such order may be renewed or repeated, again and again, as often as may be requisite, until the vaccination of the child is effected. (See *Allen v. Worthy*, 39 L. J., new series M. C. 36; 21 L. T., new series 665; 5 L. R. 5 Q. B., 163.) It is important to bear in mind this distinction between the proceedings under Section 29 and those under Section 31.

9. The certificates of unfitness and of insusceptibility, which under the Act of 1867 were to be given to the parents, but were not required to be transmitted either to the registrars or to the guardians, must now (under Section 7 of the present Act), as well as the certificates of successful vaccination, be transmitted to the Vaccination Officers, and be registered by them. The period for the transmission of any of these certificates is, also by Section 7, limited to seven days from the examination on which it is founded; and it is of great importance for the avoidance of unnecessary trouble to parents and others in carrying out the Act, that this limitation

should be noted, and the direction of the law strictly observed by those on whom the transmission of the certificates devolves. When the certificate is one of unfitness, the vaccination is merely postponed; when the certificate is one of insusceptibility to vaccination, or of successful vaccination, or where the child has already had the small-pox, no proceedings will be required to be taken. It may, however, happen that the child has been successfully vaccinated, although the certificate may not have been transmitted, as the law requires, to the Vaccination Officer; and it is provided by Section 11 of the present Act, that in such a case the person erroneously charged with neglecting to procure the vaccination, may, if the facts require it, be convicted of the offence of neglecting to transmit the certificate.

10. With respect to proceedings to be taken under Section 31 of the Act of 1867, some important facilities are introduced by Section 11 of the present Act, which provides that such proceedings may be prosecuted with respect to any child who is not within the union or parish, if either the child or its parent was within the union or parish at the time of the information; and further, that the parent who fails to produce the child when summoned shall be liable to a penalty not exceeding twenty shillings.

11. The Board do not consider it necessary at present to do more than call the attention of the guardians generally to the other provisions of the Act which relate to proceedings against offenders, as well as to those provisions in Sections 7, 9, 10, 12, and 13, which have reference to Public Vaccinators, Medical Practitioners, and Poor-law Medical Officers. The Board request, however, that the guardians will direct the attention of their Medical Officers and Public Vaccinators to those provisions. The fees recoverable in certain circumstances under Section 9 should be collected, as it seems to the Board, by the collector of the guardians, if there be one; but the guardians may, if they think fit, appoint their Vaccination Officers as collectors for this purpose, under the General Orders of the Poor-law Board of October 7, 1865, and November 27, 1866.

12. In conclusion, the Board desire to refer to the 16th Section of the Act, which substitutes the Local Government Board for the Poor-law Board and for the Lords of her Majesty's Privy Council, respectively. The Act under which the Local Government Board is established (34 and 35 Vic., c. 70), transfers to that Board the powers and duties vested in or imposed on her Majesty's Privy Council by the enactments specified in the schedule, amongst which are the 30 and 31 Vic., c. 84 ("The Vaccination Act, 1867"), and any Acts amending it. I am further to refer to the extension given by Sections 14 and 15 of the present Act, to the powers of the Local Government Board, in substitution for the Poor-law Board, with respect to vaccination contracts and forms of certificates; and also to the duty imposed on the Board by Section 5, of framing, providing, and distributing appropriate books and forms for the use of Vaccination Officers, Public Vaccinators, and Medical Practitioners. The Board propose to communicate with the Guardians again, on the subject of these books and forms.

I am, Sir,

Your obedient servant,

(Signed)

JOHN LAMBERT,

Secretary.

To the Clerk to the Guardians.

REVIEWS.

Animal Plagues: Their History, Nature, and Prevention. By GEORGE FLEMING, F.R.G.S. etc. London: Chapman and Hall. 1871. Pp. 548.

THIS book has occupied a place on the table for a much more considerable time than we had intended, awaiting notice in our columns. More explanation is scarcely needed than to say that it aspires to present the condensed histories of all pestilences among the lower animals, in consecutive order, from the dim records of earliest times down to the present century. In pursuance of this truly gigantic task all sorts of sources are utilised, and a vast accumulation of material is brought together, of which, especially when the record dates from early centuries, the precise value in a scientific sense is often dependent on the style in which a poet, historian, Physician, or philosopher has, perhaps by chance, alluded to some legendary or contemporaneous pest. The author launches his venture thus:—"No attempt has yet been made in this country to trace the history of these diseases, or to afford an indication of the sources from whence such a history was to be derived. It is, therefore, with diffidence that I venture to offer this history of British and foreign epizootics from the earliest recorded events of that kind up to recent times. For Professional reasons my opportunities for research have been few, else this contribution to the literature of the subject would undoubtedly have claimed more pretensions to accuracy and completeness. Nevertheless, no pains have been spared to make it what I intended it should be. The collection of materials for such a work was no easy task, the references to animal diseases of a general character in the early ages being found only in books which treat also of other matters, and are often very rare."

The general arrangement adopted is that of distinct paragraphs, to each of which the year-date is prefixed, and so regularly down, through eight chapters, each representing some more or less defined epoch in the series of pestilences. To the ordinary reader few chapters are more interesting than the first; for in this, beginning with Ireland, where in B.C. 2048 the carcasses of the giants "slain in war with Parthalani" bred a pestilence, and so on to Egypt, with the murrains, through Trojan plagues, Athenian records, Roman history, with Virgil's first wondrous description of the actual cattle

plague, through stories of Huns, and prodigies of locusts, the record lands us in A.D. 400. This will give some idea of the richness in matter, often most interesting, often mythical, frequently of doubtful value. What are we to do with this for example?—

"A.D. 314. In the reign of Constantine the Great, the large island of Cyprus was thirty-six years without rain. So great a famine ensued that all its animal inhabitants forsook it and fled."—*Petavius*.

Chapter II. (400 to 1500) illustrates well the science and art of Medicine as they existed in an age of mysterious phenomena and innumerable superstitiously regarded portents. Space fails, or we might quote many instances of singular character from these records. Respecting one of the most common portents, the "*signacula*," preceding or accompanying pestilences, we find an explanatory note at page 122, which is not up to our present knowledge on the subject. "Blood spots" and "blood rain," referred by Ehrenberg, in 1848, to the animal kingdom, and named "*monas*," have since then been the subject of monographs by Dr. Montagne, of Rouen, the Rev. M. J. Berkeley, and Dr. H. O. Stephens, of Bristol. The last-named cryptogamist, in 1853, in accordance almost entirely with the two former, gave a clear description of this curious growth, deciding conclusively that it is a true algoid, and that the carmine spots (*palmella prodigiosa*) which appear on articles of food, as even more than once, to the consternation of all, on the sacred wafer, should be distinguished from *palmella cruenta*, the colour of which is dull red, and the cells much smaller. While we write, a saucer of paste is before us, on the surface of which the algoid is exhibiting its blood-red spots. The particles transplanted from decaying meat grow readily, and the characteristic structure is not difficult of verification.

Entering upon the next period (Chapter III., 1500 to 1700), the author considers that we leave "a most unprofitable era for one pregnant with great results to the sciences in general, but especially to Medicine." The great revival of learning in the sixteenth century was not less favourable to veterinary than to human Medical art. In 1506 there reappeared the works of Dioscorides; in 1525 those of Galen; and in 1526 those of Hippocrates. While we all acknowledge the extent to which early Medicine was indebted to the Arab Physicians, it is not so well-known that, in reference to one branch of the science—the diseases of horses—more attention seems to have been expended than perhaps upon any other. The maladies of the Arab horse were more fully recorded even than those of his rider.

Chapters IV. and V. are occupied largely with the supposed commencement of the cattle plague in 1733, and its gradual extension over the Continent of Europe. Quotations of much value are given regarding this disease, which is characterised as "a malignant fever"; and its invariable progressive advance from place to place is shown to have been by contagion. In 1745 the cattle plague appeared near the metropolis, spread through Essex, was sent (in two cows from a fair) to Berkshire, and by way of Hertfordshire to London itself, whence it soon overspread the entire kingdom. From 1745 to 1800 (Chapters VII. and VIII.) this terrible pest continues to occupy the most prominent place, and necessarily dwarfs a vast number of epizootics—anthracoid, varioloid, foot and mouth disease, rot, influenzas, rabies, glanders, and others—several of which we feel are deserving of more space for details. At the last-mentioned date the work is brought to a close.

In each case the authorities are enumerated at the foot of the page, in a manner very admirably facilitating reference; and while, as regards the excellence of the matter, we cannot but be pleased with the length of certain quotations, they seem to us important enough to have taken the form of an appendix. We allude especially to Dr. Mortimer's Royal Society paper on Cattle Plague (9 pages), and Mr. Dossie's, on the same subject, from the "*Memoirs of Agriculture*" (49 pages). Doubtless difficulties of no ordinary kind will attend the continuation of this work into our century, but that the record should terminate at 1800 seems purely arbitrary, and it is to be hoped that the success of the present effort will encourage Mr. Fleming to deal with the wide and confused historical material of the last seven decades.

The subject of animal pestilences presents distinctive features of interest to the agriculturist and the pathologist; it is with the latter point of view that we, as Medical Practitioners, chiefly have to do. In turning over the records of morbid phenomena registered by such admirable observers as Fracastor, Lancisi, Heusinger, Ramazzini, Kanold, Ens, Haller, Darwin, and others, we are not surprised to find everywhere traces of

their genius; and, indeed, there is often a completeness about the details of their pictures, as compared with some vague and conflicting records of human plagues, which startles us. There is, at least, one advantage in the observation of disease among dumb animals—in so far, *i.e.*, as all the data must be objective; so that mental forces, apt to be wasted in weighing the relative value of a patient's own impressions, are here diverted into the channel of direct scrutiny and rigid inference.

These varied historical sketches form a mine for the inquirer into epidemic pathology, but we doubt if all the collected records, though they may assist the coming discoverer, will reveal to him the great mystery of *origin*. Innumerable events have been noted from the earliest ages as forerunners of pestilences, and a curious list might soon be made. Thus, we find more or less repeated mention of the following:—Comets, blood-rain, eclipses, clouds of dust (Philo), locusts, severe winters, earthquakes, famine, drought, wind tempests, rain and floods, hailstorms, hot summers, much snow, meteors, volcanic eruptions, caterpillars, leaf-eating insects, moist air, mould, corn-smut, mist, damp, stinking fogs (Heeker), and others. One leading idea, however, runs through the records of all great cattle epidemics—recognised from the earliest periods as their all-important source, frittered away from time to time by the speculations of some *doctrinaire*, to be reasserted by the stubborn fact of widely spreading death, the dominating feeling holds its own that contagion is the one known source. Is there, then, no historic time when *variola ovina*, cattle plague, skin disease, anthrax, or foot and mouth disease arose? Probably, no. Newman ridicules our doubt that human diseases are now arising. Small-pox began undoubtedly once, it may therefore be begotten afresh; but we may reply that the race of man did so too, and yet we do not find here and there new independent formations of human beings in this our day. But do our epidemics originate in those of lower animals, or *vice versa*? Seemingly, no; for the rare and doubtful instances of such supposed relations rather prove an opposite rule. Of course, we can only conceive of diseases as having once commenced; and a morbid mark upon a fossil of some long extinct species is, as to time, in an epoch modern compared with the ages which must have rolled over shapeless masses of eozoon. That pestilences originated, though very remotely, we may well believe, and their known alterations of type in modern times support the conjecture; but for all practical purposes it is of the first importance to feel that the infected animal and its *reliques* or emanations have been, and are still, the invariable sources of danger and death. As the learned author of "Considerations concerning the Distemper which spreads itself among the Horned Cattle" in 1749, well remarked, "Nothing in my humble opinion did so much to contribute to the spreading of this terrible distemper at its first breaking out as the belief that it was not contagious, and the expectation of an effectual remedy for it."

Again, as to the treatment of diseases of an epidemic type, the impression produced in our mind by these histories may be summed up in two words—isolation, and disinfection. No timidity, begotten of the reverence which hedges the human patient, has prevented a trial of any conceivable remedy, however grotesque, on the beast, but all evidence of curative action is limited to the most common-sense procedure—in fact, to proper nursing and diet. As to the main point, there is no doubt; to stay the plague, the Physician can only stand between the diseased and the healthy—get rid of the former, and isolate the latter. Disinfection with sulphur and bitumen was enjoined by Vegetius, of Constantinople, in A.D. 400, "because these preserve other animals from the plague," and we have perhaps, after 1470 years' experience, no better advice to offer.

Contagion, then, whatever the remoter origin, has been the source proximate of cattle plagues in historic time; but while we have no positive knowledge of the poison conveyed, that so many of the above-mentioned antecedents have been such as would preserve, foster, and disseminate the lowest forms of organic life, may be taken to favour the so-called germ-theory. At all events, the gradual progress, *e.g.*, of true cattle plague, like that of cholera, to parts of a country uninfected, however bad the hygienic conditions may have been for a long period, speaks strongly against the mode of origin *de novo*. In the same direction would appear to argue the use, from the earliest ages, as means of arresting the pestilence, of fire, sulphur, entire and deep burial of the carcasses, or the free employment of the pole-axe. Thus only can Virgil's herdsman—

"With speedy knife the fault coerce, ere yet
The dire disease creeps through the careless flock."

We find, however, that space will scarcely permit us to add to these few of the thoughts which crowd around Mr. Fleming's book. The contrast is strange between the vigorous legislation indulged in when *cattle* plagues are in question, no subject liberty being awkwardly infringed, and the general lack of interest in a matter so important to the political economist. As Mr. Bentinck, at 10.40 p.m., on June 2 last, was making this very remark in the House of Commons, it was observed that there were only twenty-one members present. Excellent speeches by Messrs. Read, Jacob Bright, and Forster had not sufficient attractive power, and twice was the House counted out, on the Contagious Diseases (Animals) Act. And yet corn-culture, at home, is yielding slowly but surely, as we increasingly import the competing crops of countries a shade better adapted than our own for cheap surplus production, to *grazing*. Again, "the losses from only two exotic bovine maladies ("contagious pleuro-pneumonia," and the "foot and mouth disease") have been estimated to amount, during the thirty years that have elapsed since our ports were thrown open to foreign cattle, to 5,549,780 head, roughly valued at £83,616,854. The late invasion of 'cattle plague,' which was suppressed within two years of its introduction, has been calculated to have caused a money loss of from five to eight millions of pounds." A vegetarian philosopher tell us that we are all under a mistake; that neither the maximum individual health nor the highest development of civilisation is compatible with the slaughter of animals for food. We cannot, at the moment, either refute his arguments, or give up our sirloin. Be it as it may, Medicine waits not till people are what they ought to be, nor till its own remedial agencies are theoretically perfect. The suffering animals are there, and it is our present duty to relieve their pains and stay those plagues which the refined intellect of the poet has felt to be truly undergone for our sake. Pathological science may justly rejoice, however, at the realisation, wonderful in this, our so-called "practical" country, of the new Brownian Institution for the study of diseases of domestic animals. It is now established at Battersea, with Dr. Burdon-Sanderson approved as its first Professor by the University of London, and something like £30,000 to support it. We cannot but repeat the question asked by Dr. W. Budd in 1869, referring to the grants for investigation of cattle plague: "Are the lives of bullocks more sacred than the lives of men, and sheep more precious than children?" In face of the above foundation we really feel hopeful, and may be pardoned for dreaming that some similar phenomena may take place in the matter of human pathology, thus contributing still more directly to the good of man's estate.

A Descriptive Catalogue of the Calculi and other Animal Concretions contained in the Museum of the Royal College of Surgeons of England. By THOMAS TAYLOR, F.R.C.S. 4to. London: Taylor and Francis. Pp. 87.

THE Profession, especially those members of it who avail themselves of the opportunity for study of the contents of the invaluable Museum of the College of Surgeons, will be much pleased with this additional catalogue—or, rather, supplement—to those already published by the same author, under the direction of the Council, to whom great credit is due for so carefully selecting the best authorities on each particular subject—such men as Owen, Paget, Quekett, Morris, Cobbold, Flower, Stanley, Bader, Erasmus Wilson, and Taylor. The last-named gentleman was the author of Part I. of "Human Urinary Calculi"; this was followed, in 1845, by Part II., "Calculi from the Biliary Organs, Stomach, and Intestines of Man, and Calculi from the Lower Animals." Since the last publication—twenty-six years ago—356 specimens from the urinary tract of man have been added; making, with the former, a total of 1005.

Of calculi of infrequent occurrence from the urinary tract of man, Mr. Taylor states that the most remarkable additions to the Museum are the half of a xanthic oxide calculus extracted from the bladder of an Indian child by Mr. George Coles, of Her Majesty's service, and presented by the late Mr. Bransby Cooper, and a calculus consisting chiefly of carbonate of lime taken from the bladder of a man, and presented by Mr. William Bird, of York. Of the latter species of calculus the collection formerly possessed no specimen, although, on account of its great rarity, drawings of some carbonate of lime calculi in the possession of Mr. R. Smith, of Bristol, were published in a former volume.

To the Medical Officers of the Queen's Indian Service the College is indebted for a large collection, of considerable interest as illustrating the effect which the diet and habits of

living of the natives have upon the composition of these concretions, and also because, in almost every instance, they are accompanied by a statement of the age and sex of the individual from whom they were taken, the duration of the malady, and the progress and result of the operation. Chief amongst these contributors is Mr. H. C. Cutcliffe, F.R.C.S., whose donations are numerous, illustrating also his great success, as we find eighty-two recoveries and only four deaths; in twelve cases the result, perhaps from forgetfulness, is not stated. With regard to lithotomy, this gentleman informs us that, notwithstanding the most favourable cases, the operation is objected to by the natives. The other Indian donors are Dr. W. B. Beatson and Messrs. W. E. Allen, T. Atchison, G. Cole, and J. G. Pilcher. The members of the Council of the College, past and present, are important contributors. Mr. Hodgson's collection is large and valuable. Mr. George Cooper, F.R.C.S., the late Master of the Society of Apothecaries, has, amongst other specimens, sent a large uric acid calculus, accompanied with a curious history—that it was “cut from James Clitherow, of Boston House, August 13, 1680, then aged 62.” The following curious statement of the expenses attending the operation was taken from his books, and sent with the stone:—“To £150, paid by agreement to Monsieur Callot, y^e Frenchman, for cutting me of the stone; to Apothecary, Surgeon, and nurse that attended me, £26 10s. 6d.; for rent of my lodgings in Hatton-garden, and diet there, £28 15s. 2d.; for a pallet bed, and y^e furniture of it then used, £6 17s.; for charges of removing to and from London, £1 10s.; making a total of £213 12s. 8d.”

The list in the Catalogue is divided into nine series, viz. :—(1) Calculi of which the nucleus or primary deposit consists of Uric Acid; (2) Calculi of which the nucleus or primary deposit consists of Urate of Ammonia; (3) Calculi of which the nucleus or primary deposit consists of Oxalate of Lime; (4) Calculi of Cystic Oxide; (5) Xanthic Oxide; (6) Phosphate of Lime; (7) Phosphate of Magnesia and Ammonia; (8) Phosphate of Lime and Phosphate of Magnesia and Ammonia mixed in various proportions (the fusible calculus of Wollaston); and (9) Calculi consisting of Carbonate of Lime.

From the following table it will be seen that uric acid forms the largest proportion of all simple calculi; while, on the other hand, in those consisting of several layers (alternating calculi) it constitutes the nucleus in the smallest proportion, or, in other words, it is less frequently followed by a secondary deposit than either urate of ammonia or oxalate of lime, the relative numbers being—uric acid, 105; urate of ammonia, 251; oxalate of lime, 148.

	Simple.	Two layers.	Three layers.	Four or more layers.
Uric acid	277	68	36	1
Urate of ammonia	22	160	75	16
Oxalate of lime	90	118	21	9

Mr. Taylor does not consider it necessary in the work in question to make any change in the chemical nomenclature; the term “phosphate of lime” is therefore used, instead of “calcium” or “calcic phosphate.”

The Catalogue is highly creditable to the author and to the Council of the College under whose auspices it has been produced.

La Calentura Roja. Por D. RAMON HERNANDEZ POGGIO, etc.

The Red Fever. By D. RAMON HERNANDEZ POGGIO. Large 8vo. Pp. 74. Madrid. 1871.

It is under this head and title that Dr. Poggio describes to us an affection variously spoken of as “dengue,” “breakbone fever,” “scarlatina rheumatica.” It is the “dandy fever” of St. Thomas's, which has been called elsewhere “*la pantomima*.” Once again we smile as we remember one of our dear colleagues who had the name fixed on him by the negroes of “Dandy Doctor,” whilst practising in that island. He had been lifted on horseback, and ventured abroad to see his patients, while yet suffering and tormented by this complaint, affording much amusement at his expense. Its chronic and fleeting nature giving no opportunity for post-mortem examinations, little light has been shed on the pathogeny of the disorder, and much remains in its pathological relations that is cloudy and obscure. The character of this affection is essentially that of fever; but, as to the eruption, it varies exceedingly in its expression; and even its presence, as well as intensity, is unequal and uncertain. The same with regard to the pains. This disorder is felt as epidemic in America, as well as both the Indies. In England it occurs, if at all, unfrequently and sporadically, or at least obscurely. It has

been described in Calcutta, by Dr. James Mellis, under the name of “inflammatory fever.” It is the “*exanthesis rosalia arthrodynia*” of Dr. Cock, the “anomalous epidemic complaint” of Stedman (St. Thomas's), and is variously described by other writers as articular (or rheumatic), exanthematous (or eruptive) fever. During the years 1865-7 it occurred in Andalusia and other provinces of Spain, where it bore the name, bestowed upon it by the vulgar, of “*trancazo*”—literally, a blow by a bar, or stroke. Nor is this its first appearance in the Peninsula; in both Seville and Cadiz it was known between the years 1784-8, and was then called the “*piadosa*.” It was seen, too, in Teneriffe in 1865. It has visited the Canaries, Cuba, and other Spanish dependencies. The present work is the reprint of a *mémoire* presented to the Royal Academy of Medicine, Madrid, in the year 1808, when the author was fresh from observation of the disease. More than any other man the knowing Physician will be apt to say “What's in a name?” However strange it may be to our ears, already, in the French African possessions, it is by the name of red fever that the disease is known. It is true that a French Physician, Dr. Fl. Thaly, has made protest against this. In his observations on the epidemic in Goree in 1865 (see *Archiv de Med. Navale*, 1866, vol. v., p. 57), he insists upon the fact that the blacks do not show a red eruption, but merely a certain want of uniformity in the natural colour of the skin, with unevenness of surface (from papules) to the touch. In a topographical notice of the Isle of Bourbon, the term “red fever” is also employed for this complaint by M. Dutrouleau (see his “*Traité des Maladies des Européens dans les Pays Chauds*,” Paris, 1861, p. 50); and M. Barmer (*Archiv de Med. Navale*, vol. iv., p. 526), has mentioned it as the “red exotic fever.” The description given in his “*Science and Practice of Medicine*” by Dr. Aitken is very good as far as it goes; but, as the Practitioner in foreign climes may desire a fuller account, we would bid him take note of the present production as likely to enrich his stores, and to make him more able to encounter the invasion of so troublesome and annoying an enemy as the “red fever” is shown to be.

NEW BOOKS, WITH SHORT CRITIQUES.

Asiatic Cholera in Bristol in 1866. By WM. BUDD, M.D., F.R.S.

* * * There are few more instructive works on sanitary matters than is this history of cholera in Bristol in 1866. The cholera came and found a city singularly congenial for its ravages; but it also found those in authority ready prepared to oppose it. They had a well-organised staff of officials ready to deal with the disease, and, above all, they had a clear notion of what they had to do. Disinfection was their motto, and they carried it out thoroughly, with what good results let those who care to imitate their example under similar circumstances learn from Dr. Budd's pamphlet.

Some Simple Sanitary Precautions against Cholera and Diarrhoea; with Suggestions concerning Dietetic Treatment, especially with regard to Infants. By M. A. B. Lewis, Gower-street.

* * * This little pamphlet deserves extensive circulation, abounding, as it does, in good sensible and practical information. The influence of diet on the diarrhoea of infants is very little known to the public. M. A. B. gives excellent advice on this point. It would be well for mothers in general to become acquainted with it. The *brochure* costs but 3d., or, for distribution, may be obtained at 2s. a dozen.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

October 23.

WE had scarcely begun to breathe freely after the recent epidemic of small-pox when we are attacked by another disease. Relapsing fever has again made its appearance, and is spreading rapidly in the densely crowded and dirty streets in the northern parts of the town. It commenced in the same parts as during last year—viz., Milton, Addison, and the adjacent streets. In bringing this matter before the Health Committee on Thursday, the 19th inst., and asking that carbolic acid might be freely used in the cellars of unoccupied houses, Dr. Trench said that something more potent than inspection was required for them, and that, with law or without law, he trusted the Committee would find some means to assist the owners to

close them altogether. The indescribable filth that is allowed to accumulate and decompose in these places, immediately over which hundreds of human beings are crowded, renders it a matter of surprise, not that we have so many epidemics, but that we are ever free from them.

The question of the appointment of a public analyst, which has for some time been under the consideration of the Health Committee, is deferred until the meeting of the new Committee at the commencement of the municipal year.

GENERAL CORRESPONDENCE.

ON THE FOOD OF THE ARMY CORPS DURING THE RECENT MANŒUVRES.

[To the Editor of the Medical Times and Gazette.]

SIR,—In continuation of my former letter on this subject, I beg permission to make a few remarks on Yateman's beef-sausage, Aberdeen soup, Australian mutton, salt pork, and commissariat biscuit, the materials on which the life of the army corps was sustained during the second and more active half of the campaign. Everybody has heard of the famous "Erbswurst," or pea-sausage, which was so largely used by the German army. It has the great advantage of containing a good proportion of vegetable matter, and of being good to eat either hot or cold, or in the form of soup. Yateman's beef-sausage was judged by the men to be fit to eat only in the cold state. It contains no vegetables, but a good deal of seasoning, and, unless cut into thin slices and eaten with plenty of bread, is likely to give the stomach a little trouble. It is a serviceable article of food, but for these reasons inferior to the Prussian invention. Half a pound of it looks but a very moderate supply of animal food for twenty-four hours to a hungry man in active work. Doubtless another essay in the same direction may produce a more convenient comestible.

The praises of Aberdeen soup, or "Cardwell's skilly," can be adequately sung only by those high-minded militiamen who threw it away rather than make a pretence of subsisting on it. I am afraid, however, that the militiaman's ode, flowery as it would doubtless be, would wind up with the expression of a fervent wish to see Mr. Cardwell drowned—or, at all events, well ducked—in carrot-soup. When a man is roused from his uneasy slumbers at 5 a.m., gets his frugal breakfast of coffee and commissariat biscuit, strikes the camp, marches all day, fights a battle, pitches tents again at a new encampment, and awaits his next meal at about 7 p.m., it is rather trying to his endurance to be presented with the thirteenth part of a six-pound tin of soup as his ration for the day. Yet this is what actually occurred. True, when a complaint was made it was said to be a mistake, as the amount intended to have been sent was one can for every six men; and, on the general's demand, a ration of Yateman's sausage was served out in addition. But after six months' preparation such mistakes ought not to be possible. The soup itself was by no means bad; it was not very strong, and was perhaps a little greasy, but it was palatable enough for hungry men. The quantity of meat in each can was very small; nearly half the space seemed to be filled with pieces of chopped carrot, about one-third of an inch cube. It requires more experience than I possess to see the reasonableness of giving men who have been accustomed to solid food a pint of this decoction as their sole meat-ration at the end of a hard day's work. If it were desired to administer a mild aperient to the force, probably a more convenient and elegant form might have been devised. As it was, the diarrhoea, which had greatly abated, was immediately renewed after the soup, the issuing of which was stopped after one or two days, so great was the clamour against it.

The Australian mutton, coming after the fluid nutriment just described, had the advantage of contrast. It was liked by the men, and seemed in every way a valuable aid to the victualling of an army. It was in six- or eight-pound tins (which would pack better if they were square instead of cylindrical). The salt pork was also very good, and sufficient in quantity.

Commissariat biscuit is doubtless wholesome, but is not interesting as an article of diet. It is inferior to the ship-biscuit of our own service, and to the "hard tack" of the American army. Men at the camp irreverently called it "dog-biscuit." Our people are in the habit of eating the whitest wheaten bread that the baker can furnish them with, taking no account of its nutritive value. Probably there would be some difficulty in inducing them to take kindly to the coarse

rye-bread consumed with much satisfaction by the German army; but the faculty of keeping moist and good for three weeks or more possessed by this last gives it a great advantage over white bread, in addition to its greater nutritive power. Perhaps some form of "whole meal" wheaten bread could be contrived which would be both highly nutritious and palatable.

A method of preserving meat used in Germany during the war seems valuable enough to deserve imitation. As it was described to me, the meat cut into quarters and cleaned was plunged for a few minutes into boiling water to coagulate the surface, and then hung up under large sheds in the open air for some days, to dry. I saw large quantities of meat being treated in this way at Mainz. It was said to remain fresh for a month, and thereby to save the trouble of conveying large herds of cattle and the forage necessary for them to the front, so long as railway communication was available.

I should be going beyond my province if I were to inquire into the causes of the irregularity and delays of the control. Those who had to draw the supplies attributed them in a great measure to minute obstructions and useless formalities, such as appear to be the besetting sin of all systems of intendance. Be this as it may, there can be little doubt that if the victualling of the army before Troy had been so defective, my revered ancestor would have asked Calchas, the soothsayer, to dinner, and given him nothing but carrot-soup; upon which the seer would have promptly found out that the omens were against retaining the existing supply department in office, and would have had them all packed off in a ship to consult the oracle, or on some like errand, with orders not to come back till they were sent for. Probably this summary process is now out of date; but some measure of the kind is needed, notwithstanding that the gallant chief of the department, with more than the traditional bravery of the British soldier, has issued an order praising everybody connected with it.

By the way, what law of nature is it that makes nine-tenths of her Majesty's Army Medical Officers hail from the sister isle? The fact is unmistakable; and that it is no novelty is shown by my own patronymic. No wonder the printer did not recognise my name; sure, I ought to have written it

McHAON, jun., M.D.

OUT-PATIENT DEPARTMENTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—According to a "daily," the Poplar Hospital has closed its out-patient department, there being sufficient gratuitous opportunities for advice where necessary in the district. Let the other Hospitals inquire into their out-patient departments. It must be borne in mind that, in addition to the vast sums spent in drink by highly paid (because skilled) mechanics, waste is not limited to that source. How many must have the best cut from the best butcher in the locality—not even denying themselves salmon at tenpence to fourteenpence a pound, or an occasional bottle of sherry with "a friend"; the Sunday excursion to Hastings or Brighton, with its additional extravagance in eating and drinking!

Let those ambitious young men who give their advice to persons (often "well-to-do" tradesmen) in the hope of creeping through the kitchen into the drawing-room elsewhere, reflect that all this gratuitous advice is not rarely given to those who can easily find a guinea for consultation in a dangerous case, but can also without difficulty find half-a-crown for a phial and medicine from the general Practitioner close by their own door.

A still more glaring abuse must be remedied: that of the tradesman—with his "Sunday trap," and his family at Ramsgate for six weeks or a month in "the season"—getting his own Medical attendance and medicines for the heavy expenditure of three or four shillings per annum under the active, organised abuses of the club system. A well-organised club, with a graduated scale of payments, according to the earnings of the member, is in my view the only way to diminish the mortality arising from the prescribing of druggists and the inefficient out-patient departments of Hospitals. The subscriptions to the latter must diminish in a steady ratio unless a reform take place, for the philanthropic public will cease to tax themselves to support a system so demoralising, and so conducive to pauperising undeserving persons. I am, &c.,

October 21.

NEMO.

THERE were 709 deaths in Paris last week, including four cases of small-pox, twenty-nine of typhoid fever, and one of cholera.

REPORTS OF SOCIETIES.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, OCTOBER 21.

Dr. DRUITT, President, in the Chair.

THE first meeting of the Session 1871-2 was held at the Scottish Corporation Hall, Crane-court, Fleet-street. After the minutes of the last meeting had been read and confirmed, a ballot took place, when Dr. Dudfield, Medical Officer for Kensington, was declared to have been unanimously elected a member of the Association; Dr. Mouat, late Inspector of Prisons in Bengal, and Dr. Fergus, President of the Sanitary and Social Section of the Philosophical Society, were proposed as associated members; Professor Corfield, Medical Officer for Islington, and Mr. Skegg, Medical Officer for St. Martin-in-the-Fields, were proposed as ordinary members.

Dr. LIFFE moved a vote of sympathy with Dr. Puckle, Medical Officer of Health for Lambeth, who is now lying in a dangerous state through illness contracted, in great measure, in the discharge of the duties of his office. The motion was unanimously carried.

The PRESIDENT paid a tribute to the memory of Dr. Beale, Medical Officer of St. Martin-in-the-Fields, who had been taken from among them by death since their last meeting, and moved a vote of sympathy on the part of the members with the friends of the deceased. Since their last meeting Dr. Ballard had been promoted to the office of Medical Inspector under the Local Government Board. The President regretted having been unable to attend the meetings of the Association during the latter part of last session, in consequence of illness; he had also been kept away several months in Scotland in enforced idleness; but now, he hoped, they would enter on a vigorous campaign for the eradication of abuses.

Mr. GARDNER BROWN exhibited and explained a new Self-acting Disinfecter, for water-closets, etc., lately invented by him. Mr. Brown explained very clearly in what manner the apparatus was self-acting, and what means he had devised for regulating the amount of carbolic acid or other disinfectant used, and for securing economy and efficiency in the use of the disinfectant.

Dr. STEVENSON thought the invention a very useful one; he had watched its progress with great interest, and thought that Mr. Brown had now brought his apparatus to a great state of perfection.

Mr. LIDDLE, Medical Officer of Health for Whitechapel, read a paper "On the Intimate Relation between Defective Ventilation and the Mortality from Tubercular Diseases, Convulsions in Children, Teething, Atrophy, and Debility, with a few Practical Suggestions thereon." At the outset, Mr. Liddle remarked that hitherto the attention of the Local Board had been mostly confined to epidemic diseases; they had not paid that attention to the prevention of consumption and its allied diseases which their importance demanded. He proceeded to dwell on the importance of fresh air—a subject little understood, and that not by the poor alone. It was thoroughly appreciated, however, by the owners of animals when stirred up by pecuniary interests, and the state of their stalls contrasted painfully with the wretched dens of the poor. Mr. Liddle then quoted the authority of eminent members of the Medical Profession, showing the injurious effects of impure air in corrupting and enfeebling the constitution of the poorer classes and their offspring—not only the poor, but others, such as clerks, who are compelled to keep late hours in offices where much gas is used, and no sufficient provision is made for carrying off the products of its combustion; shopkeepers' assistants, tailors, milliners, and others who have not sufficient exercise in the open air. The very large mortality in young children Mr. Liddle believed to be, in a great measure, attributable to this cause. He regretted that while such large sums had been expended in ornamenting the metropolis, and opening out thoroughfares for traffic—improvements which, for the most part, benefited only the better classes—so little had been expended in improving the dwellings of the poor. How the same people, whose health was so indifferent in their ill-ventilated homes, improved in health when placed under proper sanitary conditions, was shown by the concurrent testimony of Medical Practitioners that the health of prisoners in gaol is in

general much higher than that of the surrounding population. Mr. Liddle corroborated this by an interesting incident in his own experience. A few weeks ago he went down to visit a number of boys (the children of pauper parents) who had been transferred from the Forest-gate School to the training-ship *Goliath*, moored in the river off Grays, in Essex. Mr. Liddle gave statistics of the height, weight, and breadth of chest of eighteen of these boys when received on board the ship, and compared them with what they were at the present time. The improvement in all these respects was most remarkable. In addition to this, the downcast and sullen look had given place to an expression of intelligence and cheerfulness. Returning to his district of Whitechapel, Mr. Liddle lamented its overcrowded state; in some places not more than four square yards were allowed for each person. No wonder, then, that the mortality from consumption stood so high. Coming now to the means for preventing these evils, he spoke of the existing laws which give power to the Medical Officer of Health to deal with these abuses; and urged the members to use their utmost endeavours to get the Local Board to put these laws in force. He maintained that, even if no action were taken, the Medical Officers ought not to fail to make their reports as to the unsatisfactory state of this or that property. Besides, they could not ask Government for additional legislation until they had put in force existing laws. They had, however, a right to ask for an Act to prevent the building of unhealthy houses in the future. An opportunity for this was offered in the Building Bill, which had come before Parliament several times, and so far without any result. The part referring to the materials, etc., might well be left to the Metropolitan Board, but the sanitary clauses he considered were the province of the Medical Officers of Health, and he trusted the influence of the Association would be exerted in seeing that effective sanitary clauses were inserted in the Bill.

A vote of thanks was accorded to Mr. Liddle for his valuable paper.

Dr. LIFFE was of opinion that the ordinary space insisted on in front and in the rear of houses ought to depend on the height of the boundary walls. In his opinion the Peabody Fund would have been better employed in buying up unhealthy property and putting it in proper sanitary condition.

The Rev. Mr. COHEN complained that the poor could not be prevailed upon to open their windows. They must be taught the benefits of ventilation. It was hard for the ratepayers to be called upon to pay for people who would do nothing to help themselves.

Dr. SUTTON thought that insanity might have been included by Mr. Liddle among the diseases arising from close and foul air; and proceeded to explain the connexion existing between phthisis and insanity. It was not to be wondered at that the poor, living in such houses as they did, should find themselves unable to support their daily labour. Dr. Sutton enumerated some of the difficulties he had encountered in his personal experience, and contended that a New Building Act was needed, giving power to the Local Board to prohibit the erection of unsanitary buildings.

Mr. GLADDEN spoke of the injustice that would be done to owners if house property should be condemned without compensation, and of the heavy burden to the ratepayers if they should be called upon to pay the full amount. He thought some middle course ought to be devised.

Mr. FINLAY thought the difficulty would be best met by preventing the building of new houses under unsatisfactory conditions, allowing the old ones to die out with the lapse of time.

Dr. HARDWICKE spoke of the difficulty of dealing with houses built originally for one family, but now occupied by five or six. He likewise condemned suburban cottages, the extra space in front and behind being made receptacles for filth. The best plan to his mind was the system adopted by a large employer of labour in Picardy, who has built for his workpeople blocks of houses, which are kept in a perfect state of cleanliness by the appointment of servants for that purpose, the cleaning being taken out of the hands of the tenants.

The PRESIDENT corroborated what had been said about the health of prisoners. The unsatisfactory state of the houses of the poor showed a very bad state of conscience on the part of owners, and lamentable ignorance on the part of the ratepayers. Men built houses, for the sake of gain, that could only undermine the health of the occupants, and make them a burden to the ratepayers. It was for the latter to remonstrate, and prevent such proceedings.

Mr. LIDDLE having made a brief reply, the proceedings came to a close.

MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 16.

DR. ANDREW CLARK, President, in the Chair.

AFTER a few words of cordial welcome to the Fellows, the President said that he was happy in being able to congratulate them on the prosperity of the Society, which had never been better off. The Fellows numbered 400; of these, 180 were non-subscribers. The Honorary Treasurer, Mr. J. Gay, had a balance of £211 in his hands, while the Fothergillian Fund has risen from £500 to nearly £1000. The Society's freehold, No. 3, Bolt-court, which was bequeathed by Dr. Lettsom, was let for £50 a year; but as the present lease would expire in another year, it was estimated that the Society would derive at least £100 a year from this source. How was this prosperity to be kept up? By maintaining and, if possible, in improving the work—by trying communications by this test: Do they add to, correct, or confirm what is already known?—by aiming in all work at precision; by making it compendious and practical—by recording results of therapeutical experiments—by endeavouring to cultivate the spirit of good-fellowship, and to find out in one another what is worthiest and best—and so, working with singleness of heart and purpose, it cannot be but that their work will be fruitful in all manner of good. In speaking of the character of their work, he would refer, 1st, to the early history of a disease—say of phthisis. It was by the co-operation of Fellows of such a Society as this that a perfect knowledge of such a disease could be had. There was, unfortunately, a want of faith and a want of precision in the use of drugs; a great want of reliable knowledge. Such important investigations as these might well be made by committees appointed from time to time, and means might be furnished from the surplus Fothergillian Funds. A second way to increase the prosperity of the Society was for each Fellow to endeavour to induce another to join. "It is in such a Society as this that we get fresh knowledge, our errors corrected, our doubts resolved. It is here that a man is delivered from his own crotchets, follies, and ignorance, secured from one-sided views, and brought face to face with every side of the problems which he studies. A man does not know what he knows or what he does not know till he has taken an active part in the debates of such a Society." The President then alluded to the great loss the Society had suffered in the death of the late Dr. Hyde Salter, who had been for three years Secretary to the Society, and had discharged the duties attached to the office in a most exemplary manner. He had accepted the Lettsoman Professorship, but, finding his health failing, he resigned the appointment early in the year.

Dr. RICHARDSON then read a paper "On the Possibility of Destroying Animals intended for Human Consumption without the Infliction of Pain." After reviewing the various means employed in the execution of this humane project, with partial success, he recommended the following vapours:—1. Hydramyle and bichloride of methylene. 2. Carbon disulphide and methylene bichloride. 3. Chloroform, or methylene and coal-gas. In sleep all sensibility is destroyed in fifty or one hundred seconds. Two drachms is poured on domette, in a conical inhaler; the animal does not struggle; the butcher kills in the usual way; bleeding follows. First, primary syn-copal convulsion (after loss of forty ounces of blood); second, fatal convulsive paroxysm (after the loss of ten ounces more); the heart ceases to play. During narcotism the primary convulsion is suspended, or much reduced in force. The second convulsion (an entirely reflex and painless phenomenon), insensibility, is quickly produced; no odour or taste is left. An ingenious apparatus was shown, to contain the narcotic vapour and to allow coal-gas to flow through. For oxen, a number of chambers could be devised, with swinging doors, through which oxen could be drawn on trucks by means of an endless chain, the chambers to be filled with the narcotising vapour. Animals could pass through the Lethal river of vapour, and be made oblivious of death, at the rate of sixty per hour.

Mr. GAY read a paper on "Hypo-Venosity of the Lower Limb," of which the following is an abstract:—The term hypo-venosity is used to express a condition of the limb in which there is a deficiency in the veins belonging to the saphenous system: as hyper-venosity might be used to express the opposite condition, or that in which there is an excess in the development of these veins, even to varicosity. The characteristic features of a hypo-venous limb are the reverse of those which obtain in a limb affected with hyper-venosity; for whereas in the latter, especially with varicosity, the limb is usually lean, and the outlines of bone, muscle, and tendon are, as a rule,

sharp and well-defined, in the former these outlines become gradually effaced, the skin becomes of a dusky colour, the whole limb dense or brawny, and muscular action difficult and painful. With the exception of sometimes, it may be, a few dilated or varicose venous twigs below the ankles, or on the dorsum of the foot, there is scarcely a vein to be seen, except, as it may be, here and there as a thin blue line, which exercise or heat fails equally in filling. The disease is advanced by rest and elastic stockings, the remedies usually employed; and, with its advance, the subdermoid fat layer becomes denser and loses its elasticity. Whilst its remote causes are any disease of those vessels of an active or passive character, such as phlebitis (especially in its gouty or rheumatic forms), insufficient muscular exercise, systemic asthenia, etc., degeneration and consequent incompetence of the saphenous veins and their branches is its exciting cause. Secondly, it is presumed, the deep trunk veins become dilated, their valves partially inert, and fatty deposit and degeneration take place in the muscles and their connective tissues. The grounds for this inference are—(a) that functional deterioration of the saphenous system, through thickening, atrophy, retrecissement, or thrombus, is an occasional pathological fact; (b) and that saphenous inefficiency as shown by a varicose condition of the venous radicles—tegmentary or figurative varicosity—as well as by a dusky colour of the skin, otherwise than from melasma, or skeleroderma, are habitually associated with and indicate dilatation of the deep trunk veins. (These facts I observed in the course of dissections made some years since, with a view of elucidating the subject of varicosity.) Throughout the systems of organic and muscular life the venous system is double—the superficial and deep, or the main and complementary; the former playing to the latter the part of a waste-pipe, or compensating system, ready to relieve it when its vessels are unduly filled. The deep veins—*i. e.*, those which are radically interwoven with the organs of vegetative and animal life—constitute the real venous system; therefore the current through these veins, in the healthy performance of the double circulation, is maintained by a combination of forces, of which voluntary muscular is not a necessary co-efficient, since it would go on with the limb at perfect and continued rest. The current through the complementary veins, on the other hand, derives its chief importance from the fact of its receiving—in the limbs, more especially—its principal impulse from voluntary muscular action. In case its vessels become inefficient, the surplus quantity of blood, due to muscular exercise, is poured into the deep veins with a force that, as the result of this abnormal diversion, is expended on their coats, and results in dilatation, valvular incapacity, muscular deterioration, and other changes yet to be noticed. The forces which determine the returning current of the blood are complex: the principal of which are the heart's action, arterial elasticity, and the influence of the nervous system. These are factors, each to a certain extent only; whilst experiments show that each may separately be cut off, and yet the blood will find its way back to the heart. Moreover, the blood will pass from the arteries into the veins without the aid of any of these forces. The blood passes into the femoral vein if the corresponding artery is tied, its flow being only retarded; and, according to the experiments of Dr. J. Reid, as relates to the nervous system and muscular tissue, it is clear that the only ascertained final causes of all endowments bestowed on nerves in relation to muscles is not to make muscles irritable, but to subject their irritability in different ways to the domain of the acts and feelings of the mind, and I might add to the exigencies of the organism. To complete the sum of the required forces, another has been hypothesized, the "capillary" force. Can such a force be shown to exist? I made the following experiment on dogs some few years since, in the presence of many members of our Profession. The whole of a dog's thigh was enveloped in ligature with the exception of the femoral artery, so as to permit of the free ingress of blood into it, but completely to prevent its exit. The result was that the whole of the saphenous system to its minutest capillary vessels, and the deep trunk veins, were filled to their utmost point of endurance; but there was no corresponding sanguineous repletion of muscular tissue. It showed no signs even of congestion. This, with another ascertained fact—*viz.*, that after death the temperature of the body may rise, and muscular contraction occur, giving rise to its well-known "hum" (Drs. Haughton and Collongues), and the disposition of the minute capillaries in relation to muscular tissue (which, through the kindness of Dr. Dempsey, I hope to be able to demonstrate at the next meeting)—together go far to prove the existence of such a force in a condition of perpetual activity; that it exists in connexion with muscular tissue or

sarcode—that organic molecular action, perhaps, which exists in all sarcode, from that of the amoeba to the higher organisms—and that to it the venous current is mainly due; that, in fact, as an agent in the circulating system, it is to the capillary, very analogous in some respect to what the heart is to the arterial system. As this department of the venous system belongs to vegetative life, so embarrassment to the current of blood through it results in defective elimination of the hydrocarbons and their allies from the tissues indicated; and hence solid œdema, superfascially, fatty deposit and degeneration, subfascially, and ultimately elephantiasis or a disease closely akin to it. As the deep or main system of veins is thus associated with the nutritive processes, so the superficial or complementary is essentially eliminatory, for it is from these veins in the lower limb that dropsical effusion takes place. Edematous fluid is chiefly and usually solely superfascial; and it is not improbable that in other dropsies, as of the pericardium, pleura, or peritoneum, the fluid escapes from veins of the same class—viz., from those of the complementary system. The disorder described is due, then, to inefficiency in the saphenous system of veins, followed by deep vein dilatation and embarrassment. The treatment is the reverse of that ordinarily employed—viz., an entire freedom of the limb from all compresses, enforced walking exercise, begun in moderation and periodically increased, hot applications, especially hot sea-water to the limb, and it may be the internal administration of the liquor potassæ—in short, by the use of all those measures, hygienic and therapeutical, which can, on the one hand, restore the circulation of the limb, upon the principle that its right use is its stimulus to health and perfection; and on the other, relieve it of its superabundant fat.

OBITUARY.

JAMES FAWCUS, M.D.,

INSPECTOR-GENERAL of Gaols in Bengal, whose death, at the age of 38, we have to-day to record, was educated at University College, London, and took his Doctor's degree at the University of London in 1858. His short career was marked by peculiar activity and usefulness, and it was just at his entrance into new and important spheres of duty that he has been lost to his Profession and his country.

He got his formal schooling at Mill-hill, but the education that did most to form his character and to gain him his future success was chiefly acquired among the influences of the English lakes, where many of his early years were spent. He brought to University College a strong body and mind, and a faculty of easy, steady, and unostentatious work. He was hardly out of his studentship before he found an opportunity for using his abilities, and for turning to account the singular power of mastering circumstances that served him all through his life. When, in the spring of 1855, during the Crimean war, Dr. Parkes organised the Hospital at Renkioi, in the rear of the allied armies, Mr. Fawcus was appointed one of the Medical staff. There, with the keenest interest in his work he combined the happy disposition that knew of no difficulties and made others forget them. To be in a new position, where his knowledge and resources were taxed to the utmost—where he could work hard and be useful, forgetting that there was such a thing as his own comfort—was an unmixed pleasure to him. He earned the Crimean medal by services rendered in the trenches of the Malakoff, where his love for stirring action made him volunteer as one of the Surgical staff on actual service in the field.

On his return from the Crimea he graduated with honours in the University of London, and studied for some time at Paris and Vienna. After passing his Indian examination, Dr. Fawcus was appointed, in the spring of 1859, to the 47th Native Infantry, at that time ordered for service in China. There, however, he saw little actual war, and, returning to India, remained for a year or two as Civil Surgeon at Jaunpore. Then, on leave of absence, he made an experimental visit as a colonist to New Zealand; but as his career there did not yield him Professional opportunities, he came back to India, and now he found there the vocation of his life. He had carried with him from England letters of introduction to Dr. Mouat, then Inspector-General of Gaols in Bengal, and was at once recognised by Dr. Mouat as the man to develop the scheme of dealing with prisoners that was then just being introduced into Indian gaols. His first opportunity had been at Monghyr, and Dr. Mouat, appreciating what he had done there in reclaiming the savagery of the prison, obtained for him the more im-

portant appointment of Superintendent of the Alipore Gaol, with over 2000 prisoners. At that time the notion of giving to a prisoner an object for existence—of letting him do intelligent work as a reward, while his labour should pay for gaol expenses—was as little known in India as it is as yet known in English gaols. Into this system Dr. Fawcus threw his whole heart. It had to struggle against many prejudices and obstacles. Thus, the opponents of prison labour had contrived that jute should not be supplied to the prison looms except at artificially raised prices, which they intended to be prohibitory of prison weaving. It was found necessary to surmount this obstacle by spinning-machinery procured from England, and it was arranged to be a further employment, and a further source of revenue for the prison, to manufacture the yarn from the raw material, while thenceforth occupation was given to an increased number of looms. With what singular power Dr. Fawcus overcame every hindrance, and brought about this and other valuable results, is witnessed by the fact that Alipore Gaol soon became altogether self-supporting, and has for some years earned an income in considerable excess of its cost. At the same period Dr. Fawcus held the appointment of Assistant-Surgeon in the Civil Hospital at Calcutta; and here his special Surgical abilities had play. He was known there not only as a clever operator, but as a man who, without regard of personal convenience and ease, would do anything to save his patient. Besides the duties of these two offices, he was also employed in scientific researches. With Dr. Cunningham he did much valuable work on the Pathology of Cholera, published in Dr. Mouat's annual volumes. His own most recent contribution was a short but well-grounded thesis disproving some of the currently received doctrines about Embolism in Cholera.

Dr. Fawcus had repeatedly been charged with the duties of his superior officer when he was on leave of absence, and in 1865 he was made Deputy Inspector-General. Last year, on Dr. Mouat's retirement, he was appointed, at an early age, to the high rank of Inspector-General of Gaols. By this time, long work at Calcutta, with no holiday, had told seriously on his health; but upon receiving his appointment he thought it his duty to make a personal tour of inspection of his gaols. He had visited those in Orissa and Assam, when his health completely broke down, but as there was no one able at once to supply his place, he still stayed at his post; and when at last he came to England, in the spring of the present year, his Indian intermittent had produced considerable organic disease. Pneumonia superadded to this was the immediate cause of his death.

In person, Dr. Fawcus was ruddy, youthful, and handsome, with particularly easy and engaging manners. He endeared himself to everyone by his brave tenderness, his genial humour, and his perfection of truth and honour. Twelve years spent in India gained him a host of friends there, and lost him no jot of love from his old friends in England. He has left a widow and a family of young children to mourn his loss.

GEORGE FAITHORN, M.R.C.S., ETC.

MR. FAITHORN met his death in course of attendance upon the poor of the town in which he was in practice—Chesham, Buckinghamshire—where a malignant fever (typhus) has lately broken out, in consequence of neglect of sanitary arrangements, against which Mr. Faithorn had often and earnestly protested. Mr. Faithorn and his junior partner were the only Medical men in the place. The junior partner, Mr. Churchill was first taken with the fever, but is recovering. This obliged Mr. Faithorn to take the whole of the parish and private practice; and not being a man likely to spare himself, he toiled night and day—in fact, till he was absolutely too ill to stir—for there can be no question that he was hard at work after he had contracted the fever. Twelve days after, he was dead. He was educated at St. Bartholomew's. He was not the author of any Medical work; all his energies were in other directions.

ARTHUR KEMPE, F.R.C.S.E., L.S.A.,

Was found dead in his bed on Wednesday morning last. He was a Surgeon of good abilities and large practice, and his loss will be felt by a large circle of friends and patients. He had just before his death presented to the city of Exeter a handsome public clock and fountain. At the meeting of the City Council, which was held on the day of Mr. Kempe's death, the Mayor announced his decease, when the announcement was received with general regret. Mr. Kempe was Surgeon to the Devon and Exeter Hospital and Exeter Lying-in Charity, and Consulting-Surgeon to the Exeter Dispensary. He contributed to this journal, in 1867, "Successful Cases of Ovariectomy."

L.R. HENRY ABERGAVENNY WOOTTON.

THIS gentleman died at Dumfries on July 26, in the 82nd year of his age. He was the youngest son of Dr. William Wootton Knight, who formerly practised in Brook-street, Grosvenor-square. In early life Dr. Henry Wootton served in the Royal Navy, and was present as a midshipman at the battle of Trafalgar. He was afterwards made prisoner of war by the French, and escaped from Toulon in female attire. He then entered the army, and went through the Peninsular war. He was present at Badajoz, Salamanca, and afterwards at Waterloo and Ava. On leaving the army he turned his attention to Medicine, and was a pupil of Sir Astley Cooper. He practised for a short time at Blackheath, but afterwards went to India and again entered the army, and was for many years in active service. He was wounded several times, and received three medals with two clasps. On one occasion he also received a reward for saving a garrison from the bursting of a shell, which he took up and threw over a parapet. He afterwards held several Medical appointments in Australia, and on returning to Europe he practised at Havre and Dieppe. Dr. Wootton was a kind and skilful Physician, and was much respected and beloved by his family and friends.

JOHN S. SNOOK, M.R.C.S.

WE regret much to announce the death of this gentleman, which took place at Colyton, Devon, on Sunday, October 15. Mr. Snook had been in the enjoyment of his usual health up to three weeks before his death. He then was taken ill with gout, but no anxiety was felt on his account until Friday, October 13, when he became suddenly weaker, cardiac symptoms supervened, and he sank. Mr. Snook was educated at the Middlesex Hospital. He practised all his life at Colyton, where his family had resided for generations. He was a skilful Surgeon, an excellent, kind-hearted gentleman, and his loss is felt as a public calamity in Colyton and the neighbourhood. He was Medical Officer to the Axminster and Honiton Unions, and Honorary Surgeon to the East Devon Rifle Volunteers. We subjoin an extract from an obituary notice of Mr. Snook which appeared in a local paper:—

“His Medical ability was very great, and in the course of a large practice he had proved himself always equal to the emergency. Cases of unusual difficulty were met by him with singular success. As a Surgeon, too, he was highly distinguished for his skill, and his nerve, decision, and acumen never failed. In a wider sphere—in the metropolis, indeed—he would doubtless have made his mark. But he preferred to labour where he was born, in the place he loved—amongst those by whom he was personally beloved, and amongst whom he died. This is not the place to allude but cursorily to the loss of those who mourn a husband and father of rare tenderness and devotion. But there are many others who will also mourn for a constant friend, whose warm genial feelings no time nor trials (of which he had not a few) could change; whilst the poor have lost a friend indeed. It may well be said of him what once was said of another of his noble Profession—

‘In misery’s darkest cavern known,
His useful care was ever nigh;
Where hopeless anguish pour’d its groan,
And lonely want retired to die.’

And the numerous instances in which with more than Medicine was the good he did, can be only known to the Great Physician. How shall we miss that cheery greeting he had for all—that genuine kindly humour and friendly warmth! His clear judgment and strong sense made him a delightful companion, a friend so reliable—and, with his high honour, sterling, straightforward, truly manly character and firm principle, we may well feel that no ordinary man has passed away from us, but rather one of those whose name, example, and good deeds remain. The funeral took place on Saturday afternoon. A large concourse of people lined the streets, and the shops were closed. Besides the family, there was a large following of neighbours and friends. The 27th Devon Rifle Volunteers, headed by their commanding officer, Capt. Dick, formed a guard of honour. It was the unanimous wish of the corps to pay the last tribute of respect to their Honorary Surgeon. The church was filled in every part, and the service impressively read by the vicar, the Rev. M. Gueritz, who also read the service at the grave in the cemetery. Seldom has public respect, attachment, and sympathy been so spontaneously and unequivocally manifested.”

MR. DAVIDSON, of King William’s College, Isle of Man, has been elected to a Natural Science Scholarship at Sidney Sussex College, Cambridge.

MEDICAL NEWS.

APOTHECARIES’ HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, October 19, 1871:—

Carey, Richard John, Northampton.
Kindon, Joseph, Croydon.
Robinson, Edmund, Leeds.
Wall, William Barrow, Wedmore, Somerset.

KING AND QUEEN’S COLLEGE OF PHYSICIANS IN IRELAND.—At the monthly examinations, held on October 10, 11, and 12, the following candidates were successful:—

For the Licence to practise Medicine.

Barnardo, Fredk. Adolphus Ernest. | Hughes, William Robert.
Cox, Henry Thompson. | Smith, Nicholas Skottowe.
Gavin, Patrick Freebern. | Smyth, Sydney Richard.

For the Midwifery Diploma.

Barnardo, Fredk. Adolphus Ernest. | O’Flaherty, Richard George.
Cox, Henry Thompson. | Smith, Nicholas Skottowe.
Gavin, Patrick Freebern. | Smyth, Hatton.
Hughes, William Robert. | Smyth, Sydney Richard.

THE APOTHECARIES’ HALL, DUBLIN.—At the Preliminary Examination in Arts, held on October 19, the following gentlemen received Certificates entitling them to commence their Medical studies:—

Cullinan, Michael Cormac. | Mulvany, Peter.
Deacon, Oliver William. | Nagle, James Roche.
Donovan, Robert Edward. | O’Brennan, James Henry.
Dunne, William. | O’Meehan, John Albert.
Lynch, Francis John. | O’Neill, Henry.
McLaughlin, James Maurice. | O’Shea, Michael Joseph.
Moore, William.

The following candidates, having passed their Professional Examinations, obtained the Licence to Practise:—

Myles, Thomas William, Limerick.
Orr, Hugh, Virginia, co. Cavan.
O’Reilly, Francis Augustine, Killeshandra, co. Cavan.
Peacocke, John, Limerick.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- ALLEN, MARCUS, L.R.C.P., M.R.C.S., L.S.A., L.M.—House-Physician to St. Bartholomew’s Hospital, London.
BURTON, JOHN, jun., L.R.C.P. & S. Edin.—Medical Officer to the Walsall Union.
CLIBBORN, CUTHBERT J., M.B., M.Ch., L.M., B.A., T.C.D.—Medical Officer for the Kiltegan Dispensary District of the Baltinglass Union.
DANSON, C. E. B., M.R.C.S.E., L.S.A.—Medical Officer for the Pocklington No. 1 District of the Pocklington Union.
JACKSON, ALFRED, L.R.C.P. Edin., L.R.C.S. Edin.—Medical Officer of the Pocklington No. 2 District of the Pocklington Union.
KNOTT, MIDDLETON O’MALLEY, L.R.C.S.I., L.R.C.P. Ed.—Surgeon to the Mayo Infirmary, Castlebar.
MARRIOTT, CHAS. WM., M.R.C.S. Eng.—Surgeon to the Warneford Hospital, Leamington, vice J. E. Male, Esq., deceased.
OGLE, JOHN WILLIAM, M.D.—Inspector of Anatomy in England and Wales, in the room of George Cursham, M.D., deceased.
PUDDICOMBE, EDWARD MORGAN, M.R.C.S. Eng.—Medical Officer and Public Vaccinator for the Silvertown District of the Tiverton Union, vice Chas. Elworthy Cutcliffe, M.R.C.S. Eng., L.S.A. Lond., deceased.
REYNOLDS, HOWARD DAVID, M.R.C.S., L.R.C.P.—Medical Officer for No. 5 District of the Pembroke Union.
RUTHERFORD, D. J., M.D. Edin.—Medical Officer of the Parish of Unst, Shetland, in room of H. L. Saxby, M.D., resigned.
THOMAS, LLEWELLYN, M.R.C.S.E., L.A.C.—Resident Medical Officer to the Guest Hospital, Dudley.

BIRTHS.

- ALLEN.—On September 20, at Chittagong, East Indies, the wife of William Edward Allen, F.R.C.S., Surgeon H.M.’s Bengal Army, of a daughter.
FRODSHAM.—On October 21, at Upper Streatham, the wife of John Mill Frodsam, M.D., of a daughter.
HEYGATE.—On October 20, at Kibworth Beauchamp, Leicester, the wife of W. N. Heygate, M.R.C.S.E., prematurely, of a son, still-born.
HOPE-ROBSON.—On October 21, at Iver, Bucks, the wife of F. Hope-Robson, M.D., F.R.C.S., of a son.
MARRIOTT.—On October 20, at 7, Welford-place, Leicester, the wife of C. H. Marriott, M.D., of a son.
OGILVY.—On September 17, at Mussoorie, East Indies, the wife of John Ogilvy, M.D., Surgeon Royal Horse Artillery, of a son.
REID.—On October 22, at Haulbowline, county Cork, the wife of Dr. Reid, R.N., of a daughter.
RICHARDSON.—On October 22, at Cheswick House, Beal, Northumberland, the wife of Henry Richardson, M.D., Staff-Surgeon R.N., of a daughter.
SMITH.—On October 23, at 129, Clapham-road, the wife of William H. Smith, M.R.C.S. etc., of a daughter.

TEALE.—On October 20, at Headingley, near Leeds, the wife of T. Pridgin Teale, Esq., of a daughter.

THORNE.—On October 20, at 42, Seymour-street, Portman-square, W., the wife of Dr. R. Thorne Thorne, of a daughter.

MARRIAGES.

DOBSON—BOURNE.—On October 24, at the parish church, Edgbaston, Thomas Dobson, M.D., of Windermere, to Marianne, youngest daughter of the late Henry Bourne, of The Limes, Edgbaston.

HAMER-OLIVER—SINGH.—On October 20, at St. George's Church, Bloomsbury, J. Hamer-Oliver, Assistant-Surgeon Royal Artillery, to Henrietta Melvina, widow of his Highness the late Rajah Rundheer Singh, of Kuppoothalla, G.C.S.I.

LORRAINE—LAKE.—On the 11th inst., at Trinity Church, Ossett, near Wakefield, William James Lorraine, M.R.C.S., L.R.C.P.E., Wakefield, to Catherine Mary, fourth daughter of Thos. Lake, of Flushdyke, near Wakefield.

TAYLOR—HINCHCLIFF.—On October 19, at St. Mark's Church, Hamilton-terrace, Gabriel, third son of John Taylor, M.D., Girvan, N.B., to Lucy, eldest daughter of Andrew Hinchcliff, Esq., Sydney, N.S.W.

TULLOCH—ANTON.—On October 21, at St. John's Cathedral, Hong-kong, James R. Anton, Esq., of Hongkong, to Jane Stewart, elder daughter of J. Stewart Tulloch, M.D., of 1, Pembroke-place, Bayswater.

VAWDREY—WHITTING.—On October 19, at Uphill Church, George Vawdrey, L.R.C.P., only son of George Vawdrey, Esq., Hayle, Cornwall, to Annie, eldest daughter of Charles Whitting, Esq., of Sandcroft, Uphill.

DEATHS.

CHRISTIAN, JAMES STANLEY, M.D., of Thurloe-place, South Kensington, at 7, Prince of Wales-terrace, Kensington, on October 17.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Assistant-Surgeon. Candidates must be F. or M.R.C.S.E., not practising midwifery or pharmacy. Applications and testimonials to the Secretary, on or before November 3.

FULHAM UNION.—Medical Officer and Public Vaccinator for No. 5 District. The gentleman appointed must have the qualifications prescribed by the General Orders of the Poor-law Board. Applications and testimonials to Mr. T. Applin Marsh, Clerk to the Guardians, on or before October 31. Election on November 2.

GREAT NORTHERN HOSPITAL.—House-Surgeon. Candidates must be M.R.C.S. Applications and testimonials to the Secretary, Mr. G. Reid, 46, Great Coram-street, W.C., on or before October 30.

GREAT OUSEBURN UNION.—Medical Officer and Public Vaccinator for the Workhouse and the Ouseburn District. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to H. H. Capes, Esq., Solicitor, Knaresborough, Yorkshire, on or before October 28. Election on the 30th.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, S.W.—Resident Clinical Assistant. Applications and testimonials to the Secretary, on or before November 4. Further information may be obtained at the Hospital.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Assistant-Physician. Must be M.R.C.P.L., or pledged to become so within twelve months. Applications and testimonials to the Secretary, on or before November 11.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Clinical Assistant. Gentlemen applying for this appointment must possess at least one qualification. Applications and testimonials to the Secretary, on or before November 11.

HULME DISPENSARY, MANCHESTER.—House-Surgeon. Must be duly qualified. Applications and testimonials to the Chairman of the Medical Committee, on or before November 6.

LIVERPOOL INFIRMARY FOR CHILDREN.—House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to the Chairman of the Committee, on November 11.

LONDON FEVER HOSPITAL.—Physician. The necessary qualifications are—F. or M.R.C.P.L. Applications and testimonials to the Secretary, at the Hospital, on or before November 7. Election on the 10th.

MIDDLESEX HOSPITAL MEDICAL COLLEGE.—Lectureship on Materia Medica. Applications to the Dean, on or before November 11.

NORTH DEVON INFIRMARY.—House-Surgeon. Must be M.R.C.S.E., and be registered. Applications and testimonials to Mr. John Bridgman at the Infirmary, Barnstaple, on or before November 4. Election on the 14th.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD.—Operating Surgeon. The qualifications required are—F. or M.R.C.S.E. not practising midwifery or pharmacy. Applications and testimonials to Mr. C. L. Kemp, on or before November 7. Election on the 21st.

ROYAL SURREY COUNTY HOSPITAL.—House-Surgeon. Must be duly qualified in Medicine and Surgery. Applications and testimonials to the Assistant-Secretary, Guildford, on or before November 6.

St. GEORGE'S, HANOVER-SQUARE, DISPENSARY.—Physician-Accoucheur. Must be M. or F.R.C.P.L. Applications to the Honorary Secretary, 59, Mount-street, on or before October 30. Election the following day.

UNION AND PAROCHIAL MEDICAL SERVICE.

. The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Ashton-under-Lyne Union.—The Tenth District is vacant; area 820; population 19,981; salary £60 per annum.

Amersham Union.—The Chesham District is vacant.

APPOINTMENTS.

Honiton Union.—Walter Hugo Reed, M.R.C.S. Eng., L.S.A., to the Second A and Ninth B Districts. Frederick Morgan, M.R.C.S. Eng., L.S.A., to the Second B District.

York Union.—John J. F. Marshall, M.R.C.S. Eng., L.S.A., to the Third District.

THE *Gazette* of Friday, October 20, contains the announcement of Dr. Ogle's appointment as Inspector of Anatomy.

DR. CHAS. HILTON FAGGE, of Guy's Hospital, has been elected Physician to the London and Westminster Bank, in the place of the late Mr. Solly.

THE stipendiary magistrate of Salford last week sent a woman to prison for a month, for having exposed a shirt which had been worn by one of her sons, who had suffered from small-pox, without having had it previously disinfected.

DR. LEGRAND DU SAULLE, Physician to the Hospital of Bicêtre, in a work just published, entitled "Le Délire des Persecutions," has given a graphic account of the influence of political troubles on the different characteristics of madness.

IT is reported that, owing to proper sanitary precautions having been taken at the port of debarkation, there has been no epidemic outbreak amongst the 100,000 and upwards of hadjees or pilgrims that have visited Mecca this year.

A YOUNG man from Cardiff, named Howard, has drowned himself at Carlisle, who, in a memorandum, gave as his reason for self-destruction that the Darwin theory having proved men to be descended from monkeys, he did not desire to live.

PRELIMINARY EXAMINATIONS.—The next Examination in Arts, etc., for the diplomas of Fellow and Member of the Royal College of Surgeons, will take place on December 19, 20, and 21. Already a large number have entered.

THE HUNTERIAN COLLECTION.—By the death of Sir R. I. Murchison, Bart., there is another vacancy in the trustees of the Museum of the College of Surgeons, which, with that caused by the death of Mr. George Grote, will be filled up at the next meeting.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—At the conclusion of registration at this School on October 20, the number of new students was 28; old students, 42; making a total of 70.

SMALL-POX IN POPLAR.—During last week six deaths from small-pox had occurred in the Poplar Union; nineteen new cases had been admitted. In the same week sixty-five persons had been vaccinated at the public station.

THE INDIAN MEDICAL SERVICE.—The *Homeward Mail* gives in its last impression the following. (We are not quite certain as to the meaning sought to be expressed, but the passage is at least equivocal):—"The uncertainty which attends the competitive examination for the Indian Medical Service is so great that young men are thoroughly discouraged in entering upon the necessary preparation."

QUEEN'S UNIVERSITY IN IRELAND.—On November 22 next, the Senate of the University will proceed to elect examiners for the next academical year in the subjects of Medicine, Surgery, Midwifery and the Diseases of Women and Children, Materia Medica, and Medical Jurisprudence. The salaries are—in the case of Medicine and Surgery, £100 each; in the remaining instances, £75.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.—At the General Annual Meeting of the Society, held on Wednesday, October 18, the following were elected office-bearers for the ensuing session:—*Council*: Samuel Gordon, James Little, Lombe Athhill, T. W. Grimshaw, Henry Kennedy, Thomas Hayden, William Moore, Robert Law, Thomas Fitzpatrick, Alfred H. McClintock, John Thomas Banks, and George Johnston. *Honorary Secretary*: Henry Eames.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At the annual meeting of the Royal College of Surgeons of Edinburgh, held on the 18th inst., the following office-bearers were elected for the ensuing year:—*President*: William Walker. *Secretary*: James Simson, M.D. *Treasurer*: John Gairdner, M.D. *Librarian*: Archibald Inglis, M.D. *President's Council*: Andrew Wood, M.D.; Robert Omond, M.D.; James Dunsmure, M.D.; James D. Gillespie, M.D.; James Spence; Henry D. Littlejohn, M.D.—*Ex Officio*: John Gairdner, M.D. *Examiners*: Archibald Inglis, M.D.; Robert Omond, M.D.; James Dunsmure, M.D.; Peter David Handyside, M.D.; James D. Gillespie, M.D.; H. D. Littlejohn, M.D.; Patrick H. Watson, M.D.; David Wilson, M.D.; John Smith, M.D.; Argyll Robertson, M.D.; Joseph Bell, M.D.; Thomas Annandale. *Assessors to Examiners*: James S. Combe, M.D.; William Brown; James Spence; James Simson. *Conservator of Museum*: James B. Pettigrew, M.D. *Assistant to Conservator*: James Grandison. *Officer*: John Dickie.

PROFESSOR WYVILLE THOMPSON, of the Queen's College, Belfast, was on Friday, October 20, presented with a testimonial on occasion of his removal to the Chair of Natural History in the University of Edinburgh. The Mayor of Belfast presided. Professor Redfern read an address, and presented Professor Thompson with four splendid dessert-stands and centre, and a handsome claret jug.

PROCEEDINGS OF THE ROYAL COLLEGE OF SURGEONS.—At the last meeting of the Council, on the 19th inst., the President, Mr. Busk, reported the death of Mr. Samuel Solly, F.R.S., and added that the vacancy would not be filled up until the annual meeting of the Fellows in July next. Mr. Smith, the senior member of the Council, then proposed the following resolution, seconded by Sir William Fergusson, Bart. :—"That the President be requested to convey the sincere condolence of this Council to Mrs. Solly and her family on the irreparable loss they have sustained by the death of Mr. Solly." The thanks of the Council were unanimously voted to Mr. Francis Kiernan, F.R.S., F.R.C.S., for his valuable donation of pathological specimens to the museum. The following report of the 16th inst. of the Committee on the Financial Arrangements proposed in the Draft Scheme for an Examining Board for England was read, viz. :—

"Your Committee, appointed by the Council on the 24th of July last, 'to consider and report to the Council on the Financial Arrangements included in the Appendix' to the Draft Scheme for an Examining Board for England, have held two meetings, on the 31st of July last and on this date, and, having considered the same, have agreed to the following Report to the Council, viz. :—

"That the following are the propositions contained in the Appendix to the Draft Scheme, viz. :—

"That one-half of the Fees received for the Examinations be appropriated to the payment of Examiners, Assessors, and other expenses incidental to the Examinations, in such manner as the Committee of Reference may determine, subject to the approval of the co-operating Medical Authorities.

"That the remaining half of the Fees received for the Examinations be appropriated in the following manner :—

"Towards the maintenance of the Museum of the Royal College of Surgeons as an Institution of National as well as Professional importance, for its unendowed Professorships, and other allied expenses One-third

"In respect of Medical Qualifications to be granted One-third

"In respect of Surgical Qualifications to be granted One-third

"And that, in the opinion of your Committee, the said propositions should be adopted by the Council, with the following alterations, viz. :—

"That the Fees received for the Examinations be appropriated to the payment of Examiners, Assessors, and other expenses incidental to the Examinations, in such manner as the Committee of Reference may determine, subject to the approval of the co-operating Medical Authorities; and that the residue be divided in the following manner, viz. :—

"Towards the maintenance of the Museum of the Royal College of Surgeons as an Institution of National as well as Professional importance, for its unendowed Professorships, and other allied expenses One-third

"In respect of Medical Qualifications to be granted One-third

"In respect of Surgical Qualifications to be granted One-third

"Richard Quain, Chairman."

Moved by Mr. Clark, and seconded by Mr. Hawkins—"That the report of the Committee be adopted;" whereupon the following amendment was proposed by Mr. Hancock, and seconded by Dr. Humphry—"That the financial arrangements, as originally proposed in the Appendix to the Draft Scheme for an Examining Board for England, be adopted, in lieu of those contained in the report from the Committee." The votes of the Council having been taken on the amendment, a majority was in favour thereof. The sum of ten guineas was voted towards the memorial window to John Hunter in Kensington New Church, on the application of Messrs. Buckland and Merriman, the honorary secretaries.(a) The Secretary reported that Mr. Charles Hawkins had offered for the acceptance of the Council a small coloured engraving of the picture of "Henry VIII. presenting the Charter to the Barbers and

(a) It may not be generally known that the Council has already subscribed the large sum of £420 towards the statue of Hunter, the removal of his remains to, and reinterment in, Westminster Abbey, with memorial brass, independent of private subscriptions of individual members of the Council.

Surgeons."(b) The donation was accepted, with thanks. Mr. John Gay gave notice of the following motion at the next meeting of the Council, viz.—"That the proportionately large number of rejections at the preliminary examination for the diploma of the College was a fact which demanded the serious consideration of the Council; and that a committee be appointed to consider the subject, and to report to the Council thereon."

CHLORAL IN CHOLERA.—During the epidemic which has recently prevailed at Riga, Dr. von Reichard has had recourse to chloral, administering it according to the following indications :—"1. To relieve the cramps at the commencement. 2. To assuage the præcordial suffering which is so distressing during the latter stages. 3. To arrest vomiting. 4. To procure the sleep so urgently demanded by the patients. Not only were these indications fulfilled, but the success obtained from the medicine surpassed all expectation. In one case in which the ordinary treatment had been pursued, and the patient seemed as if he had only a few hours to live, a drachm of chloral was given him in four times the quantity of water, so that a strong sense of burning was felt while swallowing it. In two minutes sleep had commenced, and, troubled at first, it became calm, and lasted three hours. Respiration became easier, the warmth and turgescence of the surface reappeared, the cholera *facies* disappeared, and the pulse diminished from 130 to 90. The vomiting and stools ceased, and, in fact, a true resurrection was effected, the patient rapidly recovering. M. Blumenthal, also of Riga, has employed it successfully in two bad cases, giving the chloral in doses of a drachm, which were repeated two or three times within the hour.—*Union Méd.*, Oct. 17.

TREATMENT OF FRACTURE OF THE CLAVICLE BY ADHESIVE PLASTER ONLY.—Dr. Sayre, of New York, has finally reduced the treatment of this fracture to two strips of adhesive plaster, without any axillary pad, and believes it to be the simplest and most efficacious plan yet devised. His method of keeping the inner portion of the clavicle from riding over the outer portion is by putting the clavicular portion of the pectoralis major muscle on the stretch, and compelling it to pull the clavicle in place, and thus overcome the tendency of the clavicular portion of the sterno-cleido-mastoid to elevate it, which it always will do unless this precaution be taken. After drawing the arm backward, and retaining it there by a strip of adhesive plaster, pass another piece from the well shoulder across the back, and, by pressing the elbow well forward and inward, the first plaster around the middle of the arm is made to act as a fulcrum, and the shoulder is necessarily carried upward, outward, and backward; and the plaster, being carried over the elbow and forearm (which is flexed across the chest) to the opposite shoulder, the place of starting, and then secured by pins or stitches, permanently retains the parts in position. Dr. Sayre uses strong and good adhesive plaster (Maw's mole-skin being the best), cut into two strips three or four inches wide, and narrower for children. The patient can resume even laborious manual labour immediately after the application is made. The union takes place perfectly, without deformity.—*New York Medical Record*, August 15.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

- Dr. Young, Salisbury.*—Your wishes shall be attended to.
- Dr. Leslie, Battersea.*—The matter was settled by the General Medical Council, and we cannot reopen it.
- A Foreign Subscriber.*—The volume of the Reports is still in print, and may be obtained of Messrs. Longmans and Co., Paternoster-row, E.C.
- Aliquis* will be allowed to register if he made application to the Secretary of the College.
- A. N.*—The work mentioned is an excellent one on the subject on which it treats.
- Inquirer.*—Nearly every Hospital in London has a pharmacopœia of its own. A copy of each may, no doubt, be obtained without difficulty.
- Censor* is right; the quotation should be as follows :—
"Why drew Marseilles' good Bishop purer breath,
When Nature sickened, and each gale was death?"
- A. C. Cameron.*—A "burr" is a peculiar mode of sounding the letter "r," common especially in the neighbourhood of Berwick. The sound is something like a mixture of "ch" and "r."

(b) This is an interesting little picture of great rarity, unknown to the authorities at the British Museum.

Student.—The Medical school in connexion with the Harvard College, Cambridge, Boston, Mass., is in North Grove-street, Boston. Affiliated with the original academic foundation are the four Professional schools of law, theology, Medicine, and science. Of late years the standard of study has been greatly raised, the curriculum has been extended, and means have been afforded for advancing in special pursuits those who develop a strong aptitude for them. It is the oldest—1639—institution of the kind in the United States.

Quint.—One pound *per week* during the first five weeks is a good beginning, but we doubt if it will do to continue the reducing process at so fast a rate. We should be satisfied, now, with a quarter of a pound per week, or about 250 grains *per diem*. Continue to exclude sugar and fat, but take a little more mashed turnip or other cruciferous vegetable.

Dr. Charles Royston.—Breaches of Professional etiquette such as those detailed in our correspondent's letter are, we hope, very uncommon. It is certain that, as the gentleman mentioned was the *locum tenens* of Dr. Royston, he was bound to cease to have any connexion whatever with Dr. Royston's patients after Dr. Royston's return. Nothing can justify such grave breaches of etiquette. They do more to injure us in the eyes of the public than anything else could do. It is useless to talk of elevating the character of the Profession by improved preliminary education, better laws, and a shorter curriculum if we attempt thus to forestall one another.

POSTAL CHARGES ON CIRCULARS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—About a week ago I posted a number of circulars, directed to various gentlemen of the Medical Profession. I have since learnt, to my great annoyance, that the Post-office officials have demanded an extra 1d. on delivery of a number of them, on the ground that they were "closed against inspection." On reference to the one I enclose, I am sure, sir, you will agree with me that such a charge is, on the face of it, ridiculous, as, being open at both ends, every word it contains may be read with ease. I trust you will give publicity to these facts, as I cannot tell how many gentlemen are feeling naturally annoyed, and perhaps prejudiced, at what they no doubt think my impertinence in sending them circulars for which they have to pay. I have written to the Postmaster-General for explanation, but, although a week has since elapsed, I have not received any acknowledgment of my letter. I am, &c., W. C. WESTERTON.

55, Abingdon-villas, Kensington, W., October 24.

CURIOUS ECCENTRICITIES IN MEDICAL ETIQUETTE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The best thanks of our "noble Profession" are due for the manly letter of "An Oxford Man," published in your last number, exposing as it does, in the most gentlemanly yet candid manner, a few of the abuses—and their name is Legion—which afflict the body corporate of our calling. To take a familiar example, what can be more contemptible in the sight of gods and men than the grudging respect evinced by some elderly, purblind Practitioner, dropping into dotage, towards a man who may be some twenty years younger than himself? and how can we reconcile the title of "liberal Profession" with the conduct of its members, who greedily grasp office long after their talents, if they ever possessed any, have been in abeyance! That rapacious greed of office which prevents men from retiring at a befitting age, when they can yet do so with dignity and self-respect, is one of the most unseemly features of Medical life, and its effect is so injurious on the prospects of the Profession that it is almost to be wished some inter-Professional law could be enacted, rendering the resignation of public appointments after 60 or 65 years of age actually compulsory.

I am, &c., ANOTHER UNIVERSITY MAN.

OCTOBER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The prosperity of the wicked puzzled the Psalmist; Talleyrand passed a sleepless night wondering what another diplomatist *meant* by having scarlet fever. The longer one is in practice the greater the perplexity to account for the amount of suffering and the number of children inflicted upon women.

Many girls never menstruate until marriage, and the pain at the regular periods is occasionally acute. "I lock myself up, and writhe on the floor with agony," confessed a religious handsome patient. To-day a very pretty woman, under treatment for uterine neuralgia, affords the following history:—Married at 17; has given birth to eight living children, five of whom died of convulsions, bronchitis, or diarrhoea. She has aborted seven times—in short, to sum up, although scarcely 30 years of age, making a general total, she has started fifteen children. During pregnancy intolerable tingling of the feet causes indescribable torture. Her sisters incline to twins, and her mother, after giving birth to fifteen children, died of uterine cancer.

The month of October is very trying to nursing mothers. To-day three ladies are suffering from pneumonia: their young infants, suddenly deprived of breast-milk, become all the more liable to whooping-cough, especially if animals (without including Hampstead donkeys) are kept in the house. A few months ago a child affected with the latter complaint, and smuggled on board a vessel at Bombay, communicated the disease to a number of others. Returning through the Suez Canal, stopping at Malta, Gibraltar, and Plymouth, at last Woolwich was reached without the coughs abating. In many instances it is judicious to give such children quinine during the day, belladonna at night, plenty of milk and lime-water, and to keep them out of doors constantly in fine weather. Chloral hydrate does harm. Certainly the child sleeps, the cough persisting, but next morning there will be increased lumbar debility, disinclination to get up or to eat—*ergo*, greater prostration, the paroxysms will be more numerous and violent. In October unpleasant recollections of hot climates are forced upon dyspeptics as well as on ladies and children. On one occasion three women in contiguous beds, recently confined, developing alarming symptoms, great was the relief to diagnose the fevers of Malta, the Mauritius, and Peshawur instead of the puerperal variety. Some Indian fevers are shaken off by migration to Nova Scotia; and many subjects intolerant of quinine swear by Warburgh's tincture. Old Indians now suffering from liver risk their lives by taking Turkish baths, our best remedy for chronic rheumatism. A number of brain-workers who have damaged themselves by incessant ravel or Alpine feats in the holidays also suffer. Two years ago a

distinguished officer, whose love night and day was ever too much in his work, when sent hygienically to Maidstone Gaol, returned as fresh as paint. Excruciatingly painful chilblains now may be averted by taking iron and strychnine to improve circulation, by wearing flannel over the stomach, a galvanic chain down the leg, taking plenty of exercise, and applying local stimulation. We must be careful about vaccination: children at this season are so liable to bronchitis and epidemic ailments.

When the leaves begin to fall, the old and the young suddenly swelling the bills of mortality, will it be heartless to suggest that Medical men should be spared the mental distress of attending funerals?

Ourselves fathers of families, heartily we sympathise with a parent bereaved.

"Grief fills the room up of my absent child,
Lies in his bed, walks up and down with me,
Puts on his pretty looks, repeats his words,
Remembers me of all his gracious parts,
Stuffs out his vacant garments with his form."

But other patients have to be considered. The battle with death requires a cool head and calm judgment, matured by experience; nor are we exempt from private troubles—either a drunken partner, a sickly wife, or the struggles of poverty will sorely try many

A PRACTITIONER.

MEDICAL APPOINTMENTS IN THE MILITIA AND OTHER RESERVE FORCES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In Lord Northbrook's clear and able speech, when bringing the Army Bill before the House of Lords last July, it was stated that part of the Government plan of army reform consisted in the determination to allow officers of the line to go on half-pay after a comparatively short period of regular army service, on condition that they agreed to serve in the militia. If this is actually to be the case, it would obviously be unfair if the same rule is not extended to the Medical officers of the regular army, who should certainly be allowed to go on half-pay and join the militia after comparatively short service, quite as much as the combatant officers. With respect to the latter, comparatively short service can never be held to mean twenty years' service; it must mean after service far, far short of that number of years; and if the combatant can go after a few years to the militia to suit his own taste, and at the same time to give promotion in the service he left, to refuse the same boon to officers of the Medical branch of the army, and the acceleration of promotion consequent upon it, would be rank injustice. Besides, it must be remembered that all the years during which he is learning his profession count to the combatant as service, while the years during which the Medical man is learning his Profession are not counted at all to him as service, being previous to the period when he joined the army; so that, in nine cases out of ten, he joins the service an older man than the combatant, and if either ought to be allowed to retire before the other, it certainly ought to be the Medical officer. Besides, if the reserve forces of the country exist in any numbers, it would probably be found quite impossible to find sufficient Medical officers for them, if reserve Medical officers were only selected from those who were willing to join them after twenty years' service in the first line—and let us hope that it will become an absolute rule that no Medical appointment in the militia, or in any other reserve force, shall be held by any Medical man who has not served a certain time in the regular army. It is a strange anomaly that promotion should be slower in the Medical than in the combatant branch of the army, when we consider, as mentioned before, that the time he is learning his profession as a young officer counts towards promotion for the combatant, who, it may be further remarked, is taught his profession by the State, receiving pay while he learns it; while the Surgeon, on the other hand, enters the service with his Profession ready learned. And what assistance or pay did he receive when at Medical School or College he was acquiring his knowledge?—None from the State, certainly. And yet this qualified man is kept in the position of a subaltern for fifteen or sixteen years—learning what?—and examined again before promotion. As if any examination could test the power of applying knowledge, without the possession of which he ought never to have been permitted to enter the army at all! Have fifteen or sixteen years of Medical subaltern work a tendency to cause improvement, or to set up a process of deterioration? But in the formation of reserves, Government have a chance, if they will only use it, of enabling men tired of the service in part to leave it, and a certainty that, by their retiring, acceleration of promotion throughout the Department will be the result. And let us remember that if once we lose the entire reserve forces as a retiring field for the Medical officers of the regular army, and allow civilians to creep in, we shall have lost what we may never regain. Let only the rule be absolute, that no civilian shall hold any Medical appointment in the reserve forces of the country, and quick promotion for some, and optional early retirement for others, must follow. And let us hope that contentment will reign where grumbling and discontent have reigned for years. Perhaps the Medical press will help us to obtain this one key of the whole position, by keeping the subject before the authorities; and perhaps Mr. Cardwell may not consider it beneath his notice to try and reform even the Medical Department of the army. Nothing can be worse for the life of a military department than to have men keeping up their connexion long after they have lost all interest in its work, disgusted by being kept long in a subordinate position, or who never were fitted for an army life, and yet who, once in the service, hang on, year after year, perhaps for fifteen or twenty years, in order to obtain a pension, they believing that they cannot afford to leave, as there are no openings into semi-civil life (such as would be formed by throwing open the reserve Medical appointments) for them to slip into; and should Mr. Cardwell neglect to use his present splendid chance of getting rid early of all those who, for some reason or other, are not well fitted for the regular army, increasing the flow of promotion to an extent difficult to calculate, and should stagnation, whether tempered by jobbery or not, but certainly accompanied by discontent, be the future state of the Army Medical Department, he cannot grumble if the evil is laid at his door. On what terms (as to pay, claim to pension, etc.) men should be allowed to enter the reserve from the first line is not a matter of such great consequence just at first, if only the principle were once introduced that Medical officers of the regular army could claim sufficiently early to go on half-pay on condition of joining the reserve, whether it be called militia or by some other name. Let the rule allowing the combatant officer to join the reserve after comparatively short service be extended to the non-combatant officer. If the terms first offered failed to attract sufficient numbers, they could be altered; and we may be pretty sure that terms would soon be hit upon that would both pay the State and suit individuals. Perhaps men might even be found to give up their claim to pension, if allowed, when once in the reserve, to engage in private practice. In fact, the chance of engaging in private practice might be made to stand in lieu of pension—an obviously paying plan for the State. And as men, when finding their private practice increas-

ing so that they could not attend properly to their public duties, would either voluntarily retire out of even the reserve into complete civil life, or be called upon to do so, a certain number of reserve appointments would by this means be falling vacant every year. A reserve appointment would hardly give employment entirely to anyone, and a Surgeon had far better engage in private practice than rust. Besides, if the engaging in private practice was prohibited, the reserve appointments would have to be better paid, and men would stick on, retarding promotion; but for any hope of a rapid flow of promotion through the reserve retirements into it, it must be allowed at a comparatively early period of life. Medical officers of twenty years' regular army service would not take kindly to private practice in most cases, and are after that service entitled to pension, which of course they would not give up. With respect to men who have already retired upon their pensions, they certainly ought not to be offered a fresh start in the reserve. They have taken their retirements, and gone absolutely. No promotion in the present Medical Department would be given by filling up the militia and other reserve Medical appointments by men who have already accepted terms of absolute retirement. When we consider that the reserve forces of the country will equal, probably exceed, in numbers, the entire regular army, we may calculate what an enormous number of appointments there would be for the regular army Medical officers if they could only be retained for them, as in justice they ought to be, and how promotion would be accelerated. What an opportunity for Mr. Cardwell thoroughly to revivify one part of the army! Let us hope that he will not throw such a chance away. It is all in accordance with his own ideas, also, to pass regular army men and officers on to the reserve. Let him carry out those ideas with respect to the Medical branch of the army.

I am, &c., DELTA.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Pharmaceutical Journal—The Scotsman—The New York Medical World—Journal of the Boston Gynæcological Society, October—The Scarborough Gazette.

APPOINTMENTS FOR THE WEEK.

October 28. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

30. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. Victor de Méric, "A Case of Traumatic Phthisis." Dr. Alfred Wiltshire, "Œdema of the Lung following Small-pox." Mr. F. W. Teevan will exhibit some Instruments. Mr. John Pennefather, "On the Sense of Hearing" (with illustrations).

31. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

November 1. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

OBSTETRICAL SOCIETY, 8 p.m. Dr. Rasch, "On a Novel Way of using the Uterine Sound in Flexions of the Uterus." Mr. Eugene Goddard, "On a Case of Ovariectomy during Pregnancy." Dr. Conrad (of Pesth), "On Prolapse of the Female Genital Organs."

ROYAL MICROSCOPICAL SOCIETY, 8 p.m. Dr. Robt. Braithwaite, "On Bog Mosses." Dr. J. J. Woodward (U.S.A.), "On the Scales of *Degeeria domestica* as seen with Black-ground Illuminations." Mr. W. S. Kent, "On some New Infusoria."

2. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

3. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, October 21, 1871.

BIRTHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.74 in. The highest was 30.00 in. at the beginning of the week, and the lowest 29.52 in. on Thursday morning.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

HYGIENE.—ECONOMIE.

Cheap and Pure Wines, especially

recommended in Dr. Druitt's "Report on Cheap Wines."
 Per Doz. in London. Per Doz. in London.
 GOOD CLARET (Bordeaux)... 12s. PURE GRAPES COGNAC ('65) 42s.
 CHATEAU FRONSAC ... 16s. CHAMPAGNE, Dry qly., from 32s.
 MERCUREY, White and Red Dry and Light SHERRY and
 (Burgundy) ... 18s. PORT ... from 30s.
 (Specially recommended.) (First-class.)

All warranted; with a great variety of other Wines ready for supply in sample dozens.

EDWARD GOLBERGER, 63, DEAN-STREET, OXFORD-STREET, W.; and Libourne, near Bordeaux.

HUNGARIAN WINES

Mr. MAX GREGER (from HUNGARY)

WINE MERCHANT TO HER MAJESTY THE QUEEN AND THE GENTLEMEN OF THE HOUSE OF COMMONS,

Begs to inform the public that he has appropriated a convenient room above his vaults at 7, MINCLING-LANE, E.C., and 2, OLD BOND-STREET, W., London, where every description of Hungarian Wines can be tasted free of any expense.

Ready for supply, sample dozen cases, each containing two bottles of six different kinds of such wines, which are highly recommended by the Medical Faculty. Prices at 30s., 36s., and 44s. per case. Carriage free. Cash on delivery.

Country orders to be accompanied by P. O. O. or cheques crossed "the Bank of England."

OLD MARSALA WINE

Guaranteed the finest imported; free from acidity or heat, and much superior to low-priced Sherry. One Guinea per dozen. Bronte Madeira, a full, soft, golden Wine, 30s. per dozen. Mazzara, a stout, brown Wine, with Sherry character, 28s. per dozen. 3 dozen and upwards carriage free by rail to all England and Wales. For highly favourable opinion of W. D. WATSON'S Old Marsala Wine, see *British Medical Journal*, Dec. 26, 1868; *Medical Times and Gazette*, No. 770, April 1st, 1865, p. 345, or Dr. Druitt's "Report on Cheap Wines," p. 174.

W. D. WATSON, Wine Merchant, 373, OXFORD-STREET (entrance in Berwick-street), London, W. Established 1841. Terms Cash.

Allsopp's Pale or Bitter Ale.—

Messrs. S. ALLSOPP and SONS beg to inform the trade that they are now registering orders for their SEASON-BREWED PALE ALE, in Casks of 18 gallons and upwards, at the Brewery, Burton-on-Trent, and at the Branch Establishments.

Messrs. ALLSOPP and SONS take the opportunity of announcing to Private Families that their ALES, so strongly recommended by the Medical Profession, may be procured, in Draught and Bottles, Genuine, from all the most respectable Wine and Beer Merchants and Licensed Victuallers, on "Allsopp's Pale Ale" being specially asked for.

**Bass's East India Pale Ale**

(October Brewings are arriving), BARCLAY'S STOUT, recommended by the first Medical authorities for Invalids and Ladies nursing. In 18-gallon Casks, Bottles, Half-bottles, and Imperial Pints. Also, DEVONSHIRE CIDER.

BERRY BROS. & CO., 3, St. James's-street, London, S.W.

CHALYBEATE LEMONADE

AND

CHALYBEATE SALINE LEMONADE.

"Messrs. May-Davis have introduced steel as a refreshing beverage, in which no steel is tasted except as an *arrière pensée*. One form is dosed with saline matter, for the benefit of those whose kidneys require a fillip. Both are useful and palatable conversions of the 'nauseous draught' into the sparkling beverage."—*Medical Times and Gazette*, March 11th, 1871.

"Messrs. A. May-Davis and Co., Esher-street, Westminster, have introduced a really admirable Chalybeate Lemonade, which will be likely to be largely used in private practice. The one objection to chalybeates is the strong flavour of 'flat-irons.' Not only is this entirely overcome in the very agreeable Lemonade which they have produced, but the beverage is most enticingly pleasant. Each bottle is warranted to contain five grains of citrate of iron; and of the Chalybeate Saline Lemonade each bottle contains also twenty grains of citrate of potash. Medicine is here not merely disguised, but transformed. We think many a prescriber will be glad to know of a preparation which is an undoubted boon to patients."—*British Medical Journal*, March 4th, 1871.

Chalybeate Lemonade may be obtained from chemists, &c., at 4s. per dozen; direct and wholesale from the Proprietors and Sole Manufacturers, A. MAY-DAVIS and Co., Esher-street, Westminster, S.W., who will be happy to forward samples, free of charge, to any member of the Medical Profession.

PURE AERATED WATERS.

ELLIS'S RUTHIN WATERS, Soda, Potass, Seltzer, Lemonade, Lithia, and, for GOUT, Lithia and Potass.

CORKS BRANDED "R. ELLIS & SON, RUTHIN," and every Label bears their Trade Mark. Sold everywhere, and Wholesale of R. ELLIS & SON, Ruthin, North Wales.

London Agents—W. Best & Sons, Henrietta-street, Cavendish-square.

KINAHAN'S LL WHISKY.

This celebrated and most delicious old mellow spirit is the very CREAM OF IRISH WHISKIES, in quality unrivalled, perfectly pure, and more wholesome than the finest Cognac Brandy. Note the words "KINAHAN'S LL" on Seal, Label, and Cork. Wholesale Depot, 6A, GREAT TITCHFIELD-STREET, OXFORD-STREET, W.

CAUTION.

THE

GENUINE ORIGINAL BRIGHTON SELTZER WATER

is that prepared by

STRUVE & CO., at the ROYAL GERMAN SPA, BRIGHTON.

* * * All others are Feeble Imitations.

Struve's Seltzer, Spa, Kissingen, Vichy,

and other MINERAL WATERS. Under Her Majesty's especial patronage.—ROYAL GERMAN SPA, BRIGHTON.—The bottled waters are sold at the Pump-room; and by GEORGE WAUGH and CO., Pharmaceutical Chemists to the Queen, No. 177, Regent-street, London, W.; and by other respectable houses in London and the provincial towns, where Prospectuses, with the highest Medical testimonials, may be obtained gratis.

CAUTION.—Owing to the use of Struve's bottles by other parties attempting imitations, sold as "BRIGHTON Seltzer," "BRIGHTON Vichy," &c., an analysis of some of which has shown an utter disregard of their true chemical composition, please to observe that STRUVE'S name is on the label, and red-ink stamp affixed to every bottle of Struve's manufacture.

A recent Author, in his work on "The Spas of Europe," says:—"If artificial mineral waters are prescribed, we should insist on STRUVE'S alone being used."

LITHIA with CITRATE of POTASH. BROMIDE of POTASH WATER. CITRATE of POTASH WATER. CITRATE of POTASH with IRON. CARBONATE of POTASH, SODA, &c.

HOGG, Pharmaceutical Chemist to the Queen, 9, Albion-place, Hyde-park-square.

HOOPER'S**Brighton Seltzer**

AND VICHY WATERS

per 4/ doz.

SIX DOZEN CARRIAGE FREE.

Aerated Lithia Water.—Messrs.

BLAKE, SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr. GARROD's instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain 2 grains and 5 grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA.

The following Waters as usual:—Potash, containing 18 grains of the Bicarbonate in each bottle; Citrate of Potash, 30 grains; Soda, 15 grains; Ammonia, 10 grains; Seltzer and Vichy from their respective analyses, and a very delicious, as well as useful, MINERAL ACID WATER. BLAKE, SANDFORD, & BLAKE, Pharmaceutical Chemists, 47, Piccadilly.

QUININE WINE,**As supplied to the Sick and Wounded**

during the late War. The many and expensive forms in which this well-known medicine is administered too often preclude its adoption as a general tonic. The success which has attended "WATERS' QUININE WINE" arises from its careful preparation by the manufacturer. Each wineglassful contains sufficient Quinine to make it an excellent restorative to the weak. It behoves the public to see that they have WATERS' QUININE WINE, for the result of Chancery proceedings, a short time since, elicited the fact that at least one unprincipled imitator did not use Quinine at all in the manufacture of his wine.

All grocers sell Waters' Quinine Wine, at 30s. per dozen.

WATERS and WILLIAMS, Original Makers, Worcester House, 34, Eastcheap, London. Agents, E. Lewis and Co., Worcester.

Algonicon Balm.—Cre-Fydd's New

REMEDY.—Cures Rheumatism, Neuralgia, Lumbago, Sprains, Bronchitis, Sore-throat, Mumps, Stiff-neck, Tic, Face-ache, Cramp, Chills, &c. To be had (with testimonials) of J. B. Westrup, Chemist (Special Agent), 76, Kensington-park-road, Notting-hill, W.; Sanger and Sons, 150, Oxford-street, W.; F. Newbery and Sons, 37, Newgate-street; W. Edwards, 38, Old Change, E.C.; Barclay and Sons, 95, Farringdon-street, E.C.; and through all Chemists. In half-pint bottles, price 4s. 6d.

ORIGINAL LECTURES.

CLINICAL
LECTURES ON OPHTHALMOLOGY,

DELIVERED AT

St. Thomas's Hospital,

By R. LIEBREICH,

Ophthalmic Surgeon and Lecturer to the Hospital.

LECTURE III.

EXAMINATION OF THE EYE WITH THE
OPHTHALMOSCOPE.—(Continued.)

GENTLEMEN,—Having obtained a general aspect of the fundus, you may direct your attention to the optic disc. In order to observe this important part, it is necessary to make the patient turn his eye twenty degrees inwards towards the nose, and to make him fix his eye on a point on a level with your own eye. You will then immediately recognise the optic disc by the vessels of the retina which emerge from its surface. The aspect of the optic disc in the normal eye offers no fewer variations than that of the choroid.

In order to analyse well these variations, it is necessary to understand the signification of certain lines, drawings, and shadows appearing in the optic disc under the illumination given by the ophthalmoscope. There are, first, three different lines in the periphery of the optic disc, to which I gave the names of choroid limit, sclerotic limit, and nervous limit. The choroid limit is the external contour of the papilla. It indicates the edge of the choroid foramen, through which the optic nerve passes. This limit is ordinarily very sharp, and forms, by a stronger pigmentation, sometimes a fine dark circle, sometimes a more or less black crescent, or even a large black circle. The sclerotic limit is not so easy to distinguish. It is more visible in some pathological cases than in the normal eye. It forms a fine, clear, white circle, or ordinarily only half a circle, near the choroid limit, and it is produced by the light reflected from the edge of the sclerotic, where it extends backwards to form the sheath of the optic nerve.

By the side of this white line the darker periphery of the nervous substance is marked by a very fine grey line—the nerve limit proper. Starting from this line to the centre, we find a very delicate shading forming a lighter centre. In this lighter central part we recognise in a certain number of physiological cases a very characteristic drawing, forming a network, the *clear* lines of which represent the connective tissue of the "*lamina cribrosa*," while the grey meshes represent the transverse aspect of the nervous fasciculi which pass through the network of the lamina cribrosa. The clearness and extent in which we see this central drawing depends upon the form of the papilla, and especially upon the form, size, and depth of its physiological excavation. The variations of this are very numerous. Making transverse sections of the anterior part of the optic nerve, you will find the anterior contour of the papilla sometimes almost flat, sometimes prominent in the periphery, and with a little depression in the centre. Sometimes this latter is more marked, and has the form of an *infundibulum*, or it even constitutes a large and deep excavation descending very near to the lamina cribrosa. If the anatomical section you have made were vertical, the excavation would occupy the centre; but if your section were horizontal, the excavation would always be situated on the temporal side of the centre, and could even reach to the contour of this side. It would never be formed on the nasal side of the optic disc. These modifications have the greatest influence on the general aspect of the papilla and its colour.

It is very important to study these variations of colour, so as not to make the mistake of taking for pathological changes some exceptionally decided individual, but only physiological, appearances. The normal optic disc has sometimes an equal reddish-grey colour; sometimes it is grey in the periphery, and has a very clear luminous centre. In some cases it appears nearly as red as the fundus; and it is in such cases chiefly that we often find established the diagnosis of congestion of the optic nerve,—while I proved that this red colour is not produced by a stronger vascularisation of the optic nerve itself, but only by an optic effect depending upon the choroid. If the border of this membrane encircles the optic disc more closely, the light, after having traversed the choroid and

become red, gives, by dispersion, a red aspect to the papilla. I give the proof of this by the following experiment:—

Whilst examining the straight image, I formed with the mirror a very small inverted image of the flame. If this little image of the flame appears in the centre of the optic disc, the latter shows its ordinary colour and outlines. If, on the contrary, by a slight movement of the mirror the image of the lamp is placed in the choroid close beside the papilla, the latter seems to be entirely red, because it is illuminated only by light that has traversed the choroid before reaching the optic nerve.

The manner in which the vessels of the retina are extended upon the optic disc increases, by its variations, the number of different aspects of the papilla in its normal state.

I should say that these variations are almost as numerous as those of the human face, and you will scarcely find the two optic discs of two different individuals perfectly alike. It is, therefore, far more difficult to decide in a given case whether the optic disc is normal than it would be in regard to the choroid. Even very experienced observers may be deceived by the aspect of exceptional appearances. I will just tell you of a case which was submitted to me the other day, and which will show you the disagreeable consequences of such a mistake. An American Physician, whilst working at the microscope after his recovery from malarial fever, suddenly observed that his sight was failing. This soon increased so much that he could not only not work with the microscope, but could not even read or write so long as usual, his eyes becoming also very sensitive to light. He consulted a distinguished ophthalmologist of his country, whose diagnosis was—retinitis; and after unsuccessful treatment he was advised to give up his practice and to go to Europe. Here, again, he consulted the authorities of different countries, all of whom confirmed the first diagnosis. Thus one year passed, during which the state of his vision remained unchanged. Lately he came to see me, and I found the acuteness of his vision normal; the asthenopia dependent on hypermetropia complicated with insufficiency of the recti interni. In examining his eye with the ophthalmoscope, I could then conceive how the reddish colour of the papilla, the unusually tortuous arteries of the retina, and an exceptionally strong reflection of the nervous substance caused the mistake. Having frequently seen the state just described in perfectly normal eyes, I did not hesitate to consider the case one of simple asthenopia, which diagnosis was soon confirmed by the effects of decentrated convex spectacles. I ventured even to say that, had there been a retinitis before, some visible marks, at least, must have remained as the consequences of the inflammation.

Beyond the papilla the configuration of the vessels of the retina is more uniform, and takes, at least so far as regards the principal branches, nearly always the same direction. This is the reason why it is possible to make the vessels serve as an indication in determining the places in which we have observed some changes. For this purpose I have given, in the first edition of my "*Atlas*," Plate I., a network of vertical and horizontal lines, each corresponding to a number or a letter serving as an indication of one point in the fundus.

The retina itself exerts only a small influence on the aspect of the normal fundus. Being nearly transparent, it reflects only a very small quantity of light, giving that peculiar hazy appearance which we see the more distinctly as the choroid is darker, because, in such cases, the weak light from the retina is not so completely overpowered by the light returning from the choroid. In children the retina reflects the light with more intensity, and forms a real lustre, most strongly pronounced near the papilla and the great vessels, forming illuminated circles around the "*macula lutea*."

The macula lutea or yellow spot, the centre of the retina, merits, from its great physiological importance, our particular attention, and it is generally insufficiently investigated. It is true that, by reason of its position in the centre, and the stronger contraction which the illumination of the most sensitive part of the retina produces, but especially from the absence of more striking outlines, that this point is more difficult to observe than any other in the fundus. Thus it happened that a very distinguished observer denied the presence of any characteristic sign in the macula lutea, even after my detailed description of this part. The characteristic signs of this important point are the following:—In the irregular round spot, the size of which is nearly equal to that of the optic disc, the choroid shows a darker pigmentation, both in the epithelium and in the tissue, so that, in dark eyes, this part appears almost black. In the centre of this spot appears a very small reflection, forming either a luminous point or a little ring. This is the reflection of the central foramen.

Surrounding this latter we observe a clear yellow film before the choroid, the more intense as it is nearer to the foramen, occupying a different part of the macula lutea in different eyes. This yellow colour is situated in the retina, and is, as I proved many years ago, not merely a cadaveric phenomenon, but exists also in the living eye, although to a smaller extent and with less intensity.

The reflection of the retina, of which we have spoken before as dependent upon the anterior layer (the nerve-fibres), is completely absent in the whole macula lutea, which does not contain a real layer of nerve-fibres.

The great vessels of the retina do not approach the central part, but small branches are directed from all sides to the border of the macula lutea, and often pass even through this place, the only characteristic of which, indicated by Jäger, should be the absence of vessels. It is difficult to observe all the characteristic signs of the macula lutea in old persons, but you will easily discover them by observing children with dilated pupils, in the inverted and also in the direct image.

THE
DISCUSSION ON PURULENT INFECTION
AT THE
PARIS ACADEMY OF MEDICINE.

By Professor VERNEUIL.

(Continued from page 521.)

En résumé, septicæmia may occur in our Surgical wards :

1st. By auto-infection, starting from the morbid spot, and either favoured by the anatomical condition of that focus, or by the previous or acquired constitutional state of the patient.

2nd. By hetero-infection, also introduced through a wound and by means of the inoculation of the palpable contagion, or the contact with the septic particles in the air.

3rd. And, probably, by hetero-infection having its source in the surroundings, but choosing the respiratory mucous membrane for the door of entrance, as though the wound did not exist, and as though the patient were simply exposed to the mephitism of poisoned air.

It is impossible to know anything as to the degree of frequency of these three modes of origin, and this will be the more difficult to find out, inasmuch as in a good number of cases the three are doubtless associated. All that can be affirmed just now is the existence of the two first. Auto-infection is undeniable; it explains the cases of sporadic septicæmia and those in which the morbid focus is absolutely shielded from the direct action of the atmosphere (osteo-myelitis, etc.). To reject hetero-infection would be a denial of positive evidence, and would deprive us of the only possible explanation of the endemic and epidemic forms of Surgical septicæmia.

Although the auto-infection, in my opinion, plays the most important part, I should be the first to defend hetero-infection if anyone were to deny it. I doubt not but that M. Guérin will be opposed to these views, and will not admit of so many ways of penetration for the poison. If I understand rightly, he rejects auto-infection in the name of physiology; he also rejects hetero-infection from immediate contagion, and offers, as a contrary argument, the immunity of Surgeons and nurses. This argument, however, is anything but decisive; and if it were it would overthrow the theory of miasmata at the same time. He even rejects hetero-infection by inoculation—that is to say, in dissecting-wounds, contracted either in the anatomical theatre or in the course of an operation. Nor does he pronounce on the penetration of miasma through the lungs; so that, by exclusion, he only admits for the miasmata one way of entrance, and that is by the recent or chronic wound of the contaminable subject. The arguments against so absolute an opinion are as numerous as they are decisive; and, if M. Guérin persists, I shall produce them at the first demand.

Every case of poisoning involves degrees and forms in relation with the quantity and the quality of the grain and the nature of the soil. Every case of poisoning is also liable to be modified by the invasion of an intercurrent pathological state. The same thing holds true of septicæmia. For the sake of rendering the study of the fevers consecutive to wounds easy, divisions have been traced; but these divisions are decidedly too radical, for we often find them effaced at the bedside. The forms generally admitted are—primary traumatic fever, secondary traumatic fever, inflammatory or suppurative fever. Is such a classification legitimate? Certainly

we find, upon attentively following a wounded patient from the first day to the termination of the case, notable variations in the rise and fall of the fever. In case of a slight or severe wound, and if the conditions of the patient and the surroundings are exceptionally favourable, the traumatic fever begins from the second to the fourth day, and ceases from the fifth to the eighth. But the following anomalies are also observed:—

1. A total absence of symptoms.
2. A tardy apparition, as late as the sixth or eighth day, and even still later.
3. A prolongation of the primary fever beyond the usual time.
4. An uninterrupted continuation until death, even though this should not take place till after a month or more.
5. If the wounds are of a serious nature—apparition precise, intensity great, remission notable though imperfect—recrudescence more or less sudden, followed by a new depression which continues progressively until complete suppression, or, on the contrary, succession of relapses imparting to the symptom the regular or irregular remittent type.

The fortuitous recrudescences, very important to recognise, can be often explained by the invasion of an intercurrent disease, of an inflammatory or other nature, or by the invasion of an organ not primarily affected by the injury. But in the general complex state which results from the association of the morbid foci, it is ordinarily easy to find the part belonging to the primordial septicæmia. If some evident complication does not account for the irregularities of the fever, I can only explain them by the variations (already mentioned above) in the production, the absorption, or the elimination of the sepsine; but I can see nothing else in them than varieties of the ordinary septicæmia.

I have attentively read a very remarkable article by Billroth on secondary fever (*Nachfieber*), and I have not changed my opinion. I may say, moreover, that I have never observed any special characters in secondary fever excepting the intensity and the real prognostic signification, and therefore do not recognise in it any distinct causes. I have a patient in my wards at this moment with a complicated fracture of the leg, which I treat by rigorous occlusion and immobility. He remained seven days without the slightest fever. On the eighth, the general state and the thermometer denoted the invasion of fever; the focus began to suppurate a little, and the integuments around the wound became somewhat inflamed. The late appearance of the reaction might go to show the absence of primary fever in this case, but a secondary fever due to the secretion of pus or the inflammation of the wound. As for myself, I only see in it a traumatic fever, retarded by the treatment employed, which for a few days had the power to impede the production and the absorption of the sepsine.

There is one form of fever—that of suppuration—which I reject altogether. If we wish to distinguish it from the inflammatory and the traumatic fever, classed among the secondary fevers, it would have to come up late after the primary traumatic fever, and coincide with the appearance of pus on the wounded surface. It would have for its cause the organic process which generates the pus, just as the milk fever would have for cause the lacteal secretion. Milk fever, speaking of it in the sense of a specific variety, has disappeared from the nosological catalogue, and it should be the same with the fever of suppuration. If, apart from this inflammation, which so often accompanies it, the production of pus could in itself excite a febrile reaction, the reaction in that case should follow the different phases of its generating cause, begin and finish with it, and last as long as it does. But the least observation will suffice to prove that this relation does not exist, and to show that the pus is formed with or without reaction, before, during, and after the so-called suppurative fever. This term should therefore disappear, and no longer complicate the history of traumatic septicæmia. I am inclined to believe that the theory of traumatic fever is to-day complete, or about to become so.

I hope that the preceding account is lucid, and free from all ambiguity, and especially incapable of causing that "inextricable confusion" which M. Chassaignac speaks of. I still believe it to be immovable, because it is built upon a solid tripod—physiology, experiments, and clinical observation. Lastly, it is of incontestable utility, for it contains in itself the prognosis, the prophylaxis, and the therapeutical treatment, properly speaking. Once the origin of the poison, its source, its ways of entrance and outlet, and its effects upon the organism known, the Practitioner finds himself fronted by an enemy which he can keep at bay or battle face to face. Vanquisher or vanquished, the Surgeon knows at least what he is doing, and he may always hope that the progress in

science will furnish him with new weapons. Any other conception of traumatic fever is, to say the least of it, sterile; and when it is said that "this fever is due to an important change which takes place in the wound, or to a revolt of the organism against the lesion which is to be repaired," we remain in the dark, and actually explain nothing.

As in my first communication, but this time in more explicit terms, I conclude thus:—

1. Traumatic fever is one and the same; it shows itself early, but can last as long as the conditions for the production and the absorption of the sepsine exist. It often ceases at the end of a few days, when the sepsine is eliminated, but it can also last for an indefinite period, cease and reappear, present the remittent, regular, or irregular type, without changing in its essential character on that account.

2. It may be observed combined with fevers which have been provoked by some intercurrent, inflammatory, or other lesions, having their origin in the wound, such as erysipelas, lymphangitis, phlebitis, diffuse phlegmon, etc., or by diverse lesions developed in distant organs. In that case, we have two fevers superposed, one septic, the other inflammatory.

3. There is no inflammatory traumatic fever in case the inflammation of the wound does not exceed the degree of legitimate plastic inflammation. If this form were admissible, we should also be obliged to admit a variolic traumatic fever, in case a wounded person is attacked by intercurrent variola.

4. The suppurative fever is equally absent when the production of pus is limited to the normal proportions, and when this fluid is of a healthy nature. If the pus becomes putrid and is absorbed, it determines a recrudescence of the septicæmia, which is nothing special.

5. The traumatic fever may appear early or late, be of short or long duration, regular or irregular, light or severe, just like septicæmia—of which it simply represents a variety—consecutive to the traumatism and imputable to the numerous anomalies in the reparative process.

6. Be it generated within or without the patient, traumatic septicæmia always preserves the same nature and the same general physiognomy.

7. It is impossible to trace a perfect demarcation between traumatic fever and acute or chronic septicæmia; this I affirm more than ever.

8. I hope to be able to prove that pychæmia is nothing more than a severe septicæmia, with special complications, having special causes, but which, in spite of these special characters, enters, nevertheless, into the series and does not break the unity.

(To be continued.)

ORIGINAL COMMUNICATIONS.

ON RHEUMATISM.

THE PRINCIPLES OF ITS TREATMENT.

By J. JAMES RIDGE, B.A., B.Sc., B.S., M.D. Lond.

(Concluded from page 495.)

In reviewing the various agents at our disposal we may divide them broadly into the remedial and the prophylactic, and I shall endeavour to arrive at the method of their action in the light of the principles which have been enunciated.

The remedial agents include—

1. *Means by which an Attack can be cut short.*—That it is possible to arrest a catarrhal attack or incipient rheumatism by various measures is unquestionable. Even after distinct and localised joint-symptoms have appeared, appropriate treatment can often cause them to disappear more or less suddenly, together with all the general symptoms. This, of course, is what we aim at in all cases; but it is an end which seems to be at present attained almost exclusively in those that are recent. If, after exposure to cold, febrile symptoms are setting in, without any distinct disease being yet produced, various remedies are employed; diluents, hot or cold, with abundant warmth and covering to the surface, or hot stimulants, or a Turkish bath, will all frequently effect a cure. Of course this is the old, but very vague, "determination to the skin" by which the disease or the poison was supposed to make its corporeal exit. I should employ them as means to divert the morbid excess of energy to the secretory nerves of the skin, and so to let the system safely down to equilibrium. Diuresis can be produced at our pleasure by most of the same means, merely by keeping the skin cool at the same time, and will also act as a safety-

valve for the excess of energy. Yet diaphoresis seems to produce a profounder effect, probably because the extent of surface is so much greater, and the skin has relation with a far more extensive series of nerve-centres.

Even if arthritis has been established, we are not unable sometimes to arrest it suddenly, especially in recent cases. Again and again the preliminary warm-bath administered to most patients on admission into Hospital has removed the disease before the visiting Physician has seen them; and when not removed it is very often alleviated. The influence here is probably something more than the production of diaphoresis, although that occurs; we have the very opposite of a chill applied to the whole surface of the body, capable, to some extent, of really reversing the changes which cold produces in the various nerves. Some may say, "Why, then, does not heat cure every case as quickly as the cold produced it?" I believe the true reason is, because the cold acted when the nervous system was evenly balanced, or even already inclined to inflammatory action; whereas the heat has to act on the system when least inclined to its influence. It is all the difference between accelerating a body, or starting it from a position of rest, and reversing the direction of its progress.

All the other means at our disposal may be employed to assist in this process, and their action only differs, perhaps, in being somewhat slower, although this may only seem so because they generally act at less advantage, being employed when the complaint is already established. The distinction between the action of these and of the means to be immediately noticed is quite artificial.

2. *Means by which Acute Rheumatism can be removed.*—The inflammatory action may be either checked or diverted. Nerve-excited inflammation may be checked in two ways—(1) either by directly reducing the nerve-energy, or (2) by locally diminishing the activity of tissue oxidation.

By "reducing the nerve-energy," I mean a process quite distinct from its diminution in one form through diversion into another channel; I refer to a simple decline of its intensity. The application of continuous heat, whether as simple warmth, or to such an extent as to be an irritant, acts partly in this way, having an action on the nervous system exactly opposite to that of cold. Some sedative drugs probably include in their action a directly antagonistic influence of this kind. Among such are opium, camphor, aconite, and most likely colchicum, although these can act powerfully in other ways. Nitrate of potash has a somewhat similar action on the nervous system, since it relaxes bloodvessels (so promoting the catamenia), and increases the perspiration, and depresses the pulse; it is quite a mistake to regard it as an alkali.

Another mode of checking the process is by directly retarding the oxidation of the tissues. Some of the remedies which have long been used in rheumatism partly produce their beneficial effect thus, although they have not been given with this idea at all. I refer to the various vegetable salines which have been employed with the intention of rendering the blood and the secretions alkaline, and so of neutralising the peccant poison. It is well known that in passing through the system these salts are decomposed, and form carbonates of their base: in this process a large amount of oxygen is consumed. The comparative quantity required in each case for complete oxidation is as follows:—

226	grains of potass. tart.	require about	235	cubic in. of oxygen
188	" potass. tart. acid.	"	235	" "
306	" potass. citr.	"	423	" "
98	" potass. acet.	"	188	" "
77	" ammon. acet.	"	376	" "

The last valuation supposes that the ammonia as well as the acetic acid are completely oxidised—nitric acid and water being formed in one case, carbonic acid and water in the other. The comparative value of these salts for this purpose can be better seen in another way. Thus, the same amount of oxygen is consumed by the complete oxidation of—

2	grains of ammon. acet.
5	" potass. acet.
7	" potass. citr.
8	" potass. tart. acid.
9	" potass. tart.

This order will be found to correspond with the generally entertained idea of their value as febrifuges.

If we take the case of liquor ammoniæ acetatis (P.B.), which contains about 28 grains of acetate in each fluid ounce, and suppose that half an ounce of the liquor is taken every four hours, about 84 grains will be taken in the twenty-four hours; and, roughly speaking, some 400 cubic inches of oxygen will be required to oxidise this completely. When we recollect

that from 30,000 to 80,000 cubic inches of oxygen are daily absorbed by the lungs, the effect which might result from abstracting 400 of them at first sight appears to be insignificant. But, on the other hand, it should be remembered that we do not aim at reducing the oxidation below the normal by means of these salts, but to diminish all that is in excess of the normal, and to this excess of oxygen consumed 400 cubic inches may often bear a much larger proportion.

Again, when completely oxidised, most of these salts form alkaline carbonates, and alkalies promote oxidation: will not their secondary action neutralise, or even reverse, their primary effect? In answering this question, I shall also give my view with regard to the value of alkalies. The tendency of these, as far as oxidation is concerned, is doubtless to promote it; and the process is already too active. Some circumstances, however, diminish this apparently harmful influence. In the first place, the process of oxidation seems to go on more rapidly than oxygen can be supplied, and many lower products are formed—such as uric acid and other suboxidised transition forms—in the direction of urea. As complete oxidation of albuminous materials is approached, there seems to be a less degree of affinity for oxygen; so that, when the quantity of this gas is limited, the non-nitrogenous and highly organised albuminoid substances seize upon it with more avidity than those materials which have been nearly completed. If, now, the alkalies supplied more oxygen, they would promote the process amazingly. Since they cannot do this, but only render combination with oxygen more easy, I think it is probable that they render possible the still further oxidation of those waste products which had begun to be oxidised more sluggishly; if so, every grain of oxygen thus employed is hindered from assisting in the destruction of the remaining tissue elements. In those cases of rheumatism called gout, where irritating collections of acid urates have been formed, alkalies will help to dissolve the concretions and remove this source of irritation. The spasmic effect on the blood which alkalies exert (in some cases of rheumatism most disastrously), by which the number of oxygen-carriers is sensibly diminished, will also diminish the amount of oxidation possible from this source of oxygen supply. But to whatever extent they promote the primary oxidation of the tissues, it appears to me that they cannot but do harm; and it remains a question, which may be differently decided in different cases, whether their beneficial or injurious effect will predominate. Their diaphoretic influence will be noticed further on.

We possess, however, more powerful retarders of oxidation than the vegetable salts. I refer to the acids, both vegetable and mineral, but especially the latter. Citric acid has long been employed; more recently a mineral acid has been unwittingly recommended—namely, in the approval bestowed upon the tincture of perchloride of iron by Dr. Russell Reynolds. I believe its beneficial effect is chiefly due to the large amount of free acid which it contains, although its influence in tending to obviate the rapid destruction of blood-globules is most valuable. Both before and since this plan of treatment was published I have been in the habit of treating acute rheumatism with advantage by means of the mineral acids, principally sulphuric. The cases are much too few to decide the exact value of these remedies, especially as I have not felt justified in neglecting general and external treatment, or other drugs which are indicated on the theory I now uphold. The cases should be numbered by hundreds before an irresistible conclusion can be drawn from experience; but I believe a careful trial will prove these drugs to be of great value in rheumatic fever, and not least in preventing the extreme prostration and anæmia so usual as the result of full and long-continued alkaline treatment.

In the next place, the morbid process may be arrested by diverting the excess of energy into another channel. This is the old theory of derivation, but with a more extended application and a more precise explanation. Under this head I include all those diaphoretic, diuretic, counter-irritant, and derivative measures, which form so large a proportion of our aggressive weapons, and the principles of whose action I have before tried to explain. I have little further to add than to direct attention to the fact that the remedies mostly employed in this complaint have therapeutic actions consistent with this hypothesis, and that remedies of a similar nature are those we must look to for most assistance. These agents either produce a change of action in the inflamed part itself, and substitute vaso-motor contraction or secretion, or they restore the normal trophic action by diverting the excess of energy to establish inflammation, organic muscular contraction, or secretion in some other part "alternatively" connected with it by its

sympathetic nerve-supply. The establishment or increase of some secretion is the method most often adopted, and to this end opium, camphor, ipecacuanha, tartar emetic, colchicum, guaiacum, alkalies, salines, and some purgatives are administered, besides the application, either locally or generally, of warmth and moisture. Secondly, we may promote vaso-motor action by means of quinine, digitalis, and ergot: the first of these remedies is largely used abroad in this complaint. Thirdly, the use of counter-irritants is widely spread, and their value unquestionable. In addition to their irritant action, they tend to reverse the primary action of the cold by their warmth and moisture, and they should be carefully followed up with constant warmth, in order to preserve the unsettled nerve-territories from fresh disturbance. The use of stimulating embrocations frequently relieves the pain, and is often associated with some swelling of the part to which they are applied; and it is not without significance, that, when œdema occurs spontaneously, the pain is often greatly alleviated. The (so-called) counter-irritation of the bowels is usually rather a process of counter-secretion, imitating the natural alternation by which nasal catarrh or bronchitis often subsides.

In chronic rheumatism, the direction of more than its proper share of nerve-force into one channel, and the expenditure of extra stimuli in the same way, have become confirmed by the influence of habit. It is consequently more difficult to divert it, or restore equilibrium, and it is more likely to revert to its old course. It is only by the long-continued influence and persevering application of the less energetic alternative remedies that we can hope to effect a permanent change in the distribution of energy. And while we promote secretion we must carefully avoid the reduction of the general power, but rather adopt also such measures as will give tone to the system, lest we render it generally more susceptible to morbid influences.

Prophylactic measures.—The means useful for the purpose of diminishing susceptibility are such as promote the general health, and preserve the due balance of all secretions. There are also those which diminish the morbid power of some particular exposure. Among these latter warm clothing is universally approved of. Anointment with oil is also a very useful measure, apparently diminishing the rapidity with which heat can be abstracted. But I wish specially to notice three plans which seem to confirm the views I have been advocating. The liability to take cold in any form is diminished by exercise during the exposure, or by a previous full dose of quinine or of opium. I attribute this to the fact that in exercise nerve-energy is being more particularly directed in certain channels—not that of inflammatory action, but rather of muscular contraction and secretion. Stimuli, therefore, besides having probably less influence upon the trophic system, are diverted—carried with the stream, as it were—or, at least, unable to arrest it, and are thereby exhausted and rendered harmless. In the case of quinine we have the vaso-motor nerves thus pre-occupied, and perhaps also a positive reduction of trophic energy. In the case of opium, besides diminishing metamorphosis, the secretory system is stimulated to activity.

In concluding these remarks on Rheumatism, I have only to add that they principally serve to show how much yet remains to be discovered; but I trust that they also indicate the direction in which we must look for further light. The exact course of the influence of cold is still unknown, and also how it can convert potential into actual energy, or disarrange its normal distribution. All these problems of molecular mechanism remain to be solved, with many others. The correctness of the view I have taken—the simple catarrhal nature of rheumatism, and the relation existing between the various kinds of work effected by sympathetic fibres, by means of which inflammation may subside spontaneously, or may be induced to do so—I leave to time, which testeth all things.

Grafton-square, Clapham.

THE BRITISH MEDICAL BENEVOLENT FUND.—Twenty-two applications for assistance were laid before the Committee at their meeting on Tuesday last, and in eighteen of these grants were made, amounting in the aggregate to £135. The Treasurer (Dr. Hare) reported the receipt of a legacy of £500, free of duty, from the late Dr. George Cursham. This sum has, in accordance with the laws, been invested and added to the Annuity Fund. We regret to find that the Committee are unable, from want of funds, to increase the number of annuitants this year, there being as many as thirty candidates admitted as eligible who are eagerly awaiting their election.

NOTES ON MENSTRUATION.

By FRANCIS R. HOGG, R.H.A.,
Fellow of the Obstetrical Society.

Initial period.—Out of 2000 inquiries personally made, 1 woman commenced to menstruate at the age of 9, 6 at 10, 59 at 11, 146 at 12, 253 at 13, 437 at 14, 502 at 15, 270 at 16, 157 at 17, 97 at 18, 45 at 19, 19 at 20, 4 at 21, 1 at 22, and 1 aged 30 and married seven years not at all. This instance suffers monthly from otorrhœa, lasting one day.

Initial period commenced after marriage in 17 instances, at the ages of 14, 15, 16, 17, 18, and 19.

During pregnancy, 21 menstruated up to quickening—not as a rule, but chiefly, with boys, and frequently with alternate children—4 instances menstruated up to six months, rare instances up to seven and eight months, and 3 instances during the whole period. The children as a rule born alive, but extremely attenuated.

Menstruation ceased in one instance at 23, initial period being 16; now aged 50; the mother of four children, and a grandmother; is well and strong. One woman ceased at 34, 1 at 35, 2 at 37, 5 at 38, 10 at 40, 2 at 41, 6 at 42, 3 at 44, 5 at 45, 3 at 46, 9 at 47, 2 at 48, 3 at 49, 2 at 50, and 2 at 53.

The following facts were related by patients; there is no reason to doubt their accuracy. In a former paper in the *Lancet* it was mentioned that one woman did not menstruate until the birth of her first child, and at the stage of 17. This is a solitary instance up to the present date.

Statements.

A. Commenced to menstruate at 19; one sister, aged 19, not as yet. A second sister, married at 19, was five years before falling pregnant, and after eighteen months' nursing, weaning her child, she menstruated for the first time. A third sister, aged 18, had disease of the left elbow-joint, requiring excision; also right mammary abscess, which bursts out periodically; now aged 22, and married two years; has never menstruated.

B. Menstruated once at 17; then for four years, until marriage, vicariously from ears, nostrils, and finger-nails. Curiously enough, although her husband contracted variola, through smoking the pipe of a person affected, she did not contract disease.

C. Deaf when menstruating; hears best when pregnant.

D. Mammary abscess occurred through suppression.

E. Temporary loss of prehensile power at the regular periods.

F. Initial period at 20, immediately preceded by scarlet fever. Married at 30; bears four children to husband, who dies of sunstroke. During her last (posthumous) pregnancy, uterine hæmorrhage or else menstruation took place. The child, considered by competent judges of six months' growth at birth, is now an idiot at Earlswood.

G. Unvaccinated; when 15 years old attacked with variola, initial period occurring after twenty-four days' illness; is terribly marked.

H. Since marriage and birth of two children the breasts enlarge most painfully a few days before each regular period, and an uncontrollable, causeless feeling of jealousy temporarily makes her life wretched.

I. Up to initial period at 14 had a hydrocephalic tendency, which subsided.

J. Initial period preceded by bronchocele.

K. In India the period nine days, regularly preceded by Peshawur fever.

L. Regular period always preceded by agonising pain of the right knee.

M. Severe attack of measles at 15; initial period at 20; two sisters commenced at 19.

N. Never pregnant; married some years. Twelve months ago the steel of her crinoline caused ulcer of the right shin; the wound nearly healed; always burst out afresh one day preceding regular period.

O. Never regular unless she has plenty of dancing.

P. At the age of 12, hearing groans of parturition, in a fright fell against a fender; temporarily paralysed, mouth drawn to one side, and the jaw rigid fourteen days; initial period at 18.

Q. Eight years ago fell into the ice skating on the initial day; fished out insensible; was irregular three years.

R. Suffers from blistered feet, the dregs of scarlatina; the pain at the regular periods agonising.

S. Four years ago, when 34 years old, fell out of window on to the roof of a shed, about twenty feet, breaking three ribs; menstruation ceased.

T. Initial period at 18, preceded by abscess of right knee and right thumb.

U. Initial period preceded by erysipelas of the face.

V. In excellent health; menstruates every two months for one day only.

W. Through menorrhagia temporarily monomaniacal, entertaining the idea that everyone is in love with her innocent husband, and that men who come to the house are women disguised.

X. Aged 43; for eighteen months has vicariously menstruated from the feet. Married twice; has given birth to ten children; deliveries with one exception instrumental. That exception alone survives, the remainder died of convulsions. As a rule menstruated up to quickening; has aborted twice in addition to a mole pregnancy.

In a recent lecture Kingsley reminded us that the miserable *chiffonnier* poking about with his little stick amongst rubbish, hoping to find a coin, occasionally discovers a jewel. Equally, the statist in monotonous search may at any time stumble across Professional practical treasures.

Amongst other researches, the late Sir Roderick Murchison, in pointing out the gold fields of Australia, created princely fortunes for others, and for himself—" *Exegit monumentum ære perennius.*"

FOOT AND MOUTH DISEASE IN THE HUMAN SUBJECT.

By T. E. AMYOT, F.R.C.S.

For some weeks past I have intended to send you a notice concerning the occurrence of "Foot and Mouth Disease" among my patients, but I should probably have neglected to "crowd my thoughts with acts," had I not noticed in your last impression a request for such information.

Here, then, the foot and mouth disease among neat cattle has been epidemic to a very great extent during the past summer. I need say no more of it than that in this district, as elsewhere, it appears to be highly infectious, to have a distinct incubative stage, to affect the animals for two or three weeks after the appearance of the eruption, and finally to subside—fatal terminations being rare. The milk from the sick cows, even during the incubative stage, is capable of producing a like disease in other animals which consume it—pigs, for instance, suffering severely. It has sometimes a faint, and at other times a slightly putrid odour, decomposes quickly, and its ill-effects are not, I think, entirely removed by boiling. When the febrile symptoms are at their height, the cows often become dry.

Now, proceeding *pari passu*, both as to time and symptoms, with this epidemic, has been the disease affecting my patients, both infantile and adult, but more especially (as the great milk consumers) the former. After a few days of poorliness, hardly noted by the parents, an eruption shows itself on the lips, the lining membrane of the cheeks, and on the sides of the tongue; and generally a few yellow-headed pimples (they are not vesicles) show themselves on the hard palate. The child refuses food—more on account of the tenderness of the mouth than from want of appetite—becomes feverish and restless, and so remains till the subsidence of the rash, which, under favourable circumstances, takes place in the course of ten or fourteen days, leaving no further ill-effects than a certain degree of debility, from which the patient quickly rallies.

The above is a description of a simple and uncomplicated case, and from such I have seen no fatal effect—in fact the symptoms are hardly alarming; but it is far otherwise when diarrhœa occurs as a complication, especially when it assumes, as it frequently does, a dysenteric form, which is particularly intractable. I mention diarrhœa as a "complication" because it existed as an epidemic at the time, and I am by no means sure that it forms part and parcel of the affection under consideration, although its subjects were probably peculiarly open to its attack, and suffered more severely in proportion to the degree of debility and fever already established. One of these cases I lost—a poor "farmed out" child of eleven months, which, however, I am bound to add, was tended carefully and even affectionately by the she-farmer. Another case, which for a time looked badly, was that of a child about 9 years old, whose lips, uvula, and tongue became densely covered with false membrane, and who obstinately refused food, both fluid and solid, for many days, although evidently suffering from both hunger and thirst. Now, I have put these cases down as

“foot and mouth disease,” because they were almost all distinctly traceable to the use of milk from diseased animals, but I must admit that the *foot* symptoms were in general conspicuous by their absence. In one case, however, an adult female, it was not so, for in addition to the usual mouth symptoms the feet became hot and covered with painful tubercles, which disappeared with the attack. She also suffered sharply from diarrhœa.

The treatment of the disease was of course principally dietetic—the substitution of good milk for bad, or the use of the condensed Swiss milk, which I find answer admirably, and to be much approved by my patients, young and old. Liebig’s extract, too, did good service, and in some cases, where the exhaustion was great, a few drops of brandy added to the food produced good results. One medicine was extremely useful, and apparently extremely grateful to both young and old—even to the child whom I mentioned as refusing all forms of food for many days—and that was the sulphurous acid, frequently given, in doses of five to twenty minims, with a little syrup of oranges and water. No treatment seemed very effectual in controlling the dysenteric symptoms; but the administration of small doses of tinct. ferri perchlor., with spirits of chloroform every four hours certainly did good both during their continuance and in convalescence.

In conclusion, I may note the difficulty which exists as to tracing these cases to their true cause, dealers in milk being of course unwilling to acknowledge the existence of disease among their cattle.

Diss, Norfolk.

REPORTS OF HOSPITAL PRACTICE

IN MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

CONDURANGO-ROOT IN CASES OF CANCER.

(Under the care of Mr. HULKE.)

[For notes of these cases we are indebted to Dr. DAVIDSON, House-Surgeon.] MANY of our readers may be aware that in the first part of the present year a quantity of condurango-root—vernacularly called the “vulture plant”—was sent by the President of the Republic of Ecuador to the Queen of England, with the statement that it had been tried by several of the Doctors in the Republic, and had proved to be a cure for cancer, syphilis, and phthisis. As any remedy reputed to be of service in such destructive and fatal diseases was worthy of trial by Physicians and Surgeons in this country, Lord Granville, at the expressed wish of her Majesty, sent a packet of the condurango-root to the College of Physicians, at whose disposal it was placed. Accordingly, it was divided by them into three parts, one to be sent to the Radcliffe Infirmary, Oxford, another to St. Bartholomew’s Hospital, and the third to the Middlesex Hospital. The report which accompanied the quantity sent to the Middlesex Hospital contained the account of one or two cases of syphilis and of epithelioma in the ulcerative stage which were said to have been cured by the administration of the drug. It was stated that those who were submitted to the treatment were “reconstituted” in four or five days, and that improvement began to take place from the date of “reconstitution.” But it was also asserted that nervous commotions, such as those produced by strychnia, in some cases followed its exhibition. From Mr. Hulke’s report of the cases on whom he tried it in the Middlesex Hospital we learn that he commenced its use in four cases, of which one was a scirrhus of the breast and the other three epitheliomata. After a few days, however, as it appeared that the quantity of condurango received from the College of Physicians would be insufficient to supply all the patients with the proper daily doses of the decoction for more than a very short time, it was discontinued in the case of scirrhus of the breast and in one of the cases of epithelioma of the penis.

None of the patients while taking the condurango exhibited the “serious nervous phenomena” mentioned by Dr. Joseph Equigusen, and in none of them has the reputed remedy exerted the slightest influence in retarding or modifying the course of the cancer, or in improving the general condition of the patient. In each patient the pulse-rate and temperature were recorded twice daily during the whole time the condurango treatment

was continued. Mr. Hulke adds—“As a reputed remedy for cancer, condurango is in my opinion perfectly inert and useless.”

The condurango was given in the form of a decoction, prepared strictly in accordance with the directions contained in the memorandum received with the stems from the College of Physicians. It was of the colour of brown sherry, and each pint of the decoction contained an ounce of the plant. Of this decoction five ounces were taken night and morning, and after a few days, as all the patients complained of flatulence, half a drachm of tincture of ginger was added to each dose.

Case 1.—*Epithelioma of Penis and Surrounding Tissues.*

James P., aged 34, a thin, haggard, pain-worn man, with a sallow complexion and hollow cheeks, was admitted into Handel Ward on August 15, with primary cancer of the penis, and secondary infection of the lymphatic glands in both groins. The end of the penis, where the glans had been, was an unshapely tuberos, ulcerating, and granulating mass. A larger ulcer reached from near the left anterior superior iliac spine, along the groin, across the pubes, measuring in its long diameter 7 inches, and from 2½ to 3 inches in its short diameter. At its outer half the growth predominated over ulceration, and its floor was studded with cauliflower buttons and masses of small granulations, while at its pubic end the erosion was so deep that it seemed surprising that the peritoneal cavity was not opened. The edges of this ulcer were very irregular and sinuous—in parts undermined and overhanging, in other parts swollen and everted. Near the outer end of the ulcer were some small outlying buttons. The lymphatic glands in the right groin were enlarged. The discharge from the ulcer was very profuse, thin, ichorous, and nauseously fetid.

August 23.—Patient has a tolerably good appetite. Pulse 100; temperature 100°.

24th.—R. Decocti conduranginis ʒv., night and morning commenced. The sore is dressed with cotton-wool steeped in a solution of chloralum, and the whole covered with oakum.

25th.—Very slight elevation of temperature; no alteration in the sore.

27th.—Sore looks rather cleaner. No constitutional changes further than that the patient expresses himself as feeling rather stronger.

28th.—Sore continues to clean. No nervous or other phenomena are observable.

29th.—Complains of a feeling of distension in the abdomen; bowels freely opened, tongue clean, appetite good. Yesterday complained of throbbing pain in the sore.

30th.—Rather more pain in the sore; the discharge, which had been healthy for a few days, has become watery. Is much troubled with flatulence. R. Decoc. conduranginis ʒv., tinct. zingib. ʒss., to be taken night and morning.

31st.—Less pain in the sore. There has been slight capillary hæmorrhage from the surface.

September 2.—No change for the better in the sore. The discharge has increased, and the ulceration has extended deeper.

He continued to take the condurango-root up to September 18, and on the 19th he died exhausted, the growth having steadily progressed, and the small outlying buttons in the left groin having become large cauliflower masses.

Case 2.—*Ulcerated Epithelioma of the Roof of the Mouth.*

Hugh L., aged 68, a short, thin, wiry-looking stableman, was admitted into Handel Ward, August 17, with an ulcerated tumour of the roof of the mouth. A few days later, when he came under Mr. Hulke’s care, it involved the entire left half of the roof (implicating the hard palate and velum), and also the right half of the velum, extending in this direction as far as the right anterior faucial pillar. It had a bony nodular surface, and depended from the alveolar border of the right maxilla in curious wattle-like masses. The centre was irregularly eroded by ulceration. The floor of the ulcer was partially coated with tawny-yellowish fibres, amongst which were nodules of growing tumour, and red clusters of granulations. He was suffering a good deal of pain in the cheek and left side of the head. There was no enlargement of the neighbouring lymphatic glands discoverable, and no appearance of cachexia; on the contrary, his aspect was that of sound health. He related that when in excellent health, about one year before, whilst smoking, a child in his arms hit his pipe, and jogged the end of it into the roof of his mouth, where it made a little round hole, which bled freely for ten minutes. A month later he noticed a small warty lump where the wound had been, and in two months this had grown to the size of a halfpenny. The physical characters of the ulcerated tumour,

and its history, made it impossible to doubt its cancerous nature. A weak gargle of myrrh and liberal diet were ordered.

August 25.—Commenced to take condurango.

26th.—Previous condition unaltered. Pulse 78; temp. 99°.

28th.—Less pain in the cheek and head. Pulse 80; temperature 99°; bowels regular; urinary secretion not altered.

29th.—Complains of headache; feels very languid, and at times giddy; has smarting pain in the roof of the mouth. Pulse 72; temperature 100°.

30th.—Patient still feels giddy at intervals, and the pain in the head continues. Bowels regular; complains of flatulence. Add thirty minims of tincture of ginger to each dose of condurango. Pulse 80; temperature 100·3°.

31st.—Yesterday had slight hæmorrhage (5j.) from the roof of mouth. Still complains of smarting pain in the sore; the surface is clean. He still washes his mouth with a gargle of myrrh. Pulse 74; temperature 99°.

September 1.—Has had no more attacks of giddiness. Yesterday he suffered a good deal of pain in the left ear. Pulse 76; temperature 99·4°.

3rd.—There is no change in the character of the sore; it seems to be spreading in the front, and it occasionally bleeds—about a drachm at a time. Pulse 76; temperature 99·5°.

9th.—No improvement, either constitutionally or locally, can be noted. The growth is increasing. Pulse 67; temperature 98·8°.

11th.—Last night suffered from choking sensation. The pain is now more severe. Pulse 70; temperature 99°.

12th.—To-day patient feels rather better. No more chokings. Pulse 76; temperature 99·8°.

14th.—Has great pain in the mouth, difficulty in swallowing, and the left cheek is swollen. Passes restless nights. Pulse 80; temperature 100·4°. R. Liq. opii sed. ꝑxv., aquæ camph. ʒjss., bis die.

15th.—Is in less pain to-day. There is marked increase in the size of the growth, appetite has greatly failed, and the patient's countenance is anxious and distressed. Pulse 64; temperature 99·1°.

18th.—The growth still increases. A pendulous lobe hangs from the left side of the roof of the mouth. Pulse 72; temperature 99·4°.

20th.—Last night had slight hæmorrhage from the roof of the mouth, and much aching pain in the temple. Pulse 76; temperature 99·2°.

25th.—Took the last dose of condurango to-day. The growth has more than doubled its size since the condurango treatment commenced. The cheek is now bulged outward on the left side. Pulse 84; temperature 98·8°.

27th.—The ulceration now extends into the fauces, and deglutition is increasingly painful and difficult.

HOSPITAL FOR WOMEN, SOHO-SQUARE.

CASES ILLUSTRATIVE OF DISEASES OF THE RECTUM IN THE FEMALE SIMULATING UTERINE DISEASE.

(Under the care of Dr. EDIS, Assistant-Physician.)

THE following cases may serve to illustrate, and at the same time direct attention to, a by no means infrequent train of symptoms met with in females, both in Hospital and private practice, who have been the round of the several institutions or special Physicians without obtaining any definite relief. In many instances they are looked upon as hysterical or exaggerated, and their intractability to ordinary remedies, directed specially to the uterus, exhausts the patience of most Practitioners, and confirms the patients in the belief that their disease is incurable. A more careful study of the subject would, I feel sure, enable the Practitioner to detect in many cases some hidden mischief susceptible of relief if only proper treatment be employed, and thus rid our patients of what may have been years of discomfort and misery.

Case 1.—G. R., aged 25; married seven years; resides in India; sterile. For years past she has suffered from intense pain in sacral region; worse on exertion and defæcation. The periods were regular, scanty, and painful. After being under Medical care for several years in India, her husband sent her over to England to consult the Doctors here, and see if any benefit could be obtained. At the time of my seeing her, in June, 1869, five weeks before her return to India, she had been under the care of several Medical men, had had the cervix divided, had worn an intra-uterine stem, as also a Hodge's pessary; had been leeches and blistered, and had evidently gone through the usual routine treatment, without any alleviation of her

sufferings. She now despaired of ever getting better, and was very miserable at the thought of having to return to India after a twelvemonth's absence, having spent a little fortune on Doctors, and derived little or no benefit as regards the pain in sacrum, although the dysmenorrhœa was certainly less, and her general health improved. On examination she complained of much pain the moment the finger entered the vagina, which induced me to examine carefully the rectum, and there I discovered an ulcer the size of a shilling on the posterior wall, just above the sphincter, which was exposed, and was very painful; the margin was indurated, and the ulcer was evidently of long standing. Having given a small dose of calomel to clear the portal system, and instructed her to use an enema, I divided the ulcer through its centre and on either side, confined her to bed, gave opium suppositories, restricted her to spoon-diet, and at the end of a week induced the bowels to act by castor oil. A solution of nitrate of silver was applied once to stimulate the surface, and some pills consisting of pil. hyd. ipec. and rhei. co. were ordered, to secure the regular action of the bowels, which for many years had been very costive.

September, 1871.—Patient has just returned from India and called to report herself and tell me how well she has been, having had no return of the disease.

Case 2.—L. M., aged 37; married twelve years; sterile. Had been doctoring for fifteen months before my seeing her in March, 1871. Complained of vaginal discharge, which caused excoriation of the vulva and anal cleft; dreadful aching pain in groin, burning and smarting at times; aching pain in loins and lower back, "as if it opened and shut." Could not walk a hundred yards without wanting to pass water, or feeling so weak that she was obliged to sit down; had constant desire to go to the closet, especially on first rising of a morning and after eating or drinking anything, when she noticed blood and slime with the motion, and on some few occasions she passed large quantities of blood. Coitu was so painful, she dreaded the idea of it. She felt so miserable, her life was a burden to her. She got little sympathy from her Medical men, who, after leeching and lotioning the uterus and pouring in no end of tonics, failed to afford her any relief.

On examination a long fissure extended up the anal cleft, and the skin generally was dry and irritable. The lower portion of the rectum was extensively ulcerated and intensely painful, thick slimy mucus tinged with blood covering the surface. An ethereal solution of arg. nit. ʒij. ad ʒj. was applied pretty freely externally. Liq. hyd. nitrat. acid. was carefully applied to several of the ulcerated points, and an enema of glyc. acid. gallici with tinct. bellad. in lotio plumbi was ordered to be used night and morning; the bowels kept gently open with conf. sennæ, and a mixture of ferri and mag. sulph. with liquor strychniæ administered thrice daily. Within a month from this date she was nearly well. The mixture was persevered in for a few weeks longer, when she was discharged convalescent.

I saw her on October 24, as she had a slight return of the external fissure; but with this exception she had remained perfectly well, and has had no return of the distressing symptoms from which she suffered. Her general health is vastly improved, and the change in her mental condition is gratifying to witness; she is quite a different being.

Case 3.—M. B., aged 44; married twenty-two years; two children. Complains of constant aching pain in lower back and in right iliac region; frequent desire to micturate; feeling of pressure and bearing down, worse on walking; bowels generally confined; sense of weariness and fatigue; aching in upper part of thighs; irritation in privates, and feeling of fulness, as if they were swollen; has frequent spasms in lower abdomen. Has suffered from these symptoms for the last ten months, spite of all treatment, until she began to fear it must be cancer, and came up 150 miles from town to consult me.

On examination, the uterus was found to be bulky, but mobile; not tender on pressure, and not misplaced. The pain was principally referred to the right iliac region; the cæcum seemed to be much distended, and was apparently blocked up with fæces. A mixture of nitro-muriatic acid, quinine, and sp. chlor., and pills of extract of belladonna, with aloes and rhubarb, were ordered, with confectio sennæ if necessary. She returned home, and, after persevering with the treatment for a month, wrote to inform me that she had quite lost all her symptoms, and was very much improved in health.

Remarks.—This seems to have been one of those cases so frequently met with in females, of pain in the cæcum caused by over-distension, either from wind or fæces, due entirely to constipation. It is here that belladonna acts so beneficially in relieving the spasm and ensuring regular action of the bowels.

people before the Committee, "communications" from members of the Committee and other persons, correspondence, and "notes of *séances* communicated to the Committee": and these are the interesting and amusing parts of the volume. Some of these "evidences" and "communications" may be commended to the psychologists as studies of mental twists and weaknesses, and some are real curiosities. We suppose that if anyone can bring himself to believe it possible that "he or anyone can call, the spirits from their golden day," to play fantastic tricks or practical jokes, to talk illiterate twaddle, or make frivolous and utterly useless communications, or at the best only to help curious inquirers to kill time, or professional mediums to gain a few guineas, he may believe the very wildest and most absurd improbabilities, and may seriously set himself to explain them. How are we else to comprehend how a sane man can offer the following as a satisfactory solution of the strange phenomenon of a spirit appearing in a dress? Mr. Varley says—"We may infer that everything is solid in respect to something, and that nothing is solid in respect to all things, and therefore thought, which is power, may be in some sort solid; so that if you take an old English farmer, for instance, he would be ashamed to be seen without his top-boots, his coat with the buttons, and his hat. They are part of his identity; he cannot think of himself without them; they form part of his nature; and the moment he leaves the body and becomes a thought man, the thought boots, the thought coat, and the thought hat form part of his individuality."

We have here, certainly, a new reason for our very carefully studying the history of costume; as, with a full knowledge of this subject, we may be able to know, at any rate, the nationality of the spirits we may meet in this world and the next, and the age in which they lived on earth. We hope the Education Commissioners and School Boards will note this. Do spirits always appear in their "Sunday clothes"? and are they compelled to keep for all eternity to the fashions reigning at the time they respectively left the body? A good deal more information on this subject is much to be desired.

From Miss Anna Blackwell we learn that we may educate and improve the spirits. She tells the Committee that "We say to the spirits that wish to deceive us, 'Dear Spirits, we are all imperfect; we will endeavour to benefit you by our lights, in so far as they are superior to yours.' Sometimes they would overturn and break the table, yet they were rendered better by our kindness. From one who was very violent, and by whom I have myself been struck, we have received progressive messages, showing how he has become better. They have often sent us messages, saying, 'We are going up higher now; we have through your help broken the chains of earth, and we leave you.'" This is encouraging, though it must be saddening to lose the society of spirits as they improve. This lady stated that "she considered that the creative act which gave rise to all was such that we progressed from gases to crystals, from animals to man"; yet, to the query "Then, the spirit which animates a man may have once animated a horse?" she replies, "No; that is not so. A horse is a horse; it is capable of being taught to go better, but it cannot learn mathematics. Nevertheless," she adds, "everything is progressive, and spirits that have progressed may become purified and combined so as to reach a higher stage." Miss Anna Blackwell was also kind enough to favour the Committee with a very lengthy written communication, which in the index to the volume is entitled, "The Theory of Re-Incarnation Expounded." She calls it "A Sketch of the Theory of Existence that has been gradually built up on the basis elaborated by" the late Allen Kardec; and she announces herself to be "an English disciple of the School of Spiritist Philosophy founded" by that gentleman. We cannot say that we ever heard of him before, but he appears to have been a rather copious writer, and, if his style is like that of his English disciple, his volumes must be uncommonly hard reading. Miss

Blackwell's "Sketch" fills some forty pages of close small print, and though she makes a most liberal and generous use of capital letters in the Immense Vastness and Depth of Potentiality of Expression of which she has evident profound Belief, yet we dare not pretend that we comprehend it; and as excuse for this dulness we must quote one or two specimen sentences. Thus, she says—"We are told by the more advanced minds with whom we are beginning to enter into communication, that IT—the Absolute, Self-Existent Source and Container of all things—may be approximatively conceived of by us as Intelligence (Essentiality), Thought (Movement or Diversity), and Fluid (Source of Substance and of Life); what we call the 'Universe' having no original or independent Existence, but being the Ultimatum, into the plane of Derivation, of the Causal Possibilities inherent in the Divine Essentiality;" and that, "we see that the old idea of Creation, as the *making of something out of nothing*, must give place to the idea of Creation as an evolution, into the plane of corporealised manifestation, of the potentialities of Self-Existent Reality." The nearest idea that we can form to ourselves of the Creative Process is, we learn from the Spirits, "the gradual assumption, by the Efflux of the Divine Thought, of a state or mode of Concretion only to be remotely imagined by us as that of a Fluid of a quintessential subtlety inconceivable by our present mental organs. This Primordial Fluid, which contains all the elements of Derived Existence, and which may, therefore, be said to be both the matrix and the generator of the Universe, is not God, but is the first Substantiation of the Efflux of Creative Thought. Its molecules—declared to be the earliest product of the inter-radiations of that Thought, but quite out of reach of our observation or comprehension—are the substratum and continent of all the modes, forms, and attributes of Derived Existence that are to be progressively evolved from them by the attractive and repellant vibrations of the vast arsenal of Cosmic Forces." In this very superior kind of language we are taught how the creative power creates "the Psychic, Dynamic, and Material elements from which, by which, and through which Creatures are to be evolved; and in order that they may acquire the only co-relation to the Divine Autonomy that is possible to Derived Existences, they are created at the lowest state of rudimentary germination, and made to elaborate their own individuality under the fostering tutelage of those who, having started before them from the same point on the same path, are further advanced than themselves on the road to the common goal." In working this out we are certainly told some rather startling things—as that some species of plants not only have the rudiments of motility, sensibility, and contractility, but also "give evidence of possessing the first faint glimmerings of memory, confidence, and apprehension." But we can only afford to note one other piece of information—viz., that every planet is surrounded by a sphere, or region of matter in a mixed state, "which is the abode of the souls who have put off the body of more or less 'compact' matter appropriated to its surface, and have assumed the body of matter, more or less 'fluidic,' appropriated to its 'spirit-sphere';" and that "this 'fluidic-sphere' or 'spirit-sphere' is said to commence, for our earth, at about five miles from its surface." As some of our mountains are calculated to be more than five miles in height, our love of Alpine climbing is thus fully accounted for and more than justified, and we hope that the Thunderer will never again protest against or find any fault with the "rage" for mountain-scaling. We cannot notice the various examples of spiritual phenomena mentioned by Miss Blackwell, not even that of the little old spirit-woman who, when walking on gravel, made the same noise that an ordinary mortal would: Could we have persuaded ourselves that Miss Blackwell had amused herself with playing a practical joke on the Committee, we should acknowledge that her communication is a decidedly clever, though over-elaborated and ponderous, satirical parody of spiritist philosophy; regarding it as written in all earnest-

ness and sincerity, it seems too saddening an instance of misguided talent and misdirected labour to be merely called, as it has been called, portentous twaddle and balderdash.

The most greedy lovers of the marvellous will find plenty of food in the hearsay evidence and the communications given to the Committee; they include accounts "of trance-speaking, of healing, of automatic writing, of the introduction of flowers and fruits into closed rooms, of voices in the air, of visions in crystals and glasses, and of the elongation of the human body." The "spirits" are luminous and transparent, so that the wall can be seen through them, yet they throw shadows. Tested by a delicate thermometer, their hands are of the same temperature as that of the room; but on waving their hands the air becomes intensely cold. They dissolve and reappear like views of a magic lantern; but they laugh aloud, their clothes rustle like silk, and sometimes they tread so heavily as to make the floor vibrate. And so on. One cannot but think that if even spiritualists would peruse their statements in cold blood they might arrive at much more common-place solutions of, at least, some of the tales they tell than the theory of spirit phenomena. Lord Lindsay says that at one time he "used to see the spectre of a black dog. It seemed to glide along. I often went up to it, and sometimes passed a stick through it." And he adds—"It was the result of overwork. I was at that time studying for the army, and reading sixteen hours a day." But it did not occur to him to refer his later visions also to mental strain and excitement.

Some of the members of the Committee send communications of a very different character. Mr. Grattan Geary concludes his by saying, "The most remarkable phenomenon brought to light by the labours of the Committee is, in my opinion, the extraordinary number of eminent men—never suspected to be otherwise than sane—who firmly believe that spirits do what spiritualists assert them to do." Mr. Henry Jeffery, in a very cautiously and moderately expressed communication, perhaps the most sensible bit of writing in the whole volume, directs attention to the very unsatisfactory nature of the alleged "spiritual" utterances; that these have given us "no information of any practical value, no new thoughts, no fresh expressions of worthy sentiments," but, on the contrary, their general character "has been either frivolous or absurd"—so that, if accepted as messages from the departed spirits of relations or friends, "a belief in them cannot be reconciled with an exalted conception of the state of disembodied souls," and is for the most part "repugnant to minds of high religious and spiritual faculty." He remarks that "the theories propounded by the witnesses are vague and contradictory, and that there is a scarcity of evidence from persons accustomed to investigate, in a scientific manner, physical facts, which these phenomena are primarily to be"; and that the phenomena inquired into "are of a kind particularly open to imposture and credulity; that many of the votaries of spiritualism have such an eagerness of faith as to render their evidence unreliable; and that the boundary between wilful imposture and self-deception is not a clearly defined line, but an extensive mental territory, on which many popular delusions have, for a time, played their pranks and disappeared." Nevertheless, he observes, "Several of us have witnessed some remarkable phenomena which we have not been able to trace to imposture or delusion; and these, added to the gathered testimony of respectable witnesses, justify our recommendation of the subject to further cautious investigation."

If such an inquiry is to be of any real value and service, it must be entrusted, not to a large hotch-potch Committee of Medical Practitioners, barristers, clergymen, civil engineers, women, and what not, like the Committee of the London Dialectical Society, but to a very small Committee of really eminent scientific men—men who will carry on their researches by help of true experiments and tests, as Faraday did when he inquired into table-turning, and work out an investigation into

the nature of the so-called "Psychic Force" as Faraday worked out the science of magnetism.

Finally, Dr. Edmunds very properly points out the dangers run by those who practise "spiritualism." He says that, of the few people who were conspicuous either as advocates or "mediums" in connexion with the spiritualistic phenomena that had come under his own notice, "one has been the subject of well-marked mental illness, and another has been confined in a lunatic asylum." And plenty of evidence could be found, we believe, both at home and in America, to show that in indulging in "spiritual" *séances* and the like pursuits excitable and sensitive persons run the most serious risks of injury to mental and bodily health.

THE WEEK.

TOPICS OF THE DAY.

It will be in the memory of our readers that Mr. Corrance has a Bill on the subject of Poor-law Medical Reform, which is to be introduced early next session. This Bill, it is understood, will embody the principles which it has been the business of the Poor-law Medical Officers' Association to promulgate. We are glad to see from a circular which has been sent us that the health of the President of the Association, Dr. Rogers, is sufficiently restored to allow him again to take a prominent part in its proceedings. The same circular, we notice, contains a call on the members of the Association to forward their annual subscriptions. The expenses attending the introduction of Mr. Corrance's Bill will be considerable, and funds will be required. The annual subscription to the Association is only five shillings, which should be forwarded at once to Mr. J. Wickham Barnes, the Secretary.

We hear of a rumour that there is a movement amongst certain Members of the Royal College of Surgeons, or their friends, to bring their claims prominently before the Council of the College, in order to obtain their election as Honorary Fellows under that section of the College Charter which allows the election of Members of twenty years' standing. Without expressing opinion on individual cases, we think that the Council will do well to discountenance Fellowship by election except in case of Members who have passed the meridian of life, and who have fairly earned the distinction. To grant it to men who are in the full tide of life, and who have only to burnish up the necessary knowledge to pass the examination which would entitle them to it, is scarcely fair to the great mass of Fellows who have obtained the distinction by the usual and more difficult path.

The Managers of the Royal Infirmary, Edinburgh, are advertising for a General Superintendent of the Infirmary, who is to have the general control of the whole establishment. A gentleman with a Medical education is preferred. The salary is to be £420 per annum, with a house, or £80 until the house be provided.

The election of Assistant-Physician to Charing-cross Hospital is postponed until the month of January.

FATTY DEGENERATION.

K. VOIT (*New Rep. Pharm.*, vol. xx., p. 340) has recently contributed a highly interesting paper on this subject, containing the results of his own experiments. The fatty degeneration of organs, occurring so frequently in disease, may be brought about in one of three ways: the fat which takes the place of tissues (and that fat does take the place of tissues we have confirmed by our own researches) might be derived from the fat in the food; it might be derived from other parts of the body which usually contain fat, as, for instance, the subcutaneous adipose tissue; or it might be generated in the cells of the affected organs by the splitting up of the albuminoids contained in these into nitrogenous and fatty substances. In the

last case, the nitrogenous products of the metamorphosis of albuminoids—as, for instance, urea—would not be altered in amount, but the consumption of oxygen in the body would be diminished. Further, it is possible that the cells of the structure may become atrophied, and disorganisation of the tissue ensue, from more albumen than usual being decomposed; more especially that which enters into the structure of the cells themselves. Obviously, in this case the azotised constituents of the excretions would be increased, whilst the oxygen consumed would be either diminished or unaltered. The happy idea was conceived of giving phosphorus to dogs, after depriving them of food for several days—it being well known that fatty degeneration of many, if not all, the organs is produced by the administration of phosphorus—and this was found to be the case when food was withheld. As the animals ingested no food, the fat here could not have come from that source, nor from the adipose tissue of the body, for it was found that that had all disappeared, and, in consequence of abstinence from food, the animals were emaciated before the administration of the drugs. Hence the fat must have been the result of metamorphosis of albumen in the organs themselves. A dog, placed in Voit's respiration apparatus, exhibited a diminution of 47 per cent. in the carbonic acid excreted, and of 45 per cent. in the oxygen absorbed, when phosphorus was administered. The excretion of urea, previously constant, rose after the ingestion of the phosphorus, and increased as the symptoms of poisoning became more severe. The experiments of Voit, with whom Bauer was associated, show that in phosphorus-poisoning fatty degeneration is due to two causes—the decreased oxidation of fat, and the increased production of fat by the metamorphosis of albumen. It is shown that this latter is independent of the supply of oxygen, and is dependent not so much on the oxidation of albumen as on the decomposition of the oxidised products of this substance. Voit and Bauer observed that no abnormal products are found in the urine except sarcolactic acid in fatal cases, thus confirming the results of Schultzen and Riess. Leucin and tyrosin were looked for in vain in the urine of the poisoned dogs, although, as is known, these substances are abundant in cases of acute atrophy of the liver. They were found, however, in the liver, heart, and blood. It is thought very probable that leucin and tyrosin are among the first products of the decomposition of albumen, and that the nitrogenous bodies formed by the metamorphosis of albumen are changed into urea in the slighter cases of poisoning by phosphorus, whilst in the more severe cases the decomposition is imperfect, and the less simple products of decomposition are excreted.

Voit is of opinion that the main difference between acute atrophy and phosphorus-poisoning lies in the greater rapidity of degeneration which occurs in the former disease. Since the fat in fatty degeneration is solely that which has been formed in the organs, and either not oxidised or formed in too great quantity, it cannot be said when the diseased process begins and the healthy process ends. At first, the fat will be formed in its usual quantity from the circulating albumen, then from the stored-up albumen in the organs, and finally from the albumen forming an essential constituent of the cells; and thus the disorganisation and destruction of the organs composed of these is brought about.

THE HAMPSTEAD SMALL-POX HOSPITAL.

NOTWITHSTANDING the inquiry respecting the condition of this institution, still pending, has revealed some unpleasant truths, the admissions into the Hospital have recently increased by twenty a day. During the past fortnight 71 fresh cases had been received, 7 had died, and 36 had been discharged, leaving 141 under treatment, as against 113 at date of last report. The total number of patients treated up to the present time had been 5696, of whom 1073 had died, and 4482 had been discharged.

ARMY MEDICAL DEPARTMENT.

THE *Army and Navy Gazette* states that, in consequence of the approaching retirement of an Inspector-General of Hospitals, there is likely to be a run of promotion through the Army Medical Department. In this we believe our contemporary to have been not quite correctly informed, as no Inspector-General, so far as we have learned, at present contemplates retirement. We understand, however, that Deputy Inspectors-General Summers and Meikleham are shortly about to retire.

Rumour also has it that Inspector-General Muir, C.B., is soon to return to England from India to the Sanitary Branch of the Director-General's office, and will be succeeded as Principal Medical Officer of British Troops in India by Inspector-General Beatson, C.B.; also that Deputy Inspector-General F. W. Innes, C.B., at present principal Medical Officer at Woolwich, is likely to be promoted to the vacancy in the list of Inspectors-General on the home establishment caused by Dr. Beatson's return to India, and will succeed him as principal Medical Officer at Netley.

A second tour of Indian service in the highest paid appointment in the Army Medical Department is a piece of good luck not likely to fall to the lot of many Medical Officers of Dr. Beatson's rank, and affords a stronger instance than any that has yet occurred of the inequalities of fortune resulting from the system of promotion by selection of younger men to offices in which there is, practically, no limit to tenure. Dr. Beatson is still very far from the age at which retirement becomes compulsory, and while he is reaping the rich harvest of Indian pay and allowances, amounting to £3360 per annum for five years, other Medical Officers, still unpromoted to the inspectorial rank, are drawing near the 55 years of age which will compel them to retire in the subordinate grade.

The recently published Army Warrant, however, in its provisions for the tenure of the command of regiments for five years only, holds out some reason for the hope that a similar regulation, adapted, of course, to the different circumstances of the case, will shortly be applied to the Medical service of the army. We have long held that to be the only course for keeping the current of promotion flowing at an equable rate, and we hope at last to see it enforced.

THE HEALTH OF OXFORD.

WHEN the Vice-Chancellor issued his minute, some weeks since, respecting the revaccination of all young men who should come to Oxford during the present term, some persons thought the regulation severe, or at least unnecessary. The health of Oxford at the present time, however, will prove that the Vice-Chancellor exercised a wise and sound discretion in the matter. Thus, the returns of small-pox cases last week show 25 fresh cases and 5 deaths; total number under treatment, 40; cases in Hospital, 27; in other parts of the town, 13; 1 case not under treatment. Of the 27 patients in the Hospital, 12 are convalescent; of the 25 fresh cases, 13 have been sent to the Hospital; of the 5 deaths, 3 occurred in the Hospital. With the view of meeting contingencies, the House of Convocation have decreed "that the delegates of lodging-houses be authorised, if they find it necessary, to place a temporary Hospital in the University park, or in the grounds attached to the Museum, as may be recommended by the Medical advisers of the delegates." Dr. Child, the University Sanitary Inspector, states that, though small-pox is still active, the precautions taken had minimised the risk as regards the University. The present measure giving provisional powers was desirable, but purely precautionary.

Since writing the above, we learn that the epidemic of small-pox at Oxford seems at last to be showing signs of abatement. The weekly returns, which are looked after by an active committee of the Local Board, and by the Medical Inspectors of the University and City, show a decided decrease within the last fortnight. The number of

new cases this week is eight, against sixteen last week; and the deaths amount to three, as against five. Of the three deaths this week, two were unvaccinated cases. Much distress prevails among the poorer lodging-house keepers, whose occupation has been taken from them by the epidemic.

PROVINCIAL MEDICAL SCHOOLS.

THE annual return of the number of students pursuing their anatomical studies at the Provincial Medical Schools has just been made to Dr. Ogle, the recently appointed Government Inspector of these Schools. From this report it appears that the total number amounts to 368, being an increase of eleven over the number of last year—distributed amongst the following recognised institutions, viz. :—

	1871.	1870.
Manchester Royal School of Medicine and Surgery	111	98
Birmingham Royal School of Medicine and Surgery	60	76
Liverpool Infirmary and School of Medicine and Anatomy	54	58
Leeds School of Medicine	45	46
Bristol Old Park Medical School	36	30
Cambridge University School	27	—
Newcastle-upon-Tyne College of Medicine	25	35
Sheffield Medical Institution	10	14
	<hr/> 368	<hr/> 357

From the above statement it will be seen that, notwithstanding the slight increase in the gross amount, there is a falling off at all the Schools except those of Manchester and Bristol. There has been a slight addition to the number attending the Metropolitan Schools since that published in the *Medical Times and Gazette*. The number of new entries now amounts to 472, making the total number of registered students now pursuing their Professional studies in this metropolis 1491, or, with those in the Provincial Schools, a grand total of 1859. Well might John Abernethy exclaim, "What is to become of you all?"

HOMŒOPATHY AND SPIRITUALISM.

As a matter of personal experience, we have often observed a correlation between the superstitions of homœopathy and spiritualism. The supporters of the one delusion are very frequently the victims of the other. It may have the good effect of liberating some homœopathic spiritualists from at least one of the phases of error to which their peculiar mental constitution renders them liable, to be informed that, according to the evidence of Miss Houghton before the Committee of the Dialectical Society for the Investigation of Spiritualism. This lady says that the spirits with whom she is familiar—and of whose beneficence, especially in aiding the sick, she said she could cite numberless instances—used, during the last five years of the life of Miss Houghton's mother, to prescribe for her, through her daughter, either allopathically or homœopathically, as might be most suitable at the moment. Now surely such gross inconsistency should be sufficient to shake the faith of homœopathic spiritualists either in the active interference of spirits or in the homœopathic system of Medicine. A doubt having been induced on one point, the other likewise might be found to give way on further examination. As for ourselves, being neither spiritualists nor homœopathists, we do not think there is a pin to choose between the two systems.

TESTIMONIAL TO A PHYSICIAN.

DR. G. C. MILLAR, the Medical Officer of the Hackney Workhouse, has been presented with a handsome dressing-case by a number of patients who had been under his care at the temporary Hospitals for small-pox in connexion with Hackney Union. Moreover, the Guardians voted £100 lately to Dr. Millar for his services.

UNQUALIFIED PRACTITIONERS.

SCARCELY a week passes without cases being reported in the newspapers, illustrative of the evils and dangers attending the treatment of disease by unqualified Practitioners. In a case which occurred last week, an inquest was held in Shoreditch, by Mr. Humphreys, the coroner, on the body of a woman, aged 43. It appeared from the evidence that, on the Sunday week previously, the deceased was in her usual health, but became unwell towards night, and gradually worse until Wednesday, when Mr. Morris, a "chemist," came to see her, and ordered some medicine for her. He said the woman was suffering from a severe attack of erysipelas. On Thursday morning she was found dead in bed. Mr. Morris was applied to for a certificate on the assumption that he was a qualified Medical Practitioner, and he called in a Doctor named Lilley, who refused to give a certificate. Mr. G. D. Phillips, Surgeon of Police, made a post-mortem examination of the deceased. Death resulted from extensive disease of the lungs. There was not the slightest trace of erysipelas, and if Mr. Morris treated the deceased for that disease he made a gross mistake. The coroner in summing up said—"All I can say is, the Government ought to step in and stop the pernicious practice which exists, whereby duly qualified Practitioners are cheated out of their fees—for, if a chemist visits a patient and receives a fee, he is liable to a penalty of £20. A chemist is a very useful person in the sphere in which the Government directs he should move; but the law should be enforced in all cases where he oversteps the prescribed limit." The report in the papers states that "a verdict was returned in accordance with the Medical evidence." It is to be regretted that the exact words of the verdict were not made public. Did the jury censure the unqualified Practitioner? Did they offer any opinion on the evils of illegal practice? These are questions which we hope may be answered.

POISONING BY SYRUP OF Poppies.

INFANTILE mortality from poisoning by syrups, cordials, and carminatives was generally thought to have all but ceased. "Carminatives" and "cordials" have of late years gone almost out of use, and the evil effects resulting from them have diminished in proportion. Syrup of poppies now appears to be the favourite "soother" of infants; at all events, the papers last week contained two cases in which death resulted from the administration of this "harmless dose." In one case the child was eighteen weeks old, and a teaspoonful of syrup of poppies was administered to it, in consequence of its being restless after vaccination. The child died in about twenty-six hours. Eventually the verdict returned was—"That the deceased died from the administration of sixty drops of syrup of poppies, given by its mother medicinally, in ignorance of its poisonous properties and effects." In the second case the infant was five weeks old, was suffering from a bad cough, and three parts of a teaspoonful of the syrup of poppies was administered to it, and it died in the course of a few hours. The verdict was that "Deceased had died from an overdose of poison, administered with no felonious intention." Much misapprehension exists in the public mind respecting the strength of syrup of poppies. It is always a most uncertain preparation, and should never be used except under the advice of a Medical Practitioner.

A TEMPERANCE MOVEMENT.

ALCOHOLIC stimulants, when pure and used with moderation and care, are not to be condemned. No one is justified in showering on them indiscriminate abuse. When their use is carried to excess, or when temperance ceases to be the law that regulates the imbiber of "strong drinks," then they are a curse indeed. The French Academy of Medicine, in consequence of the abuse of alcoholic drinks having much increased in Paris since the civil war, has lately appointed a Commission to draw up a popular warning against strong liquors, from which it appears that brandy and absinthe are the curses and ruin of the working-classes.

PROFESSOR HUXLEY'S LECTURES ON THE ELEMENTARY PHYSIOLOGY OF MOTION, CONSCIOUSNESS, AND THE SENSES.

PROFESSOR HUXLEY, on Monday last, commenced a course of eight lectures at the London Institution on the above subjects. Besides the pupils of the Institution, there was a very large audience of both sexes and all ages. The introductory lecture was admirably suited to attract the attention and excite the interest of his non-Professional hearers, and particularly of the younger portion of them, to whom the course is more directly addressed, and of whom there will be an examination at its conclusion, and prizes awarded to such candidates of either sex under 18 years of age as may have attained the most extensive knowledge of the subject of the lectures.

Commencing with the saying of an ancient philosopher, that in all her operations "Nature worketh by motion," Professor Huxley observed that although very generally true, the aphorism does not include all the phenomena of nature. That the conditions of our consciousness, sensations, ideas, emotions, and volition, although frequently related to and connected with motion in its various forms, are yet essentially distinct from it. Motion as respects individuals is of four kinds:—(1) Independent, or entirely extraneous to, and uncontrollable by, the individual; (2) voluntary; (3) involuntary; (4) mixed, or partly voluntary and partly involuntary. The first he exemplified by the general street traffic of London, the falling of a pebble, or the floating in the air of a feather or piece of down, all of which are perfectly beyond the control of the individual will—at least, such is the general idea concerning motions of this sort, and until the spiritualists establish the contrary opinion by more irrefragable evidence than they have succeeded in bringing forward, such will Professor Huxley's opinion continue to be. Voluntary motion he exemplified by the act of flexion of his own forearm, the mechanism of which he demonstrated by diagrams and by the dissection of the forearm of a rabbit. He traced the whole series of conditions on which the power of flexing the forearm depends, supposing himself to have been requested to perform that motion: 1st. That the weight in his hand should not be greater than he could move. 2nd. The integrity of the tendon of the biceps. 3rd. That the muscle should retain its contractility. 4th. The integrity of the nervous connexion with the spinal cord. 5th. The integrity of the spinal cord above the points of issue of the nerves supplying the limb. 6th. The integrity of the cerebral hemispheres. 7th. The integrity of the auditory nerve. 8th. The integrity of the auditory apparatus acting on the nerve. Commencing again with the sensory organ, he traced the series back again through all its links, and made the matter so plain and distinct that the youngest of his audience could hardly have failed to understand him. This part of the lecture, in fact, struck us as a masterpiece of elementary exposition. The involuntary motions he exemplified by the action of the heart and iris, and the mixed motions by those of respiration. He also described how, under certain circumstances in which artificial conditions overcome the will, as in galvanic action, severe pain, and such-like, voluntary movements become involuntary. The object of the lectures, however, he stated, was not to account for the relation between bodily motion and mental states, which is incomprehensible in the present state of our knowledge, but to analyse the conditions necessary to motion. Finding, at the conclusion of the programme of his first lecture, that he had still a little time to spare, Professor Huxley proceeded to the subject of his second lecture—namely, the contractility of muscle. He exemplified the peculiarity of contraction of all living contractile tissues, as differing from the contraction of other substances—such as iron on decrease of temperature—by being a change of shape without diminution of size. He described in such vivid terms the phenomena of contractility as they may be observed in their simplest and most rudimentary form in the colourless corpuscles of the blood, on a warm stage under a powerful microscope, as must

have stimulated to a most healthy and invigorating degree the curiosity of his younger hearers, many of whom, doubtless, must ever since have been longing for the possession of an instrument capable of displaying such wonders as blood discs, granules, nuclei, and contractile colourless corpuscles. As an educational effort, such a lecture as we had the pleasure of hearing from Professor Huxley, on Monday last, was first-rate. Its true value is to be estimated not alone by the lucidity and extent of the information which it imparted, but by the thirst for more which it must have excited.

DEATH OF DR. WILLIAM DANIEL MOORE.

WE deeply regret to have to announce the death of this distinguished writer and Physician, and excellent man, which took place at his residence, 40, Fitzwilliam-square West, Dublin, on Saturday last. Dr. Moore's health had been failing for some years, and lately his condition had given his friends the greatest anxiety. Next week we hope to give our readers some account of the life of one of the most laborious Medical writers and workers of the day—one to whose learning, industry, and talent our own columns have been so frequently indebted.

OFFENSIVE UTERINE DISCHARGES.

WE understand that Dr. John Day, of Geelong, has recently been using with great advantage a new kind of pessary as a means of removing the offensive odour given off in certain uterine diseases, as cancer, etc. These pessaries are made by gently melting cacao butter, and then adding to it ozonic ether in the proportion of a drachm of the latter to an ounce of the former. The addition of about one-eighth part of white wax will give greater solidity to the mass, and in hot weather seems an improvement. Each pessary should weigh about a drachm and a half. The mass thus prepared retains its active agent, the peroxide of hydrogen, for a month or longer, as may be readily proved by scraping a few fine shavings from a pessary on a drop of blood or pus lying on a piece of white paper, then folding the paper, and holding it between the forefinger and thumb for a minute or two, so as to dissolve the cocoa butter, and lastly adding a drop of tincture of guaiacum (oxidised if pus is used), when a blue reaction will at once take place. We may take this opportunity of directing the attention of our readers to a very commodious and inexpensive case of the test-fluids requisite for the detection of blood, pus, mucus, and saliva, which has been prepared, under Dr. Day's direction, by Messrs. Robbins and Co., of Oxford-street.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

A general meeting of the members was held on Friday at the Society's rooms; Dr. Burrows presided. The statement read showed that the total receipts for the past year were £764 15s., and the total resources of the Society at the end of the year 1870 were £4908 2s. 6d. After deducting the grants made to widows and orphans, and for expenses, the balance in hand was £1848 up to the end of 1870. This most valuable Society is not supported as it deserves to be. It is lamentable to think how many persons there are entitled to belong to it that hold aloof.

FROM ABROAD.—INJECTION OF SEROUS COLLECTIONS WITH ALCOHOL.—THE SIEGE OF STRASBURG—OSTEO-MYELITIS AND PURULENT INFECTION.

M. MONOD has read a paper at the Société de Chirurgie, in which he recommends a simple mode of Treating Serous Collections by the Injection of Alcohol. He finds that the equilibrium between secretion and absorption may be re-established by removing a very small quantity of the fluid, and then injecting a still smaller quantity of alcohol at 40°. His

attention was first turned to the point about three years since, when he was consulted for a goitre. A tablespoonful of fluid was removed by a small trocar, and a somewhat less quantity of alcohol was injected through the canula. No pain or inflammation followed, and a diminution of the tumour soon took place. The injection being repeated in a fortnight, the cure became complete. He has employed the same means successfully in hydrocele in three cases (he himself forming the subject of one of these), and contrasts the simplicity of this mode of treatment, which allows the patient to at once go about his affairs, with the more painful and tedious procedure in the ordinary mode of injection. A modification of Pravaz's syringe, by Luer, was employed, and no pain or inconvenience resulted while absorption took place. When this was slow, the injection was repeated once or twice. The quantity of alcohol injected varied from two to five grammes. M. Dolbeau remarked that, although little could be said of the plan at present, it deserved a trial, its originality consisting in the not emptying the tunica vaginalis, as in ordinary injection. M. Després pointed out the resemblance the plan had to that adopted by Maisonneuve, of first withdrawing a portion of the liquid of hydrocele, and then injecting it again, under the idea that its exposure to the air might confer upon it modifying properties. M. Verneuil was of opinion that this operation, followed as it is by no ill-effects, is well-deserving of farther trials in hydrocele, but he hesitated in recommending its extension, as M. Monod does, to the various forms of hydrarthrosis, and certainly he would not venture to employ it in order to cure more rapidly an hydrarthrosis of the knee-joint. It is even questionable whether in M. Monod's cases the small quantity of alcohol injected exerted such modifications on the tunica vaginalis and the contained fluid as to have led to the cure. Possibly the mere puncture would in these cases have sufficed. At all events, as relapse frequently occurs after simple treatment of hydrocele, M. Monod's success requires confirmation. M. Trélat observed that much depends upon the date of the hydrocele; for when this is recent it sometimes disappears with astonishing facility. He referred to a case of double hydrocele, in which the injection of the one side rapidly cured the hydrocele of both sides. He has, indeed, met with three examples of this. In young subjects, too, recent hydroceles are easily cured. M. Larrey said that hydrocele is so easily cured in young subjects, that mere puncture will usually suffice. M. Monod, in reply, said that he was not desirous of instituting any new mode of practice, but only to call attention to an innocent operation. He regretted that his colleagues had confined their attention to hydrocele, and had not adverted to the case of cystic goitre which he had related. He is quite aware that double hydrocele may be sometimes cured by injecting one side only; and he has met with a still more remarkable case, in which double hydrarthrosis of the knee was cured by an injection of one joint. All he was now desirous of was to induce his colleagues to investigate the effects of the injection of a small quantity of alcohol into serous collections.

We transcribe some passages from an interesting account of the siege of Strasburg furnished by Dr. Beaunis to the *Gazette Médicale* :—

"In spite of every day's emotions, one at last attained an astonishing impassibility, becoming a fatalist in spite of oneself—perhaps the only mode of living quietly amidst such a din. Indeed, one may become habituated to anything, even to being bombarded; and during the latter days of the siege it seemed as if one had never known any other kind of existence. Besides those whose affairs or duties compelled them to traverse the streets, there was an entire category of *bourgeois* and *rentiers* who were under no kind of necessity to leave their abodes, and yet they were to be met with everywhere, continuing, for better or for worse, their ordinary course of life. I have known old men who, during the whole siege, took their usual walks three times a day, frequenting the most exposed districts to gaze like true idlers on the mischief done during

the preceding night. They had only to plant themselves against a wall when the tiles and chimneys came tumbling down, or slip into an alley when they heard the well-known hissing of a shell or the explosion of its fragments. A singular fact, which was remarked by all the Doctors, was that so small an amount of disease was observed during the siege. Apart from the wounded, the sanitary condition was excellent, the children alone suffering from a want of milk, and great mortality among new-born infants resulting from this cause. The immunity was the more strange inasmuch that the conditions of habitations and food were far inferior to their ordinary state, and it is only to be explained by the powerful influence exerted by the moral over the physical condition. In ordinary times the slightest derangement attracts attention, and we are on the look out for ailments; but under these changed circumstances the moral impressions to which one was a prey dominated over the entire economy. For them alone was there room, and the fleeting *malaises* and trifling indispositions which constitute three-fourths of our practice were no longer met with. When disease was really perceived, the economy was already attacked in its innermost depths, and the subjects fell like a mass, and often never rose again. When the siege was over, matters were changed, reaction making itself felt; and among many of the inhabitants a class of affections sprang up, which some Physicians regarded as a special morbid entity, which they termed cellar-disease (*maladies des caves*), but which in reality was only the result of the combined influences which had been in operation during the siege—bad lodging and diet, with moral emotions and exhausting fatigues of every description."

M. Demarquay, in continuation of a former communication (*Medical Times and Gazette*, September 30, p. 414), read a paper at the last meeting of the Academy on "The Permeability of the Bones in relation to Osteo-myelitis and Purulent Infection." In his former communication he had insisted on the absorptive power of the medulla of the bones, the results of his experiments having confirmed those obtained by preceding inquirers; but as these only possessed a physiological interest, he felt desirous of ascertaining how far they explained the pathological phenomena which he had observed in osteo-myelitis. To this end he examined the point whether pure pus, or putrid pus diluted with water, when injected immediately into the medullary canal, is absorbed and carried into the circulation. His experiments, twelve in number, were performed on strong male rabbits, from 60 to 120 drops of pus being injected by means of Anel's syringe into the medullary canal of the femur. The same results always followed—all the rabbits dying between the second and seventh day, after undergoing emaciation, and their temperature rising sometimes as high as 41° or 42° C. until just before death. The autopsies exhibited more or less phlegmon around the seat of operation, pulmonary congestion with pneumonic collections (*foyers pneumoniques*), congestion and ramollissement of the liver, spleen, and kidneys, and metastatic abscesses of the liver.

In respect to the question whether the deaths of the animals were produced by the absorption of the pus in its totality, or merely of its serous constituent, M. Demarquay observed that the appearances noticed by him so exactly accorded with those produced by M. Sédillot by injecting pus into the veins, that there would seem to be no doubt that all the elements of the pus were absorbed. And in order to prove that pus may thus pass from the medullary canal into the venous system, he instituted other experiments, in which he found that absorption by the medulla took place so rapidly that he was tempted to believe that there must be some point of direct communication between the medullary canal and the veins of the osseous tissue. Water rendered of a violet colour by means of fuschine penetrated so rapidly that at first it was erroneously believed that it had been thrown into the muscular tissue. All the viscera were coloured in violet; and in order to prove that pus itself might be in the same manner absorbed, water holding in suspension vermilion, oxide of copper, and gamboge was injected, the injected matters not merely colouring the bones, but penetrating to the heart, lungs, and liver. Similar sub-

stances injected into the medullary canal of the long bones of children issued by the emergent veins of the ends of these bones, which are much more permeable than their diaphyses. In relation to purulent infection as a consequence of osteomyelitis, it is to be observed that intra-medullary injections penetrate into the general circulation like those which are practised in erectile tissues; and this must be permitted either by the osseous veins opening directly into the medullary canal, or by these separations only consisting of a thin wall, like the internal membrane, which yields to a feeble pressure. We can easily understand that pus in its entirety passes into the venous system, where we see vermilion, etc., penetrate with such facility. As a final consequence, it may be admitted that osteomyelitis plays an important part in the production of purulent infection.

M. Vulpian, while admitting that the facts brought forward by M. Demarquay are of high interest, demurred to his explanation of a free communication existing between the medullary canal and the general venous system, inasmuch as anatomical researches have exhibited no difference between the vascular system of the bones and other parts of the body. In experiments which he had performed with Flourens, M. Vulpian had found purulent infection producible in the dog by crushing the medullary substance of the long bones, although, as M. Bouley has shown, the dog is an animal which is very refractory to suppuration and purulent infection.

M. Richet believed that M. Demarquay's injections penetrated the cells of the spongy tissue of the bones, wherein the venous network takes its origin, in which case its spreading thence into all the venous system is nowise surprising.

M. Giraldès observed that in this description of experiments we should carefully bear in mind absorption by the lymphatic system. Recent anatomical researches show that lymphatic vessels exist in greater abundance and in more organs than had been suspected. The vascular network gorged with blood which is found on the surface of the lungs of persons dying of purulent infection, scarlatina, variola, etc., is nothing else than network of the lymphatics. The same disposition exists at other parts of the body; and the researches made in tattooing by Follin, and those of Lacauchie, have demonstrated the great absorbing power of the lymphatics.

M. Colin and other speakers insisted that M. Demarquay had in his experiments produced rupture of the veins, and thus gained access for his injections; but he entirely denied this, affirming that he had always carefully injected the medullary canal without using any force.

AUTOBIOGRAPHICAL RECOLLECTIONS OF THE PROFESSION.

By J. F. CLARKE, M.R.C.S.,

For nearly forty years on the Editorial Staff of the "Lancet."

A STRANGE CHAPTER IN THE HISTORY OF MEDICINE.—Continued.

Experiments on the O'Keys—Failure as to the expected Results—Is Mesmerism entirely False?—Should we not further Investigate it?

As might have been expected, the experiments carried on by Dr. Elliotson at University College Hospital in the summer of 1838 gave rise to a desire on the part of many persons that some investigations should be made into its assumed influence by unbiassed and capable individuals. This desire was expressed by several persons to Mr. Wakley; and accordingly an appointment was made on August 16, 1838, for the girls O'Key to be present at Mr. Wakley's house in Bedford-square. It should be stated that on a previous day Dr. Elliotson had exhibited several of the results which he considered to have arisen from magnetic manipulations and processes. Dr.

Elliotson on this occasion conducted the experiments entirely himself. Mr. Wakley did not believe in the reality of the phenomena displayed, and accordingly the appointment was subsequently made for the 16th, as stated above. In consequence of the note of Dr. Elliotson not arriving until twelve o'clock on the day appointed for the meeting (to be held at three), Mr. Wakley had not invited any persons to witness the experiments; but Baron Dupotet, Dr. Richardson, Mr. Hering, and myself had been invited by Dr. Elliotson, and attended accordingly. Mr. George Mills, the sub-editor of the *Lancet*, was also present. The experiments were first performed on Elizabeth O'Key, and were repetitions of those which had been performed on many occasions by Dr. Elliotson with various results. The first experiment had reference to the powers of nickel in producing "startling mesmeric effects." Dr. Elliotson believed that this metal exerted a more powerful influence on O'Key than any other agent. On this occasion, the girl, seated in a chair, being, as was stated, in the "ecstatic delirium," a piece of thick pasteboard was placed in front of her face, and held so that it was impossible she could see what was passing below or in front of her. The experiment was to test the nickel in opposition to lead, which, Dr. Elliotson asserted, might be employed freely without producing any effects whatever. Mr. Wakley seated himself immediately in front of O'Key, and at a short distance from her. He managed to hold the metals in his fingers in such a manner that she could not possibly know from merely touching the substance, or from its form when he applied it to her hands, which metal was being used. The lead was said to be ineffective when applied to the skin, whilst the nickel produced most extraordinary results. In the first experiment the lead was applied alternately to each hand of the girl, but in such a manner as might have led her to believe that both metals were used. There was no effect whatever. After some time, Dr. Elliotson having held the nickel in his hand to charge it strongly with magnetic influence, the metal was applied. Of course the metal had been increased in temperature by having been in Dr. Elliotson's hand. The lead had been held by Mr. Wakley previously, to heat it in a similar manner. Thus mere temperature would offer no guide to the girl as to which metal was being employed. The nickel was now used as the lead had been applied. A pause ensued: but the expected results did not appear. In the space of about a minute the lead was again used, and then again; and after the last application of the nickel (the lead having been repeatedly applied during the interval) the face of the girl became violently flushed, the eyes were convulsed into a slanting squint, she fell back in the chair, her breathing was hurried, her limbs were rigid, and her back and abdomen assumed the position which is produced in an attack of opisthotonos. In this state she remained nearly a quarter of an hour. Now arose a dispute as to whether the results were obtained by the nickel or not—Dr. Elliotson contending that they were, but at a longer interval than usual; and Mr. Wakley declaring his belief that they were not. Besides, what was the value of experiments when no *certain* results could be relied on, and if the effects were to be attributed to one metal so long after another had been employed, as on that occasion? It was eventually decided that another experiment should be tried, Dr. Elliotson suggesting that nickel in its magnetised state should be alone employed. It was now arranged between Mr. Wakley and myself that no nickel whatever should be employed; and the moment Mr. Wakley received the magnetised nickel from Dr. Elliotson he put it on one side, and I, unseen by any person, placed it in my waistcoat pocket, and walked to the window, a distance of at least eighteen feet, and there I remained until the termination of the experiment. Mr. Wakley again employed both hands, but his fingers were so placed that it was impossible for anyone excepting the operator to know what he was holding. On applying the substance which he held in his left hand to the right hand of the girl, Mr. Hering, who was standing near, said, with much sincerity of feeling, in a whisper, "Take care, do not apply the nickel too strongly." In a moment after all the symptoms mentioned in the former experiment came on, only with increased violence. Dr. Elliotson again observed "that no metal but nickel had ever produced these effects; that they were most extraordinary"—in fact, "that they presented a beautiful series of phenomena." The paroxysm lasted upwards of half an hour. On retiring to another room, Mr. Wakley informed Dr. Elliotson that no nickel whatever had been used on that occasion—he had not even approached the patient with it; that the nickel had been put away unobserved, and that he had merely rubbed upon the skin of the girl a piece of lead and a farthing, which

he had respectively held in either hand, the metals being so held that no person could see what he was applying. Dr. Elliotson asserted that he had seen the nickel used; he believed Mr. Wakley had applied it without knowing it himself. He was positive that the effects could be produced in no other way. After a good deal of discussion, which at one time assumed an angry aspect, I was called forward, and produced the piece of nickel from my waistcoat pocket. The experiment was again and again repeated, always with the same results, the nickel on no one occasion having been used. Dr. Elliotson was much puzzled, but said he had no doubt that some satisfactory explanation would be found of the circumstances, which would explain all appearance of anomaly in the results. After the girl had some time recovered from the apparent paroxysm, Mr. Wakley suggested that the magnetised nickel should be rubbed over both hands freely on the skin in different places, but not exactly in the manner in which the lead and farthing had been employed. No effect whatever was produced by this application of the nickel. Dr. Elliotson after this admitted that he could "not explain how the thing had occurred; it was most extraordinary, but still he had not the slightest doubt that the subject would yet admit of a satisfactory explanation." Mr. Wakley contended that the experiments were conclusive with reference to the character of the supposed phenomena, and that no further experiment was necessary. Eventually it was determined that the nickel should be again tried on the following morning. Accordingly, at nine o'clock the following morning the girls came to Mr. Wakley's house with Mr. Wood. The Doctor now stated that he believed that the apparent contradiction which had been exhibited on the previous evening arose from the circumstance that the lead in the last three experiments had been rubbed on that portion of the skin where the nickel had been applied in the first experiment, and thus the effects exhibited arose, in reality, not from the mesmeric influence of the lead or the farthing, but from the mesmerised nickel. Mr. Wakley replied that he believed O'Key could herself give a better explanation of the supposed phenomena than anyone else. The experiments were now again renewed, Mr. Wakley stating, however, that he could take no interest in them after the exposition of the previous evening. The piece of pasteboard being held before the girl's face, instead of applying the nickel, Mr. Wakley used the lead. The girl repeatedly fell back in the chair during these operations, in what has been called the "mesmeric sleep." The apparent sleep was produced so repeatedly from the use of the lead, that Dr. Elliotson said he must admit that he had been deceived in supposing that lead could not convey the magnetic influence. After a considerable time had elapsed, the nickel was applied to her hand in the same way that the lead had been, both metals being of the same temperature. Apparent sleep was still the result, without convulsions or rigidity. At length Dr. Elliotson proposed that the nickel should be applied to the inside of the lips. The two metals were therefore thus used—first the lead, then the nickel; but the lead by far the more frequently. Presently all the effects which were represented to be the results of the application of the nickel were apparent, and the patient appeared to be thrown into as violent a paroxysm as she had exhibited during the trials of the previous evening. Dr. Elliotson, in the performance of these experiments, complained "that the lead had been applied too soon after the nickel, that time had not been given for the latter to operate, and that it was not fair to use the lead so much more frequently than the nickel, but that the same chance should be given to the latter as to the former." Mr. Wakley, however, contended that in testing the truth and accuracy of the alleged phenomena any person would be justified in using the lead throughout the entire day, and not employing the nickel at all, especially since it had been contended that when the nickel was once used, frictions on the same parts at subsequent periods or remote dates, with any other metal, would produce the results which were attributable to nickel alone. Mr. Wakley being called away immediately after these experiments, Dr. Elliotson and Mr. Wood left the house; but the experiments were again repeated with a piece of nickel which I obtained from Mr. Garden's shop in Oxford-street. The results were quite as unsatisfactory as those of former experiments.

After the experiments on Elizabeth O'Key with the lead and nickel, a series of experiments were commenced on Jane O'Key—a tame imitation of her sister. These experiments, which were numerous and somewhat complicated, consisted mainly in the testing the supposed effects of mesmerised water and mesmerised gold. For instance, it was said that water which had been mesmerised by having the fingers of any individual immersed in it for a few moments, would "mesmerise" either of

the O'Keys immediately they drank of it; that gold "mesmerised" by being held in the hand would have the same influence on the O'Keys if they touched it. Many experiments were tried with the object of testing this assumed power: they signally failed in proving any uniform or satisfactory effect. Mesmerised water and gold produced no effect; unm mesmerised water and gold did produce apparent effects of a most startling kind.

Well, it cannot be doubted that the *exposure* of Mr. Wakley was conclusive on the point that nickel did not exert the specific influence which Dr. Elliotson believed it did on Elizabeth O'Key. But how are we to explain the phenomena which result from mesmeric "passes"? It surely cannot be assumed that the terrible convulsions, the opisthotonos, which were observable in the O'Keys during the experiments were the result of simple voluntary power. We believe it impossible that it could be so. The experiments of Mr. Wakley, whilst they proved some things, failed to prove others; and, in fact, left the subject under discussion still more mysterious. Most people doubted—indeed, denied—the reality of the prophetic power of Elizabeth O'Key, and some of the more striking phenomena exhibited by her sister Jane. But there were some experiments so fairly performed, and the results so palpable to all, that no one could fairly deny that there had been "effects," whose cause, by whatever name we might call it, was mysterious, strange, and called for calm and deliberate inquiry. Perhaps, after all, the question may be fairly put upon the grounds urged by a writer at the time when the experiments in question were performed. "How," says he, "does the question stand? The existence of somnambulism, and catalepsy, and delirium is admitted on all hands; and it is an elementary truth that one human being can affect another; that the whole system can be agitated in a great variety of ways, and driven into action voluntarily and involuntarily. But all these influences act through the senses; they are submitted to laws of distance, etc., and, under the same circumstances, give rise to phenomena which only differ in intensity in different individuals. The mesmerists assert that the body can be influenced independently of the senses, independently of the intellect, independently of anything that can excite the imagination; that in this respect it is like iron to the magnet, acted upon as an unconscious thing is acted upon, and thrown into mesmeric sleep, catalepsy, motion, delirium, by an unseen wave of the hand, or a look, a sovereign grasped for a minute, or water in which the fingers have been dipped. Now, we never declared any of these things impossible, we never denied the possibility of prophetic power; but we demanded evidence adequate to the improbability of the alleged phenomena. O'Key lays her hand upon a sovereign, and is fixed or prostrated to the earth; we lay our hands upon the same sovereign, and perceive no such influences; other persons place their hands on the mesmerised sovereign, and no effect is produced—a thousand persons handle the metal and remain unaffected. Gold is exchanged in every part of England by all classes of persons, and has been so exchanged for centuries, and sometimes in large "mesmeric batteries"; but no individual, as far as is known, has ever been thrown into a state of catalepsy by it, or exhibited the mesmeric phenomena. The experience of mankind is in the one scale, the O'Keys' in the other."

There is much eogeny in this and similar kinds of argument; but it is doubtful whether the experiments to which they refer were sufficiently varied to test the real effects of animal magnetism, if such exist. It is admitted by most persons that there is such an agency; but great differences of opinion exists as to its power and degree. It is certain that Dr. Elliotson did much to bring the whole subject into ridicule, and to make sober-thinking men disgusted with it. It will remain for some future observers, probably, to draw more definitely the fine lines which separate the true from the false. The arguments advanced by believers in mesmerism is, that there is no phenomenon said to be caused by the mesmeric influence but has its counterpart in what we observe where no such agency has been applied. Thus, the somno-vigilium of O'Key had a likeness to somnambulism; her "midsummer madness," to delirium; and her long insensibility, to trance. Knowing so little as we do of the causes producing these different states of the nervous system, it would be at least premature to denounce "animal magnetism" altogether as "a delusion and a mockery." It has occupied the minds of some of the greatest philosophers, and some of the least imaginative amongst them have declined to altogether reject it.

Whatever may be the final result of future inquiries, the history of the O'Keys will always remain "a strange chapter in the history of Medicine."

THE HAMPSTEAD HOSPITAL INQUIRY.

TWENTY-SEVENTH DAY.

The inquiry was continued on Thursday, October 26, before Mr. Henley and Dr. Buchanan. Mr. Williams and Mr. John Humphreys appeared for the Managers, and Mr. Collins and Mr. Bucknill represented the "complaints" in the *Times*.

The witnesses examined were the manager to Messrs. Nettlefold, eggs and butter contractors; Jones, the wardsman of the convalescent wards; Mr. Charles Game, a meat contractor; and Taylor, a wardsman. These all gave evidence relating to the management of the Hospital. Mr. Game stated that no "clods" or "stickings," nor even "chucks," were sent out by his firm to the Hospital—only the best parts of the animal. Jones and Ward gave evidence as to the filthy condition in which patients were admitted, and asserted the excellence of the food and the cleanliness of the arrangements. In answer to a question by Mr. Collins, Mr. Williams declined to call Mrs. Hughes, the night superintendent, on the ground that she had been in communication with the Assistant Medical Officers.

TWENTY-EIGHTH DAY.

The witnesses examined on the part of the Managers were Mary Provost, a nurse; Mr. Drake, the Steward of the Hospital; and Mary Bonfield, another nurse. Nothing fresh was elicited. The nurses gave evidence contravening the charges, and the Hospital Steward deposed to the excellency of the provisions supplied.

TWENTY-NINTH DAY.

On this day Dr. Grieve, the Medical Superintendent of the Hospital, was called and examined by Mr. Williams. He said that he had been Superintendent of the Princess Alice's Hospital at Darmstadt, had been in the Royal Navy as Medical Officer, and had held other appointments. The Hospital was built on an admirable plan, in his opinion, and the system of ventilation was perfect. The space allowed 1800 cubic feet to each bed. The bath-room and lavatories were quite separate from the wards, and hot as well as cold water was laid on to each, except to Nos. 4 and 5 wards (those which were brought from the Fever Hospital Grounds at Islington). The water-closets were also separate from the wards, and had a separate system of ventilation, apart from the wards. The bedsteads were of good construction, and the bedding was everything of the best. He then described his daily duties in the Hospital. At 9.30 each morning he went to the Hospital, and was there at prayers. At 9.50 the Medical officers had consultation. Between that time and 10.30 he saw the other officers and received reports from the artisans and others, and gave instructions for work to be done. The other part of the morning was taken up with going through the wards. Then he had to make the daily returns to the Local Government Board and to see visitors. He went to Islington at four, and returned from Islington at half-past six, and visited the Hospital at half-past eight. The duties of the Assistant Medical Officers were to take Medical charge of the wards allotted to them, to draw special attention to any case presenting any peculiar features, and they were to order the class of dietary requisite for each patient, and if the patient did not get what was ordered, the Medical officers should have reported to him. They should have called his attention to any case requiring "extras," and his sanction was to be obtained by initialing the order. Their duty was also to see the incoming patients, and they should have seen every case admitted. They knew their instructions, as he had given them repeatedly, and he had required that one should be in constant attendance at the receiving-wards when patients were admitted. If the night nurses had found short supplies of milk or beef-tea for the wards, it was their duty to have come to him for an order for more. This was requisite, for the Assistant Medical Officers did not make their evening visit until nine at night, and as the cook necessarily went off duty at some time the order had to be there before the Assistant Medical Officers came. The duties of the Assistant Medical Officers were purely Medical duties, and they should have reported any nurse who left her ward without the supplies necessary. He had general duties himself. He was put into the position of Medical Officer to meet a great emergency, with orders to do the best he could. He reported from time to time to the Committee, and consulted the Chairman of the Committee (Mr. Wyatt) whenever it was necessary. He was frequently in the wards at dinner-time, and spoke frequently to the people. On one or two occasions in the hot weather it was pointed out to him that meat was tainted, and he ordered fresh meat to be

given. There were no general complaints of insufficiency. The man Ridley complained, not that there was not enough served out, but that the wardsman Gee served it out unequally on account of a "grudge." Another man, named Wade, said he could eat from a pound to a pound and a half of meat for dinner and drink plenty of milk for breakfast. The witness asked him to be weighed, and witness put the man on a working party, with the superior rations given to workers, and the man, when he went out, weighed 10 lbs. more. There were no complaints of shortness of milk. Mr. Kynaston had suggested only one thing in regard to the diets—that persons on the low diets should have an unlimited supply of milk; but witness pointed out that this would be impracticable, for no institution could be carried on on such uncertain data. The order was given in the beginning of June that complaints or remarks by the Assistant Medical Officers should be given in in writing on the daily reports. It had never occurred that any patients had wanted for food. The dietary tables contained a sufficient supply of food for the patients, but those tables (No. 1 and No. 2—the low and the ordinary diets) were not regarded at all as the limits of the dietary to be supplied, but only as guides as to the quantities to go to the wards. In addition to the ordinary diet on the dietary tables, the patients did receive other vegetables than potatoes. The reason he took the uncooked meat as a standard was that he believed the patients would prefer to see the meat cut off the joint; and then, too, the appetites varied, and the nurses could suit the appetites of those they served by giving some more and some less. Mutton was by order sent chiefly to the acute wards, and beef to the convalescent wards—this by requisition, at one time the convalescents saying they had too much mutton. He had heard no complaints of the hardness of meat—that it was like "gutta-percha," or as "hard as a board." This was untrue, and the only complaint he had heard was that one had had too much fat. He commenced his duties at Hampstead with a great objection to mechanical restraint, but he held that mechanical restraint was above all to be recommended as against manual restraint, and of restraint by the strait-jacket or by the sheet, he should choose the latter. The delirium in small-pox was a peculiar delirium, and was more frequent in men than in women. In persons who had been of intemperate habits it particularly showed itself, and partook of the character of delirium tremens. The patient would wake up suddenly in delirium, and so cunning as to be on the sill of a window without the nurse having any idea of his condition. He had seen patients restrained with a folded sheet, but never with a twisted sheet or with a rope. The strait-jackets were obtained at the request of one of the Assistant Medical Officers. Where restraint was not used, the injury to the patients was likely to be great, for fights would go on, and once even Mr. Greaves was said to have been knocked down by a delirious patient. The Assistant Medical Officers had never once made anything like a complaint of persons being restrained by mechanical means, and they well knew his own dislike to restraint, as, indeed, did everyone in the Hospital. Light occupations were found for those convalescent patients who would work, and for those who could not or would not work plenty of amusements were found—papers, books, games, music, and the like. Each convalescent had to keep his bed in order, and assist in keeping the ward in order. Of those in the convalescent wards, 95 per cent. were physically well, of whom 60 per cent. were as well as ever they were in their lives, and they were only kept in to prevent a spread of the disease; in fact, they were in a sort of quarantine for the public safety. There was no nursing required in the convalescent wards—only an occasional poultice. The only punishment in the Hospital was stoppage of beer, and that was only inflicted, from first to last, in twenty cases. Coming as the patients did from all parts of London, they were not all "lambs," and it was absolutely necessary to have wardsmen for the men's convalescent wards. The beef-tea was made from the Australian extract on Liebig's process, and he tasted it every day. Arrowroot was added to supply starchy matter. It was very good. The cooking arrangements in the Hospital were excellent, and the food was roasted on an excellent principle by a gas apparatus. He considered the Sisters and nurses all did their duty admirably, and in addition to these convalescent help was given from the very first. With regard to the alteration which was made in the low diet, the Assistant Medical Officers got into the habit of sending down pieces of paper up till midnight, and the steward complained that he could not get to bed; and, for another thing, no idea could be obtained of the quantity required from day to day. Witness, the morning after this was complained of, called the

Assistant Medical Officers together, and spoke to them on the subject, and as Mr. Aikman considered that milk diet was better than beef-tea diet, witness made the changes of giving an extra pint of milk and reducing the beef-tea. Mr. Kynaston had made random statements as to patients having unlimited food and such-like; but he could not advance any facts in support of his views, and witness had asked him to show a patient who had suffered from want of diet or nursing, or anything else, but he could not and did not. Mr. Greaves had complained of a nurse being drunk, and witness spoke to Sister Frances, who discharged the woman. The Committee had given everything ordered, and there had been no undue economy recommended or acted upon. A limitation was placed upon the ordering of such extras as eggs and stimulants, by his signature being required, because they ordered a very large number day after day for a week. He had had no unpleasantness with Mr. Greaves in regard to the Poor-law Orders. Mr. Greaves had spoken to him about taking in patients who were sent when the Hospital wards were full. He had taken in some two or three above the ordered number, and on Mr. Greaves saying, "What would the public say if it were known the Hospital was over-full?" he said that he could defend himself before the public, for he believed he was doing what was necessary for the public good, for if these patients were sent back they would have spread the disease. These cases had been sent by the parishes even when it was known the Hospital was full, and the patients' lives would have been endangered if they had been sent back.

The witness was examined on many other points given in evidence at first. Some of the statements he controverted and others he explained, and made them appear in a light different from that in which they were first presented.

The inquiry was then adjourned.

THIRTIETH DAY.

Dr. Grieve was then recalled, and questioned by Dr. Buchanan. He said there was no hard-and-fast line laid down that Mr. Greaves, when he first came, should have no power regarding the diets, and it was certainly understood that if anything was required beyond the diets, Mr. Greaves should send a nurse for it. There were no complaints from Mr. Greaves at any time of an insufficiency of diet, and, as a matter of fact, Mr. Greaves did order extra supplies, even before, as well as after March 6, when an alteration was made in the low diet by an addition of half a pint of milk *per diem*. Mr. Greaves had certainly made no general complaint of the quantity of meat. If any patient had complained to Mr. Greaves of not receiving a sufficiency of food, as was stated to be the case with regard to the witness Owen, the butcher, who told Mr. Greaves he wished he could get a joint in, Mr. Greaves had the power to order the man another diet, and he should have mentioned the complaint. Mr. Greaves had actually ordered persons a diet and a half and two diets, but not the "extra" diet. It would certainly not be proper to give some patients, when in particular stages of convalescence, all they could eat. Mr. Greaves and the other Assistant Medical Officers had repeatedly ordered one and a half and two diets for one patient, and witness repeatedly told both Medical officers and nurses to give the patients all requisite food, and not to stint them. Mr. Kynaston had certainly made no definite report of shortness of nurses. He had said that the nursing was not "equal to Guy's"; but he expressed no nearer or more definite opinions—for they were not official "complaints" in any shape or way. There were certainly no "constant complaints" from Mr. Kynaston as to want of nurses, or as to their being overworked and unable to attend to the duties of nurses. The nurses worked hard, as they all did. The matter spoken of by Mr. Greaves with regard to that gentleman giving a sanction to restrain mechanically at one time and then retracting it was never referred to witness. Even if there had been any general regulation about mechanical restraint, the Medical officer of a ward would have had power to modify the regulation according to circumstances. The matter of mechanical restraint was never referred to witness, and his opinion and objection to it were well known. With regard to the dead body left in the bath-room, witness went about it immediately he was told of it, and found that it had been removed before he could get there, for one of the Sisters had taken the trouble to get the man to remove it. It might have been removed earlier if anyone had sent for the man, and when witness had the matter brought to his notice he at once severely reprimanded the man, and took steps to prevent such a delay again. When he was absent the senior officers were responsible for the care of the Hospital, these officers being the Senior Assistant Medical officer, the Steward,

and Sister Frances. He had never been away from the Hospital more than on three occasions during the whole time the Hospital had been opened, except on official duties at Islington and these offices.

Dr. Buchanan: The Committee ought to have made you go away for a time. They should have compelled you to go, and not to remain so shut up.

Witness replied that the Committee were kind enough to try and draw him away from the Hospital many times, but he did not leave except for a couple of hours a day to go to the Islington house. He proceeded to say that it came to his knowledge in June that the Assistant Medical Officers did not regularly see the patients on admission because the Medical Officers could not be found, and witness at once requested the Assistant Medical Officers to leave word at what part of the place they would be when patients came, so that they could be found when wanted.

Cross-examined by Mr. Collins, the witness said he was in Glasgow Hospital in 1860 and 1861 for nine or ten months as House-Surgeon and House-Physician. He was twice at Greenock, once in 1858, and in 1859 for a year as Resident House-Surgeon of the Hospital, of practically 150 patients, but nominally of 250 beds. He left Greenock for a winter, and returned there for a time. He left Scotland for Shanghai in 1861, and fitted the *Acorn* as a Hospital ship, under a commission from Admiral Sir James Hope, and was in charge of it. He came home in the *Snake*, served in the *Warrior* for a few months, then left the Royal Navy, and went into private practice in Yorkshire. He went afterwards to Germany, and took service in the Princess Alice's Hospital at Darmstadt, but not as Medical Superintendent—that was a mistake. He was candidate for the charge of Homerton and also for Stockwell Hospital, but was appointed at Hampstead before the others opened. He had no fault to find with Mr. Aikman, and, to the best of his memory and belief, he did not say anything about Mr. Aikman taking one "Guy" and he taking the other. Mr. Aikman and the others had not made frequent representations about tying down or restraining; no complaints of such a character were made. The witness's examination then ran upon the number of nurses in the wards, especially in the children's wards, the purpose being to show the number of nurses to the actual number of children in an acute stage. The witness said that only one-half of the children at the worst time were in an acute stage, and the other half, therefore, did not require so very much attention. There were two night nurses to the acute cases. Children were kept in bed by a sheet being tied to the sides of the bedstead and broadly folded across the children. This was done with his sanction. The number of nurses in the Small-pox Hospital was in the same proportion as when it was the Relapsing Fever Hospital, and he was responsible for the number. Small-pox patients did not require more nursing than fever patients, for small-pox patients quickly convalesced, and they were brought in to assist; but this would not be the case in general fevers, and therefore more nurses would not be required in small-pox than in fever. He would not speak positively of relapsing fever, for he had had no experience of that. He had repeatedly told the Assistant Medical Officers that it was their duty to see that the supplies of milk and other nutrition were served out judiciously by the nurses, and to report any who did not; but, as a fact, they never did report one nurse. He did not complain of the orders, as orders, which the Assistant Medical Officers gave for irregular supplies in consequence of the injudicious serving out of supplies, but he had spoken to them about the irregular manner in which these orders were given, and of the inconvenience caused by their sending orders up to a late hour at night. He had told Mr. Kynaston that he would not alter the dietary, for that officer advanced no reasons for altering it. The nurses in the earlier time frequently came for additional supplies of milk, and even when the dietary was altered, but he could not say whether the Assistant Medical Officers sent them or not. The whole of the dietary was in his hands, and he kept it, so as to know what was going on in the Hospital, and when any application was made to him he attended to it, and he never refused any application for food. He never had reported to him, and he never knew, that the beef served to the children for a whole fortnight had been very hard and black, as spoken to by the child Cripps. He was often in the children's wards at dinner-time, and he never saw such beef. He altered the dietary of the children's wards (in regard to giving stew for meat) on Sister Agnes asking him. In small-pox cases the sheets would be stained two minutes after being put on the bed. As a fact, he never told the

Medical officers not to complain respecting the diets, and that the nurses were to do so instead; and the fact that the Assistant Medical Officers did make references to the diets on the back of their daily reports proved the contrary. He had told them that the nurses were to report anything regarding the administration of the wards direct to him, and that it was not part of the Medical Assistant's prescribed duty to report otherwise than on direct Medical matters. If anything wrong had come under the Assistant Medical Officers' attention regarding the wards, and they had reported it before the nurse, he should have reprimanded the nurse for not reporting. Mr. Kynaston reported about some bed-cords breaking, and witness told him that the nurse had already reported it; but witness never said, "It don't matter to you if the patients die upon the floor—it's out of your province." It was not at all unlikely that he said, "Kynaston, you would not have been responsible for such a thing," although of course it was expected that an Assistant Medical Officer would mention anything he saw wrong. The Assistant Medical Officers had no responsibility in the administration of the Hospital. The written reports of the Assistant Officers were kept in his office, which was used as the committee-room. These reports were never officially placed on the committee-table, and he never more than incidentally mentioned the existence of these reports. These were made up and sent in to him for his own information, and he used these reports for making up his statistical papers of the Hospital. He never brought the reports to the Committee until after the letter appeared in the *Times*. He never told the Assistant Officers that the Committee did not see their reports, or that it was no use to go to the Committee. On some matters, in regard to private complaints of their own, he told the Assistant Medical Officers to go to the Committee; but on others he told them that it would be of no use their going to the Committee with opinions without facts. The rule regarding the initialing of "extras" was objected to by Mr. Aikman, who resigned, as he considered this an insult, and he withdrew the resignation when witness pointed out to him that this applied to all "extras." The rule was not modified to suit Mr. Aikman. An egg was an "extra," and eggs stood in the same category as champagne and chickens, and freedom to order one would have included freedom to order the others, or anything else. He had a good opinion of Mr. Aikman's abilities, and he had not found fault with that gentleman's conduct while in the Hospital. But, though he had confidence in Mr. Aikman's abilities, and no reason to find fault with him, he did not make any difference between him and the others in regard to this matter.

The witness was then cross-examined in respect to the child Stokes, and he said that when he had his attention called to the child he looked at her, and approved the treatment, but he did not take the case out of the hands of the Medical attendant, Mr. Aikman. The witness was taken over the points of evidence in the case, and he said he had a case now lying in the Hospital nearly as severe as that of the child Stokes, and she was recovering. When he was taken to see the child he did not supersede Mr. Aikman, but he approved the treatment. He held that from the time he saw the child her treatment was proper. He was taken over other matters at some length, and the Court was then adjourned.

THIRTY-FIRST DAY.

The cross-examination of Dr. Grieve was continued. He was taken in detail over many matters, and he said he did not reserve any cases in the wards for special treatment by himself. He relied upon Mr. Kynaston in the wards under that gentleman, and as to his opinion of Mr. Kynaston, he would say he believed that gentleman did the best he could; but witness differed from him at times as to the Medical treatment he pursued in cases.

Regarding the "statement" signed by the nurses, he stated that this was only a paper of questions asked and answered.

Questioned by Dr. Buchanan, the witness said an order for a poultice was not entered on the bed-card of a patient. A case-book was kept in the Hospital at first, but it was given up after a time. In his opinion, an order of such a thing as white precipitate should have been entered on a card, but he did not think stavesacre or carbolised oil was entered on a card. It was certainly advisable that all medicinal treatment should be recorded, but he never called the attention of the junior Medical officers to the necessity of this. Verbal orders regarding applications to the head were, the witness thought, carried out; but a Medical officer should see the patient on whom it was proposed to apply such things. In the case of

the child in whose sore head the maggots were found, he thought the Assistant Medical Officer (Mr. Aikman) was responsible, and he was not exculpated from his responsibility by his having given general orders that the heads should be kept moistened with carbohc acid. There was no pressure upon the nurses at that time, and it was not their place to see to such things. When he saw the case he asked Mr. Aikman how he had allowed the head to come to that state. Mr. Aikman made some excuse, but he made no complaint regarding the nurses.

By Mr. Williams: He never gave the young men to understand that they were not responsible for the well-being of the patients committed to their charge, nor said anything to them which could be tortured into that. He had always told them that if they saw anything which was in the least way detrimental to the Hospital, they were to speak to him as gentlemen. The Assistant Medical Officers had sole Medical charge of the wards handed over to them, and it was their duty to call witness into consultation in any peculiar case; but it would not have been his duty to interfere in that particular case after the consultation without the knowledge of the Assistant Medical Officer. The first persons who should have seen the patients when admitted to the Hospital were the Assistant Medical Officers, and in so dangerous a disease as small-pox it was a gross breach of duty for them not to have seen the patients, and he implicitly trusted to them to discharge this duty. He had no means of knowing that the patients were not Medically inspected unless the fact had been reported to him; and when these gentlemen knew, as they must have known, that patients were admitted without being Medically inspected, it was their duty to report to him. It was the duty of the Assistant Medical Officers to see bedsores dressed, and of the nurses, superintended by the Medical man, to dress them. In some cases bedsores would arise, and he would not take a bedsore as an evidence of neglect; it was not a fact that Ward No. 9 was without a night nurse for a fortnight. His work in the Hospital varied in the amount of time it took. At first he worked from twelve to sixteen hours a day, and the minimum of the work up to August would be ten hours a day. If it had been brought to his attention that meat was unfit to eat he should have reprimanded the steward and reported him. The number of nurses at Hampstead had not been decreased since September, and there was good reason for not decreasing the number, for small-pox was again on the increase, and on the previous day thirty patients were admitted. The witness was taken over many points, and in the course of a very long and exhaustive cross-questioning gave his version of facts dealt with by others. He wished it to be explained in regard to a mistake as to his position in Germany, that he was attached to the Orangeries Hospital at Darmstadt, and not to the Hospital under Dr. Mayo.

Dr. Bridges and Dr. Radcliffe, Medical Inspectors of the Local Government Board, each of whom had visited the Hospital on six occasions, deposed to having found things in excellent condition in the Hospital. Dr. Radcliffe said at no time when he made these visits was he expected or his coming known. He visited the wards five times, and he thought the condition of every patient excellent. What he saw at Hampstead he saw with unmixed admiration and astonishment altogether; and in this he spoke of the state of the wards, the state of the patients, the state of the linen and beds, as far as he saw, and the state of the officers, and he could appreciate the difficulties the Managers had to deal with in the unprecedented features of this epidemic. He had not been questioned as to his views before coming here, and, in fact, he could not communicate with anyone regarding his views.

Mr. Ernest Hart, Deputy Inspector Gordon, C.B., Dr. John Murray, and Dr. Perry, of the Fusilier Guards, deposed to having visited the Hospital at various times, and having found things clean and in excellent order. Dr. Gordon said that, having visited the Hospital on his return from Paris, he found it "a picture of completeness and efficiency." Wards, linen, and patients were very clean.

The inquiry was then adjourned.

MORE BABY-FARMING.—A woman named Murrant, 49 years of age, was charged on Monday, at the Lambeth Police-court, with having caused the death of an infant 5 weeks old. The deceased was the illegitimate child of a young woman who had entrusted it to the care of the prisoner, but it was weak and sickly from its birth, and when it died the body weighed only 3½ lbs. As there was no proof of neglect on the prisoner's part, she was discharged.

REVIEWS.

Pulmonary Consumption: its Nature, Varieties, and Treatment.

With an Analysis of One Thousand Cases to exemplify its Duration. By C. J. B. WILLIAMS, M.D., F.R.S., and CHARLES THEODORE WILLIAMS, M.A., M.D. Longmans. 1871. Pp.402.

It will be universally acknowledged that the claims of Dr. C. J. B. Williams to be heard on the subject of pulmonary consumption are of no ordinary character. Himself one of the pioneers—or, at least, in this country, one of the earliest promulgators and cultivators of the science of physical diagnosis, as learned from auscultation and percussion—he has lived to see a practical knowledge of disease of the chest perhaps more thoroughly and extensively possessed by the Practitioners of the Healing Art than a knowledge of the diseases of any other region of the body. That the earlier writings of Dr. Williams contributed in a large degree to the extension of the study of chest disease, will be readily allowed by all who have any acquaintance with the history of our Medical literature. But it is not only as a writer on the diagnosis and clinical history of diseases of the thoracic viscera that Dr. Williams has a claim on the present generation, but also as an original worker in the field of microscopic pathology. The germs of many of the modern discoveries in tissue pathology will be found in the "Principles of Medicine," and Dr. Williams's early views on the subject of tubercle, although confessedly imperfect, were clearly in advance of the time at which they were enunciated.

Very few living Physicians could offer an *apologia* for a book on disease such as that to be found at pp. vi. and vii. of the Preface to the volume before us, with the same truth and good taste with which it falls from the pen of Dr. Williams. He there recounts that during a period of nearly fifty years pulmonary consumption has been one of the objects of his most constant study; that he learned what Alison, Laennec, Andral, and Chomel had to teach from the men themselves at the bedside and in the dead-house; that for the following twenty years the knowledge thus obtained was applied and extended in the wards and at the post-mortem tables of St. George's and University College Hospitals; and that during the last forty years he has had an amount of experience in diseases of the chest in private practice which has probably not been exceeded by that of any other Physician. Such a career entitles a man to arrange and offer to the world the results of his life's labour.

As we cannot hope to epitomise any considerable portion of Dr. Williams's book in the small space at our disposal, we extract the summary of his views on the pathology of phthisis contained in his preface:—

"It is not possible to convey in a few words the views on the nature of phthisis to which I have been led by observation on the facts and opinions of others as well as my own; but the popular terms *decline* and *consumption* are the most significant which I can employ to represent them. I believe pulmonary consumption to arise from a decline or deficiency of vitality in the natural *bioplasm* or *germinal matter*; and this deficiency manifests its effects not only in a general wasting or atrophy of the whole body, but also in a peculiar degradation, chiefly in the lungs and lymphatic system, of portions of this bioplasm into a sluggish, low-lived, yet proliferating, matter, which, instead of maintaining the nutrition and integrity of the tissues (which is the natural office of the bioplasm), clogs them and irritates them with a substance which is more or less prone to decay, and eventually involves them also in its own disintegration and destruction. This degraded bioplasm, which I will call *phthinoplasm* (wasting or decaying forming material), may be thrown out locally as a result of inflammation; or it may arise more spontaneously in divers points of the bioplasm in its ordinary receptacles, the lymphatic glandular system; and then it commonly appears in the form of miliary tubercles, scattered through the adenoid tissue of the lungs.

"I would characterise all consumptive diseases heretofore classed under the terms tuberculous and scrofulous, together with the products of low and chronic inflammation, as instances of a *lowred vitality of the bioplasm*; and I would strongly insist on their being totally distinct, on the one hand, from cancer and other malignant diseases, the characteristic of which is a new *kind* of vitality, a new growth, perhaps parasitic, with new organic elements, foreign to those of the tissues which they invade and destroy; and, on the other hand, distinct also from *total loss of vitality*, death of the bioplasm, which would speedily result in decomposition, gangrene, and putrefaction; to such a result phthinoplasms do occasionally lead, but it is

not a part of their common history. That this latter distinction is not sufficiently observed by some German writers is evident by their applying the term *neerobiosis* to caseation, which, although a process of decay from *lowered* vitality, does not indicate the absolute death of every living part, as in a slough or gangrene. It will be seen in the chapter on fatty degeneration (which thirty years ago was a special object of my study), that I have traced a resemblance to vegetable life in its process and products; and, although ultimately destructive, it is the most gentle step towards the death of the tissues. Nay, various proofs will be adduced that fatty transformation is often a salutary process, assisting materially in the removal of phthinoplasms and other superfluous products of inflammation."—*Preface*, pp. vii.-ix.

This being the author's general conclusion as to the nature of the disease of which he treats, we may proceed to notice a few of the points to which he gives prominence. But, before doing so, we hope we shall not be esteemed hypercritical if we remark that, in any author except Dr. Williams, we should object to the coinage of the new word "phthinoplasms." Pathological science is surely loaded with enough terms already, and we are not clear as to there being any essential difference between the phthinoplasms of to-day and the cacoplastic deposits of five-and-twenty years ago.

Dr. Williams has fully vindicated his own claim and the claim of other British pathologists to the merit of opposing Laennec's exclusive views of the pathology of consumption. He shows that, long before the school of Niemeyer, the inflammatory origin of phthisis was maintained by Alison, Abercrombie, Stokes, and himself in opposition to the views of Laennec and Louis. The chapter (the second in the book) in which this question is discussed, completely disposes of the assertion that Laennec's views were only called in question by Dr. T. Addison in this country until an opposition was raised to them by German pathologists.

Dr. Williams, in the outset of his examination of the intimate nature of tubercle, pays a deserved tribute to the researches of Mr. Gulliver on tubercle, which were published between 1842 and 1844. He then proceeds to show in what respect he differs from the views of Virchow, who described miliary tubercle as a heteroplastic lymphoma, a new growth of lymphatic tissue where none exists naturally, having its origin in the cells of connective tissue only. He does not allow that tubercle is a new growth in the sense that cancer is a new growth. He rather accepts Dr. Sanderson's view, that miliary tubercle in the lung is an overgrowth of pre-existing adenoid tissue. But although he thinks that Dr. Sanderson has proved that miliary tubercles are modifications of the adenoid tissue, he does not admit that any and every inflammation or overgrowth of the adenoid tissue will produce miliary tubercle; nor does he admit that adenoid tissue is essential to the production of other phthisical consolidations, especially of what is called yellow tubercle, either crude or caseous.

The Relations of Inflammation to Tubercle and other Phthinoplasms is the title of the chapter in which Dr. Williams enunciates his view of the part played by leucocytes in the production of lymph, pus, and tubercle. This subject is of so great interest at the present time that we offer no apology for quoting Dr. Williams's views *in extenso*:—

"It is the scrofulous inflammation of lymphatic glands that makes them enlarge first, and then harden, and at length degenerate into caseous masses, which soften eventually and discharge from scrofulous sores. It is a similar type of inflammation which may develop miliary induration in the adenoid tissue of the lungs, tending in like manner to caseation, softening, and spreading, and to the formation of vomicae. In both cases the death and destruction of the tissue are preceded by induration, and the microscope reveals the nature of this induration in the abundant production of cells which change their colour from red to grey, and eventually so press on each other and on their containing fibrous stroma as to choke their nutrition; and they then become cheesy—that is, undergo fatty degeneration and disintegration. It is, therefore, not the mere inflammation or simple growth of the adenoid tissue that constitutes the destructive changes of scrofula and tubercle, but the excessive multiplication of perishable cells doomed to speedy decay. These cells have the closest resemblance to *leucocytes*, the ordinary corpuscles found in lymph, and circulating also in considerable numbers in the blood; and there are good grounds for concluding that these all are identical in nature. The strong probability is therefore in favour of the opinion which I have entertained, and in general terms expressed during the last forty years, that variations in the plasma,

as represented by these bodies, constitute the essential element in the production of lymph, pus, and tubercle.

"The coagulable lymph, composing the plastic exudations from inflamed serous membranes, contains more or less of these corpuscles or leucocytes, their greater abundance causing a more opaque appearance and a lower capacity for organisation in the inflammatory product, and constituting the kind of lymph termed *corpuseular* by Paget, *croupous* by Rokitansky, and by myself *caecoplastie* and *aplastie*, having the further varieties purulent and tubercular."

It is well known that Dr. Williams was one of the first to observe the great increase of white corpuscles, which he termed sarcophytes, in the blood-vessels of the frog's foot on irritation, and that he was the first to notice their adhesive qualities—their sticking to the walls of the vessels. He also saw the accumulation of these corpuscles outside the vessels of the inflamed tissue. His observations, however, did not go so far as to enable him to assert that the pale corpuscles passed through the coats of the capillary vessels, although he suggested that small nuclei or granules might so pass and then grow larger. The fact of emigration was first described by W. Addison, and soon after by Waller. Later it has been rediscovered by Cohnheim; but Dr. Williams, although he himself did not see the actual process, early adopted the emigration theory: that the more distinctive products of the inflammatory process—lymph, pus, and tubercle—and albuminous and fibrinous matters in other varieties of form, are truly *exudations* from the inflamed bloodvessels; and it was in accordance with this view that he classed the products of inflammation as deposits.

We cannot, however, linger over Dr. Williams's most interesting, original, and instructive chapters on the Pathology of Tubercle. In his work he has references to the latest researches of the chief workers of the day. An examination of these proves unmistakably the remarkable confirmation and expansion given by recent observations to views which he was in the habit of propounding to his class at University College twenty-five years ago.

We have left ourselves but little room to notice the remainder of the work. The chapter on Physical Signs is remarkable for its clearness and simplicity. Dr. Williams's Record of a Thousand Cases proves convincingly that the ordinary form of phthisis, under favourable circumstances, is a very slow disease. His results are more favourable than those of any previous author; but probably there is no malady the treatment of which has been so much improved within the last twenty years as pulmonary consumption. To ourselves, Dr. Williams's chapters on Treatment are amongst the most valuable and attractive in the book, and would alone render it a standard work of reference.

Dr. Theodore Williams has contributed the statistical parts of the work, on which much labour has evidently been spent. The chapters on Family Predisposition, on Hæmoptysis, on Dietetic and Hygienic Treatment, and on Climate, are also by him. We can scarcely give them higher praise than when we say they are worthy to be placed side by side with the chapters contributed by his father. If we wished to find fault we might observe that the book deserves a better index; but this is a failing which must be mended in another edition.

In conclusion, we would record our opinion that Dr. Williams's great reputation is fully maintained by this book. It is undoubtedly one of the most valuable works in the language upon any special disease.

NEW BOOKS, WITH SHORT CRITIQUES.

Cholera as Treated in the Royal Free Hospital. By WILLIAM MARSDEN, M.D. Fourth edition. Edited by ALEXANDER MARSDEN, M.D., F.R.C.S.E., Surgeon to the Royal Free Hospital and Cancer Hospital. London: Wyman and Sons, Great Queen-street, Lincoln's-inn-fields, W.C. 1871. Pp. 73.

*** We cannot say that the small book above named contains anything which at the present day can be considered of interest or value to the Profession. It contains, on the other hand, ideas concerning cholera—such as that it is neither infectious nor contagious; that nothing can be more unnecessary than quarantine; that, in the premonitory diarrhoea, calomel cannot be administered too boldly, inasmuch as small doses produce no effect, while a full dose acts almost like magic, and the happiest results ensue—which, however justifiable they may have been thirty-seven years ago, when the original edition was issued by its author, being now repeated without explana-

tion or qualification, are likely to misinform the non-Professional public, to whom the book bears the appearance of being more particularly addressed. We would also observe that the treatment of cholera by salines and saline injections into the veins, as originally suggested by Dr. Stevens—though frequently tried, and occasionally with such favourable results as may render the repetition of the experiment with such modifications as the progress of our knowledge in the pathology of the disease may suggest not only justifiable, but advisable—has not, in the experience of other observers, attained such a remarkable standard of success as to justify nowadays the republication of the confident opinion expressed by Dr. William Marsden in 1834: that we have in this method of treatment such a successful means of combating cholera "that we need no longer view with horror and dismay the approach of this enemy to human existence."

The Nature and Prevention of Cholera. Hamilton. W. Naismith. 1871.

*** This is an anonymous pamphlet, in which the discovery is announced that the nidus of cholera is anæmia, and the remedy and means of prevention iron. The author is evidently an enthusiast, prone to jump at conclusions, and we notice his pamphlet merely to advise him of the necessity of establishing a foundation of facts before raising a superstructure of theory. We do not believe that anæmia has *per se* any influence in inducing an attack of cholera, any more than that its opposite condition, plethora—the yet unrecognised factors of the disease being in operation—will succeed in warding it off.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

EDINBURGH, October 30.

ON ever-shifting ground, and with fluctuating success, the female Medical movement still continues. Its amazon champions seemed at first to carry everything before them; but more recently they have met with considerable check. A year ago it was found that no University teachers were forthcoming to instruct them, and an effort which was then made by them to gain admission into the ordinary classes of the University along with the male students was effectually resisted.

The Royal College of Surgeons Medical School then came to the rescue, and permission to have mixed classes was granted to any of its lecturers who liked such an arrangement.

One session of this experiment sufficed. In a year when an almost unprecedented number of students entered the Edinburgh Medical Schools, there was a marked falling off in the number of students in every class into which the mixed element was introduced. Consequently, at a meeting of the lecturers, held last summer, it was resolved that this permission should be withdrawn.

An application was made last year by the females for admission to the wards and clinical instruction of the Royal Infirmary. This was opposed by the managers, who refused to recognise the right of these women to enter the institution as students. Their decision was approved of by the Court of Contributors to the Infirmary, and their example has since been followed by the managers of Leith Hospital, the Royal Hospital for Sick Children, Chalmers' Hospital, and the Maternity Hospital. In this awkward position of affairs, the University authorities, who bore the responsibility of having been the first to recognise them as students, had now the prospect of being applied to by some of their number for admission to the first Professional examination.

They now began to question the legality of their position, and determined to seek the advice of counsel on the matter. The subject was presented to most eminent counsel in the form of a memorial, drawn up by the law agent of the University, advised by the deans of the Faculties of Law and Medicine. Great care was taken that the case should be fairly and accurately stated. They obtained the following opinion in reply:—

"It may be that the Senatus or other authorities can give permission to the Professors of the University to teach persons not legally entitled to demand admission as students; but we do not think that persons who have attended lectures by virtue of such permission have, even when permitted to matriculate, any right to claim the position or privileges of students. We are of opinion that the Senatus have not power to admit to examination for a degree persons who, though they may have

attended the course of lectures necessary to graduation, were not, in our estimation, entitled to the legal status of students of the University."

It will be apparent that this must have been news of a rather startling kind to the University authorities, when we bear in mind that there stand, and for two years have stood, in the Calendar of the University, the following regulations:—

"1. Women shall be admitted to the study of Medicine in the University.

"2. The instruction of women for the Profession of Medicine shall be conducted in separate classes confined entirely to women.

"3. The Professors of the Faculty of Medicine shall, for this purpose, be permitted to have separate classes for women.

"4. Women not intending to study Medicine professionally, may be admitted to such of these classes, or to such part of the courses of instruction given in such classes, as the University Court may from time to time think fit and approve.

"5. The fee for the full course of instruction in such classes shall be four guineas; but in the event of the number of students proposing to attend any such class being too small to provide a reasonable remuneration at that rate, it shall be in the power of the Professor to make arrangements for a higher fee, subject to the usual sanction of the University Court.

"6. All women attending such classes shall be subject to all the regulations, now or at any future time in force in the University, as to the matriculation of students, their attendance on classes, examination, or otherwise.

"7. The above regulations shall take effect as from the commencement of session 1869-70."

The responsible authorities were thus placed in the awkward dilemma of having made laws which it was, apparently, illegal for them to carry out.

They might still, however, have revoked those laws, and have had them removed from the official Calendar. But in reality nothing further was done, until in the present month applications were made by female students for admission to the preliminary and first Professional examinations. In both instances the *Medical Faculty* refused to admit them, and thereby broke one of their laws. In both cases the ladies now, in their turn, sought legal advice, and received in reply a decided opinion to the effect that the course of action taken by the *Medical Faculty* was illegal.

The *Medical Faculty*, thus jammed between two opinions of eminent counsel—one implying that they had no legal right to frame the laws which they had framed; the other, that, having made such laws and published them in the Calendar, they had no legal right to break them—withdrew their prohibition, and allowed the ladies to appear for examination.

It is difficult to understand how the *Medical Faculty*, *Senatus*, and *University Court*, with the approval of the *Chancellor* and *University Council*, should have framed, and for two years acted upon, laws which, in the end, turn out to be either illegal or of doubtful legality. It is equally difficult to understand why, after the discovery was made, the matter was not at once rectified. The *Medical Faculty* might thus have been saved the humiliation of first attempting to break laws which they had themselves made, and of being summarily forced by a legal opinion into compliance with them.

It is to be hoped that the *University authorities* have had enough of this female innovation, and that means will be taken to put an end to a state of matters which is doing incalculable damage to the good name and fame of the *Edinburgh University*.

Taking advantage of the evident difficulty in which the *University authorities* had placed themselves, an attempt was made, at the meeting of the *General Council* on Friday last, to get up a reaction in favour of the female students.

Dr. Alexander Wood moved the following resolution:—

"That, in the opinion of this Council, the *University authorities* have, by published resolutions, induced women to commence the study of Medicine at the *University*; that these women, having prosecuted their studies to a certain length, are prevented from completing them from want of adequate provision being made for their instruction: that this Council, without again pronouncing any opinion on the advisability of women studying Medicine, do represent to the *University Court* that, after what the *Senatus* and *Court* have already done, they are at least bound in honour and justice to render it possible for those women who have already commenced their studies to complete them."

Mr. Alexander Nicholson (*Advocate*) seconded the motion.

Professor Turner moved the following amendment:—"The subject to which the motion of Dr. Alexander Wood refers being at present duly under consideration by the proper

authorities of the *University*, the *General Council* decline to interfere in the matter at present, being confident that the cases of the several ladies who have commenced their *Medical education* will be considered with all favour compatible with the *Universities Act*, the *University Statutes*, and the *University Charter*."

Professor Wyville Thomson seconded the amendment. For the motion 97 voted; while 107 voted for the amendment, which was therefore carried.

The decision of the *University Court* is looked forward to with interest and anxiety. It is to be hoped that the follies and blunders of the past will be neither perpetuated nor added to, and that the experience which teaches even fools will not be lost upon so august a body. Many experiments, which are daily carried on within the buildings of the *University*, are difficult and dangerous to the experimenter. But this is a more serious affair—this difficult experiment of female Doctor-making, which the *University authorities* have been making—it is dangerous to the very *University* itself.

October 31.—Since writing the above I find in the *Scotsman* of to-day that a meeting of the *Senatus* was held yesterday, and that they "declined by a majority to recommend to the *University Court* any means by which the ladies might be enabled to complete their education."

It is not unimportant that this decision was arrived at in the face of the following letter which was laid before the meeting:—

"Craighouse, Lothian Burn,

"Friday, October 27, 1871.

"SIR,—In the absence of the *Hon. Secretary*, I am desired by the *Executive Committee* for Securing a Complete *Medical Education* to Women in *Edinburgh* to inform you that they have passed the following resolution, in the hope that the removal at least of all pecuniary difficulties may facilitate the arrangements of the *Senatus* for completing the *Medical education* of those ladies who have already matriculated in the *University*:—"That the *Secretary* be instructed to write to the *Senatus*, in view of their approaching meeting, to state that, in the event of special lecturers being appointed by the *University* to give qualifying instruction to women, the *Committee* are willing to guarantee the payment to them of any sum that may be fixed by the *Senatus* for their remuneration, in case the fees of the ladies are insufficient for that purpose, and that, if necessary, they are willing further to undertake to provide such rooms and accommodation as may be required for the delivery of the said lectures, if it should be found absolutely impossible for the *University* to provide space for that purpose."

"I am, &c.,

KATHERINE BURTON.

"To the *Secretary* of the *Senatus Academicus*."

Surely this indicates a great change in the views of the *Senatus* since 1869! Let us hope that we see the beginning of the end.

GENERAL CORRESPONDENCE.

THE QUEEN'S ILLNESS.

LETTER FROM SIR WILLIAM JENNER.

[To the Editor of the *Medical Times and Gazette*.]

SIR,—A statement having been widely circulated to the effect that the *Queen's* recent illness was the result of revaccination, I trust you will, by inserting this letter, permit me to give the most unqualified contradiction to the report. There is not a shadow of foundation for it in facts. Her Majesty's recent illness did not commence till many months after the revaccination. There was no connexion, direct or indirect, between the two.

I am, &c.,

October 31.

WILLIAM JENNER, M.D.

P.S.—I should not have contradicted a statement so entirely without foundation had I not heard that, in consequence of the positive terms in which the assertion is made, it is receiving a certain amount of credence, and is so causing harm to the public health.

CROTON-CHLORAL.

LETTER FROM DR. JULIUS ALTHAUS.

[To the Editor of the *Medical Times and Gazette*.]

SIR,—I think it will be interesting to the readers of your journal to hear that Dr. Oscar Liebreich, of Berlin, to whom

we owe that valuable therapeutic agent, hydrate of chloral, has lately been engaged in investigating the physiological and therapeutical properties of a new organic compound called croton-chloral, which is formed by conducting chlorine gas into allylene. A peculiar action of this new substance in animals is, that at first a high degree of anæsthesia in the head is produced, while sensibility in the other parts of the body remains intact. The second stage is, that the spinal cord loses its function, and reflex excitability is everywhere extinguished. During that stage both pulse and respiration remain unchanged. The third stage, which is induced by large doses, is characterised by paralysis of the medulla oblongata, and death. Animals may, however, be kept alive by artificial respiration, because the function of the heart is not interfered with; while the ultimate effect of hydrate of chloral is to paralyse the heart. The first therapeutical experiments with the new compound were made in the University Clinique of Berlin. Complete anæsthesia of the fifth pair of cerebral nerves was produced in a child, reflex excitability in the other parts of the body continuing unchanged at the same time. Pulse and respiration remained exactly the same during the whole time of the narcosis. Further experiments in insane patients showed that we possess in croton-chloral a remedy by means of which the brain may be profoundly narcotised without any other functions being disturbed, while by chloral not only the brain, but the nervous system altogether, is rendered anæsthetic, and the heart's action is diminished, which must always constitute a source of danger. Croton-chloral, therefore, promises to produce all the good effects of hydrate of chloral without any drawback being attached to its judicious use. Its apparently specific effects on the fifth pair of cerebral nerves makes us indulge the hope that it may perhaps be found useful in that most intractable affection—true tic doloureux, or epileptiform neuralgia of the face.

I am, &c., JULIUS ALTHAUS, M.D.
18, Bryanston-street, Portman-square, W., Oct. 31.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, OCTOBER 17.

T. HOLMES, F.R.S., Vice-President, in the Chair.

The Chairman, in presenting to the Society the new volume of *Transactions*, remarked that, if not quite so large as some previous volumes, it was equally valuable. For that evening the list was not large—but that, perhaps, was an advantage, as it allowed of fuller discussion. Too frequently there was an excess of specimens.

Dr. PEACOCK related a case of Extensive Disease of the Heart of very long duration: Obstructive and Regurgitant Disease of the Mitral Valves, and Obstructive Disease of the Aortic Valves, in a patient, aged 17 (a baker), who was admitted into the Victoria-park Hospital under his (Dr. Peacock's) care on April 15, 1871, and died on August 6. The patient stated that he had had an attack of rheumatic fever when 4 years old, and four or five attacks since. He had also suffered three times from chorea. He had never been free from cardiac symptoms during his recollection, but he had suffered more severely within the last few months. When admitted, he complained of shortness of breath, palpitation, and cough with expectoration; he was very livid in the face and extremities, and the fingers were clubbed, and the face and lips were puffy. The pulse was small and irregular. The præcordial dulness on percussion was much increased in extent, both vertically and longitudinally. There was a loud, soft systolic murmur, heard most distinctly at the nipple and lower end of the sternum, but audible also over a large space at the base, at the apex towards the left axilla, and feebly at the lower angle of the left scapula. The second sound was at first scarcely to be heard, but subsequently the sound became intensified. The murmur was distinctly heard in the course of the pulmonary artery, as well as in that of the aorta. Soon after his admission, he had an attack of urgent difficulty of breathing, with syncope, and stated that he had had similar attacks before his admission. He also became exceedingly livid and very sallow, and had spitting of blood, and the œdema increased. The liver became engorged, and the urine was loaded with lithates, but free from albumen. He also had, some time before his death, several convulsive fits, and was afterwards very morose and torpid. On examination after death, the pericardium was

found entirely adherent to the heart by old and firm attachments. The heart was greatly increased in size, weighing, with some of the pericardium attached, 17½ ounces—or probably 16 ounces independently. The left auriculo-ventricular aperture was very greatly contracted, giving passage only to a ball measuring 21 French lines in circumference, and the valves were greatly thickened, indurated, and cretaceous, the aperture being permanently open. The aortic valves, also, were thickened, and the orifice at its outlet greatly contracted, giving passage to a ball of 33 French lines in circumference. The lining membrane of the left auricle was very thick and rough, and the cavity, together with that of the right side, much dilated. The tricuspid valves were somewhat thick. The aperture admitted a ball 54 French lines in circumference, the pulmonary aperture one of 45 lines. The other organs of the body, although very much engorged, were not otherwise diseased. There could be no doubt, from the long duration of the symptoms, and the condition of the heart, that the boy had been the subject of cardiac disease since his attack of rheumatism, when 4 years of age, and it was, indeed, during life, doubted whether the disease might not be congenital.

Dr. GREEN exhibited a specimen of Interstitial Hepatitis. The liver was removed from a boy aged 9, who was admitted into Charing-cross Hospital under Dr. Green's care in July last, and died after eight days' stay in the Hospital. He was delirious, intensely jaundiced, and his stools contained no bile. The liver was slightly diminished in size, and the interlobular tissue was infiltrated with leucocytes, which in many places almost completely replaced the proper liver tissue. The hepatic cells were but little altered. Two enlarged lymphatic glands were found lying over and obstructing the common bile-duct. The stomach and intestines contained a large quantity of dark blood. The case was interesting, from the acuteness of the inflammatory process, the accidental occurrence of jaundice, and the complete absence of any pyrexia during life.

Dr. MURCHISON presumed the jaundice was due to the enlarged glands; were it not for that, the diagnosis might have been difficult. The temperature was of great importance in acute atrophy of the liver. In some forms of disease resembling it the temperature was remarkably high; in it, it was not much above the normal standard.

Mr. HOLMES asked if it was not unusual to have inflammation of such an organ as the liver without rise of temperature.

Dr. GREEN considered that the important point in the case.

In reply to Dr. Bäumlér, he stated that the liver-cells were unaltered; the bodies observed were merely leucocytes.

Dr. MURCHISON exhibited specimens of Hydatids removed from the peritoneum during life by Mr. Spencer Wells. The patient was aged 29, and came into Middlesex Hospital last December. She complained merely of the size of her abdomen, which presented nodulous projections, soft, elastic, and of various sizes. There was no tenderness. She did not long remain in the Hospital; but afterwards she came under the care of Mr. Wells, who punctured the abdomen, confirmed the diagnosis, extended the opening, and removed three or four pounds of hydatids. The patient was quite comfortable in a few days, and, as far as he knew, was now alive. She had, first of all, on the beginning of the attack, eleven years ago, something like local peritonitis, and, subsequently, repeated attacks of the same. She had borne healthy children during this illness. A somewhat similar case, in the person of a man, aged 45, had been also under his care. The history was similar. They appeared to begin from the liver. He had tapped one, and taken away hydatid fluid. Nothing was done for permanent relief.

Mr. HOLMES considered this the first removal after a diagnosis.

Dr. WILKS had seen them removed by Mr. Bryant, but he could not say whether a diagnosis had been made. Was the origin of these from the peritoneum or liver?

Dr. MURCHISON said Mr. Wells had not attempted to remove all, and he did not know if any recurrence had taken place. The origin was not clear in the first case, but it was probably the liver; there was little doubt of this in the man.

In reply to Dr. Church, Dr. MURCHISON also said that the cysts had not been examined for echinococci, but the fluid was undoubtedly hydatid.

Mr. HULKE said they were not uncommon in pigs. In one instance, besides peritoneal hydatids he had found a large withered cyst in the liver.

Dr. MOXON had not long ago seen a case of spinal hydatids. There was nothing in the liver. He asked if the parent cyst was represented by the pushed-out wall.

Dr. PHILLIPS remembered the case referred to by Dr. Wilks. It greatly resembled the one first narrated by Dr. Murchison,

and had lasted many years. It was determined to make an exploratory incision with a view to certainty of diagnosis. A quantity was removed, and the patient did well. He thought they were scooped out of the interior of a large cyst.

Mr. HOLMES said the peculiarity in this instance was, that the operation had been undertaken after the diagnosis was made.

Dr. ROBINSON exhibited the Throat and Larynx of a Soldier who had expired very suddenly after slight illness. He was aged 21, and had been complaining of sorethroat. His tonsils were large, but not very. On the second evening he was better at the visit; but two hours after, almost immediately after swallowing a chloral draught, he died. There was a good deal of swelling about the glottis, but nothing else was remarkable.

Dr. MURCHISON thought the mode of death was rather by syncope than asphyxia. Was the head affected?

Dr. ROBINSON said the heart was rather loaded with fat; that was all. He did not think the draught had anything to do with the death.

Dr. PAYNE exhibited Microscopic Specimens of an Enlarged Lymphatic Gland from a case of lymphadenoma, or Hodgkin's disease, the particulars of which had been communicated by Mr. Squire. Clinically, the case was remarkable for exhibiting, in addition to enlargement of lymphatic glands in various parts of the body, consolidation of the lungs, and some symptoms indicating disease of the spinal cord; but as a complete autopsy could not be obtained, these points were not elucidated. Dr. Payne took occasion to make some remarks on the minute anatomy of the diseased glands in such cases, in which he pointed out the frequent occurrence, in early stages, of the large and many-nucleated cells, some resembling myeloid cells, observed by Dr. Ogle and himself.

Dr. WILKS asked if this new formation were destructive. Virchow, he thought, looked upon it as an increase of tissue merely.

Dr. PAYNE wished to imply that increase came first, destruction after. The cells were smaller latterly.

Dr. GOODFELLOW exhibited a specimen of Aneurism originating close to the Aortic Valves. The patient, a man aged 48, a porter, was well till April. He then began to experience increased difficulty of breathing, with palpitation. He never felt anything giving way. There was a loud basic bruit, systolic and diastolic, louder on the right side. He had also epistaxis and hæmoptysis. After death the aortic valves were found calcareous, and a dilated pouch just below the valves. The endocardium was healthy, and the mitral valves healthy.

Dr. MURCHISON had a somewhat similar case, which he had thought was mitral, there being a loud systolic bruit. After death, a pouch the size of a small orange was found projecting from the ventricle just behind the valves.

Dr. MOXON wished to bring before the Society a specimen which he thought showed that after stricture there might be inflammation of the kidney ending in abscess, with ultimate recovery.

Mr. HOLMES thought most Surgeons would agree with him in the possibility of such a sequence.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, OCTOBER 4.

Dr. BRAXTON HICKS, F.R.S., President, in the Chair.

JOHN M. TAYLOR, M.D., Scarborough, was elected a Fellow of the Society.

Dr. BARNES presented to the Society, on behalf of Dr. Boddaert, of Brussels, the lever employed by Dr. Boddaert; also a memoir, "On the Rational Use of Forceps and Lever," by the same gentleman. Dr. Barnes drew attention to the form of the lever, which was a solid bar, nearly straight, and without fenestra. Such a bar could only be a lever, and in no sense a tractor.

Dr. BARNES exhibited a specimen of an Iliac Artery obstructed by a Clot. The case was described by Mr. Williams, of Truro. The subject was seized during an abortion with prostration, coldness, failure of pulsation, and gangrene of the leg of the side on which the artery was plugged.

Mr. SPAULL exhibited a Fœtus the subject of Hydrocephalus. The child presented by the breech, and the head had to be perforated.

Mr. MITCHELL said he had met with several cases of the kind in his practice. In every case he had perforated the head, and delivered the child by the forceps, all having been head presentations.

Dr. MURRAY thought that, in such a case as that related to the Society, much diagnostic information could be obtained by placing the hand on the lower part of the abdomen, and feeling the unusually large size of the uterus after the birth of the extremities and body of the child. The possibility of the existence of twins should, however, be remembered; but then the uterus would be still much larger than when distended by the hydrocephalic head.

The PRESIDENT read a paper on the "Intermittent Contractions of the Uterus during Pregnancy: their Physiological Value and Assistance in Diagnosis." He showed, as the result of eight years' constant observation, that the habit of the uterus was to contract at intervals of from five to twenty minutes, and then to relax. These contractions, he said, lasted about three or four minutes, although under circumstances of irritation they might continue longer; and even in diseased states of the ovum were almost continuous. Only one apparent exception had been noticed—namely, in a case of paraplegia, in which the contractions were not observed. They were observable as early as the third month of pregnancy; indeed, as soon as the consistence of the uterus permitted. They were not owing to the irritation of examination, for, as frequently as not, the uterus would be found hard on first handling it, and then shortly to relax. After describing the physical state of the uterus and its contents during these conditions, Dr. Hicks alluded to the value of these contractions physiologically. He thought at least two advantages were derived from them—the one to supplement the heart-impulse in a part remote from its influence, the other to assist the ultimate disposition of the fœtus. He then proceeded to discuss at length the assistance these contractions gave the Practitioner in the diagnosis of extra-uterine from uterine tumours, of uterine tumours from pregnancy, and of extra- from intra-uterine pregnancy.

Dr. BARNES called attention to the work of Dr. Tyler Smith, in which the peristaltic movements of the pregnant uterus were well described, not only as forming the basis of the expelling force during labour, but also as diagnostic of pregnancy.

Dr. HICKS said the extract quoted from Dr. Tyler Smith's work had escaped his notice. But Dr. Tyler Smith had referred to the peristaltic movements the result of external excitation, while those which had been just described occurred without any such.

Dr. COPEMAN (of Norwich) related three cases which he had met with in practice; the first being one of induction of premature labour on account of excessive vomiting, the second a case of large fibrous polypus of the fundus uteri, and the third a case of *procidencia uteri* in a maiden lady.

The discussion turned on the best mode of inducing premature labour.

Dr. BARNES agreed with Dr. Copeman that the introduction of a bougie or catheter into the uterus was the best mode of provoking labour; but, like all simply provocative means, it could not be depended upon to complete labour. Accelerative means were often necessary. The best of these were—rupture of the membranes, dilatation of the cervix by the water-bags, turning, and the forceps.

Dr. PROTHEROE SMITH referred to an instrument shown him by Dr. Tarnier, of Paris. It consists of a metal grooved director, about eight inches long, carrying a tube of india-rubber, thin at its distal extremity. This is introduced into the uterus, towards the fundus, separating the membranes. It is then distended with water so as to form a bulb-shaped bladder, when the metal director is withdrawn. Uterine action usually sets in within a few hours.

Dr. PLAYFAIR generally used a simple catheter, which he passed between the membranes and the uterine wall; but on more than one occasion he had seen it fail. The uterus was occasionally roused into activity with great difficulty, and this probably depended on some peculiarity in the individual case.

Dr. BRUNTON had induced premature labour successfully nine or ten times by injecting warm water into the uterus. He had, however, now given up that method, both on account of the danger said to attend its use, and because in one case it proved a total failure. He now used a bougie (No. 12) in which no eye had been cut.

Dr. MURRAY expressed his belief in the value of the plan recommended by Professor Lazarewitch of injecting water into the uterus. He had nothing to say against the use of the catheter, except that it had occasionally failed to bring on labour.

The PRESIDENT said that the safety of the child depended on two conditions—viz., the rapidity with which the uterus came into action, and the freedom with which the child passed

through the os uteri. Dilatation of the cervix certainly answered the latter requirement excellently.

Dr. WILTSHIRE suggested the desirability of inducing premature labour at a period in pregnancy which, in respect of time, corresponded to a menstrual epoch.

Dr. ROGERS had, early in his career, been accustomed to puncture the membranes high up, so as to save some of the liquor amnii, having first dilated the cervix with sponge tents. Of late years he had used a long catheter with an opening at its rounded extremity. This had been successful in all except two cases, and in these he found it necessary to inject some water through the catheter to excite uterine action.

OBITUARY.

THE LATE DR. FAWCUS.

SIR,—An old Indian, who knew Dr. Fawcus intimately, has obliged me with the following note, which I hope you will be good enough to insert. It is partly in correction, partly in addition, to the notice of Dr. Fawcus in your journal of last week.

I am, &c.,

THE WRITER OF THE NOTICE.

October 30.

“The foundation of the system of converting the prisons of Lower Bengal into productive schools of industry, of rendering the prisons thereby self-supporting, and of relying upon well-regulated industrial labour as the best means alike of punishment and reformation, was laid in 1856, immediately after the holding of a successful exhibition of gaol manufactures in Calcutta. In 1861 the gaols of Alipore and Hooghly were entirely self-supporting, and the former has remained so ever since. In 1863 the jute machinery for the Alipore gaol was sent from England. Dr. Fawcus became Superintendent of the Alipore gaol on January 12, 1865. Although, therefore, Dr. Fawcus originated none of the measures on which the existing Bengal system is based, he threw himself heart and soul into the work with an amount of success of which it is impossible to exaggerate the value and importance. Dr. Fawcus was in Medical charge of the Monghyr gaol from November 23, 1863, to December 10, 1864. Prior to his incumbency, the mortality in that gaol was 18.62 per cent. in 1854, and 45.11 per cent. in 1863. He reduced it at once to 4.35 per cent., and it has remained at a low figure ever since. In 1864 the dry-earth system was introduced. Dr. Fawcus was recommended to the Government for a special acknowledgment of his valuable services. In Calcutta he was attached to the General Hospital, in which his zeal, devotion, and success were as marked as they were in the prison department.”

JAMES STANLEY CHRISTIAN, L.R.C.P., ETC.,

Was born at Sligo; studied and obtained his diploma in Dublin, both as Physician and Surgeon, and afterwards in London as M.R.C.S. He practised in the county of Monaghan with success, and became distinguished in management of the Dispensaries, and particularly so in the treatment of cholera and fever, for which, indeed, he acquired great repute. He did not publish any Medical work, and the only occasion on which he sustained his views in print was when Dr. Marshall Hall, some few years ago, advocated certain views of his own, by publishing an attack on the treatment of the drowned pursued by the Royal Humane Society, to which Dr. Christian was Honorary Surgeon. Dr. Christian's views met with much opposition, and were criticised with severity in the pages of a contemporary. Dr. Christian regarded the observations as libellous, and threatened an action against the journal containing them. Dr. Christian came to England upwards of twenty years ago, and, after some time spent in practice in East Kent, settled in South Kensington, where he attained a very large reputation, and enjoyed an extensive practice. He became, as above stated, the Honorary Surgeon to the Royal Humane Society, which, within the last few years, voted him their gold medal for his great and generous service—an honour which, we believe, has not been conferred more than four times since the existence of the Society. He was very popular with the leading members of the Profession, and obtained the personal affection and high regard of his numerous patients, all of whom became his friends. He was only 57 when he died from effusion of blood on the brain. A fortnight ago last Sunday week he was sitting with his brother-in-law in his dining-room, at 7, Prince of Wales-terrace, Kensington, conversing, when suddenly he felt faint, and asked for a little brandy. Before it could be given to him he

was struck. Drs. Sievcking, Barclay, and Seton were soon in attendance. The most unremitting and affectionate attentions were unavailing, though for the first three days it was thought that the treatment was producing good results, and a complete cure was anticipated; but he expired on the following Tuesday week.

DR. RICHARD T. EVANSON.

WE regret to have to announce the death of Dr. Richard T. Evanson, which took place at Torquay, on the 26th ult. Dr. Evanson had been in the Profession for upwards of forty years, and had attained to a good old age, being 72 when he died. He was elected a Fellow of the Royal College of Surgeons, Ireland, as far back as 1830, and was for some time Professor of the Practice of Physic in that institution. He graduated M.D. at Glasgow in 1832, and in 1859 was made a Fellow of the Royal College of Physicians, London. Though Dr. Evanson's name was not often mentioned lately apart from his practice at Torquay or in social circles, it was at one time very well known, inasmuch as he, in conjunction with Dr. Maunsell, produced the first really good book on the diseases of children. This, which was termed a treatise “On the Management and Diseases of Children,” was really an excellent work on the subject; but for some reason or other a second edition of it never appeared, and it gradually dropped out of date. In private Dr. Evanson was highly esteemed. He was a man of many accomplishments, and was fond of writing poetry. The last volume he published was a collection of poems, the most notable it contained being entitled “Nature and Art: a Reminiscence of the last International Exhibition.” At Torquay Dr. Evanson had obtained a goodly share of private practice, and was greatly beloved and respected by his patients.

OSMER KING, F.R.C.S. ENG.

ON October 24, at Walton Villa, Eccleshall, Stafford, died this much-respected and beloved Practitioner, whither he had gone some months before for the benefit of his failing health. Mr. King was the son of the late George King, Esq., of Burgate and Royal, in Surrey, and became a Member of the College of Surgeons in 1839, and an honorary Fellow in 1859. Having commenced practice as the junior partner in the much-respected firm of Sutton and Sanes, of Blackheath, his polished manners and Professional abilities soon became appreciated, and from that time up to the day of his death he carried on one of the largest and most aristocratic practices in the county of Kent. At the beginning of the year 1870 he took as his partner Dr. Ralph Gooding, of Blackheath, and, owing to his own rapid increase of feebleness, he soon retired to country life. His winning smile and kindly gentleness, his noble character and sympathetic bearing, will never be forgotten by his many friends and patients, who must all feel that they have sustained an irreparable loss.

LEGAL INTELLIGENCE.

RETAINING A DOCTOR.

THE following case is not only interesting, but most important to the Profession, and especially to the general Practitioner. In the Maidstone County Court, Charles Hadler was sued by John Fitzpatrick, Surgeon, for 15s., amount alleged to be owing for Medical services agreed to be rendered by the plaintiff. It should be stated that the plaintiff alleged he brought the action merely to have the point of law cleared up. On February 8 last, the defendant called upon the plaintiff to pay some money in respect of a Medical club to which he belonged, and of which club the plaintiff was Medical attendant. The defendant was then in the employ of another Medical gentleman, who had recently come to reside at Lenham. As defendant was leaving, he said, “I should like you to attend my wife in June or July”—meaning that she would then be confined. Plaintiff told him that he had better have his own master to attend her; but he replied that he should not like to have such a young gentleman. Plaintiff then agreed to attend her, and entered the engagement in his memorandum-book. In June he heard that the defendant's wife had been confined, and that she was being attended by defendant's employer. On going to the house and finding it to be so, he left word that he should claim his fee of 15s. on the engagement. A message had been sent to plaintiff's house, on the same day that plaintiff went to defendant's house, to the effect that his services would not be required any more by the defendant in his family.

In cross-examination by the Judge, the plaintiff said he considered he had undertaken to hold himself in readiness to attend the defendant's wife at any moment. He should not, however, stay away from his other patients about the time of her expected confinement; but if a message were left at his house, he should have gone directly he came home, or at any hour of the night. The defendant denied the engagement altogether, and called a witness, who stated she had taken a message to plaintiff's house about eight days before the confinement, to the effect that his services would not be required in defendant's family any more; but this, as the Judge remarked, went to prove the engagement, and the plaintiff would not have made the entry in his pocket-book (produced) without some cause; but he (the Judge) thought, although there was an engagement, it was not binding in law. There was no mutual advantage, as was necessary to support a breach of contract. The plaintiff's undertaking consisted almost entirely in booking the engagement, and if he was not at home (as he had never undertaken to be) when the confinement took place, and could not attend it through detention elsewhere, he could scarcely bring an action for breach of contract. He would, however, reserve his decision on the legal point till the next Court.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At the ordinary quarterly meeting of the College on Thursday, the 26th ult., the following gentlemen, having passed the required examination, were admitted Members:—

Cook, John, M.D. Edin., 3, Upper Wimpole-street, W.
Glynn, Thomas R., M.B. Lond., 1, Rodney-street, Liverpool.
Payne, Edwin, M.D. St. Andrews, Walton House, Selhurst-road, South Norwood.
Squire, William, 6, Orchard-street, Portman-square, W.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.—The following gentlemen passed their first Professional examinations during the October sittings of the examiners:—

Anderton, William, Ormskirck.
Hart, Henry, Kent.
Moir, Alexander, Bridge of Allan.
Orpen, Richard Hungerford, county Kerry.
Smith, Charles Edward, Essex.

And the following gentlemen passed their final examinations, and were admitted L.R.C.P. Edin. and L.R.C.S. Edin.:—

Cagney, Daniel, Croome.
Evans, Robert William Jonathan, Ruthin.
Fair, Robert Campbell, county Mayo.
Henry, George Fraser, Alyth.
Mason, William, Tralee.
O'Connell, James, Drinagh.
O'Hanlon, William Palliser, Bandon.
Sparrow, Thomas Francis, county Kilkenny.
Steuart, Duncan, Edinburgh.
Sutherland, Daniel, Wick.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen were admitted Fellows of the College at the annual meeting held on the 18th ult.:—

Crerar, Alexander, L.R.C.S.E., Rannoch.
Hicks, John Sibly, L.F.P. and S.G., Liverpool.
Meikle, Robert, L.R.C.S.E., Douglas, Lancashire.
Sainter, James Dow, M.R.C.S. Eng., Staff Assistant-Surgeon, Army, Military Barracks, Sligo.
Smith Robert, L.F.P. and S.G., Assistant Colonial Surgeon, Sierra Leone.

The following gentlemen passed their final examinations, and were admitted Licentiates of the College, during the recent sittings of the examiners:—

Maunsell, John, county Down.
M'Carthy, John Patrick, Glenogra.
Smith, Samuel John, Downpatrick.
Weir, Alexander M'Cook, Cookstown.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, October 26, 1871:—

Burgess, Edward Arthur, Bethnal-green-road.
Cane, Leonard, Queen-square, W.C.
Gatsell, Thomas, East-street, Walworth.
Harries, Thomas Davies, Llaneast, Fishguard.
March, Frederick Kimbell, Braunston, near Rugby.
Meredith, William Henry, Netherton, Worcestershire.
Rees, Albert Barnes, Swansea.
Watson, John Wilcocks, Heigham Hall, Norfolk.

The following gentleman also on the same day passed his first Professional examination:—

Godding, Charles Cane, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

AVELING, CHARLES TAYLOR, M.B. Lond., F.R.C.S.E., and L.S.A.—Divisional Surgeon to the Hackney Police.
BRODIE, EDWARD F., L.R.C.S.I., L.K.Q.C.P.I.—Medical Officer for the Lawrencetown Dispensary District of the Ballinasloe Union.
CAMPBELL, WM. MACFIE, M.B., C.M.E.—Senior House-Surgeon to the Liverpool Northern Hospital, *vice* Thos. Dodson Chalmers, M.B. Edin., L.R.C.P. Edin., L.R.C.S., resigned.
CROSS, F., M.R.C.S.—House-Surgeon to King's College Hospital.
EARLEY-WILMOT, R., M.R.C.S.—Resident Accoucheur to King's College Hospital.
EMSON, ALFRED, M.R.C.S.E., L.S.A.—Medical Officer of the Dorchester District, and of the Workhouse of the Dorchester Union.
HANNAY, R. STRICKLAND, M.R.C.S.E.—House-Surgeon to the Westminster Hospital, *vice* Mr. William J. R. Ray, M.R.C.S.E. and L.S.A., resigned.
REEVE, EDMUND, M.R.C.S., L.S.A.—Medical Officer of the Saliham Toney District of the Swaffham Union, subject to the approval of the Local Government Board.
VASEY, C. LYON, L.R.C.P.L., M.R.C.S.E.—Junior House-Surgeon to the Liverpool Northern Hospital, *vice* Wm. Macfie Campbell, promoted.
WARNER, F., M.R.C.S., L.S.A.—House-Physician to King's College Hospital.

MILITARY APPOINTMENTS.

ROYAL ARTILLERY.—Staff Surgeon Edmund M'Grath, to be Surgeon, *vice* Tertius Ball, M.D., who exchanges; Staff Assistant-Surgeon William Robertson, M.B., to be Assistant-Surgeon, *vice* Hugh Mackay Macbeth, who exchanges. Surgeon Alexander Scott Fogo, M.D., having completed twenty years' full-pay service, to be Surgeon-Major, under Article 342 of the Royal Warrant of December 27, 1870.
24TH FOOT.—Assistant-Surgeon William Tobin to be Assistant-Surgeon, *vice* Campbell Millis Douglas, M.D., V.C., appointed to the Staff.
31ST FOOT.—Staff Assistant-Surgeon Thomas Babington, to be Assistant-Surgeon, *vice* Charles Edward Jones, deceased.
MEDICAL DEPARTMENT.—Surgeon Tertius Ball, M.D., from the Royal Artillery, to be Staff Surgeon, *vice* Edmund M'Grath, who exchanges; Assistant-Surgeon Hugh Mackay Macbeth, from Royal Artillery, to be Staff Assistant-Surgeon, *vice* William Robertson, M.B., who exchanges. The surname of the Staff Assistant-Surgeon appointed in the *Gazette* of September 19, 1871, is Cruickshank, *not* Cruikshank, as therein stated. Staff-Surgeon Robert Thomas Buckle, M.D., having completed twenty years' full-pay service, to be Staff Surgeon-Major, under Article 342 of the Royal Warrant of December 27, 1870. Assistant-Surgeon Campbell Millis Douglas, M.D., V.C., from the 24th Foot, to be Staff Assistant-Surgeon, *vice* William Tobin, appointed to the 24th Foot.

BIRTHS.

AUSTIN.—On October 6, at Lingfield, Surrey, the wife of Sydney C. Austin, Surgeon, of a son.
BRYANT.—On October 28, at 23A, Sussex-square, Hyde-park-gardens, the wife of John Henry Bryant, L.R.C.P. Edin., of a son.
CAMERON.—On October 25, at Nairn, N.B., the wife of J. A. Cameron, M.B., of a son.
ELLIS.—On October 28, at Shipley, Yorks, the wife of W. H. Ellis, M.R.C.S.E., of a son.

MARRIAGES.

BOXER—JACKSON.—On October 9, at Quebec, Canada, at the residence of the bride's father, Charles A. Boxer, third son of W. L. Boxer, Esq., of her Majesty's Customs, Jamaica, and grandson of the late Admiral Boxer, C.B., to Susie, third daughter of Alfred Jackson, M.D.
BOYD—CARR.—On October 26, at St. Margaret's, Lee, Kent, Robert Boyd, Esq., of Glasgow, to Annie Gertrude, elder daughter of William Carr, M.D., F.R.C.S. England, of The Grove, Blackheath.
BURN—BOND.—On October 26, at St. John's Church, Notting-hill, George T. Burn, Esq., son of Dr. G. Burn, R.N., to Margaret Sophia, youngest daughter of Mr. Wm. Bond, Chard.
FRASER—GARDNER.—On October 25, at the church of St. Michael and All Angels, Helensburgh, N.B., Henry Martyn Fraser, M.D., son of the late Rev. Hugh Fraser, of Ardchattan, and nephew of the late Sir Duncan Campbell, of Barcaldine, Bart., to Maggie Wilhelmina Dyce, second daughter of Lieutenant-Colonel Gardner, late of the 13th Bengal Native Infantry.
FREEMAN—CROSBY.—On October 24, at St. Mary's, Lewisham, Kent, Joshua Charles Freeman, eldest son of the late Charles Henry Freeman, to Ellen Sarah, third daughter of John Lescombe Crosby, M.R.C.S., of Croft House, Carlton, Cambridgeshire.
FREEMAN—HOPEWELL.—On October 26, at the parish church, Abingdon, Northamptonshire, Alfred John Freeman, M.D., of San Remo, Italy, and Southsea, Hants, to Emma Louisa Hopewell, second daughter of Edward Hopewell, Esq.
HALL—LEONVAL.—On October 25, at the parish church, Bolton, Dr. John Hall, of Ruddington, Notts, to Margaret Louise, daughter of Jean Baptiste Paul Chappe de Leonval, of Prestwich.
LINDOP—HEANE.—On October 24, at Newport, Salop, John Crump Lindop, Surgeon, Newport, to Mary Ellen Maria, second daughter of the late Henry Heane, of the same place.
MITCHELL—BURTON.—On October 26, at Tottenham-court-road Chapel, Joseph Mitchell, L.R.C.P., to Emma, eldest daughter of Richard Frost Burton, Ballarat, Victoria.
ROGERS—SHEPHERD.—On October 31, at St. Peter's, Bristol, the Rev. John Henry Rogers, curate in charge of Hemmington, Somerset, to May, only daughter of Dr. Shepherd, of Tyndall's-park, Clifton.

STEVENS—WINTER.—On October 25, at the parish church, Pewsey, Wilts, William Edward Stevens, M.R.C.S., to Eliza, only daughter of George Winter, Esq., of Pewsey.

DEATHS.

- BRADY, LOUISA, widow of the late Charles Brady, Surgeon, at 194, Blackfriars-road.
- EVANSON, RICHARD TONSON, M.D., at Torquay, suddenly, on October 26, in his 72nd year.
- HILDER, HENRY HUGH, M.R.C.S.E., at Great Berkhamstead, Herts, on October 29, aged 68.
- KEMPE, ARTHUR, F.R.C.S., at Southernhay House, Exeter, on October 25, aged 57.
- KING, OSMER, F.R.C.S., late of Royal-hill, Greenwich, at Walton Villa, near Eccleshall, Staffordshire, on October 24, aged 54.
- MOORE, WILLIAM D., M.D., at Fitzwilliam-square, Dublin, on October 28, in his 59th year.
- SHAW, DAVID DE LEON HERBERT, only son of Deputy Inspector-General of Hospitals G. J. Shaw, M.D., late of H.M.'s Bombay Army, and grandson of David Thom, Esq., of Leith, at 18, Hope-erescent, Edinburgh, on October 26, in his 23rd year.
- SIMPSON, EDWIN, M.R.C.S., L.S.A., of Long Melford, Sudbury, Suffolk, after a few days' illness, on October 24, aged 49.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

COUNTY OF WICKLOW INFIRMARY.—Apothecary. Must be duly qualified. Applications and testimonials to Mr. H. Rooke, Secretary, on or before November 13.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, S.W.—Resident Clinical Assistant. Applications and testimonials to the Secretary, on or before November 4. Further information may be obtained at the Hospital.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Assistant-Physician. Must be M.R.C.P.L., or pledged to become so within twelve months. Applications and testimonials to the Secretary, on or before November 11.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Clinical Assistant. Gentlemen applying for this appointment must possess at least one qualification. Applications and testimonials to the Secretary, on or before November 11.

HULME DISPENSARY, MANCHESTER.—House-Surgeon. Must be duly qualified. Applications and testimonials to the Chairman of the Medical Committee, on or before November 6.

KENT AND CANTERBURY HOSPITAL.—House-Surgeon. Gentlemen applying for this appointment are required to possess qualifications in Medicine and Surgery. Applications and testimonials to Mr. T. Southee, Secretary, on or before November 24. The duties commence on January 1, 1872.

LINDSEY, LINCOLNSHIRE.—Medical Officer for the County Gaol and House of Correction. Candidates for this appointment must be duly qualified and registered. Applications and testimonials to the Deputy Clerk of the Peace, Lindsey, on or before November 18. The duties will commence about the end of March, 1872.

LIVERPOOL INFIRMARY FOR CHILDREN.—House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to the Chairman of the Committee, on November 11.

LONDON FEVER HOSPITAL.—Physician. The necessary qualifications are—F. or M.R.C.P.L. Applications and testimonials to the Secretary, at the Hospital, on or before November 7. Election on the 10th.

METROPOLITAN DISPENSARY, FORE-STREET, E.C.—Surgeon. Candidates for this appointment must be F. or M.R.C.S.E., not practising pharmacy. Applications and testimonials to Mr. F. Stiles, Secretary, on or before November 7.

MIDDLESEX HOSPITAL MEDICAL COLLEGE.—Lectureship on Materia Medica. Applications to the Dean, on or before November 11.

NORTH DEVON INFIRMARY.—House-Surgeon. Must be M.R.C.S.E., and be registered. Applications and testimonials to Mr. John Bridgman at the Infirmary, Barnstaple, on or before November 4. Election on the 14th.

PADDINGTON, PARISH OF.—Medical Officer and Public Vaccinator for the Eastern District of the parish. Candidates must have the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to the Clerk to the Guardians, Board-room, Paddington Workhouse, on or before November 8. Election the same day, at 10 o'clock, a.m.

POPLAR HOSPITAL FOR ACCIDENTS, 303, EAST INDIA-ROAD, E.—Resident Medical Officer, having qualifications in Medicine and Surgery. Applications and testimonials to the Rev. J. F. Kitto, on or before November 4.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD.—Operating Surgeon. The qualifications required are—F. or M.R.C.S.E. not practising midwifery or pharmacy. Applications and testimonials to Mr. C. L. Kemp, on or before November 7. Election on the 21st.

ROYAL SURREY COUNTY HOSPITAL.—House-Surgeon. Must be duly qualified in Medicine and Surgery. Applications and testimonials to the Assistant-Secretary, Guildford, on or before November 6.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. The following qualifications are required:—Member of one of the Colleges of Surgeons of the United Kingdom, also L.S.A.; or possess a Licence to practise Medicine. Applications and testimonials to Dr. J. C. Hall, on or before November 15.

SUSSEX COUNTY HOSPITAL, BRIGHTON.—Surgeon. Must be M.R.C.S.E. Edin. or Dub. The office of Assistant-Surgeon is also vacant; the qualifications required are the same as for the appointment of Surgeon. Applications and testimonials to Mr. A. Vesey, on or before December 6.

TEIGNMOUTH, DAWLISH, AND NEWTON DISPENSARY AND INFIRMARY.—House-Surgeon. Must be duly qualified and registered. Applications and testimonials to the Chairman of the Committee, on or before November 16.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in aeres. The population is computed according to the census of 1861.

RESIGNATIONS.

- Highworth and Swindon Union.—Mr. J. K. Kenyon has resigned the Third District; area 12,840; population 2954; salary £57 10s. per annum.
- Toxteth-park Township.—Dr. Alex. McGregor has resigned the office of Assistant Medical Officer at the Workhouse; salary £100 per annum and allowances.

APPOINTMENTS.

- Bristol Incorporation.—Robert Norton, M.R.C.S., L.S.A., to the Second District.
- Bury Union.—Thos. Carruthers, L.R.C.P. and L.R.C.S. Edin., to the First Tottington District.
- Oakham Union.—Wm. J. Bonnor, M.R.C.S. Eng., L.S.A., to the Empingham District.
- Pembroke Union.—Howard D. Reynolds, M.R.C.S., L.R.C.P., to the Fifth District.
- Titchhurst Union.—Walter C. Blaker, M.R.C.S., L.S.A., to the Roberts-bridge District.
- Tiverton Union.—Edward M. Puddicombe, M.R.C.S. Eng., to the Silvertown District.
- Warminster Union.—Thomas Flower, M.R.C.S. Eng., L.S.A., to the Warminster and Corsley Districts and the Workhouse.

SIR WILLIAM FERGUSSON and DR. MORELL-MACKENZIE have been unanimously elected Corresponding Members of the Royal Buda-Pesth Society of Physicians.

THE ARMY.—We understand the subject of the abolition of the regimental Medical system has been abandoned, and eventually officers will not be allowed to hold regimental appointments for longer than five years.

CHOLERA is on the decrease in every part of Russia. A week ago the total number of cases under treatment in the whole empire was estimated at less than 5000.

SMALL-POX is so prevalent at Devonport that a temporary Hospital has been opened, and the Local Board have been recommended by the Medical Practitioners to close the schools in certain localities.

SCARLET FEVER is now epidemic in Londonderry—its prevalence amongst children is quite unparalleled; and small-pox is spreading alarmingly in Dublin. More than eighty cases have been reported in the Hospitals, and special provision has been made to meet the violence of the disease.

THE Winter Session of the Andersonian Institution, Glasgow, was formally opened on Tuesday, and Professor Herr Bischoff, recently appointed to the new Chair of Technical Chemistry, delivered his inaugural address in the great hall of the University. There was a large attendance of Medical gentlemen.

THE PHYSIQUE OF THE ARMY.—Major-General Brownrigg, speaking at a City festival a few days ago, said he was sorry to think that the *physique* of the army was not what it used to be. Certainly, the men had not the bone and sinew they used to have; and that was more especially so as regarded the artillery—the guns were becoming bigger and the gunners smaller.

THE LATE MR. FAITHORN.—At the last meeting of the Board of Guardians of the Amersham Union, the following resolution was passed, and a copy of it ordered to be sent to the family of the deceased—"That this Board desires to express its sense of the great loss which has been sustained by the death of Mr. Faithorn, the Medical Officer of the Chesham District, who was unremitting in his attention to the poor, and fell a sacrifice to his devotion to their interests."

A COMMITTEE of the Islington Guardians has been appointed to consider the propriety of disposing of the old workhouse in the Liverpool-road, with a view to prevent its being again converted into a temporary Hospital for the treatment of contagious disease.

DR. FRANKLAND, in reporting upon the results of a chemical examination of the water supplied to the metropolis during October, while acknowledging that the water sent out by those companies drawing their supply from the Thames and Lea had been "submitted to efficient filtration before transmission to consumers," adds—"The water delivered by the Chelsea, Southwark, Grand Junction, and Lambeth Companies was so polluted by dissolved organic impurities as to render it undesirable for human consumption."

THE MEETING OF THE ASSOCIATION OF GERMAN NATURALISTS AND PHYSICIANS AT ROSTOCK.—This, the forty-fourth meeting of this celebrated body, has only met with a qualified success, the number present being very limited. This has been attributed in part to the fear that outbreaks of cholera might call for attention in other directions, and also to the fact that men's minds have hardly yet become sufficiently settled after recent perturbations, while leisure has been wanting to

many. It would have been better to have postponed the meeting until another year. Such postponements have occurred five times before—viz., in 1831 and 1859 on account of the cholera, in 1848 on account of political events, and in 1867 and 1870 by reason of the war. Next year the Association will meet at Leipzig, where fifty years since (in 1822) the first meeting was held on the invitation of Professor Oken, and consisted of twenty-one persons. On the present occasion Professor Virchow delivered a very effective address (which will doubtless be published separately) "On the Position of the Natural Sciences in relation to the New National Life of Germany."

THE NEW GERMAN PHARMACOPŒIA.—A committee of twelve, consisting of four Professors of Materia Medica and of several Medical councillors and Apothecaries of various of the States, are to meet under the presidency of Geh.-Med. Rath Houssele, of Berlin, in order to prepare a conjoint pharmacopœia. The Committee has also the assistance of experts, as Privat-Docens, Oscar Liebreich, Prof. Schwanert, etc. It has been determined, notwithstanding the opposition of the Professors, to continue the adoption of the Latin language, although in South Germany the German has been long employed for this purpose; in fact, it would seem that the pharmacopœia will be little else than a new edition of the "Pharmacopœia Borussica," with the addition of some of the new remedies. If, as is said, it is to be printed by January 1, 1872, it is to be feared that its compilation will prove but a hasty and imperfect performance.

THE GERMAN BATHS IN 1871.—The following statement of the relative number of visitors frequenting the most celebrated German baths up to the end of August, 1871, may be interesting to some of our readers:—Aachen, 7162; Baden Baden, 36,614; Baden-bei-Wien, 7168; Badenweiler, 2409; Carlsbad, 16,725; Elster, 3632; Franzensbad, 7398; Gastein (Wildbad), 2194; Gleichenberg, 2302; Homburg, 14,342; Ischl, 3922; Kissingen, 8095; Kösen, 2411; Kropine-Töplitz, 1970; Marienbad, 7748; Nauheim, 4716; Neuenahr, 2671; Niederbronn, 1329; Norderney, 4654; Oeynhaus (Rehme), 3451; Pyrmont, 7017; Ragaz, 3376; Reichenhall, 4689; Rohitsch, 2202; Schandau, 1517; Schlungenbad, 1545; Schwalbach, 4627; Soden, 3292; Töplitz, 26,190; Warmbrunn, 2560; Weisbaden, 40,386; Wildbad, 5841; Wittekind, 663.—*Deutsche Klinik, September 30.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Antwerp will see the report in question in the present number. American experience confirms the opinion that it is useless.

Mr. Delamark Freeman.—We shall be most happy to receive and publish your explanation of the affair.

Stockton.—As the case was adjourned we shall delay making any comments upon it until next week, when we hope to have full details of the evidence adduced on both sides.

Herbalists.—The *North British Mail* of the 27th ult. has an able leading article referring to an unrepealed Act of Henry VIII., which appears to sanction the practice of herb-doctors and such persons; and the writer expresses his opinion that the Act should be repealed.

Leper.—Dr. Gavin Milroy is at present, we believe, investigating the alleged successful treatment of leprosy by Dr. Beauperthuy. Considerable discussion on the subject of the case has taken place in Trinidad and other of the West Indian islands. We believe that Government was induced to send Dr. Milroy on his mission in consequence of the recommendations of the College of Physicians.

Kensington.—Dr. Dudfield, in his recently issued report for the year 1870, says—

"The population in 1870, at the middle of the year, is assumed to have numbered 115,062. The births registered during the year were 3705—viz., 1897 males, and 1808 females—equivalent to an annual rate of 32.20 to 1000 persons living, 3 per 1000 less than the birth-rate of the entire metropolis, which was 35.3 per 1000. The deaths registered were 2473 in number—viz., 1231 males, and 1242 females. The annual rate of mortality, therefore, was equal to 21.49 per 1000 in Kensington (or 20.45 per 1000, excluding the deaths of non-parishioners in the Brompton Consumption Hospital), while it was 24.31 in the West districts of London, 25.28 in the East districts, 24.12 in the metropolis as a whole, and 22.1 per 1000 in the entire kingdom. It is worthy of note that the annual death-rate of females in this parish was about 18 per 1000 only, as against 25 per 1000 of the opposite sex. The births exceeded the deaths in Kensington by 1232; but the estimated increase of population during the year was 8742, the difference being due to removals into the parish."

AMPUTATION OF THE TONSILS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Would you or any of your readers kindly inform me if amputation of the tonsils is likely to be followed by atrophy of the testes, and if in the female the continued use of iodine causes atrophy of the mammae?

I am, &c.,

ATROPHY.

* * * Nothing of the kind.

DYTE FUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In addition to the £42 already announced as received for the "Dyte v. The St. Pancras Guardians Appeal Fund," I beg gratefully to acknowledge the following subscriptions. In doing so, however, I must add, that unless further aid be speedily forthcoming, Dr. Dyte will be a loser to the extent of some hundreds, in the prosecution of his just claims, admitted as such by the Guardians themselves:—

	£	s.	d.		£	s.	d.		
Andrew, Dr. James	...	1	1	0	Guy, Dr. W. A.	...	1	1	0
Beale, Dr. Lionel	...	1	1	0	Harley, Thomas, Esq.	...	1	1	0

6, Christopher-street, Finsbury-square, E.C.,

October 31.

A CANDIDATE FOR THE MATRICULATION EXAMINATION. "AUDI ALTERAM PARTEM."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Intending to be a candidate for the Matriculation of the London University in January next, will you permit me to say a few words on the subject?

Being of Medical extraction, I have frequent opportunities of seeing the various remarks made in yours and in other papers on the matriculation and other examinations, which are pointed out to me in order, I suppose, to act as a stimulus, so that I may exert myself the more. Now, I have read these various remarks, and also the questions of the previous examinations, and I have also written the answers to them, and cannot for the life of me see what there is to grumble at. The questions appear to me, with some trivial exceptions, to be quite fair; and, as to those on natural philosophy, anyone who has paid any attention to the subject cannot fail to pass. I do not mean to say that a man who has merely taken a book on the subject and has "crammed" up various proofs and formulæ without having the faintest idea of their meaning, would do so (this might have paid two or three years ago), but if he thoroughly understands the main principles, he cannot fail to satisfy the examiners. Professor Haughton's remarks on the paper given this year in the Preliminary Scientific Examination were hardly necessary; for I know several men who passed it, and who say that it was a "decent" paper, and by no means so outrageous as the above-named Professor makes it out to be.

Again, as to the chemistry, many fellows who have only played at the subject while at school have been able to do, with a very little extra work, a good paper. If the "attention" candidates pay to their preliminary studies is anything like that which they pay to their college lectures, either in Arts or Medicine, they deserve to be plucked; for it is disgraceful to see the foolish (and more than foolish) pranks that are performed during the lectures, which not only injure the doers themselves, but prevent those desiring to study from paying the attention which the subject demands.

Pray, Mr. Editor, try and shame those whose "buoyant" spirits render them a nuisance to professor and student alike, and do not try to lower the standard of the University examinations. I am, &c.,

STUDENS (age 16).

* * * We hope our young friend will find the examination as easy as he expects, and will pass with flying colours.

MEDICAL ETIQUETTE IN BAYSWATER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to call your attention to the enclosed copy of a circular which has been recently distributed in this neighbourhood, and which, as you will see, sets forth that a "Society" has been formed with the object of providing first-rate Medical attendance and medicine for an annual payment of 10s. The subscriptions are received quarterly or half-yearly in advance at the residence of Mr. Delamark Freeman, 20, Talbot-road, whose name, with that of a secretary, alone appears on the prospectus.

By what is perhaps merely a coincidence, a man has been engaged during the past few weeks calling upon the residents, including many of my patients, and soliciting them, in the most importunate manner, and much to their annoyance in many instances, to become members of this "Society." When taxed with being an agent of Mr. Freeman's, he answered that he was performing his laborious task with purely benevolent motives; that a relative of his had long suffered from a dreadful malady, which, having defied the efforts of all the Medical men in Bayswater, was cured with marvellous rapidity by Mr. Freeman, and that he was therefore anxious that every sufferer should avail himself of Mr. Freeman's extraordinary skill, more especially since they could do so for the ridiculously small sum of 10s. a year, not to speak of the medicines included.

Now, Sir, in the advertising columns of the papers we read daily of cases in which wonderful cures have been wrought by means of a single box of pills, or ointment, and as we of course believe these to be true, we do not doubt that Mr. Freeman's case may be also authentic; but I and many of my confrères in this district, for whom I speak, deny that this case had been previously treated by us, and we therefore deny, at least, that it had defied the efforts of all the Medical men in Bayswater. Seriously, we think we have a right to demand from Mr. Freeman some account of the constitution of this "Society" to which he is Surgeon; and we shall also be glad at the same time to hear whether the touting to which I have alluded has been carried on with his consent, and if not, whether he has requested his officious friend to desist from so equivocal a mode of displaying his gratitude. If Mr. Freeman can give us satisfactory explanations

on these points, and if he can clear himself from the grave charges of Professional misconduct which Dr. Roystan brings against him, I am sure he will receive from the neighbouring Practitioners a welcome such as is never refused to new-comers in Bayswater when their conduct is that of Professional men and gentlemen.

I am, &c., ALGERNON C. W. NORTON. 112, Westbourne-grove, Bayswater.

[Copy.]

BAYSWATER MUTUAL MEDICAL AID SOCIETY, for securing Professional Medical and Surgical attendance, and the supply of all medicines to the subscribers.—This Society is formed to enable persons, by payment of a small sum, to secure themselves efficient Medical and Surgical aid in case of illness or accident.

COMMUNICATIONS have been received from—

Mr. W. M. CAMPBELL; Mr. LOCK; Mr. C. T. AVELING; Mr. ASHURST; Mr. CROSKERY; Dr. HANDFIELD JONES; Dr. WILLIAM THOMSON, Australia; Dr. ALLBUTT; Dr. BEVERLEY; Mr. METCALFE JOHNSON; Mr. W. R. CORNISH; Mr. T. E. AMYOT; Dr. J. WHITEHEAD; Dr. EDIS; Mr. R. E. WILMOT; Mr. T. JACKSON; Mr. J. A. CAMERON; Mr. DAN-KAERTS; Mr. C. INGLEBY; Mr. W. B. WOODMAN; Dr. FELCE; UNDERGRADUATE; Mr. DOCKER; Mr. J. ROBERTSON; Mr. HANNAY; Mr. LE GROS CLARK; Mr. GRANT; Mr. BRAKENRIDGE; Dr. MALE; Dr. SUTHERLAND; Dr. A. C. W. NORTON; Sir WILLIAM JENNER; Mr. D. H. WATSON; Mr. R. LIEBREICH; Dr. FRANCIS R. HOGG, R.H.A.; Mr. W. MACFIE CAMPBELL; Dr. GOODING; Mr. J. C. BROUGH; ATROPHY; Dr. HORION; Mr. D. FREEMAN.

BOOKS RECEIVED—

Porcher on the Resources of the Southern (American) Fields and Forests—Mr. Spencer Wells' Note-book for Cases of Ovarian and other Abdominal Tumours—Marsden on Cholera—Kidd on Decapitation as a Mode of Delivery in cases of Shoulder Presentation in which Version cannot be safely effected—Report on the Health of the Parish of St. Mary Abbots, Kensington—Bray's Manual of Anthropology, or Science of Man, based on Modern Research.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Pharmaceutical Journal—North British Daily Mail—Cope's Tobacco Plant—The Chloralum Review—Kingston (Jamaica) Gleaner—Monthly Microscopical Journal—Hardwicke's Science Gossip—Medical Press and Circular—London Medical Journal—The Morningside Mirror.

APPOINTMENTS FOR THE WEEK.

November 4. Saturday (this day).

Operations at St. Bartholomew's, 1 1/2 p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9 1/2 a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m.

6. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2 1/2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting. MEDICAL SOCIETY OF LONDON, 8 p.m. General Meeting. Dr. Lichtenberg, "Rhinoplastic Operation" (two cases, with patients). Mr. Thomas Bond, "On Urethral Rheumatism."

ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

7. Tuesday.

Operations at Guy's, 1 1/2 p.m.; Westminster, 2 p.m.; National Orthopaedic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited:—Dr. Moxon, "Circumscribed Pleurisy and Pneumonia in a Syphilitic Man; Destruction of Trachea by Syphilis." Dr. Pye-Smith, "Cystic Disease of the Kidney." Dr. Dickinson, "Intracranial Aneurism productive of Sudden Death," etc.

8. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 1/4 p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1 1/2 p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m.

9. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopaedic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1 1/2 p.m.

10. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1 1/2 p.m.

CLINICAL SOCIETY, 8 1/2 p.m. Dr. John Murray, "On a Case of Paracentesis Thoracis." Dr. Anstie, "The Continuation of a Case previously reported." Mr. Christopher Heath, "A Case of Wound of the Intestine during Ovariectomy, with Recovery." Dr. Ogle, "Notes on the Temperature in Tetanus."

QUEKETT MICROSCOPICAL CLUB, 7 p.m. Extra Meeting, for Conversation and Exhibition of Objects only.

VITAL STATISTICS OF LONDON.

Week ending Saturday, October 28, 1871.

BIRTHS.

Births of Boys, 1099; Girls, 1103; Total, 2202. Average of 10 corresponding weeks, 1861-70, 2070.9.

DEATHS.

Table with 4 columns: Deaths during the week, Average of the ten years 1861-70, Average corrected to increased population, Deaths of people aged 90 and upwards. Rows show Males, Females, and Total counts.

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

Table with 11 columns: Population, 1871, Small-pox, Measles, Scarlet Fever, Diphtheria, Whooping-cough, Typhus, Enteric (or Typhoid) Fever, Simple continued Fever, Diarrhoea. Rows list West, North, Central, East, South, and Total.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Table with 2 columns: Meteorological data and values. Rows include Mean height of barometer, Mean temperature, Highest point of thermometer, Lowest point of thermometer, Mean dew-point temperature, General direction of wind, Whole amount of rain in the week.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, October 28, 1871, in the following large Towns:—

Large table with 11 columns: Boroughs, etc., Estimated Population to middle of the year 1871, Persons to an Acre, Births Registered during the week ending Oct. 28, Deaths Registered during the week ending Oct. 28, Highest during the Week, Lowest during the Week, Weekly Mean of Mean Daily Values, Temperature of Air (Fahr.), Temp. of Air (Cent.), Rain Fall. Rows list London, Portsmouth, Norwich, Bristol, Wolverhampton, Birmingham, Leicester, Nottingham, Liverpool, Manchester, Salford, Bradford, Leeds, Sheffield, Hull, Sunderland, Newcastle-on-Tyne, Edinburgh, Glasgow, Dublin (City, etc.), and Total of 20 Towns in United Kingdom.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 30.02 in. The highest was 30.21 in. on Sunday evening, and the lowest 29.51 in. at the end of the week.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

FLUID MEAT.

A New Preparation containing all the constituents of Lean Meat in a soluble form.

Messrs. DARBY and GOSDEN respectfully call the attention of the Profession to this important and valuable improvement in a soluble animal food. The necessity for such a food in the treatment of diseases and during convalescence is fully recognised by the Profession, and even by the public, as is clearly manifested in the ready acceptance and extensive employment of Liebig's Extractum Carnis.

Whilst the public are unable to appreciate the fact, yet physiologists are well aware of the objection to an extract of meat consisting, for the most part, of the elements of nutrition in a state of retrograde metamorphosis: taking from animal flesh what is soluble in cold water, subjecting the solution to a boiling-heat and evaporation—*i.e.*, making an extract—excludes all the fibrine, albumen, and gelatine, the very substances which give meat its superiority as an article of diet over all others. These constituents are those most needed to supply the waste from wear and tear, and to restore the tissues after the rapid destruction caused by fevers, inflammations, and other exhausting diseases.

Baron Liebig himself recognises the inefficiency of his "Extractum Carnis." He has remarked ("Lancet," 1865)—"Were it possible to furnish the market at a reasonable price with a preparation of meat containing in itself the albuminous together with the extractive principles, such a preparation would have to be preferred to the Extractum Carnis, for it would contain the nutrient constituents of meat."

This is exactly what is accomplished in our FLUID MEAT. Fibrine, albumen, gelatine, together with all the saline constituents and extractive matters, exist as in meat and its tissues, but that they are brought into a soluble state—*i.e.*, the first step in stomach-digestion—by means of pepsin and hydrochloric acid, an artificial gastric juice. It will therefore be obvious how well adapted this Fluid Meat must be for all cases of weakened digestion, irritable stomach, insufficient nutrition, and convalescence from diseases which, like fever, consume the various tissues. It must also be equally acceptable as a concentrated form of food to persons in health, when subjected, by exercise or otherwise, to temporary exhaustion and wear and tear.

We may state that, before making our preparation thus public, it has been submitted to trial in a variety of cases—some of them of a very exceptional character—in each of which most satisfactory results of its value as a nutritive and restorative agent have been obtained.

For further information, see Pamphlet on "Fluid Meat," published by Messrs. J. & A. Churchill, New Burlington-street.

FLUID MEAT is sold in Jars at 10s. 6d., 5s. 6d., & 3s. each, by

DARBY & GOSDEN, Practical Pharmacutists,
140, LEADENHALL-STREET, LONDON.

BEEF-TEA AND SOUP,
So essential for the recovery and sustenance of Patients, are produced easily, cheaply, and expeditiously by
WHITEHEAD'S SOLID ESSENCE OF BEEF
AND
SOLIDIFIED SOUP SQUARES.

THE ONLY PURE EXTRACT OF BEEF IN A SOLID FORM.
ITS EFFICIENCY and Economy have been proved by the LONDON HOSPITALS.
1 lb. of the Essence represents 42 lbs. of Butchers' Meat, and one Soup Square making 1½ pint of excellent Soup.
Wholesale of Copland & Co., Travers & Sons, Preston & Sons, Crosse & Blackwell, E. Lazenby & Sons, &c., and of the Manufacturers, at 8 and 9, Lime-street-square, London.

MELBOURNE MEAT-PRESERVING COMPANY (LIMITED).
COOKED BEEF AND MUTTON, IN TINS,

With full Instructions for use. PRIME QUALITIES AND FREE FROM BONE.

Sold Retail by Grocers and Provision Dealers throughout the Kingdom. Wholesale by

JOHN McCALL & CO., 137, HOUNDSDITCH, London.

Fox's Palatable Cod Liver Oil WITH Quinine

Natural Mineral Waters of Vals, Vichy, Carlsbad, Seltzer, Kissengen, Homburg, PULLNA, FRIEDRICHSHALL, &c., direct from the Springs; also the Artificial Mineral Waters prepared by Dr. Struve and Co. at the Royal German Spa, Brighton, and the Natural Bromo-Iodine Water of Woodhall Spa, Lincolnshire.—Agents, W. BEST and SONS, 22, Henrietta-street, Cavendish-square, London, W.

WESTERTON'S PATENT
ZYMOTIC DISINFECTING FLUID

Prevents the spread of infection; protects the nurse and those about the sick-room. Sponging over the body with the Fluid disinfects the emanations from the skin and (being volatile) exhalations from the lungs of the sufferer. Destroys the noxious properties of the excretions, and purifies the atmosphere.

PREPARED BY

W. C. WESTERTON, 85, Abingdon-villas, Kensington, London;
and may be had of all Chemists, in bottles, 1s., 1s. 9d., and 3s. 6d.; 10s. per gall.

ORIGINAL LECTURES.

LECTURE ON OPTIC NEURITIS FROM INTRACRANIAL DISEASE.(a)

DELIVERED AT THE LONDON HOSPITAL.

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P.,

Physician to the London Hospital and to the Hospital for the Epileptic and Paralysed.

(Concluded from page 342.) (b)

13. *How does an adventitious product in the cerebrum lead to double optic neuritis?* I shall speak of the cerebral hemisphere only, because coarse disease of the cerebellum (or tumour under the tentorium) may exercise pressure on the corpora quadrigemina. These cases are complicated. We will consider three hypotheses:—

(a) Has the coarse disease destroyed some Centre for Sight? It can have destroyed no *known* part of the optic nervous system—taking a case of small tumour in the cerebrum. I do not believe in any “centre for sight” in the hemisphere, although I do believe that the optic and all other nerves are represented—perhaps I should say re-represented—in the cerebral hemisphere in very complex groupings. The fact is, that the coarse disease has not caused the defect or loss of sight by *destroying* any part of the hemisphere whatever; for destruction of large parts of the hemisphere may cause no obvious symptoms of *any* kind. Mark, I do not say that *disease* of the hemisphere does not; I say that *destruction* of much of it does not. If the destroying agent be a “foreign body,” it may, and often does, lead to many symptoms, and amaurosis from double optic neuritis is one of them. A tumour does not “cause” amaurosis because it has *destroyed* so much of the hemisphere, but because it has led to secondary changes. Even supposing that there is a centre for sight, and even supposing that it is altogether destroyed, there must be a similar one in the opposite undamaged hemisphere. (Coarse disease in either cerebral hemisphere may lead to loss or defect of sight.)

In strictness, disease of no part of the hemisphere, so far as I know, “causes loss of sight.” It causes inflammation of the optic nerves. This is neither scientifically nor practically a mere verbal distinction, for the optic nerves may be inflamed when there is no loss of sight (see No. 5), and loss or defect of sight may not follow, although it usually does. In Physicians’ practice optic neuritis most frequently results from the *presence of a foreign body* in parts of the cerebral and cerebellar hemisphere, *destruction* of which parts may produce no symptoms at all. I shall in future lectures show you that optic neuritis goes most frequently with vomiting, headache, and with other symptoms which are not specially nervous.

To make what I have said clearer, let us make a comparison, or rather, as it will appear, a contrast betwixt loss of speech and amaurosis from optic neuritis. Observe, I do not say betwixt loss of speech and optic neuritis. This would be to institute a comparison betwixt a symptom and a pathological condition.

Loss of speech is caused by *destruction* of certain processes superintending speech. The amaurosis is not caused by destruction of any part superintending sight. For the loss of speech it matters not what the particular pathology of the lesion may be, clot or softening; it is enough that it is a *destroying* lesion. The lesion is of great consequence as to the production of amaurosis; it is “coarse” disease. Loss of speech depends on a primary change; it comes on as soon as the destruction is effected. The amaurosis depends on a change secondary to a primary lesion, and comes on after the primary lesion is developed. Loss of speech depends on direct lesion of a special part; amaurosis depends indirectly on disease of many parts.

(b) The coarse disease may have led to pressure transmitted to the optic nerves and venous sinuses at the base. This

(a) This lecture was delivered several years ago, and, with modifications, again in June last, in reference to particular cases of cerebral disease. As since 1863 I have published numerous papers on Medical Ophthalmoscopy (Royal London Ophthalmic Hospital Reports), this lecture necessarily involves considerable recapitulation; but there is no impropriety in reproducing in a condensed form the facts stated in former papers, and the opinions therein expressed, now partly modified.

(b) Since this was written, Dr. Clifford Allbutt’s book, referred to by anticipation (page 241), has appeared. In Chapter V. of that work he goes thoroughly and most ably into the various hypotheses on the mode of production of changes in the optic discs by intracranial tumours. In the forthcoming number of the Royal London Ophthalmic Hospital Reports Dr. Hermann Pagenstecher discusses this question very carefully.

can only be entertained when there is a very large tumour—for instance, a great hydatid cyst. Now, in some of these cases there plainly is great pressure, as is evidenced in children by enlargement of the head. Thus it may be supposed that the neuritis is due to pressure transmitted to the optic nerves at the base, or that it is owing to impeded flow of blood from the eye into the cavernous sinus. I do not think it owing to pressure on the optic nerves, because none of the other nerves at the base suffer, and if the optic nerve fibres were partly or wholly destroyed by squeezing I should rather expect slow atrophy than neuritis. Nor do I think impeded exit of blood by pressure on the sinuses is the cause, because the neuritis runs through its stages, and the swelling of the discs subsides, although the intracranial pressure goes on increasing. In these cases of vast tumours, the optic neuritis does not differ from that caused by small tumours at the vertex of the brain, which cannot exercise pressure of any consequence at the base. There are the same ophthalmoscopic appearances in each class of cases. In some cases of large cerebral tumour there is no amaurosis, but, as we have seen (No. 5), there may nevertheless be double optic neuritis. But there may be no neuritis, or, at all events, no swelling of the disc. You should never omit to use the ophthalmoscope in cases of thoracic or abdominal cancer, for in these cases you occasionally find post-mortem secondary cancer of the brain, although the patient’s symptoms never led you to suppose there was any grave cerebral lesion. In one such case carefully observed by Mr. Stephen Mackenzie, we found no swelling of the discs and no enlargement of the veins, although post-mortem there was discovered, besides cancer in the thorax, extensive cancer of each cerebral hemisphere and of each lobe of the cerebellum. We must suppose that in such cases the tumours develop rapidly, and that thus they would lead to increase of intracranial pressure very quickly. I believe, then, that the intracranial disease does not lead to optic neuritis by causing increased pressure within the head.

3. I come now to the hypothesis, several times implied, that double optic neuritis is the result of irritation by the foreign body in some parts of the encephalon. This is in effect the hypothesis of Brown-Séquard. The neuritis I suppose, as Benedikt does, is probably produced by the intermediation of the arteries and their vaso-motor nerves. But observe, in the present state of our knowledge, I *cannot know* this; and, as Dr. Moxon says in an Introductory Lecture at Guy’s Hospital, “Never trust a man for what he cannot know.” I do not wish for a moment to conceal from you the great difficulties in the way of concluding. I confess that optic neuritis is a very great puzzle. But although we cannot declare how optic neuritis results from adventitious products within the cranium, there is one thing we can do now. We can, in numerous cases, note the circumstance with which it occurs, and use hypotheses to put our facts in *some kind* of order. I offer the following suggestions with this object:—

(1.) Amaurosis from optic neuritis (there may be no amaurosis—see No. 5) occurs with general symptoms which show disturbance of brain—viz., severe diffused headache, vomiting, slow and, possibly, unrhythmical pulse, and the symptoms of “cerebral fever.”

(2.) It often occurs with convulsive seizure; or, putting it in another way, with affections of grey matter—with “discharging lesions.”

(3.) In a considerable number of cases in Physicians’ practice it occurs with those convulsions (convulsions beginning unilaterally) which point to disease of the convolutions of the cerebrum in a certain arterial district. In some of these we have three symptoms: (a) right-sided convulsions, (b) epileptic aphasia, (c) temporary loss of sight. These symptoms may hypothetically be explained on the supposition that parts are affected in the region supplied by the middle cerebral artery, and branches from the internal carotid, of which trunk the middle cerebral is practically the continuation. In these cases the temporary symptoms are, as it were, occasionally written down in permanent symptoms. There follow hemiplegia (epileptic hemiplegia), temporary defect of speech, and amaurosis from optic neuritis.

In conclusion, I beg you to remember, at all events, three things:—1st. That optic neuritis frequently exists where the patient can read the smallest type. 2nd. That the ophthalmoscopic appearances vary extremely in degree in cases of adventitious products within the cranium, and that the appearances vary much at different stages in the same case. 3rd. That you should *never* omit to use the ophthalmoscope when a patient has *severe and continued* headache.

THE
DISCUSSION ON PURULENT INFECTION
AT THE
PARIS ACADEMY OF MEDICINE.

By Professor VERNEUIL.

(Continued from page 553.)

I SHALL to-day try and complete the demonstration of my first communication—namely, to prove, as stated in my eighth and last proposition, that pyohæmia is nothing more than a severe septicæmia, with special complications having special causes, but which, in spite of these special characters, enters into the series of traumatic fevers, and does not break the unity.

I have taken care to determine in a rigorous manner the meaning of certain terms. I chose a name for the putrid poison—*sepsine*; another for the poisoning—*septicæmia*; and thus it was easy to give a definition to the latter—infection of the blood by the sepsine. If I were to adopt the ideas which have been taught for the last fifty years, I should do the same with purulent infection. The name of the poison (the pus), as well as that of the poisoning (the pyohæmia), already exists, and this latter would have a definition in itself: the infection of the blood by the pus.

Unfortunately, I shall have to begin by placing myself in opposition with the most universally adopted ideas, and, without paying any attention to them, overthrow a dogma which, to tell the truth, has never been seriously questioned. In giving the name of pyohæmia, or purulent infection, to the disease attributed to a mixture of pus with the blood, it was scarcely remarked that we were simply making a *petitio principii*; for we admit as demonstrated the three things which are precisely under litigation—the toxic property of pus, the reality of its mixture with the blood, and, lastly, the dangers of this mixture.

At the time when the belief which I now contest was first established, it was never asked if the pus is always the same—if sometimes it is not deprived of, and at other times endowed with, deleterious properties; if in this complex fluid such an action might not be due to the liquid part, and such another to the figured elements; if, lastly, the matter in question, which was considered altogether foreign to the organism, was not, on the contrary, formed by the simple heterotopical hypergenesis of a normal anatomical element.

It is true these questions—secondary in appearance, though they dominate the debate—have long ago been answered; but as the answers were at times contradictory, many Surgeons, tired of the hesitations of the dogma, neglected the questions of first cause and intimate nature. Content to recognise the existence of a general disease of a serious nature—*clinically* characterised by fever, adynamia, and a fatal progress, generally ending in death; *anatomically* by the formation of abscesses in the viscera or the cellular interstices—they continued to give to these series of symptoms and lesions the convenient name of pyohæmia, or purulent infection.

As concerns the qualities and properties of pus, modern science has definitely established the following facts:—

1. Pus—a humour which might be qualified as useless without considering it morbid—like the blood, is composed of organic and mineral substances, suspended or dissolved in a serum, and of figured elements, called leucocytes or purulent globules.

2. These leucocytes do not differ sensibly from the white blood globules, excepting that they are in a state of ectopia—that is to say, situated outside of the vessels in cases of abscess, of purulent secretion, and of suppurating wounds.

3. Pus, like other humours of the body, such as blood, urine, bile, etc., may present itself in two forms—not always easily distinguished from each other, but which are incontestable—in a state of purity, and in a state of alteration.

4. Pure pus, also called fresh, laudable, or non-fetid, is not possessed of any deleterious properties, and exercises no injurious effect upon the organism; it can be injected into the connective tissue, into the natural cavities, and even into the bloodvessels themselves, without causing the slightest derangement.

5. This rule suffers one exception. If the pus globules are introduced into the circulation in too great a quantity they may, like air or any other insoluble minutely pulverised substance, bring about capillary obstructions. These *embolics* may be of serious consequences, but they only act in a mechanical way. The experiment, which consists in asphyxiating an

animal by injecting a large quantity of pus into the veins all at once, is curious, but not applicable to the theory of pyohæmia in man; it only explains how, in a few well-authenticated cases, the breaking of an abscess into a vein has been capable of causing death in a very short space of time.

6. The nocive action of laudable pus injected into the veins is alone imputable to the globules; the serosity, if carefully filtered, can be transfused in considerable quantity without fear; the functional disturbances which have been observed by certain authors are very mild, and resemble in no way the symptoms of pyohæmia.

7. Clinical observations go to confirm these experiments in more than one instance. Collections of pus sometimes sojourn for months, and years even, in the natural or accidental cavities of the body, without producing the least febrile reaction; or they may also be slowly absorbed without inconvenience, and in that case prove of benefit to the general health and certain compromised functions.

In leucocythæmia we find the bloodvessels charged with an enormous quantity of white globules; but the symptoms of this disease, however formidable, differ completely from those which characterise pyohæmia. The only and formal conclusion is this: normal pus, deprived of all toxic properties, cannot be considered as the poison of pyohæmia. Thus the *petitio principii*, before alluded to, is demonstrated.

This irrefutable argument will doubtless compel the partisans of the old theory to change their front of battle. They will quote the innumerable experiments showing the possibility of developing pyohæmia by the direct introduction of altered pus into the circulation. They are right, it is true; but unrelenting criticism finds new objections.

The expression "altered pus" is very elastic, and it is necessary to specify the nature of the alteration. Pus proceeding from syphilis, variola, glanders, or carbuncle is not normal, therefore it is altered; but it is altered in a special manner for each of the corresponding diseases. Are we to believe in the existence of pyohæmic pus, which serves as the substratum or the vehicle of a special poison as in the above-mentioned diseases, and, consequently, capable of reproducing pyohæmia by contagion, miasma, inoculation, or by any other process?—or is the altered pus which creates pyohæmia merely charged with sepsine, and equally capable of producing the simple form of septicæmia if introduced into the system in a certain manner? What pleads in favour of the latter hypothesis is, that pus, like all fluids and solids of the body, is very apt to undergo ordinary putrefaction, and it is then that it most surely creates purulent infection. Seeing the importance of the question, I shall have to ask permission to enter into it more fully. As in the case of normal pus, let us resume what the researches of the last fifty years have taught us about putrid pus.

1. Putrid pus introduced into the economy; immaterial in what way, and in the slightest quantity, surely and rapidly causes disease—a real intoxication.

2. This disease presents two distinct forms; in one may be easily recognised the characters of septicæmia, whereas in the other the progress as well as the symptomatology is somewhat different; visceral abscesses are found at the autopsy. In short, we have to do with classical pyohæmia.

3. The experimenter may, as he likes, produce one or the other of these forms. For septicæmia he need only take the filtered serosity, and inject it into the connective tissue, into the vessels, or any other part of the body; if the pus employed contain both serum and globules, care must be had not to inject it directly into the veins. It is by this process, on the contrary, that pyohæmia is sure to be brought about, and we may therefore, for the present, at least, define pyohæmia as a disease caused by the direct introduction of putrid pus into the veins.

The adverse party wins, but only upon one point; for, far from being demonstrated, the specificity of pyohæmia is absolutely contradicted by these experiments. In order to create a truly specific disease, like syphilis, variola, carbuncle, or glanders, by way of experiment, it is necessary, first of all, to procure the toxic matter from a thoroughly infected subject, and the pus, if pus is made use of, must be taken from a person affected with syphilis, variola, carbuncle, or glanders. These essential conditions existing, every part of the pus is equally efficacious—the filtered serosity, the globules alone, or both together; nor does it matter as regards the manner of introduction—connective tissue, cavities, vessels. With pyohæmia it is otherwise; it makes no difference where the pus comes from so long as it is putrid. But, to insure the success of the experiment, two conditions are requisite—the pus globules and

their direct transfer into the venous system. Any other method of experimenting will merely produce septicæmia.

If my opponents, pushed to the last extremity, were to argue that the specific properties of pus reside in the globules, I could easily prove that the said globules only act in a mechanical manner, like any other solid particles, and as simple vehicles of the septic matter. A third series of experiments will prove this latter proposition.

1. Any inert foreign body, deprived of toxic properties, introduced into the organism, is either tolerated or else causes an inflammatory process to take place in its vicinity, which, if once begun, may present all the possible terminations of inflammation.

2. If the introduction be made directly into the vessels (I leave aside, on purpose, the extra-vascular foreign bodies), and the volume of this foreign body be of any considerable size, it eventually arrives at some vascular tube which it cannot traverse. There it stops, obstructs the tube, and consecutively brings about all the secondary lesions following ischæmia on the one hand, and the inflammatory process on the other—that is to say, *ramollissement*, sphacelus, infarctus, and the so-called metastatic abscesses.

3. These results have been produced again and again by Cruveilhier, D'Arcet, Virchow, Coze, and Feltz, and many others, with mercury, gold, caoutchouc, the pith of elder, fibrine, and various powders. The theory of artificial embolus is to-day complete. I have already observed that the leucocytes of laudable pus, in their capacity of solid bodies, enjoy the same properties, although, inasmuch as their volume is in relation with the calibre of the capillaries, they rarely stop when they are isolated and free; but, nevertheless, their stoppage is possible and proven—at least, as far as the leucocytes of the blood are concerned; for nothing is more common than to observe in the disease called leucocythæmia the obstruction of capillaries by an accumulation of white globules. It may be added that, after thrombosis, the blood-clots (the most benign of all intra-vascular foreign bodies) may be displaced, become embolic, and thus exert the mechanical action already invoked.

4. *En résumé*: the action of most foreign bodies, whether coming from without or arising in the interior of the vessels themselves, is the following, in case of migration:—Vascular obstruction, according to the volume; possible toleration, but also imminence of secondary inflammatory or other lesions.

But what will take place if the foreign body is in itself, or by impregnation, poisonous? The result can be easily foreseen. Local toleration may still be observed, provided the poison is not phlogogenous; but this will be rare, and intoxication must almost inevitably follow in every instance. If the foreign body remains outside of the vessels, we have to do with a poisoned wound, complicated by the sojourn of the toxiciferous body—that is to say, with all the conditions favourable to the development of local and general accidents. If the foreign body is carried into the circulation, it first infects the blood in its course, and afterwards causes, at the place where it stops, an obstruction, creates a morbid focus, and lastly realises every condition and all the effects of an intra-vascular inoculation.

The theory of experimental pyohæmia is based entirely upon this point:—The putrid pus is injected into the veins; its serum infects the blood, and also the globules, which yield a part of the poison that impregnates them, whence the preparatory septicæmia. These same globules, once carried into the capillary network, come to a standstill, create an infarctus, which suppurates, and in its turn becomes a new focus of septicity, more dangerous than ever, inasmuch as it is inaccessible to therapeutics. But do not believe that the purulent globules alone are capable of producing such effects; any solid particle will do the same, provided it is imbibed with poison. Take any powder, sprinkle it with any putrid serosity, well filtered; in the absence of powder, take certain fluids which are insoluble in the blood (such as mercury or fat-globules), or take putrefied blood-clots reduced to fragments, and inject them into the veins—pyohæmia, with its fever, its adynamia, and its metastatic abscesses, will be the fatal and never-failing result. The demonstration of this capital fact was made by D'Arcet twenty-nine years ago.

Ten grammes of a solution of gold were injected into the jugular vein of a dog; ten grammes of putrid serum, exhaling an infectious odour, were introduced forty hours later, and in the same manner. The animal died six hours afterwards, with the ordinary symptoms of putrid infection. At the autopsy, the lungs, instead of being simply congested or ecchymotic, presented numerous lobular obstructions, of which some (six in

number) contained pus, whereas others showed a less advanced state of the inflammatory process.

From his series of experiments, D'Arcet concludes "that purulent infection is a complex disease, comprising two well-marked series of phenomena, but which are so much united and so intimately connected with each other, that they have been confounded up to this moment. These phenomena are—1. A local mechanical obstacle in the capillary circulation, due to the introduction of bodies into the vessels not in harmony with their volume or use. 2. A general state, of a very serious nature, presenting all the characters of adynamia, and caused by the development, *sui generis*, of putrid matters in the organism, probably acting like ferments—that is to say, able to produce such modifications in the blood that the initial deleterious action persists and continues under its influence."

I have cited these passages of D'Arcet not only to support my own opinions, but also to render justice to an author who should be regarded as the true creator of the modern theory of pyohæmia. Very little was wanting to this physiologist to arrive at the complete truth—to isolate, first of all, septicæmia from pyohæmia; to believe no longer in the necessary connexion of this latter disease with suppuration; and, lastly, to draw from the above-cited experiments these heretic, subversive, paradoxical conclusions, which I lay before you without hesitation:

1. There exists no necessary relation between the outer and metastatic suppurations; there is simply an habitual coincidence, but no necessary dependence.

2. Pyohæmia involves pyogænia in effect, but not in cause; or, in other words, purulent infection ends in suppuration, but does not arise from it.

(To be continued.)

ORIGINAL COMMUNICATIONS.

ON PUERPERAL FEVER. (a)

By Dr. EDWARD MARTIN,

Professor of Clinical Midwifery in the University of Berlin.

SINCE I had the honour of reading to this Society, in 1860, a Report on an Epidemic of Puerperal Fever, wherein I put forward the view that this disease depended upon a diphtheritic process set up in the female genital organs, I have omitted no opportunity of expanding and settling this doctrine; but if I venture to bring the subject again before you now, it is that I am impressed by the conviction that one reason why the views of this disease are still so divergent is, the confusion produced in the statistical reports by their comprising all the febrile diseases of lying-in women under the same rubric. Febrile conditions may be met with in lying-in women as well as in non-pregnant women, whether as a consequence of inflammation in almost any organ (but which has no connexion with the puerperal condition) or in connexion with various contagious diseases, as scarlatina, variola, etc. There may even be febrile affections consequent upon inflammatory action in the genitals of lying-in women; but which are essentially different from puerperal fever in the alarming sense of the word. Entirely unconnected with this, lying-in women may have very severe fever from inflammation of the breasts or nipples, after contusion or laceration of the uterus or vagina, as well as consequent on abscesses or ulceration which may ensue upon effusion of blood into the connective tissue. Such fever neither in its course, symptoms, or issue, resembles the conditions which arise from the diphtheritic process; and it is this which should be regarded as the essential characteristic of puerperal fever. Even the existence of thrombosis is not as a matter of course to be attributed to puerperal fever, as in many cases this remains entirely isolated, as contrasted with the thrombo-phlebitis which accompanies or follows the diphtheritic process.

Limiting in this way the conception of puerperal fever, the question naturally arises—What are we to understand by the "diphtheritic process"? You are aware that recent investigations have thrown most important light on the nature of diphtheria affecting other organs—especially the pharynx, where it has been shown to consist of a fungous formation, the spores of which are seen under the microscope to penetrate not only into the tissues, but within the bloodvessels—producing in this way a generalised disease. In diphtheria of the genital organs investigations have as yet not been extended

(a) Translated from the *Berliner Med. Wochenschrift*, 1871, No. 32.

thus far, and it remains a question calling for farther examination. Admitting, however, that the diphtheria is here due to a fungous formation, other questions arise. Is the fungus in question specifically different?—since we are familiar with various fungi which germinate in the vagina of both pregnant and non-pregnant women without giving rise to any dangerous affections;—is the fungus the mere carrier of the contagium? or is the puerperal fever produced in consequence of the special condition of lying-in women favouring the production of certain fungi, by reason of changes taking place in the organic substances and fluids?

Leaving these considerations, we may next advert to an examination of what the macroscopico-anatomical basis of puerperal fever is. In the majority of cases we find on the external genitals and the vagina a diphtheritic deposit covering those wounded spots which, in the form of larger or smaller lacerations of the mucous membrane, so frequently occur during labour. The circumference of these spots is more or less considerably swollen. In many cases the diphtheritic deposit is thus confined to the external genitals, and the disease pursues its course by casting off the deposit without any or with very little general disturbance. But in the majority of cases coming under Medical recognition, the diphtheritis is not confined to the entrance of the vagina, but is found deep within the canal, covering the large or small lacerations of the os uteri, and within the cavity of the uterus itself. Here it occupies both the site of the placenta and the upper paries of the organ; and it is sometimes found exclusively here, and in no places accessible to the eye.

It may be objected that in many autopsies of women dying of puerperal fever no diphtheritic deposit has been found. This is a fact which I have myself verified in several instances, in which not only have the symptoms been present, but careful examination of the patient during life has shown the presence of the deposit. In explanation of this apparent contradiction, we must not forget that the diphtheritic deposit in many cases very quickly disappears, and especially when injections or caustics have been employed, while its consequences may persist and undergo farther development. That we should not be able during life to see the diphtheritic deposit when within the uterus is conceivable enough, but the diphtheritic flocculi may be recognised in their expulsion with the returning uterine injections.

As a general rule, the diphtheritic process spreads rapidly from the genital organs, but it does so only rarely towards the skin of the thigh, nates, etc. These then exhibit an erythema (which has been well named puerperal scarlatina) or pass into ulceration. More frequently the diphtheria extends into the urethra or the rectum, if it have not already appeared there primarily; but its most common modes of spreading are either by means of the connective tissue surrounding the vagina and neck of the uterus, by the mucous membrane of the tubes to the peritoneum, or by the lymphatics and veins—these various modes of its extension being often combined with each other.

1. In the first of these modes, there is an infiltration of the pelvic cellular tissue, with a turbid serosity which extends to the peritoneal covering of the pelvic genital organs as far as the ovaries, there being usually also peritoneal effusion. This infiltration of the pelvic tissue may extend to the retro-peritoneal space, the kidneys, and the liver, and indeed even to the pleura and lungs; and after it has persisted for some time, it frequently gives rise to abscesses of the pelvic cellular tissue. By many authors this turbid-serous infiltration of the connective tissue is regarded as a primary occurrence, and a perivaginal or periuterine phlegmon is then represented to be the essential condition of the puerperal fever. This view I cannot accept, as it does not accord with the results I have obtained from observing cases from the first, since I have constantly seen traces of diphtheria preceding the turbid-serous infiltration. It is true that tumefactions in the vicinity of the cervix uteri may be present soon after birth, from other causes—as, *e.g.*, from contusion and effusion of blood into the connective tissue surrounding the cervix—and such swellings may also issue in abscesses. But we must distinguish these from those which are dependent upon the turbid-serous infiltration consequent on diphtheria, although in many cases the two conditions may be combined.

2. Another mode of spreading the diphtheritic process, which can scarcely be said to be of frequent occurrence, is along the mucous membrane of the internal genital organs to the peritoneum. In the cases of this kind which have fallen under my notice, I have often at the autopsies been able to follow the course of this usually rapid disease. In such cases, in which there was no other visible mode of propagation, the

inner surface of the uterus was covered with a bloody-purulent matter, and the tubes (sometimes only one of these) were reddened, especially along their external third, dilated, and filled with a purulent mass, their fimbriæ being unusually swollen and reddened, and covered with or imbedded in fibro-purulent exudations. In these cases, usually a sudden attack of the pain peculiar to peritonitis (sometimes at first confined to one inguinal region) occurred on the second or third day after delivery.

3. The third mode of extension operates through the vessels, and most frequently through the lymphatics. Many of the dilated lymphatic vessels, and especially those of the uterus, are found filled with masses of white crumbly or fibro-purulent matters. Sometimes, when life has been sufficiently prolonged, there are also circumscribed collections of pus, which it would be erroneous to regard as abscesses. This extension through the lymphatic vessels is usually complicated by the serous infiltration, the so-called phlegmon of the connective tissue; and, almost as a general rule, one or both of the ovaries is infiltrated with serum, and penetrated by dilated lymphatic vessels containing firm white coagula or purulent fluid. In some rare cases the ovary becomes completely loosened in tissue, as if from shredding away. In this form of extension exudation is seldom absent in the cavity of the abdomen, sometimes chiefly occupying the coverings of the genital organs, and sometimes having no defined limits. Finally, in some cases the diphtheria is propagated through the vaginal and uterine veins. This is especially shown in those prolonged cases in which the separation of the diphtheritic deposit from the genitals is followed by thrombosis of the veins, with its consecutive circumstances, such as breaking up, emboli, etc. Peritoneal exudations may also be met with, but not ordinarily. That the phlebo-thrombosis of lying-in women may, however, arise in other ways, quite independently of any diphtheritic process, needs only to be mentioned.

In these various but frequently combined modes of extension of the diphtheritic process of the genital organs, the great glandular organs of the abdomen, the kidneys, liver, and spleen are soon implicated, so that they are usually met with in a state of parenchymatous inflammation; and finally, the lungs, especially at their lower lobes, not infrequently exhibit the turbid-serous infiltration, pleuritic exudations being also associated with the peritoneal. A more infrequent result of the diphtheritic process, because in general a longer duration of the affection is required for its production, is inflammation of the periphatic cellular tissue, which may happen in different parts of the body. This most frequently occurs in and around the joints, around the muscles of the extremities (*e.g.*, in the pernicious form of phlegmasia dolens), or around some of the superficially placed glands, as the breast or parotid.

It is precisely this great multiplicity of local affections, and their combination with each other, that constitute the peculiar characteristic of puerperal fever. As, however, sometimes one and sometimes another of these occupies the foreground, we are furnished with the explanation of why different authors have come to regard these different local affections, whether peritonitis, phlebitis, lymphangioitis, phlegmon, etc., as the essential feature of puerperal fever.

Although, in regard to our knowledge of the etiology of puerperal fever, decided progress has been made in recent times, yet many points remain obscure. Thus, in relation to the admission that the disease is autochthonous—*i.e.*, that it may arise from the spontaneous decomposition of retained portions of the placenta—we must not overlook the fact, that remains of the placenta or membranes are not infrequently retained for days, weeks, or months within the genitals, without any putrid decomposition taking place, or any symptoms of puerperal fever appearing, while their presence often gives rise to repeated attacks of hæmorrhage. If, then, in numerous other cases the retention of such remains is followed by septic decomposition and puerperal fever, it is evident that some other circumstance has to be sought for which has determined this unfortunate occurrence. From the known influence of the air in exciting putrefaction in fermentable bodies, it results that decomposition of the retained remains of the placenta would be especially expected when these protruded from the os uteri into the vagina, while they would be more protected from the influence of the air when enclosed within the cavity of the uterus. And, in fact, in this last case putrefaction does much more rarely occur; but it must not be overlooked that the remains of the placenta are then more intimately united with the wall of the uterus. However, there are plenty of examples of the occurrence of puerperal fever, notwithstanding complete expulsion of the placenta; and in such cases we must seek for

other causes. Numerous cases have proved to me that women who are delivered while the subjects of recent gonorrhœa frequently become affected with puerperal fever, the diphtheritic process being immediately set up, and proving difficult of arrest. I must therefore admit that a preceding inflammatory condition of the mucous membrane of the genital organs stands in a certain relation to the occurrence of the diphtheritis. In the great majority of cases, however, the germ of puerperal fever gains access in other manners; and this is very positively shown by the well-known fact (confirmed by the numerous figures of the Vienna Lying-in Hospital, as also by the results observed in my own clinic, that the so-called street-births (*Gassengeburt*) are scarcely ever followed by puerperal fever. The transport of the diphtheritic germs takes place beyond all doubt very frequently during labour, more rarely after delivery, and sometimes shortly prior to parturition. In what the transported germ consists is less made out. Experience has taught us that cadaveric products and decomposed animal substances place puerperal women in danger, especially when an internal examination is made by fingers that have had to do with dead bodies without having been afterwards cleansed—although Practitioners may also convey the disease who have observed care in washing. The dead bodies in question have not always been those of the subjects of puerperal fever, although these entail a greater degree of danger. Again, certain secretions from suppurating wounds and ulcers conveyed to the genitals of a puerperal woman may give rise to diphtheritis. The epidemic prevalence of puerperal fever in Berlin during the winter of 1870-71 may with strong probability be attributed to the employment of so many of the civil Practitioners in the military Hospitals. Still more decidedly are diphtheritic products—which not infrequently are produced in scarlatina, typhus, cholera, suppurating cancer, etc.—dangerous to lying-in women. The most usual mode of propagating the diphtheritic poison from the sick to the healthy is its direct conveyance by means of sponges, dirty towels, catheters, clyster-pipes, or the fingers of the accoucheurs; and in this way epidemics of puerperal fever are brought about most frequently in Hospitals, although they are also met with in private practice. What relation this origin bears to an incubation stage is uncertain; for although Veit has observed this to vary between twenty-seven and forty-eight hours, the number of cases adduced are as yet too few to allow of any general statement being made.

Diphtheritis of the genitals is not only met with in puerperal women, although they—on account of the denudation of the mucous membrane of its epithelium, and the numerous lacerations of tissue, as well as the ready decomposition of the lochial secretion—exhibit a special predisposition for contracting the disease, while the dilated vessels present a favourable condition for generalising the affection. Paul Dubois, forty years since, observed that the pupils at the *Maternité*, who, while menstruating, tended sick puerperal women, also became the subjects of an affection resembling puerperal fever. In Germany similar observations have been published, showing that, under certain favouring circumstances, a similar diseased process may be set up in non-pregnant women. I remember the case of a woman, 52 years of age, who was admitted into the gynæcological clinic of the Berlin *Charité* on account of repeated hæmorrhage. This arose from a large crumbling myoma, for the removal of which I used a forceps which probably had not been properly cleansed after a former employment. The woman died of diphtheritis of the internal genitals fifteen days after the operation. The autopsy disclosed the same lesions as are found in women who have died of puerperal fever—viz., diphtheritic deposit upon the wounded surface whence the tumour had been removed, lymphatic vessels filled with pus, and peritoneal exudation. It would seem to result, from other cases, that this diphtheritic process of the genital organs in non-pregnant women is but rarely followed by dangerous general disease.

Finally, it may also be mentioned that new-born children, and especially those of women who are the subjects of puerperal fever, sometimes are the subjects of a similar diseased condition, which in them proves fatal.

Little need be said concerning the symptoms of a disease well known to you all. The elevation of the temperature is characteristic—this rising, except in the cases in which the diphtheritis is limited locally to the genitals, to an abiding height of 39° or 40° C., or even yet higher. The rapidity of the pulse is also very persistent, frequently remaining much more than 100. The general condition appears usually, at the commencement of the affection, to have undergone but little change; yet in many patients there is soon observed a peculiar death-like aspect, although consciousness is generally retained

to the last. In some cases there is delirium, and in some rare instances maniacal paroxysms, the autopsies usually revealing no morbid changes in the brain. The diphtheritis itself is only visible to the eye within the vagina and as far as the os uteri, its presence within the uterus being discovered by the lochial fluid acquiring a peculiar smell, and by the discharge of diphtheritic masses on the re-issue of injections that have been thrown in. The features of the disease are in different cases essentially modified, according to the extension it has acquired. Very frequently the hypogastrium is painful on pressure in the region of the uterus, and tumefaction is here perceived both on external and internal examination. Such tumefaction, as already stated, may arise in puerperal women from other circumstances; and this is especially the case after laborious labours, effusion of blood having taken place into the cervix uteri or the cellular tissue surrounding the vagina. This hæmatoma may also, as well as the parametritis consequent on diphtheritis, pass into suppuration and give rise to pelvic abscess. The symptoms produced by the frequently ensuing affections of the intestine or bladder—peritonitis, pleuritis, phlegmon—call for no explanation.

With regard to the prognosis of puerperal fever in general, if we except the cases in which the diphtheritis remains localised, it is upon the whole unfavourable; for we must admit that one-third of the cases in which fever has ensued upon diphtheritis of the genitals terminate fatally. Death takes place most frequently up to the fifth day, and then up to the eleventh day. In some cases the disease may last even for months.

I have only a few words to say concerning treatment. The prophylaxis lays claim to our most earnest attention, and the etiology of the disease indicates many important points for the exercise of this. The extremest cleanliness of all having to render service to the lying-in woman, both as regards their persons and their clothes—especially their fingers and sleeves—and cleanliness in regard to all clothing, catheters, sponges, enema-pipes, etc., must be most stringently insisted upon. It is very much to be desired that all the utensils of labour should be new for each woman, and the same elastic catheters should never be employed for several lying-in women. As mere washing the hands which have become contaminated with infectious matter does not seem to afford sufficient security for internal exploration, I think it best under such circumstances to rest satisfied with external exploration. Especially does this rule apply to lying-in Hospitals when cases of diphtheritis have appeared; and my own experience on this point entirely confirms the propriety of the advice given by Halbertsma and Litzmann. How necessary, then, is that complete practice of external exploration which I have taught since I first held the Professor's chair, speaks for itself. Lastly, in regard to the curative treatment, I can only refer to what I have already stated in a detailed communication which I presented to this Society on "The Treatment of Puerperal Inflammations of the Female Sexual Organs." (b) It must be pre-eminently symptomatic, and, as long as the temperature continues high before all things the fever should be diminished. Internally digitalis with nitre or acids, and externally tepid or cold applications, contribute to this end, after due evacuation of the bowels has been secured. I cannot speak so well of quinine as do many authors. Local treatment has during the last ten years rightly been much tried. Cleansing out the vagina by syringing and injections of tar- or creasote-water, with carbolic acid, chlorine, or solution of nitrate of silver, has without doubt proved of great utility, even although it has not often happened that the process has been cut short by their agency. Injecting the same substances, suitably warmed, through a large catheter *à double courant* into the cavity of the uterus has sometimes been followed by a considerable diminution of temperature, as well as cleansing out the uterine cavity; but a decided general improvement has been by no means of such frequent occurrence as might have been hoped.

EXTIRPATION OF THE ENTIRE PAROTID.—In the *Deutsche Klinik*, 1871, No. 37, is given a detailed translation from the *Sperimentale*, of the total extirpation of the parotid, by Professor Marcacci, of Sienna, the divided carotid at its temporal end, and several other vessels, being tied during the operation. The ligature around the carotid only came away three months after the operation, but the wound had cicatrised, with the exception of the aperture for this, long before.

TWO WELL-KNOWN SYMPTOMS OF PHTHISIS—REMARKS ON THEIR EXPLANATION.

By Dr. F. A. HARTSEN.

MUCH has been written upon, and still more spoken of, a certain sound—so unwelcome to the Physician, so importunate to the invalid by its tick, tick, tick, in the silence of the night. In spite of many hypotheses, the “*cliquetis métallique*” of lung cavities (for this is the pathological music to which I allude) is enveloped in a cloud of mystery. Some try to explain it as the effect of a drop falling from the top to the bottom of the cavity; others attribute it to the bursting of a bubble.

The first explanation, to my mind, is entirely unsatisfactory. The sound in question is heard in cases even where the fluid contained in the cavity is of a viscous nature. Now, it would be contrary to all rules of acoustics, that a drop of viscous matter—even if the formation of such a drop in a cavity were probable—falling from so slight an elevation upon a viscous surface should produce a ticking sound. As to the second hypothesis, it evidently represents the “*metallic sound*” as a kind of “*râle crépitant*” on a large scale. It, however, is insufficient, so long as it has not been proved experimentally that a metallic sound can be produced by a bubble of viscous matter.

This objection cannot be made to a new hypothesis which I would offer to the judgment of competent readers. It has often occurred to me that a sound, exhibiting a remarkable analogy with the “*cliquetis métallique*,” may be produced in this manner: two surfaces of a mucous membrane covered by a small quantity of viscous matter are brought into contact, and afterwards separated. The sound is detected at the moment of separation. Such will be the case, at least, if the said mucous membrane is sufficiently stretched and has the opportunity of communicating its vibrations to a trumpet-like column of air. So, for example, the metallic sound can be imitated by the surfaces of the nostrils, and especially by the corners of the lips.

I conclude, by analogy, that most probably this mysterious “*cliquetis métallique*” is produced by the linings of the cavity losing their hold upon each other, after having been partly brought into contact by the movement of respiration. As no cavity is limited on *all* sides by bony matter, there is always an opportunity for the re-connexion of these linings.

Another pathological symptom, of which I wish to discuss the explanation, is the anti-æsthetic hooked appearance of the nails. Dr. Taylor, if I am not mistaken, attributes this to a process of tuberculisation in the root of the nails. I do not consider this phenomenon of such a serious and complicated origin.

By careful observation, we shall find that the shape of the nails varies with the state of the patient's nutrition. If he regains flesh, the nails gradually recover their normal shape. It seems to me that an abnormal growth of the nails is simply a symptom of emaciation.

The disappearance of the conjunctiva from under the nail deprives it of its natural support. It must henceforth rest almost immediately upon the bone as upon a model, and is obliged to follow the direction of its surface. This surface being rounded at the top, the nail takes a direction downwards. If my memory fail not, the late Professor Niemeyer has explained this phenomenon by the absorption of the substance under the nail.

In one case of phthisis under my observation, I remarked another particularity which has been, perhaps, hitherto overlooked. It is this: if you allow the nail to grow, its breadth, far from being the same in all parts, increases gradually towards the top—in fact, the nail assumes a cuneiform or conic shape. This curious and equally unæsthetic phenomenon confirms my explanation of the former; for this is evidently owing to the disappearance of the supporting conjunctiva.

As the surface of the phalanx bone is more or less flat on the outside, the disappearance of the conjunctiva causes the nail to be flattened. And as the disappearance increases by degrees towards the top of the finger, the flattening of the nail will increase in the same way. Consequently, the nail from cylindrical will become conic.

To me, it appears that this nail phenomenon is more apparent in the toe-nail than in the finger-nail. If this be the case, it is in accordance with my (Niemeyer's?) explanation. For it is to be expected that, the feet being farther removed than the

hands from the great source of nutrition (the heart), they will more quickly suffer from every decrease of nutrition. In fact, “cold feet” is a more common complaint than “cold hands.”

One more remark in conclusion. If this explanation of crooked nails be, as I think, the correct one, it is clear that this phenomenon has no importance whatever as a diagnostic for tubercles, but must occur in every form of emaciation. Observation must decide if this be really the case.

A very rapid growth of the nails and hair seems to belong equally to the symptoms of emaciation. This, however, may be generally known, and I do not attempt to explain it here.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ST. MARY'S HOSPITAL.

CASE OF OBSCURE RHEUMATIC FEVER, WITH HEAD SYMPTOMS—CLINICAL REMARKS.

(Under the care of C. HANDFIELD JONES, M.B. Cantab., F.R.S.)

L. B., aged 24, single; admitted October 6, 1871. Was taken ill October 1, with severe shiverings, which lasted several hours; they were succeeded by pains in all her limbs and head. Has had rheumatic fever twice before; the last attack was three years ago. She complains at present of pains in loins and hands, but none of her joints are much affected; there is no notable inflammation. The sister reports that soon after she came into the ward she walked several steps alone. Her aunt states that she used to suffer much from rheumatic pains in the feet, and applied cold cloths to them for relief. A systolic murmur at the apex of the heart is very marked; it is heard both inside and outside the nipple-line loudly; good breathing in both backs. Pulse 102, small and weak; tongue coated; no appetite.

October 7.—Bowels well opened by *podophyllinæ gr. j.*; is taking *mist. potass. citrat. ʒjss.*, and *pot. iod. gr. j. + pot. bromid. gr. v. 2dis horis*, *pt. mist. 4tis horis*.

8th.—Last evening she felt stiff and painful all over; if she raised her head felt giddy and faint. In the night she was quite stupid, anxious, tremulous, and delirious; her respiration was short and sniffling. This morning she looked wildly about her; appeared very anxious; her lips were tremulous. Temperature at 10.30 a.m. 103°.

9th.—At 11 a.m., temperature 103.6°; at 2 p.m. 105°; still seems nervous and anxious; sighs; does not attempt to feed herself, but takes nourishment well; both radial pulses compressed by 134 grammes; forehead not hot; knits her brow; is rational now; says she has got such a cold; tongue coated, and rather dry; urine red, clear, neutral, copious, not albuminous. *Acidi nitrici dil. mxxv. + aq. ʒj. 2dis horis*; *chloraī gr. xv. + liq. morph. bimec. mxx. + aq. ʒj. h. n.*; port 4 oz.

10th.—Better night, slept a good deal; respiration quiet; temperature 104.8°; pulse 140; great thirst; seems to suffer pain when right iliac region is pressed; some suspicious typhoid spots on abdomen; acid enters both lungs posteriorly fairly well.

11th.—Temperature 104.7°; pulse 135, excited; is tolerably rational; hands tremulous; has an eruption on arms and legs consisting of small red spots scattered over the surfaces. *Ammon. carb. gr. v. + tinct. cinchon. ʒj. + dec. cinchon. ʒj. 4tis horis*.

12th.—Eruption rather increased; on abdomen there are some dull red spots, and some subcuticular diffuse brownish discoloration.

13th.—Died this morning at 2.35 a.m.; sank gradually. She was conscious till about 11 p.m., but her sight failed quite early in the evening. Her face looked swollen and spotty. All her evacuations were passed in bed the last day. The motion was very offensive, clayey, and light-coloured.

Autopsy.—Remains of a spotty dull-tinted eruption on face; some spots also on abdomen. Much hypostatic congestion of trunk. Left lung pushed aside by heart. Pericardium contained some serous fluid, slightly reddened by blood, which blued reddened litmus very slightly; nothing like so much as eczema serum or nasal catarrh fluid does. In a case of acute phthisis soon after, the pericardial fluid gave the same reaction as in this. Right lung weighed twenty ounces, left sixteen ounces. Upper lobe of left lung intensely congested, blackish,

and softened; rest of this lung tolerably healthy. Right lung a good deal congested at back; quite apoplectic in some patches of lower lobe. Heart weighed sixteen ounces; there were numerous spots of white patching on its anterior surface, and on the parietal pericardium there was a notable amount of whitish recent lymph. The mitral flaps and their cordæ tendineæ were thickened, and at one spot there was a vegetation, which seemed to be of some standing, and inclined to disintegrate. Aortic valves healthy. The right ventricle was filled with colourless coagulum, which extended as a solid strand into the pulmonary artery as far as its bifurcation. The right auricle contained only black clot, filling, but not distending it. The left ventricle also contained a large decolorised coagulum. The spleen weighed twelve ounces, was soft, but apparently healthy. The kidneys weighed together sixteen ounces and a half; were large, pale, with spots and patches of congestion. In the lower part of the small intestine the solitary glands at some places were found reddened and notably enlarged; but Peyer's patches were quite unaffected. The right knee (the only joint examined) contained some thickish opaque gelatinous synovial fluid, which under the microscope showed multitudes of well-formed pus corpuscles. In the pia mater of both hemispheres there were a few minute whitish spots, situated on the fore part of the convex surface. One of these consisted of corpuscles and granular matter, and had quite the appearance of tubercle; another larger one, which seemed to be made up of three or four small ones grouped together, was less definite in structure, but in parts resembled tubercle a good deal. On the outer side of each hemisphere there was a large patch of sanguineous extravasation, the pia mater being infiltrated with blood; but there was no capillary apoplexy nor breaking down of the brain substance by clot. The patch on the left side was the larger.

Remarks.—The phenomena in this case were hard to read aright. The history of two previous attacks, and of recent rheumatics in the feet, the presence of a mitral murmur and of pains in the hands, were insufficient to make the diagnosis clear during life. But the discovery at the autopsy of a little recent fibrine on the pericardium, and of a few drops of puriform fluid in one knee-joint, go far to establish it. The opinion was expressed at the bedside that the case was one of those of rheumatic fever marked by very high temperature and cerebral symptoms ending fatally, of which several are now on record. This was not precisely verified, as the patient did not die in coma, but chiefly in the way of asthenia, the circulation being brought to a standstill by the fibrinous coagulum which filled the right ventricle. However, the main point—that the case was one of rheumatic fever—seems established, and the peculiarities it presented related to the absence during life of evident articular inflammation, and to the existence of fever of a typhoid character, and of severe cerebral symptoms. It seems that the unknown cause of acute rheumatism in this instance affected the articulations and heart but slightly, and spent its chief malignity on the regulating temperature-centres, the hemispheres, and certain vaso-motor nerves. The effusions of blood into the pia mater and lung tissue indicate a weakened state of capillaries—a state very much the same as that existing in purpura, and like it many instances associated with, and probably dependent on, loss of power in the vasal nerves. The cerebral symptoms, stupor, anxiety, and delirium seem to have been rather the immediate results of the general morbid agent than of the extravasation in the pia mater, which took place probably at a later period. The cerebral tubercles were quiescent, and took no share in the morbid process. The possible dependence of the phenomena on blood-poisoning derived from the disintegrating fibrine on the mitral valve has been considered, but seems to be negatived by the absence of any fibrinous deposits in the viscera.

MEDICAL COLLEGE HOSPITAL, CALCUTTA.

TRAUMATIC ANEURISM OF THE POPLITEAL ARTERY.

(Under the care of Dr. FAYRER.)

W. R., EUROPEAN, aged 32 years, a healthy, muscular young man, of temperate habits, and who has been about ten years in India, was admitted into the Hospital at 9 p.m. on August 3, 1871, with symptoms of traumatic aneurism of the left femoral artery, just above the knee.

It appears that about seven weeks ago—he thinks it was on, or about, June 18—when in the railway station, his attention being suddenly attracted by the passage of an engine close to

him, he walked (having turned his head, without seeing it) against an iron rail that was projecting from the place on which it rested. He felt that he had sustained a severe blow on the lower and inner aspect of the left thigh, which came in contact with the rail; the pain was severe, but it soon passed away, and he resumed his occupation. For a week he felt little or no pain, but the lower part of the thigh then began to swell, and to have deep-seated aching pain; for this he applied liniments, lotions, and fomentations. It disturbed his rest at night, and caused him much uneasiness; but still he continued to do his work as a foreman, until July 3, when the pain and swelling increased so much that he was compelled to lay up in bed, for he was no longer able to stand. The swelling appears to have been regarded as an abscess, for poultices and leeches had been applied, but without relief. The swelling continued to increase; the leg swelled, and became numb. His account of his sensations is not very clear, but he appears to have suffered much pain of a burning character, as well as that due to distension and swelling, with what he describes as a benumbing sensation throughout the limb below the knee. On July 27 he sought relief by admission into the Howrah Hospital. Three or four punctures with exploring needles, or a small trocar, were made, but only dark blood escaped. The swelling continued to increase. The leg and foot became œdematous; a sense of numbness in the leg, and a burning sensation in the swelling, caused him much distress. I saw him on August 3 with Dr. D. B. Smith; the leg and foot were swollen and œdematous, and colder than the other leg. He was in bed, with the limb slightly flexed at the knee, and resting on a pillow. There was an oblong oval swelling, commencing just above the inner side of the left knee, which extended upwards for about seven or eight inches, and transversely about five to six inches. It had a somewhat livid appearance, especially in certain patches. There was distinct fluctuation; it was elastic and tense, but there was not the faintest pulsation or thrill. It was considered to be rather rapidly increasing. The leg and foot, I have said, were œdematous and colder than the other limb, but the circulation was evidently well kept up, for there was no sign of gangrene, and he could feel perfectly in every part that was touched. Neither anterior nor posterior tibial arteries could be felt, but their pulsation in the opposite limb was unusually faint. The pain was so severe as to have rendered the use of morphia frequently necessary; and either this or the constitutional disturbance had induced irritability of stomach, and a somewhat icteric tinge of skin and conjunctivæ. His health, originally good, seemed worn by suffering and confinement. I stated my opinion that the tumour was due to the presence of blood; the question of a deep-seated abscess was discussed. A small incision decided the question. A quantity of black clots were turned out of the cavity, and a warm gush of blood against my finger, on disturbing the clots, left no doubt as to the nature of the swelling. On passing the finger deep into the wound, the femoral could be felt pulsating distinctly, and it was much thickened. The finger came on the artery just where it became popliteal, having passed through the opening in the adductor magnus. I withdrew my finger, and applied lint compresses and a bandage until measures could be taken for more effective treatment. In consultation with my friends Dr. D. B. Smith and Professor Cutcliffe, it was decided to remove him to the Medical College Hospital, where he would have advantages, in the way of the attendance of dressers and nurses, that were not elsewhere obtainable. He was easier after the puncture and evacuation of clots, and he reached the Medical College Hospital safely; a slight oozing on the way, however, rendered it necessary that immediate operation should be resorted to. With the assistance of Drs. Smith and Cutcliffe, Baboo Ishen Chunder Roy, the resident Surgeon, my House-Surgeon, Baboo Soorjee Coomar Chuckerbutty, and the dressers, I laid open the tumour by an incision in the course of the femoral artery, about seven or eight inches in length, and, turning out a quantity of clots, a jet of warm blood soon indicated the breach in the main artery, just where it lies near the bone, as it becomes popliteal. The opening in the artery was quite obvious—it was oblong, and involved at least two-thirds of its calibre; the inner coat of the vessel could be seen on that portion which remained intact. The artery was tied above and below the wound. No trace of the femoral vein could be found, but the tissues surrounding the artery and its sheath were so much thickened that it was considered that the obstructed vein probably was included in the thickened mass. The femur was also exposed for a short extent in a situation corresponding to the breach in the artery. The interior of the large cavity formed by

the clots was ragged and discoloured with dark blood; the tissues were condensed and matted. The breach in the artery could not have been less than a half or three-quarters of an inch in length. The distance between the ligatures was fully an inch and a half. The lower end was the most difficult to ligature. The cavity having been carefully cleaned out and washed, and all bleeding having ceased, the wound was brought together and dressed antiseptically; the leg was enveloped in cotton and a flannel bandage. The artery was so well compressed at the groin that very little blood was lost. Immediately after the operation his pulse was 96; temperature in axilla 101°, left foot 99°, right 98°, at the groins equal, 100°. As his stomach was irritable, an opiate enema was given.

August 4.—9 a.m.‡: He is doing well. Had some sleep; Pulse 96; temperature in axilla 101°, left foot 100°, right foot 99°. Slight oozing from the upper part of the wound, but merely a sero-sanguineous fluid. 7 p.m.: Skin moist; is still nauseated, he says, from the morphia and chloroform. Bowels have acted freely. Looks bilious; eyes yellowish; no pain; great relief to the limb since the operation. Temperature of left foot 101°, right 100°. Effervescing draughts, with hydrocyanic acid. He is in excellent spirits; feels so much better.

5th.—Slept well; slight coloured oozing from the wound. Pulse 92; temperature in axilla 101°, right foot 99°, left foot 100°. Is still inclined to be nauseated. Conjunctivæ tinged yellow. *R. Hyd. chlorid. gr. vi., pil. coloc. co. gr. vi., st. s.* Effervescing draughts; changed the dressing. 12 p.m.: At midnight, when his bowels were acting, as he strained, hæmorrhage began. I saw him soon after, and found that he had lost very little blood, but it was evidently necessary to interfere. Opened out the wound, cleared out a considerable quantity of clot, and found that the bleeding was rather free from the lower end of the artery as well as from some collateral branches. The ligature had separated from the lower end. The upper end of the vessel was not bleeding, and it could be seen and felt pulsating in the wound. The other ligatures had separated and lay loose in the wound. The tissues had been so much softened that they would not hold. The wound itself looked quite healthy. The upper end of the divided artery was evidently closed by a clot. No bleeding occurred from it whilst the wound was open, and the lower end was again secured by a ligature. Several new points also had to be ligatured. The hæmorrhage was soon checked, very little blood having been lost. The wound was again dressed antiseptically, but was not closed with sutures. During the proceeding I ascertained that part of the femur was denuded of periosteum; the bone exposed was smooth and white, probably not yet necrosed. The patient was restless, and suffering from nausea; his pulse was quick, and his skin cool and moist, though it and the conjunctivæ were still tinged with bile. During the day, especially after taking food, he had vomited bilious matter. I took this opportunity of trying to find the femoral vein; it was evidently consolidated in the thickened tissue of the arterial sheath. The left foot and leg were 101°. The circulation has evidently been completely re-established in the limb.

6th.—He is doing fairly; slept after the operation; bowels have acted again. Temperature of leg 101°; no pain. Stomach less irritable, but he still suffers somewhat from nausea. Repeat the effervescing draughts. Let him have champagne and beef-tea. Sinapisms have been applied over the hepatic and gastric regions. An opiate enema was given after the operation. Pulse good; temperature normal; skin moist. He looks altogether better.

7th.—Has diarrhœa; vomited several times, and did not sleep well during the night; pulse 112; has pain in the left side of the chest; conjunctivæ less yellow; temperature of right foot 98·5°, left foot 99°. 6 p.m.: Diarrhœa continues; vomited several times, but took a fair amount of nourishment; pulse quickening. 120; says he feels better; no bleeding; tongue clean; the ligature in the lower end of the artery separated, and was reapplied for the third time by the House-Surgeon; temperature in axilla 101°, right foot 99·5°, left foot 99·5°; temperature of limbs now equal; all swelling and numbness gone.

8th.—Had several loose bilious motions last night; slept a little; vomiting ceased; complains of dryness of the throat, but says, though weak, he feels much better; pulse 92, rather feeble; no fever; says he feels uneasy in the chest; breathing good, respiration rather harsh.

9th.—6 a.m.: Pulse 130, full; is feverish; had many loose stools during the day; no bleeding; wound looks pretty well; temperature in axilla 101°, right foot 98·5°, left foot 100°.

6 p.m.: Pulse 124, full; still feverish; diarrhœa continues; complains of pain in the left chest; abdomen tympanitic; temperature in axilla 104·5°, right foot 101°, left foot 100°.

10th.—Pulse 128; diarrhœa continues in spite of astringents; did not sleep; is still feverish; tongue dry and clean; temperature in axilla 100·5°; feet 100°. 6 p.m.: Pulse 126, small; is very restless and thirsty; starts in his sleep; says his sight is failing; three loose motions during the day; tongue dry and clean; is slightly delirious; has had no rigor, nor ever complained of chilliness throughout his illness; extremities cold; respiration hurried and gasping; much perspiration; temperature in axilla 100°; feet 91°. 9 p.m.: Is very low; no pulse at wrist; respiration hurried, laborious, and gasping; extremities cold; delirious; nothing characteristic beyond harsh respiration was detected by auscultation or percussion except slight dulness. There was no swelling in the limb, the temperature natural, and perfect freedom from tenderness along the course of the femoral vessels. It was evident that he was sinking, and on going to the Hospital on the morning of the 11th I was told that he had continued much in the same state, except that the distress of breathing became more urgent, and that he died at 3 a.m. of the 11th. The wound for the last twenty-four hours had changed in appearance, and the deeper portions of it were covered with a sloughy film of a dark colour. There was no recurrence of the bleeding, though all the ligatures had again separated, and were loose in the wound.

Autopsy, August 11.—Thorax: Lungs congested posteriorly and in the lower lobes, œdematous throughout. They were united in many places by old adhesions to the walls of the thorax. There were no pyæmic patches in the lungs. Heart soft and flabby, not firmly contracted; a small white clot occupied the left ventricle, extending a short distance into the aorta; valves normal; inner coat of aorta somewhat rough—not atheromatous, but not having the appearance of perfect health; looked, as Dr. Chevers said, as though “it had been much worked.” Right auricle contained a firm white clot, which passed into the ventricle, and was moulded in the auriculo-ventricular opening. This clot extended also into the pulmonary artery, plugging the orifices, and was drawn out in the form of a tree, with many branches forming its ramifications. Abdomen: Liver pale and fatty, but not otherwise diseased. The other viscera appeared normal. There was neither peritonitis nor symptom of any mischief in either iliac artery or vein. On dissecting out the femoral vessels, it was found that the profunda was given off very high (just under Poupart’s ligament), and was enlarged. The vein and artery were closely adherent after entering Hunter’s canal; they were closely matted together amidst thickened tissue. The coats of the vein were much thickened, its calibre diminished, and its lining surface roughened. Within it lay grumous-looking fluid; small clots protruded into it from collateral branches. Where the vein was injured, it also terminated abruptly, being closely matted to the artery; about the ends were some clots and inflammatory products. The artery was also shrunken and rough on its inner surface; no clot was found in it, but about the end where the ligature had separated there were clot and inflammatory products. The lower end being dissected out, presented a similar appearance; the tissues generally about the wound were matted together by inflammatory products. The bottom of the wound looked sloughy on the surface; the upper margins were healthy. The small portion of the upper end of the artery, included in the last ligature, lay loose in the wound, showing how brittle and diseased the parts had become. No further dissection was practicable, as the patient’s relations were much opposed to any examination. The circulation had been thoroughly re-established, for the leg had returned to its normal size and temperature. I am convinced that this was the case before the ligature was applied to the artery. The femoral vein for some distance above, and probably below, the wound had been obliterated. The circulation, both venous and arterial, had nevertheless been re-established. About two inches of the surface of the femur looked dry and denuded, and probably would have exfoliated had he lived. There were no symptoms of osteo-myelitis. It is worthy of note that the weather, since his admission, has been most unfavourable—damp, warm, and oppressive to a degree; malarious influences most rife. He had no rigor, no fever; but during the last few days he looked depressed and his countenance was pinched. He emaciated rapidly, had frequent diarrhœa and vomiting of bilious matter. Indeed, since the operation, he had forgotten the leg in his other troubles. Death was due to blood-poisoning (the septic matter probably originating in the femoral vein). Fibrinous clots in

the right side of the heart were most probably the immediate cause of the apnoea which preceded and caused death. The condition of blood which gives rise to the formation of these fibrinous coagula was the result, most probably, of the septic condition produced by absorption of matter from the femoral vein and the evil influences of a peculiarly malarious season. Had the sudden formation of fibrinous coagula in the pulmonary circulation not carried him off, I have no doubt the usual structural changes seen in death from pyæmia here, in Calcutta, would soon have been manifested in the lungs, pleuræ, and elsewhere.

SATURDAY, NOVEMBER 11, 1871.

THE HAMPSTEAD HOSPITAL INQUIRY.

THE evidence in the investigation into the management of the Temporary Small-pox Hospital at Hampstead having been now brought to a close, we are at liberty to offer our readers some remarks on the wearisome details which have lately occupied so much of our space. The verdict which the Profession and the public will ultimately form on the subject is, of course, of the highest importance—not merely to Dr. Grieve and the three Assistant Medical Officers, who may be said, in some degree, at least, to have staked their Professional and social prospects and their character for veracity on the proceedings—not merely to the Sisters of East Grinstead, who bravely devoted themselves to the repulsive task of nursing all comers through the most disgusting of maladies, but to all who lack in their own homes facilities for careful nursing and segregation when those homes are invaded by contagious diseases—not only to the pauper-classes who are supported by rates, but to persons of a higher grade, whom, for the safety of others, or under the pressure of circumstances, it may be advisable to remove from their homes when struck down by a communicable malady.

It is well that the confession should be made. This investigation arose in the first instance out of a quarrel. There were differences between Dr. Grieve and his subordinates; there were charges of insubordination and counter-charges. Dr. Grieve was not satisfied with the conduct of the Assistant Medical Officers. Representations were made to Mr. Wyatt and to the Hospital Committee. The subordinates were dismissed—ostensibly because there was no longer necessity for their services, but really because the Committee were not pleased with the manner in which they had conducted themselves. The subordinates naturally demanded an investigation, which was refused by the Hospital Committee, on the ground that Dr. Grieve had refrained from bringing formal charges

against them, whereupon they wrote their now notorious letter to the *Times* newspaper, bringing specific accusations against the Hospital, out of which accusations this inquiry has arisen. There can be no doubt that had Dr. Grieve and the Assistant Medical Officers been on good terms, or had he adopted the wise plan of obtaining from the Committee the power of enforcing his authority on pain of instant dismissal, we should never have heard of the Hampstead Hospital Inquiry. The truth is, Dr. Grieve does not appear to have had the necessary powers for maintaining discipline, and it is needless to say that without discipline the hastily constructed organisation over which he presided would assuredly get out of gear.

There is, however, another light in which to look at the matter. The charges made against the Assistant Medical Officers may or may not have been true, but they were evidently believed by certain of the authorities of the Hospital; for Mr. Wyatt, when the management of the Hospital over which he presided was impugned by the Assistant Medical Officers, had the singularly bad taste to write a letter to the *Times*, wherein he accused them of drinking too much beer and of indulging in rat-hunting. We do not know how far these amusements led to the dismissal of the Assistant Medical Officers; but, as Mr. Wyatt thought these matters of sufficient importance to offer them as an answer to the charges of neglect brought against the Hospital, we presume that they had some weight with him when, on July 24, he recommended the Committee of which he was chairman to dismiss Mr. Greaves and Mr. Kynaston. For his own part, he does not scruple to say that, in fact, "they were dismissed because their conduct was insubordinate and they showed no zeal for their duty." This may or may not have been the fact; but if this were the real reason of their dismissal (and we have Mr. Wyatt's word for it), we maintain that they were most unfairly treated when they asked for the inquiry into their conduct, which was refused them.

But, putting aside the squabbles between Medical officers and the questionable (to use Mr. Gladstone's phrase) line of conduct pursued by the Committee, the issue now arises whether it was for the good of the public and the Profession that this inquiry should be held. We answer, "Undoubtedly," for two reasons. First, because it shows how unprepared London was to meet a great epidemic; and, secondly, because it proves how dangerous it is to trust the charge of an enormous Hospital to a merely voluntary Committee—to a small staff of resident and cheaply paid Medical officers, who were the mere servants of the Committee, their duties being supplemented by an occasional visit from a Poor-law Medical Inspector. The charges were (1), that delirious patients, more particularly children, were tied down to keep them in their beds at a time when their bodies were covered with the small-pox eruption; (2) that strait-waistcoats were used for the same purpose; (3) that patients in an acute ward, in the height of the disease, had been provided with a most inadequate supply of milk and fluid during the night; (4) that patients on low diet were kept without food from 7 a.m. until 3 p.m.; (5) that complaints were continual regarding the unfitness of the food supplied; (6) that through the totally inadequate number of nurses, children had been found dead in bed, and the nurse ignorant of the fact; and (7) that the body of a patient who died at midnight had been removed into the bath-room, where it remained all night in a most offensive condition. There were other charges, but these were the chief; and the Medical Superintendent, Dr. Grieve, was pointed at as being responsible for this alleged condition of things.

Now, these charges were all proved by a certain number of witnesses. With regard to the first, the practice has been defended on high Medical authority, and, to say the least, it becomes absolutely necessary when nurses are few. Of the second the same may be said. With regard to the third, whatever some patients may have found, others came forward in

numbers to say that they had not enough milk at night. It was proved that, at least in one instance, patients on low diet were kept for some hours without food; whatever the butcher who supplied the meat may say, it is undoubtedly a fact that some patients did not find the meat tender or palatable. It cannot be disputed that more than one child died in bed without the nurse of the ward being aware of the fact; and it was also proved that a dead and offensive body was allowed to remain during part of a night and day in the bath-room. It cannot, therefore, be said that these charges were unfounded. Moreover, in the inquiry it has been proved that there were lice in the Hospital, else how did the joke about the Hampstead donkeys arise? Clean linen was not at all times plentiful, and eggs and extras were not always supplied directly they were ordered. We know enough of Hospital patients and of the working of the Hospital system to be surprised at many of these complaints. Ten years ago a book was published by a gentleman of some literary pretensions, entitled "Two Months in a London Hospital." In consequence of an accident he was compelled to pass that space of time in one of our metropolitan Hospitals; and although he was not at all unmindful of the benefits and kindness he received, his book contains a number of specific complaints. He tells his readers that had he been compelled to live on the Hospital diet alone he should have sunk; that the Hospital contained no proper apparatus for a particular injury; that gin was given to the patients instead of wine; that a patient was allowed to bleed to death; that the nurses had favourites, and joked cruelly and thoughtlessly with weak patients; and makes many other complaints which prove that even a presumably well-managed Hospital of high repute is no pleasant place for a well-educated and sensitive sick man. But, making allowance for the querulousness of some patients, and the miseries and annoyances almost unavoidably attendant on Hospital life, the conviction will force itself upon any person who attentively reads the evidence brought forward by the Assistant Medical Officers; first, that the organisation was not perfect; secondly, that the diet and general treatment, although they may have been on a par with that in workhouse Hospitals, was not of a kind in all the wards, and at all times, to suit the requirements of persons who had been accustomed to the comforts with which the lower middle-classes surround themselves in this country. The Hospital may have been fairly good for a pauper Hospital, but it was not suited for the reception of patients of various grades of society.

In his evidence, Mr. Wyatt frankly acknowledges the faults due to hasty organisation, the difficulty of getting servants, and the over-work imposed on Dr. Grieve. These may be excuses, but we doubt whether they are valid ones. Funds would not have been refused by the public for a more liberal management, had funds been wanted. The confession of hasty and imperfect organisation cedes the whole point at issue, for no one for a moment would suppose that the gentlemen who formed the Committee, the Sisterhood who undertook the nursing, and the Medical Superintendent of the Hospital were not actuated by the strongest desire to do their duty to the unfortunate patients committed to their care.

There are some lessons to be drawn from the present inquiry which should not be lost. The first and principal one is, that when an epidemic malady requires public effort to meet it, the organisation should be ready to hand. The Local Government Board may supply what is needful, but we have but little faith in voluntary committees and amateur inspection. The second is, that a public Hospital for infectious disease should at least have as good and independent a staff of Medical officers as a Hospital supported by voluntary contributions. Had one-half of the money expended in this inquiry, which will be paid for by the ratepayers of London, been expended in providing proper honoraria to secure the services of four Visiting Physicians, whose position in the Profession and in society would have made them entirely independent, this scandal could not

have occurred, and a large sum of money would have been saved. Instead of which, the staff for a large Hospital of 500 beds consists of a Naval Surgeon, whose name has now for the first time come before the public, and three young men just out of their studentship. We have already spoken of the necessity of discipline and of powers being given to the Superintending Medical Resident. This is only a part of organisation; but there is a third lesson—which is, the necessity for more constant paid official Medical inspection of rate-supported Hospitals. Dr. Bridges, we believe, paid about six visits to the Hospital in the course of some months. Surely an official Medical inspector should have visited such an establishment once a week, if not oftener. Lastly, the system, or want of system, which classes paupers and decent clerks and tradesmen together in the same wards—making them use the same linen and towels, and undergo the same hardships and indignities—is manifestly a mistake.

It will be seen from what we have said that we think there was a necessity for the inquiry, and we cannot regret that it has taken place. We may hope that Mr. Simon's well-known abilities will be concentrated, in his new position at the Local Government Board, on introducing a more satisfactory organisation in public rate-supported Hospitals, and in providing the means of meeting more satisfactorily those epidemics from which England seems destined to be never long free.

THE CHOLERA AT SECUNDERABAD IN MAY, 1871.

SURGEON W. R. CORNISH, the Sanitary Commissioner for Madras, has published an inquiry into the circumstances attending the outbreak of cholera among the 18th Hussars at Secunderabad in the month of May last. Our readers will remember that we commented on this remarkable epidemic from time to time as the earlier reports arrived in this country, and that in one of our numbers for September last we recorded the main facts of the outbreak, and observed at the same time the striking analogy between it and the instance reported by Mr. C. Macnamara in his work on Cholera, of a virulent outbreak of cholera of short duration, which occurred among a small community by whom water contaminated by cholera excreta had been used for drinking purposes. Although the Sanitary Commissioner for Madras did not succeed in tracing link by link the chain of evidence, which alone could have established the connexion as a scientific fact in the instance under investigation, between the use of polluted water by the men of the 18th Hussars, and the outbreak of cholera among them, he evidently entertains the opinion that it is only in this way that all the circumstances can be accounted for. With true philosophic caution, however, he merely enounces among his conclusions on the subject that the Hussar Regiment, so far as is known, differed only from the other European troops, among whom no cholera had occurred, in using water from a public well that was liable to receive extraneous impurities, and that the actual fouling of the wells used by the Hussars with cholera matter, though exceedingly probable, cannot be directly proved.

We find from Mr. Cornish's report that the epidemic of cholera, which in 1869 moved southward from the central provinces over a large portion of Southern India, had quite disappeared from Secunderabad in August, 1869, after having been very fatal in Hyderabad and in the Secunderabad Bazaar, but having caused only a few cases among the European troops, and none whatever in the 18th Hussars. Up to the date of the recent outbreak, not a case of cholera had been known to occur anywhere within 150 miles of the cantonment of Secunderabad. Early in January, 1871, however, there had been indications observed that, after occupying the extreme south of the peninsula and Ceylon, the cholera-wave had begun to travel northwards again along the western coast, and also in the centre of the peninsula. This being the first opportunity

which he had had of studying such a reflux of cholera, Mr. Cornish of course watched the progress of the disease with great care, tracing it from village to village through the districts under his charge; and believing it to be absolutely true that no local outbreak of cholera ever occurs which has not a defined place in a general epidemic movement of the disease, the connexion between the epidemic among the 18th Hussars and the returning cholera-wave became an essential question for his consideration.

On May 8, at Juggiapett—about 100 miles to the eastward of Secunderabad—a severe outbreak occurred, but, owing to the dilatory proceedings of the police, intelligence of it did not reach Mr. Cornish until May 25, or after the disease had become established in Secunderabad; so no warning could be given to the military authorities there of the impending danger. The interval between Juggiapett and Secunderabad being in the Nizam's country, there are no records to show the daily advance of cholera along the high road; but it is a fact beyond all question, that so far as Secunderabad is concerned, the disease was introduced along this eastern road from Juggiapett. On May 20 three travellers coming from this direction died from cholera near "James Bazaar," the most densely populated part of Secunderabad; so that the introduction of the disease was actually accomplished before the civil and military authorities had received any intimation of its approach. On May 21 a fatal case occurred in the village called "Chota Mulkapoor." On the 22nd the wife of a sepoy of the 24th N.I. was seized by genuine cholera, and on May 23 a party of cart-drivers, who had been attacked by the disease on their way from Masulipatam, near the Kistna River, and had lost several of their number, arrived at a village within half a mile to the south-east of the Hussar barracks, and close by the regimental horsekeeper's lines; on the same day two fresh cases occurred among them. Measures were immediately taken by the local authorities to stop all ingress to the barracks from the affected quarter. The next day—the 24th—was the Queen's Birthday, and there was a general parade of all the troops. The 18th Hussars were not unduly exposed in any way, and were, in fact, back to barracks earlier than any of the other regiments, being nearer home. There had been nothing remarkable in the health of the men up to this date. There were thirty-two in Hospital suffering from diseases, chiefly of debility; there was only one case of diarrhœa, and it was of a chronic nature. No change in the food or drink of the men had occurred, and there had been no drunkenness.

Two cases of suspicious diarrhœa occurred during that day among European officials who had been present at the birthday review. Five cases and two deaths from cholera occurred during the day among natives in the Secunderabad Bazaar, but these were not reported until the next morning. The day is said to have been close and sultry, but the meteorological record showed no remarkable variation as regards temperature, the maximum having been 106° and the minimum 79°. Dust-storms, rain, and sometimes hail are common in the Deccan about this season; but there had been no rain in the station since May 3, when .14 inch was registered. The wind from the 3rd till the 24th blew strongly from the north-west—a direction in which it was quite certain that no cholera existed. There is no evidence as to whether any of the subsequent victims to cholera had visited the affected village on the 23rd, or had in any way come in contact with the cholera-stricken cart-drivers. The village is so close to the Hussar barracks and stables, that it would be rather remarkable if some of the men had *not* visited it during the time the cart-drivers were suffering from cholera.

The first person in the Hussar Regiment known to have been attacked by cholera symptoms was a patient in Hospital—a convalescent from fever—who was seized with choleraic purging at 10 p.m. on the night of May 24, but who did not report the circumstance until another man had been admitted with cholera.

Other cases followed rapidly. In twenty-six hours thirty-four men and one child had been attacked, and during the next twenty-four hours there were eighteen additional admissions in the regiment out in camp. The whole stress of the epidemic fell upon the regiment during the first three or four days, and the disease was practically at an end in the corps four days after removal to camp, although several cases did occur on the fourth and fifth days of the outbreak.

Meanwhile the artillery and infantry in the Trimulgherry Barracks were in the enjoyment of their normal health; subsequently, however, isolated cases occurred among them in June, and the epidemic was prolonged among the native population. The 18th Hussars had been nearly six years at Secunderabad, and their health had considerably deteriorated of late. Their barracks in 1852 had been condemned as unfitted for Europeans, on account of defects in both site and construction. Many virulent epidemics of dysentery and fever had occurred among the troops quartered in them, but they had never been a notorious locality for cholera. Their situation is most faulty, lying in a hollow, and surrounded on three sides by higher ground. They had formerly been occupied by a full regiment of infantry, and were then much overcrowded; but on their conversion into cavalry barracks, surrounding walls and subsidiary buildings were removed. Their ventilation was thereby much improved, and other sanitary measures were effected; and for a cavalry regiment there was more than ample accommodation, the cubic space to each man of the 18th Hussars in the barrack-rooms at the time of the outbreak having been 2800 feet. The conservancy and drainage of the barracks were good, and the subsidiary buildings, although neither convenient nor well-arranged, were clean and in good order. Dry-earth conservancy had not been adopted in the latrines, but the excreta were removed twice daily.

The barrack blocks, eight in number, are arranged in the form of a square. The outbreak was almost simultaneous in all the blocks but one; but the men of this barrack began to suffer on the day of removal to camp. To windward of the barrack in which the outbreak was most severe were an old latrine and urinal, about twenty yards distant. The latrine is said to have been offensive at times. It was probably much resorted to on the night of the 24th, being more conveniently situated than any of the others. It is possible, therefore, that the inhabitants of the neighbouring barracks may have been more exposed to emanations from choleraic evacuations than any of the other troops of the regiment.

A theory was raised by Dr. Anderson, Assistant-Surgeon of the regiment, that in consequence of the disturbance of the soil during recent improvements in the vicinity of the barracks, cholera virus may have been extricated from it and carried by the prevailing north-west wind over the Hospital, in which the first case occurred, and those blocks of the barracks which were most affected. Dr. Anderson, however, at the time his report was drawn up, was not in possession of the facts of the introduction of cholera into Secunderabad; and Mr. Cornish demonstrates his theory to be inconsistent with those facts.

Mr. Cornish next proceeds to the consideration of the water-supply. The well in the barracks having some time previously been condemned, in consequence of the water containing an undue proportion of organic matter, a new well had been constructed to the north of the barrack enclosure, but the water in it being temporarily spoilt by solution of the lime used in cementing the walls, the drinking-water for the regiment was brought in barrel-carts from a public well close to the watercourse which bounds the Secunderabad general parade-ground, and near the Sapper lines. During the dry season the water in the wells along this watercourse is not more than ten or twelve feet from the surface, and in the rains it rises very near the level of the surface soil. The cantonment burial-ground lies close to the watercourse, and, as a matter of fact, the well from which the drinking-water for the Hussars was obtained

lies about 400 yards *below* the burial-ground. In this situation, and within a short distance of each other, are four wells near the public road. They are essentially public wells, open to anyone who takes the trouble of lowering a chatty and drawing water. They are lined with masonry, and have parapet walls and platforms, but the latter are insufficient to prevent soakage into the soil around. On the whole, the surface of the ground about these wells is kept clean, but the watercourse close by and its margins are occasionally defiled with ordure, probably by travellers along the high road during the night, when detection is difficult or impossible.

Suspicion immediately fell upon these wells when the outbreak of cholera occurred, but was diverted from them by the theory advanced by Dr. Anderson. The water of the old condemned well in the barracks, whatever may have been its condition on May 24, was found by Mr. Cornish, on June 28, to contain less organic impurities than the drinking-water used at the same time by the Hussars; and it was thus plain to him that the regiment had, at great trouble and expense, been procuring a dubious supply from a distance, while a cleaner water, and one less liable to extraneous pollution, existed at the barrack doors.

There is no evidence to prove that the water used on May 23 and May 24 had been obtained from any other source than the parade-ground wells; but the suspicion that the water-carriers, to save themselves trouble, had brought it from a nearer source, is probably well founded. There were nearer sources close at hand—viz., the well in the horse-lines, and another near the horsekeepers' huts, both of which are within an easy distance of the village in which the cholera-stricken cart-drivers were detained on May 23. Either of these wells might have been used by people with cholera, and have also supplied the water for night use in the barracks on May 23 or May 24; but Mr. Cornish considers the evidence for or against this view of the question to be wholly untrustworthy. Even the parade-ground wells were liable to contamination—they are crowded all day long by people from the neighbouring bazaar, who bring their own chatties and ropes to draw water; and it is quite possible that chatties from an infected house, soiled with cholera-matter, may have been washed at the wells, and that thus the *ordinary source* of supply for the drinking-water used in barracks might have been temporarily contaminated with cholera-matter. This, however, cannot be directly proved.

The only difference between the 18th Hussars and the other European troops in the Trimulgherry barracks in regard to water-supply is, that the Trimulgherry wells were kept solely for the troops and followers. The wells are of great depth, so as to be impracticable to natives, who draw for themselves by a chatty tied on to a rope. All the water from them is lifted by bullock-power, in large leathern bags, into masonry reservoirs, and thence removed to the various barracks by carts or water-carriers' bags. Beyond the water-supply, the conditions of existence of the Hussars did not differ from those of the other European troops in the command. The food, drink, canteen supplies, etc., were of exactly the same nature.

It is therefore a most important fact that, while the Hussars were suffering from the cholera outbreak, the troops at Trimulgherry escaped absolutely. Although, as admitted by Mr. Cornish, the evidence in regard to the actual pollution of the water-supply is not sufficient to convince those who decline to accept the view that water is the most common medium by which cholera is communicated from man to man, the lesson drawn from it by Mr. Cornish, in the very full and able report now before us, is easily learned, and is of extreme importance—to the effect that, without pretending to say that in every case cholera is communicated by polluted water, "it behoves those who are responsible for the lives and safety of British troops to see that every possible precaution is taken to insure

that their water-supply cannot have been exposed to the chances of defilement."

Mr. Cornish also details several other facts of this very remarkable epidemic, but we have no space to notice them at present.

TRIAL FOR ALLEGED MALPRAXIS.

AT Stockton County Court, on the last Friday and Saturday of October, was tried the case of Hutchinson against Watson. The facts may be briefly stated. The plaintiff was a single woman, and, being *enceinte*, was removed from her own home to a lodging, at which Dr. D. H. Watson attended her in her confinement. The child was born alive, and the woman, according to Dr. Watson, was left by him in a perfectly satisfactory state, the uterus being contracted. He continued to attend her for five days. The woman afterwards was found to have inversion of the uterus. Several Medical gentlemen saw her, and attempts were made to reduce it; but these failing, Dr. Murray, of Newcastle, assisted by other Surgeons, excised the uterus at the expiration of six months after delivery. The operation was successful, and the woman made a good recovery. The action was brought against Dr. Watson for "improper, negligent, and unskilful treatment," and it was sought to be proved that he had removed the placenta almost immediately after delivery, and by the insertion of his hand into the uterus. By this proceeding, it was contended for the plaintiff, the uterus had been inverted, and all her subsequent sufferings and mutilation had arisen. With the exception of the girl's evidence, there was really nothing to show that any violence whatever had been used; and it is more than probable that she was not in a condition to know exactly what did take place. Opposed to her evidence is that of Dr. Watson himself, who distinctly swore that he had examined her closely for five days, to "ascertain that the uterus retained its proper position," and that of Dr. Tarleton, who had also examined the woman some time after delivery, and found "the uterus in its proper place." Upon the meagre testimony of the patient, and some allegations of neglect by others after delivery, Dr. Watson was sued for damages; and these were laid at £2000. For the plaintiff several Medical witnesses were called, and these were examined on the assumption that violence had been used by Dr. Watson, and that the inversion of the uterus was consequent thereon. Their evidence, of course, was condemnatory of the defendant. On his part, however, the Medical evidence was conclusively in his favour. The opinion of Dr. Keiller and others was that the inversion was spontaneous, and was altogether independent of anything done by the defendant. In his summing-up, the judge said the evidence was as conflicting as could be—of course, he alluded to that of the Medical witnesses. "But," said he, "certainly no evidence was given to show that during the time the plaintiff was in the hands of the defendant there had been any negligence." The jury having retired for a short time, returned with a verdict for the defendant, which was received by those present with considerable cheering.

Such are the brief outlines of this extraordinary case—extraordinary as showing the flimsy grounds upon which a Medical Practitioner may be put upon his trial; and extraordinary that such a conflict of Medical evidence should have existed, when a few words of explanation from the defendant might have convinced all those of his brethren who appeared against him that the inversion was spontaneous, and that he was not to blame in any way. The verdict was for the defendant; but is it a triumph? A very questionable one, indeed, so far as anxiety and pecuniary loss are concerned. Here is a man, from no fault of his own, but from circumstances which might occur in the practice of any one of us, kept for months on the tenter-hooks of suspense, and incurring ruinous costs, to defend himself from a groundless charge of incompetence and negligence. The money-cost to Dr. Watson must, indeed, be very large, for the plaintiff has no means whatever of paying

anything towards it. Indeed, one of the peculiar hardships of this case is, that it was originally brought in the Court of Exchequer at Westminster, but removed by order of Judge Bramwell to the Stockton County Court, because the plaintiff could not give security for costs. By this proceeding, no doubt, the expenses of the trial were much diminished; but mark the result! Under any circumstances Dr. Watson must be severely punished—must be a great loser. This is a state of things which should not exist. The lawyers say there is “no wrong without a remedy.” Where is the remedy for the grievous wrong inflicted on Dr. Watson? This trial, as well as many others which have taken place within the last few years, show how vastly important it is for Medical witnesses, before they appear in court against a brother Practitioner, to make themselves thoroughly acquainted with all the facts of the case. It may be the turn of one of the hostile witnesses to-morrow to have his reputation, and perhaps his very existence, jeopardised by being sued on a groundless charge of “incompetence and negligence.” Are we never to be true to the interests of ourselves and our Profession?

There is one circumstance connected with this trial which we would fain omit to notice, but cannot with propriety do so. We allude to the appearance of the partner of Dr. Watson in the witness-box against him—a position which must have been painful to that gentleman in the extreme, inasmuch as he had quarrelled with the defendant. We should have been pleased if Dr. Farquharson had found it possible to decline giving evidence—conscientious evidence we are sure it was; but the defendant might well exclaim, on seeing him in the witness-box, “*Et tu, Brute!*”

THE WEEK.

TOPICS OF THE DAY.

THE Profession throughout the three kingdoms will be glad to hear that the Queen has been pleased to bestow the well-merited honour of a baronetcy on Dr. Christison, of Edinburgh. Sir Robert Christison's services to Medicine, whether as a practical Physician and pathologist, a chemist and toxicologist, or a writer on the nature and uses of medicines, require no praise from us—they speak, and have long spoken, for themselves. We cannot refrain from saying, however, that Sir Robert Christison has done more to place toxicology on a thoroughly scientific basis than any man of the present century, with the exception of Orfila. We hope he will long live to enjoy his deserved honours, and to adorn the University in which he has so long been a foremost teacher.

A young Radical baronet, who has lately acquired some notoriety (Sir Charles Dilke), has been enlightening the colliers of Newcastle-on-Tyne on the extravagant expenditure of Royalty and the enormous cost of the Royal household. He made his grimy hearers especially merry with the following account of the Queen's staff of Medical attendants:—

“The salaries in the Royal household, which amount to £131,000 a year, include a vast number of totally useless officials—Chamberlains, Controllers, Masters of Ceremonies, Marshals of the Household, Grooms of the Robes, Lords-in-Waiting, Grooms-in-Waiting, Gentlemen Ushers, and a few persons who appear to perform services, but who ought to be paid for those services as they perform them, and not be made permanent officials with great titles of honour—such, for instance, as the Historical Painter to the Queen, Portrait Painter to the Queen, and the Lithographer-in-Ordinary. Under the Lord Steward's department, and the department of the Master of the Horse, we have such officers as the Coroner of the Household, and the Chief Equerry and Clerk Marshal, and various others whose duties are not of a very burdensome description. Nothing is more singular than the constitution of the Medical department. You would hardly credit the number of Medical gentlemen who are required for the service of the Household, but I am aware that some of them are unpaid. There are three Physicians in Ordinary,

three Physicians Extraordinary, one Sergeant-Surgeon Extraordinary, two Sergeant-Surgeons, three Surgeons Extraordinary, one Physician of the Household, one Surgeon of the Household, one Surgeon-Apothecary, two Chemists of the Establishment in Ordinary, one Surgeon-Oculist, one Surgeon-Dentist, one Dentist in Ordinary, and one other Physician—or twenty-one in all; while the Prince of Wales has for his special benefit three Honorary Physicians, two Physicians in Ordinary, two Surgeons in Ordinary, one Surgeon Extraordinary, one Chemist in Ordinary, or eleven more—making thirty-two Doctors in one family.”

Now, we hardly think that such a charge requires a reply. Sir Charles Dilke himself allows that some of the Medical appointments are only honorary—which, indeed, we should think scarcely a matter on which to congratulate the Queen of England's subjects. But we may remark, *en passant*, that the Medical expenses of her Majesty's household can scarcely be comparable with the vast sums which Sir Charles Dilke's father and others assisted Prince Albert to lavish on the fine arts at South Kensington—for which services of his father Sir Charles Dilke now inherits a baronetcy, the use of which honour seems to be somewhat incongruous with his principles.

A meeting of the Poor-law Medical Officers' Association was held at the Medical Club, in Spring-gardens, on Tuesday last. The object of the meeting was the consideration of Mr. Corrance's Bill for the better regulation of Medical Poor Relief, and for establishing Dispensaries in England and Wales.

PROFESSOR HUXLEY AT THE LONDON INSTITUTION.

THE subject of Professor Huxley's second lecture, on Monday last, was, “Contractile Matter: its Structure and Properties.” He commenced with a *résumé* of the concluding portion of the previous lecture, on the contractile properties of the colourless blood-corpuscles, and then mentioned various other structures in the human body which the contractile principle endows with most important functions—such as the membrane lining the air-passages and other mucous canals, in many of which a constant current of fluid in one direction is maintained by the alternate contraction and relaxation of the opposite sides of the cilia, arranged in regular order on the epithelium. Such movements, though difficult to observe in the human subject, may be demonstrated in a frog by placing a little charcoal on the tongue extruded from the mouth, and retained for a short time in that position. It will then be observed that the stain of the charcoal gradually changes its place, in consequence of the motion communicated to its particles by the cilia of the mucous membrane of the tongue. A similar result may be observed in the motion of the particles contained in water in which a small portion snipped off the gill or beard of a living fresh-water mussel has been placed. But it is not in the higher or purely animal textures only that contractility exists—it is a fundamental property of protoplasm of all sorts; it is observed in the amœbæ and lower organisms existing in countless numbers in muddy pools. In these the contractile protoplasm converts the cilia on their surface into actual locomotive organs, by which they are propelled, without definite direction, from place to place in the field of the microscope. In plants, also, the same property of their protoplasm maintains a constant circulation of their fluids, as may be proved by careful observation of the sting of the nettle under the microscope. It may also be demonstrated in the green fungus which grows on damp walls and trees, and in which, under the favouring circumstances of heat and moisture, numerous projections of protoplasmic tissue of extreme tenuity and perfect transparency, but endowed with contractile properties, may be observed. This motion of the protoplasm of plants, however, he warned his audience, is distinct from the “irritability” possessed by the sensitive plant, and must not be confounded with it. The motion of granular material along the surface of the extremely minute and delicate projections from the bodies of various marine organisms, also illustrates

the existence of contractility in the protoplasm of which they are composed. Such bodies, by alternate contractions and relaxations, gradually move small granules along their surface—much in the same way as a horse, or other animal possessing the necessary muscular apparatus, can shake or corrugate his skin so as to detach troublesome insects; or as persons arranged in a line, to assist in extinguishing a fire pass the buckets of water along from hand to hand.

Professor Huxley next proceeded to inform his hearers as to the connexion between this contractility of protoplasm and the muscular power by which he was enabled to perform the typical motion which he had selected for illustration—namely, the flexure of his forearm on his arm. He described the experiment of Kühne, who, on enclosing a small quantity of the protoplasm of the fungus found in tan-pits, known as *æthaliium*, in an extremely fine animal membrane—namely, a piece of the intestine of a beetle, thus forming a protoplasm-sausage as it were—and fixing one end, and attaching the other to the extremity of a sensitive lever, found that on passing an electric shock through the protoplasm contained in the beetle's intestine, a contraction ensued, its result being rendered evident to the eye by the movement of the attached lever. This contraction, consisting in a diminution of length and an increase in breadth, is exactly analogous to the contraction of a muscular fibre; and there was thus artificially formed a texture essentially identical with the forms of certain muscular tissues in the higher animals—namely, the plain or non-striated muscles—which he described as simply protoplasm contained in fine membrane, and as examples of which he mentioned the muscular investment which surrounds the whole length of the tube of the intestinal canal, and which, on being submitted to the requisite stimulus, performs the important function of propelling the semi-fluid contents of the intestine; another being the muscular tissue which controls the flow of blood through the capillaries. He next demonstrated by diagrams the structure of the striated muscular tissues as observed after death—how they resemble in their essential nature the simpler structures, but that, from the contained protoplasm not being homogeneous, they assume, when closely packed together, the striated appearance from which muscles composed of them derive the name of "striped muscles." He illustrated the arrangement of the ultimate muscular molecules in living muscle by the familiar instance of the currants in a plum-pudding, and mentioned that the earlier notion of these molecules forming longitudinal fibrillæ is a mistake, the appearance of striæ and fibrillæ being a post-mortem change, depending upon the coagulation of the plasma contained in the muscular molecules, and its separation into myosin and water, and not being observed in actually living muscle. This coagulation of protoplasm may be demonstrated by squeezing out the fluid of a piece of muscle frozen in the living state; it will then be observed that, on raising the temperature above 32°, coagulation takes place, and the myosin separates from the water exactly as the coagulum of blood, which when drawn is perfectly fluid, but on cooling separates into clot and serum. There is a remarkable difference, however, in the fact that protoplasm coagulates on rise, while blood coagulates on fall, of temperature. One of the most remarkable results of this post-mortem coagulation of protoplasm is the condition known as the "death-stiffening," which occurs at varying periods after an animal dies, and is followed by complete relaxation. On battle-fields this condition often presents itself in very striking forms, the bodies of men killed instantaneously being found stiffened exactly in the position in which they received their death-wound. It has also been observed that this result was more frequent among men who had previously undergone great muscular fatigue.

The effect of muscular action is not limited to simple motion of a limb. The hand and arm, for instance, can be steadily

maintained in any desired position for a considerable period; and this is effected by the alternate and extremely rapid contraction and relaxation of the molecules of the muscle. For the maintenance of such alternating contractions and relaxations a due supply of nervous stimulus is necessary; when this fails from any cause, as age or intemperance, the steadiness of hand and limb is lost. Every such contraction involves a chemical change in the nature of the contained protoplasm, which, while at rest, is alkaline, but on contraction becomes slightly acid, the acids given off being chiefly carbonic and lactic acids. The same change takes place at the moment of death; and it thus becomes apparent that every muscular contraction involves a temporary death of the muscular molecules.

A STARTLING STATEMENT—A CASE FOR INQUIRY.

IN one of his most popular novels, Mr. Charles Reade made some revelations respecting the treatment of patients in private lunatic asylums, which, if even mere fiction, were sufficient to awaken the interest and excite the indignation of the reader. Even if they were true, they would not exceed in atrocity what is stated on the authority of Dr. Stallard to be the case respecting the Metropolitan Asylum for Imbeciles at Caterham. At the meeting of the Holborn Board of Guardians last week, this gentleman stated that he had gone over the Asylum very carefully, and had arrived at the firm conviction that there were a number of persons confined in that Asylum who ought not to have been sent there. Admission into the Asylum was too easy; and he could quite understand, when persons made themselves disagreeable in a workhouse, that the Medical officers stretched a point, and certified that those persons should be sent to one of the asylums. It was remarked by the chairman that this was a very startling statement; and, if the facts were as stated, the Board thought such a state of things ought not to continue. We should think not, indeed! Anything more disgraceful cannot be conceived. But surely there must be some mistake in the matter. Is it possible that any Medical officer would "stretch a point," and confine a sane man in a madhouse because he was troublesome? We cannot believe it. But such a statement as that made—and made, too, *officially*—demands the immediate attention of the Commissioners in Lunacy. A thorough investigation should take place, and the truth searched out. The Chairman of the Committee of Managers of Caterham, Dr. W. G. Cortis, writes thus to the *Daily News* :—

"I beg to inform you that the statement which, according to your report, was made to the Holborn Board of Guardians, that a fee of one guinea is paid to the Medical officer certifying for a patient to be sent to Caterham, is entirely incorrect. There is no fee whatever paid in the case of either of these asylums, although there is in the case of a lunatic sent to a county asylum. Neither, to the best of my belief, is there any sane person in the Asylum."

But surely, if a guinea was to be paid for signing a certificate of insanity, it is not presumed that a sane man would be sent to an asylum for the mere purpose of the Medical officer receiving such a fee!

A VETERAN ON WOMEN-DOCTORS.

At the Medical students' annual dinner, in connexion with the Manchester School of Medicine, held last week at the Albion Hotel, Manchester, Mr. Turner, who founded the School nearly half a century ago, in reply to the toast of the evening said—
"They had many competitors. Yes; and he would beg to introduce to their notice new competitors—he referred to the ladies. There were now Practitioners in the garb of ladies, inoffensive in every respect, and calculated to perform certain offices in connexion with their Profession well; but he only wished they would follow those offices in which they might excel, and that they would not meddle with those duties which would devolve more properly upon the Physician or the Surgeon. They knew that ladies were sometimes apt to get out of their proper rank very much; he liked to see them in their proper station."

CHARGE OF NEGLECT AGAINST A MILITARY MEDICAL OFFICER AT ALDERSHOT.

A CORRESPONDENT of a military contemporary last week made a serious charge of neglect against the Medical officers of a regiment stationed at Aldershot, to the effect that the wife of a soldier had died, after the birth of a dead child, without having been visited by a Medical officer. So far as we have been able to learn about the matter, the case is as follows:—The unfortunate woman was one of those married "without leave," and consequently not entitled, according to the regulations of the service, to Medical attendance of any sort. The regimental Assistant-Surgeon, however, to whom her husband applied, taking his stand upon humanity instead of regulations, told the husband he would see her if the midwife in attendance required any assistance. The husband returned to his lodgings, and brought back a written message from the midwife that the child had been born about two hours, that the placenta had been discharged, and the patient was at that time going on well. Shortly afterwards, the Surgeon of the regiment was hurriedly called to see the woman. He went at once, and found her dead—from hæmorrhage, we believe. If the facts be as we have detailed them, and taking into consideration that, as we are informed, according to the regulations of the service the Medical officers of a regiment are not required to attend even the wives of soldiers married "with leave," during their confinements at their own quarters, unless the midwife employed requires their assistance, the Medical officer against whom the charge of neglect in the present instance has been made will have nothing to fear, either in a Professional or military point of view, from the fullest inquiry into the matter.

MILITARY ETIOLOGY.

A DUBLIN correspondent informs us that cases of enteric fever have latterly become rather frequent among the troops stationed at Dublin and at the Curragh. The occurrence of some cases among the soldiers confined in the military prison at Arbour-hill has attracted the particular attention of the military authorities, who have, as we are informed, ordered a board of field officers to investigate the origin of the disease in that establishment. Except a jury of matrons, empannelled to decide as to the pregnancy of a female under trial on a capital charge, it appears to us that nothing could be more absurd, or less likely to lead to valuable results, than an investigation, into the etiology of a local outbreak of disease by a board of military officers. The procedure of such a board is, we believe, to summon the Medical officers before them as witnesses pick their brains, and then report the conclusion at which they have arrived for the information of the general in command. The supreme stupidity of military jealousy of Medical or other interference in matters concerning which professional advice may be construed into the semblance of command, prevents mixed boards of military and Medical officers considering any subject on which a Medical opinion may be required; hence arises the absurd system of a purely military board being assembled to investigate and report upon a purely Medical question. We hear, also, that in one of the Guards regiments stationed in Dublin more than a hundred cases of severe impetigo of the head and face have occurred. Although the first cases appeared among the children, some connexion is suspected between the appearance of this disease and the issue of new bearskin shakoes to the men. Here will be a nice point in the etiology of cutaneous diseases to be discussed by a board of field officers!

If we might venture a piece of advice to Medical officers summoned as witnesses before such boards, it would simply be—to give no information except in reply to specific questions from the board, to volunteer no technical or Professional opinion, but just to let the board, as schoolboys say, "pick it out of their learning." If Medical officers are not permitted to sit as members or presidents of mixed boards, according to

their relative rank in the army, or to investigate and report on Medical or sanitary matters without going through the farce of appearing as witnesses before a board of military officers, the public service cannot but suffer; and it would be to the interest of the public to inquire whether, instead of the present roundabout system, there cannot be discovered a more excellent way.

MEDICAL CORONERS IN AUSTRALIA.

THE *Melbourne Herald*, most probably inspired by some member of our Profession who objects to one of the Medical coroners in Victoria, has a laboured and inconsequent leading article on Medical coroners. According to the *Herald*, Medical coroners are "incompetent," "mercenary," and "officious." The writer proceeds in a strain of vituperation against them, and instances several cases, in which he states inquests were unnecessary; but he is sadly ignorant, not only of the duties of a coroner, but of the object of a coroner's inquest. Here is a specimen of the writer's assertion: "If the public are satisfied as to the cause of death, the coroner has no right to take upon himself to act." How is a coroner to know that the public is satisfied?—he has no decided means of ascertaining this. It is far more conducive to the public safety, to the protection of life, and the prevention of crime, for inquests to be held on all causes enumerated in the Coroners Act. But whatever may be the shortcomings of one or two Medical coroners in Victoria, it is certain that in this country they are far superior to lawyers. Not only are inquests better conducted by the Doctors, so far as the cause of death is concerned, but it is remarkable that as yet no case has occurred, in which an inquest has been presided over by a Medical Practitioner, of an attempt to quash a verdict on the score of incompetence or bias on the part of the judge. And, recollecting the great number of Medical coroners of boroughs and counties there are in the United Kingdom, this is a striking, and should be a convincing fact. Colonial legislation is, in some respects, in advance of ours; but if the Medical coroner is to be superseded by the lawyer, legislation will be retrograde. There is evidently much personal feeling mixed up in the question now being discussed in Victoria—a feeling which has the effect of ignoring the real question at issue, so far as the Profession and the public are concerned.

MEDICAL BENEVOLENT FUND OF IRELAND—BELFAST BRANCH.

THE usual quarterly meeting was held last week. Dr. James Moore presided. The branch was very flourishing. The balance-sheet was as follows:—The total available amount for distribution this year was £933 11s. 8d., and the number of actual grantees was 82, thus enabling but little more than £11 to each on an average. We have made the following analysis of those grants, and find one awarded £41; four, £31 each; one, £26; one, £25; one, £21; one, £20; eight, £16 each; one, £15; two, £14 each; one, £13; two, £12 each; fifteen, £11 each; four, £10 each; thirteen, £9 each; four, £8 each; eighteen, £6 each; and one, £5—so that the highest and lowest sums respectively were £41 and £5. We hope that the Society has by this been put in possession of the sum of £1000 so handsomely offered by a philanthropic Medical man signing himself "Nemo," provided that twenty Medical men in Dublin gave £100 each, or forty the sum of £50 each. This offer was to hold good for six months from June last. After making arrangements for the annual meeting of this branch in February next, and the transaction of some other routine business, the chair was vacated, and the meeting separated.

EFFECTS OF WAR.

WE stated in a recent number that the Medical students at Strasburg had been reduced in number to such an extent as would render the classes all but obsolete. The Faculty of Medicine of that place is now about to be settled at Nancy, where it is to be hoped a prosperous career will attend it.

THE FEVER TREE.

THE cultivation of the *Eucalyptus globulus* is making great progress in the South of France, Spain, Algiers, and Corsica; nor is this to be wondered at, if an account lately given of its virtues by Professor Gubler, in the *Bulletin de Thérapeutique*, is even partially true. It is a native of Tasmania, where it was of old known to the natives and settlers as a remedy for fever. It prefers a marshy soil, in which it grows to a gigantic height with great rapidity. It dries the soil by the evaporation from its leaves, and shelters it from the sun, thus preventing the generation of marsh miasm. Its wood is as hard as teak. Every part of it is impregnated with a balsamic, oil-of-camphor-like odour; and besides a notable quantity of astringent matter, it contains a peculiar extractive, which is supposed to contain an alkaloid allied to quinine. At any rate, its efficacy in intermittent and marsh fevers has gained for it in Spain the name of the "fever tree." It is a powerful tonic and diffusible stimulant, does wonders in chronic catarrh and dyspepsia, is an excellent antiseptic application to wounds, and tans the skins of dead animals, giving the fragrance of Russia leather. We can vouch from personal observation for the flourishing condition of the plantations at Hyères and Nice, where trees from seeds sown in 1859 are said to be now sixty metres high. We hope that experience will confirm Professor Gubler's anticipations of the remedial virtues of the *Eucalyptus*.

A FAMILY DANGER.

It has been reported on several occasions that animals fed on the milk of cows affected with foot and mouth disease have suffered considerably—some even to their death—in consequence. The *Liverpool Mercury* of last week contains a letter from a correspondent, who says that the younger members of his family have been ill—the baby seriously so—from partaking of milk supplied from a farm whereon there were cattle affected with the above disease. The writer complains that whilst the law compels owners of cattle to give notice to inspectors when animals are infected, it does not prevent the sale of milk from diseased cows. He suggests that the magistrates should pass by-laws with the object of remedying the evil, and, secondly, that parents should look carefully after those who supply milk to their families. In reference to this subject we would refer our readers to an able paper in our last number, by Mr. T. E. Amyott, on "Foot and Mouth Disease in the Human Subject."

FROZEN BEEF-TEA.

A GOOD idea comes to us from America, through the medium of the *Philadelphia Medical Times*. Dr. Burney Howe writes, remarking how difficult it often is to get children suffering from inflamed throat to take nourishment, and mentions the following case:—

"A child was seriously ill with scarlet fever, and, owing to the condition of his throat, it was almost impossible to induce him even to attempt to swallow the beef-tea which his condition imperatively demanded, although he took ice with avidity. He was evidently sinking, when his father suggested that beef-tea made according to Liebig's formula might be readily frozen into a sort of water-ice. This suggestion was immediately carried out, and without trouble—a confectioner freezing the beef-tea, a pint at a time, into a firm mass. Portions of this the child took readily, finally recovering—a result due in great measure to his father's ingenious device. It is, of course, necessary to keep the frozen mass surrounded with the freezing mixture, but with this precaution it may be kept for a great length of time."

We do not clearly understand what preparation of meat is here meant—whether beef-tea freshly prepared but deprived of gelatine, or a watery solution of the so-called extract of meat. We almost begin to wish that this preparation, useful though it be, had never been introduced; for to give a man such a solution when he is ordered beef-tea is very like giving him a stone when he asks for bread. Extract of meat is no more

food than brandy is. It is exceedingly useful for flavouring an otherwise tasteless mess; and if the patient can take it thickened with good corn-flour—not starch alone—it will do him good; but to give it alone is a mistake. We have eaten half a pot of the stuff, and remained as hungry as ever—the only effect being to produce thirst, to heighten the bodily temperature, and to increase the nitrogenous matter in the urine. Unfortunately, it has made its way into Hospitals, and we are often vexed to see unfortunate patients, ordered beef-tea, getting only a dose of kreatin, kreatinin, sarkin, and what not substances, not of the slightest value as food. But, with good beef-tea or beef essence, the freezing suggestion should prove admirable.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

AN ordinary general meeting of this Society was held on Friday, October 27, at the room, 53, Berners-street; the chair was taken by the President, Dr. Burrows. From the half-yearly statement of accounts read, it appeared that the amount of the grants for the half-year ending June 30 was £1370 10s., given to fifty-three widows and fifty children, and the expenses £125 0s. 5d.; the available receipts for the half-year amounted to £1479 10s., and the expenditure to £1442 10s. 5d., leaving a balance of only £36 19s. 7d. in favour of the Society to meet any addition to the present grants. Fresh applications have been made from three widows and four children. The directors appeal to the kind assistance of their Medical brethren, who, they feel confident, will not, from want of help, compel them to diminish the relief hitherto accorded to the widows and orphans.

MEDICAL EDUCATION AT CAMBRIDGE.

SYMPTOMS of making the curriculum of Medical studies at Cambridge somewhat more practical are exhibiting themselves. The Vice-Chancellor of Cambridge has just presented to the Senate the following report of the Board of Medical Studies:—

"The Board of Medical Studies recommend—

"1. That the following be added to the requirements prior to the third examination for the M.B. degree: That the candidate be required to produce a certificate of having been clinical clerk for six months, at least, at a recognised Hospital, or of having, subsequently to the completion of his attendance on Hospital practice, attended to practical Medicine with special charge of patients in a Hospital, Dispensary, or parochial union, under superintendence of a qualified Practitioner, unless he himself be duly qualified. This regulation to come into force in the Easter term, 1872.

"2. That 'experimental physics' be added to the list of courses of lectures in Section 10 of 'Regulations for Degrees in Medicine.'"

The Vice-Chancellor appointed yesterday for the discussion of the above report.

SEA-WATER BATHS IN LONDON.

A COMPANY has been started for the establishment of swimming- and other baths of sea-water, and for retailing sea-water to the public. The first set of baths are to be erected in Pimlico, but the projectors of the company have in view the institution of floating baths on the river, also. The great difficulty in the way of such schemes has been the expense of bringing sea-water to London. We understand the new company propose to float it up the river in enormous tanks dragged by steam-tugs. Anything which will increase facilities for bathing and personal cleanliness has our warmest approbation.

SMALL-POX AT OXFORD.

SEVEN new cases and two deaths have occurred, against eight new cases and three deaths last week. Both the deaths occurred in unvaccinated cases. The total number now under treatment is thirty-two.

SMALL-POX JOTTINGS.

IN several of the large towns of England small-pox is still epidemic. At Chorlton, twenty-seven cases of the disease had been admitted into the workhouse infirmary during the last month. Six deaths had taken place, and of these five were entirely unprotected by vaccination. In the workhouse, revaccination had prevented any spread of the disease. At Wolverhampton, during the past week, the number of cases amounted to 240—an increase exceeding by fifty the return of the week before. These cases are all, or nearly all, taken from the poorest class; and there is reason to apprehend the spread of the disease amongst the wealthier classes is even more marked—at least, that is the opinion expressed by one of the Medical officers of the union.

SCARLATINA IN INDIA.

IN the last edition of his "Practice of Physic," Sir Thomas Watson says—

"Till quite recently I had supposed scarlet fever was unknown in India. . . . Rumours of its appearance, however, had of late arisen, and Surgeon Chapple, of the Royal Artillery, has set the question at rest by a report of a series of cases of unequivocal scarlatina which happened in the early part of the present year at Kirkee. Kirkee is a large military station, within six hours by rail from Bombay. On January 31, 1871, seventy-five artillerymen, seven women, and twelve children landed at Bombay from the troopship *Euphrates*. Several cases of scarlet fever had occurred on board the *Euphrates* during her voyage from England. On February 20 a child was admitted into the Hospital at Kirkee with scarlet fever; on the 24th two more children; on the 27th another. Cases continued to occur up to the end of April, when the disease ceased to show itself."

The occurrence of this outbreak seems to have excited considerable attention in India; and the question has been raised whether scarlet fever ever occurs in Calcutta. Inquiries have been made, and the results are published in the *Indian Medical Gazette* of October 2. The general opinion is, that the disease does not prevail there, though one in some respects similar is occasionally observed. Here are the conclusions arrived at—

"On the whole, the evidence on the subject hitherto recorded in these pages amounts to this:—Scarlet fever does occur in India, in European communities, either as an isolated case or a limited outbreak. It does not appear to show any great tendency to spread, and in all cases there is a demonstration or a strong suspicion of its importation into this country from Europe. There is not a jot of evidence that the disease is indigenous, or has ever occurred among the natives of the country. As far as Calcutta is concerned, the evidence now adduced confirms our original assertion. The disease, as a contagious exanthem, may be said to be unknown here, and isolated instances are puzzling as to etiology. The subject is still open for inquiry or discussion."

ARMY MEDICAL DEPARTMENT.

DR. H. H. MASSY, C.B., Deputy Inspector-General of Hospitals, at present Head of the Sanitary Branch of the Army Medical Department, is, we hear, about to go out to India as Principal Medical Officer at Bangalore, and that he will be succeeded in the Director-General's Office by Inspector-General W. Muir, C.B., now Principal Medical Inspector of British Troops in Bengal.

INDIAN MEDICAL SERVICE.

It is intended, we believe, to admit candidates for this Service to the competitive examination to be held in February next. We have not yet learnt the probable number of vacancies.

FROM ABROAD.—M. BRIQUET ON AN EPIDEMIC OF SMALL-POX—
OPHTHALMOLOGY A FRENCH SCIENCE.

AT a recent sitting of the Académie de Médecine, M. Briquet read a paper upon an epidemic of small-pox occurring in an ambulance to which he was attached during the siege of Paris.

The cases that came under his care were 504, all occurring in soldiers, nine-tenths of the number having been vaccinated, and one-tenth revaccinated. Of 413 subjects having characteristic pock-marks, 252 had slight variola, 107 varioloid, 20 discrete variola, and 34 confluent variola. Of the 66 subjects in whom no cicatrices were present, 14 had varicella, 7 varioloid, 13 discrete variola, and 32 confluent variola. The general result was, that in properly vaccinated individuals five-eighths had the disease but slightly, two-eighths had it somewhat seriously, and only one-eighth had dangerous variola. In the non-vaccinated there was a third of slight, to two-thirds of serious cases. In the vaccinated the mortality reached about a tenth, while in the unvaccinated it amounted to two-thirds. With reference to the period after vaccination, the number of cases of variola regularly increased in proportion to the length of this. The subjects, too, who exhibited the fewest pock-marks, constituted the largest proportion of the cases of variola and the smallest proportion of those of varioloid and varicella.

With respect to the anatomical conditions of the pock M. Briquet regards it as having its seat in the rete mucosum, the variolous pimple being constituted by the development of the capillary network of the skin. After the third day, when the pearly colour appears, a greyish exudation takes place between the epidermis and dermis, and is much more adherent to the former. The central depression of the pock seems to be due to the projection of this disc of exudation, which is much thicker at the circumference than at the centre; while the brown colour arises from the transparency of the epidermis allowing the brown colour of the contents of the pustule to become visible. In discrete variola there is a disc for each pustule, only a vestige of which is seen in varioloid. In variola with "coherent pustules" the discs are in close and regular contact, while in the confluent form they become embedded and confounded with each other, and are more or less atrophied and misshapen in consequence of their reciprocal compression. In the hæmorrhagic form there is only blood, or blood mingled with pus.

In what he terms the pathological section of his essay, M. Briquet examines the characteristics of this epidemic, and, among the special facts observed in it, adverts especially to the accompanying rash, the hæmorrhagic condition, the delirium, and the mortality. The rash was observed in twelve of the cases, always preceding the eruption two or three days and lasting four or five days. It presented two forms, the one continuous (like scarlatina) on the trunk, and the other discrete or disseminated on the limbs. Among the twelve patients in whom it was observed five died. Delirium was observed more commonly than usual; appearing only during the early days of the eruption, it generally ceased after three or four days, persisting, however, in some cases, until death. The hæmorrhagic form was of frequent occurrence during this epidemic, a fact which M. Briquet attributes to the bad diet and the work in the trenches during winter. The mortality has been very considerable. According to the figures communicated by M. Worms, variola gave rise in Paris, between July, 1869, and June, 1871, to 13,611 deaths, 1800 of these taking place in soldiers. On comparing the mortality of the civil and military Hospitals from November 1, 1870, to May 1, 1871—the period during which the epidemic was at its highest intensity—it was found that it was for the former 35 per cent., and for the latter 16 per cent. Examining the dates of the deaths which took place in the civil and military Hospitals, it was found that three-fifths occurred from the intensity of the eruption, and two-fifths either indirectly from the intensity of the disease or from consecutive diseases. In M. Briquet's cases the reverse of this was observed, for the deaths imputable to the intensity of the eruption were thirty-nine, and those which resulted from various complications were forty-five. The deaths of this second category were greatly influenced by the hygienic conditions in which the patients were placed. The most ordinary causes of these

deaths were secondary hæmorrhage, prolonged diarrhœa, local phlegmasia of the skin followed by abundant suppuration, laryngitis, bronchitis, pneumonia, etc.

The objects aimed at in the treatment were the prevention or relief of the accidents which accompany the eruption. Cases of varioloid and varicella are always left to themselves; and the course of the disease was only sought to be interfered with when the eruption was either very abundant or confluent. For such cases, mercurial ointment was employed, with the view of preventing the swelling of the face, and the formation of those layers (*nappes*) of pus which, escaping through the fissures of the epidermis, cause such severe pain and give to the head so repulsive an appearance. It was applied in ninety-five cases in which the eruption was intense. When the variola was discrete, the inflammation of the pustules was either diminished or completely arrested, the red areola disappearing, and the fibro-plastic exudation taking place very incompletely. Of the ninety-five patients so treated, and who were all badly attacked, forty were cured and fifty-five died. Salivation was not infrequently produced, but it yielded promptly to the usual gargles.

M. Briquet, in this paper, laid great stress upon the fact that the variolous pustule reposed on a kind of support or disc, which seemed to consist of fibro-plastic tissue. This disc, he observed, is very easy of enucleation by means of a slight incision and a needle, the disc being very easily isolated from the pustule. He believes this disc to have its clinical importance, as it enables us to diagnose true variola, and distinguish it from varioloid, which is devoid of disc. Upon this point M. Vulpian addressed an elaborate communication to the Academy, showing that what M. Briquet regarded as a disc of fibro-plastic tissue of new formation had no existence—being, in fact, but a mass of macerated epidermic tissue. Indeed, he regarded M. Briquet's whole account of the variolous pustule as erroneous, and supplied himself a minute histological description of it. This, which is of great interest, we have not space to notice further, but the communication has been published in full in the French Medical journals of last Saturday.

M. Richet, on presenting, in the name of the author, to the Académie de Médecine a copy of Dr. Galezowski's new work, "*Traité des Maladies des Yeux*," delivered a little address that may be characterised as pre-eminently "French":

"The book which I have the honour of presenting to the Academy is, if I may be allowed the expression, a *French* work. I will explain. Ophthalmological science, since the arrival among us of our regretted *confrère*, Sichel the elder, seemed to have become *Germanic*. He imported into Paris the doctrines of the school of Beer, which he, so to speak, appropriated and taught to our students. The French Surgeons—Velpeau and Sanson among others—did indeed strongly protest, in their lectures on diseases of the eye, against those exaggerated pretensions of Outre-Rhin, which seemed desirous of seizing hold of everything. It was reserved to one of Sichel's *chefs de clinique*—to Desmarres, senior—to demonstrate that the science of ocular diseases was entirely French in its origin, and ought to remain French. M. Galezowski, a *chef de clinique* of M. Desmarres, has followed the traditions of his master, and, more generous than one of his predecessors, who has since gained great celebrity—Von Graefe—he dedicated his first work to his Professor, while Von Graefe has always studiously abstained from mentioning him in any of his numerous writings, in this way showing how much he feared lest the source whence he had drawn his instruction might be recognised. This treatise of M. Galezowski, besides the merit of doing full justice to the French School, and placing its works in the light, has another which assures it a distinguished place in our Medical literature, which is—that it is *au courant* not only of German, but also of English and Italian science."

THERE are in Birmingham whole streets in which absolutely every house belongs to the working-class. 13,000 houses are owned by working-men, and it is certified that these are the healthiest districts in the town.

REVIEWS.

The Science and Practice of Surgery. By FREDERICK JAMES GANT, F.R.C.S., Surgeon to the Royal Free Hospital. London: J. and A. Churchill. Pp. 1265.

CONSIDERING the number of excellent books on general Surgery in the English language which, if not of very recent date, have—some of them, at least—gone through quite recent editions, it might appear a work of supererogation on the part of any Surgeon to add another to the list. This has not, however, been the case with Mr. Gant, for the volume before us has its own individual merits as a text-book for students and Practitioners, and is no superfluous contribution to our Surgical literature.

Mr. Gant is known to the Profession by his previously published works; but though the present work contains the author's Lettsomian Lectures on Excisional Surgery delivered this year before the Medical Society of London, it is quite distinct from his "*Principles of Surgery*," to which, however, reference is occasionally made.

While in the latter work he systematically *expounds* the leading doctrines of *all* diagnosis, prognosis, and therapeutics from an examination of general pathology, in the "*Science and Practice of Surgery*" he systematically *describes* the individual injuries and diseases as to their pathology, course, symptoms, and treatment. Mr. Gant is fully alive to the importance of anatomy, physiology, and the whole field of Surgical pathology in forming a basis for the correct practice of Surgery, and he nowhere spares himself the trouble either of stating fully the pathology of the injury or disease he is describing, of interweaving physiology with pathology, or of introducing the normal anatomy of parts, when by so doing he can make his subject more perfectly understood, or more conveniently describe it. Thus, in the chapter on Inflammation our memory is refreshed with a summary of the processes of nutrition, growth, and development—an appropriate, if not necessary, introduction to the study of so complicated a subject.

Again, not only is the anatomy of hernia and lithotomy fully described, and the anatomy of the arteries, in connexion with ligature, detailed with such fulness and conciseness as to render unnecessary any reference to special works on anatomy for information on these subjects, but the structural relations of parts are everywhere brought into service when they can explain symptoms, assist in diagnosis, or guide treatment. No undue stress is, however, laid by the author upon the value of anatomy even in its application to operations. In his introduction he says:—"Surgical anatomy is modified throughout by constant association with pathological conditions in the performance of any operation. Such an association will tend to correct the *purely* anatomical impressions of the student, and to safely guide the operating Surgeon."

After mentioning the very few occasions on which an operation is done through healthy structures, and away from the seat of injury or disease, he goes on to say—"On all other occasions the physical properties and relations of parts disclosed during an operation are then so changed by disease as sometimes scarcely to admit of recognition; and thus it is that anatomy *plus* certain pathological alterations, or the *pathologico-anatomical* conditions of the body, are those with which the operating Surgeon is concerned." But pathologico-anatomical conditions are not the only circumstances which interfere with the appearances to which the anatomist is accustomed. Life itself vastly alters all the tissues seen even in the simplest operation—"thus the colour, consistence, size, and shape, etc., of the various parts of the body are presented to the Surgeon when modified by the twofold conditions of disease and life combined. These together may be termed Pathology, and not pathological anatomy, which represents only *dead* structural disease. Pathology conjoined with anatomy is, therefore, our guide during Surgical operations."

These quotations will suffice to indicate the comprehensive treatment which his subject receives at Mr. Gant's hands.

The work is divided into two parts: the first, on General Pathology and Surgery, occupies 241 pages, and includes the forms of disease common to all parts of the body, such as inflammation and tumours. Part II., on Special Pathology and Surgery, is subdivided into two divisions—the first, *relating to textures*, comprises burns, aneurisms, fractures, and diseases of bone, etc.; the second, *relating to organs and regions*, commences with those of the head and proceeds downwards, and embraces all the special branches of Surgery, such as the eye, ear, and teeth. Appended to the end of the volume is a Guide

to the Examinations for the Membership and Fellowship of the Royal College of Surgeons, written from personal observations during the years 1870 and 1871, which shows the nature of the preparations, instruments, and questions, both written and verbal, submitted to the candidates at the first and pass examinations. This is sure to prove of great assistance to those preparing for the examinations at the College.

Of course, in a work extending over so wide a field, many sources must contribute to its accomplishment. Acknowledgment is, however, made of the free reference to other authors; and so numerous are the references (in foot-notes) to standard works and well-known writers on all unsettled or disputed points, that the reader sees at once where to go to extend his knowledge with respect to them.

In Part I., under the head of Diseases of Nutrition, after a lengthy and instructive chapter on Inflammation, the subject of "Tumours or Morbid Growths" is treated of under two heads—(a) Localised or Non-infiltrating Growths, and (β) Infiltrating Growths. Here the general and special characteristics in respect to their structure and vital endowments are described; but they are again referred to in Part II. under the head of Diseases of different Structures and Regions, in order that the points to be attended to in their diagnosis may be brought out side by side with the other affections of the parts in which they occur.

To complete the pathology of nutrition the various forms of degeneration should have been described; but Mr. Gant having treated of these in his "Principles of Surgery," contents himself here with an enumeration of the several kinds which, as he correctly says, are of as much importance to the Surgeon as to the Physician.

Eight diseases are grouped together under "Diseases of Contagious Origin." These include some acquired from contact with a poison in the human species and others in animals. This arrangement is artificial and unsatisfactory, since it places together, and in association with each other, diseases of such different nature as syphilis, pyæmia, and hydrophobia.

The reparative processes in wounds and fractures are in their places carefully described. In the chapter on "Wounds of Arteries," certain particulars respecting the application of ligatures are given, which ought to be read and known to every Dresser and House-Surgeon, although, judging from the bungling manner in which one sometimes sees a ligature applied, the inference is that the significance of such particulars has not been generally understood.

Mr. Gant is a declared advocate of torsion, "scarcely ever employing ligature to any artery, of whatever size." The method he adopts is that of simply twisting the end of the vessel several times, but short of detaching it. He says of acupressure that experience has shown that the clot which forms and plugs the vessel when the needle is withdrawn is sufficient, "without the additional security of lymph-deposit and sealing of the vessel as at the line of ligature or twist;" but he adds, "assuming the liability to the occurrence of secondary hæmorrhage to be about equal after either of the three methods of Surgical treatment, the tendency to *primary union* of the flesh-wound, and the prevention of *pyæmic infection* of the system, must be very different. Torsion has decidedly the advantage over either ligature or acupressure in regard to both these very important considerations. The twisted portion of an artery not being killed, as its subsequent adhesion shows, no sloughing of the end of the vessel ensues when this portion is allowed to remain in the wound—yet this event necessarily and intentionally ensues after the application of ligature, or accidentally by prolonged acupressure; and no foreign body is allowed to remain in the wound, for however short a period, to possibly provoke suppuration, as after both these methods of treatment." These are strong points in favour of torsion, and deserve the consideration of those Surgeons who still mistrust every means of controlling divided arteries excepting the ligature. The twisted end of the artery, when torsion has been used, has been asserted by some Surgeons of considerable eminence to act as a foreign body; but observation appears to have settled the fact that there is no necessity so far to detach as to kill the twisted portion.

A short chapter on Morbid Cicatrices is of value, as it brings at once under the notice of the reader the various results of faulty modes of healing of skin-wounds, and also the subsequent diseases of the healed surface. But the most important portion of the book is that which treats of Excisional Surgery. It contains a vast quantity of information respecting the results of operations, as obtained by the author from a large number of public and private sources. After giving a short historical sketch of the operation of excision, he points

out its relation to the general treatment of joint disease, and gives the following indications of treatment:—"The non-operative comprise—(1) Preservation of the joint, functionally, by restoration of its mobility; (2) preservation of the joint, with loss of its mobility, by ankylosis. The operative indications are—(3) Preservation of the limb and life by sacrifice of the joint, with ankylosis—excision. (4) Preservation of the life alone, by sacrifice of the limb—amputation. The question of operative interference, it will thus be seen, can arise only when the joint disease is already past the control of the first indication of treatment—restoration of the mobility and functional use of the joint; and when it has become subject to the second indication—preservation by ankylosis. But this result is also the object of excision. The true comparison, therefore, of joint disease is with the probability of *natural* cure by ankylosis. Such comparison should have reference (1) to the joint . . . and (2) the liability to life, or the comparative mortality of the natural cure by ankylosis, and that resulting from excision, must also be considered."

Excision has been often compared with amputation, and, so far as the mortality after the operation is concerned, this comparison is not perhaps unjust. As to the time required for a cure, the true comparison is, as Sir W. Fergusson has pointed out, with compound fracture; no comparison, however, can rightly be made between the two as *alternative operations*, merely because the joint disease is incurable without operative treatment. On this last point Mr. Gant remarks, "The comparatively early period for excision is too early for amputation; and the comparatively late period for amputation is too late for excision. When either operation becomes justifiable for joint disease, the other should not be entertained." The diversity of opinion amongst Surgeons in regard to the propriety of excision *versus* amputation, springs, Mr. Gant thinks, "from a twofold view of the nature of the state in question. Thus, serofulous disease of the knee-joint may be considered incurable without operative interference, when the disease has advanced to destruction of the articular cartilaginous surfaces of the tibia and femur without the supervention of ankylosis, so that the joint has become functionally useless; or the same disease may not be regarded as incurable until it has advanced to a further and even to an extreme state of disorganisation."

We congratulate Mr. Gant upon the result of his labour, which must have been very considerable and prolonged; he has produced a book which reflects great credit upon his own ability and enterprising spirit, and which will be of service to the Profession. It is profusely illustrated, although, as is fairly acknowledged in the preface, only a portion of the woodcuts are original; for many of them Mr. Gant is indebted to the standard works of Astley Cooper and Liston. These excellent representations, of course, greatly enhance the value of the book. We do not say, however, that there are no faults to be found in it, for there are evident omissions. We do not always approve of his classification and arrangement of subjects, and are not infrequently annoyed by his punctuation—especially his constant use of semicolons—which sometimes renders his meaning obscure. But these do not detract seriously from the general merit of the work; and it must be remembered—

"Whoever thinks a faultless piece to see,
Thinks what ne'er was, nor is, nor e'er shall be."

On the Use of the Ophthalmoscope in Diseases of the Nervous System and of the Kidneys, etc. By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., Physician to the Leeds General Infirmary, and Lecturer on Practice of Medicine, etc. London and New York: Macmillan and Co. Pp. 405.

THE book now lying before us is one well deserving general attention, not only because it is the work of a highly intelligent and eminently scientific Physician, one whose opinion is always worth having;—it is not on that fact alone, nor on any similar fact—but because Dr. Allbutt has devoted his great abilities to the elucidation of a literally dark subject that this work is so well deserving of this attention. Those only who have striven to use the ophthalmoscope systematically in ordinary Physician's work can tell how difficult it has been to put the right interpretation on the phenomena observed. They also know that there was no book to which they could refer for aid in their difficulties—for the use of the ophthalmoscope in ordinary Medicine is but of yesterday. To such men as those we have just referred to, this book will be specially welcome, whilst many to whom the ophthalmoscope is an instrument unknown will be encouraged to take it up and work with it now that its value is thus made clear before them.

The author begins with an account of the introduction of the ophthalmoscope into ophthalmic practice, and its gradual application to the elucidation of other than purely ophthalmic problems. Next he speaks of the mode of using the instrument. For general use he commends a metallic mirror, and at least two object-glasses. He condemns all fixed apparatus as useless and cumbersome. Here also he gives a word of practical advice, which Physicians will do well to bear in mind. When learning to handle the apparatus it is well to operate on an eye whose pupil has been dilated by atropine; but the sooner dilatation can be dispensed with the better, for patients do not like it, as the disordered accommodation remains long after the necessary examination, and normal vision is, consequently, interfered with. One speedily gets accustomed to dispense with the use of atropine. The succeeding chapter is devoted to anatomical details, the most important of which seem to us to be the fact that the vascular supply of the optic discs is connected with the brain system rather than with the retina, and that in the coverings of the optic nerve there is an actual prolongation of the arachnoid interspace.

The anomalies of the optic disc are next considered; and they are well worth attention, for to the beginner they are most puzzling. Those here alluded to are—the varied distribution of the retinal vessels, the persistence of the hyaloid artery, pulsation of the veins of the retina, excavation of the disc similar to that existing in glaucoma, but physiological, and finally those troublesome anomalies in the colour of the disc. These last have an important bearing on the subjects next discussed—which are hyperæmia and anæmia—for it takes some experience to say what is physiological or natural, and what pathologic or the result of disease-change. Oedema and ischæmia are almost equally annoying, for the latter is by very many confounded with inflammation of the disc, under the common but perplexing title of optic neuritis. On this account we find here the term neuro-retinitis introduced, to mark out the truly inflammatory process, the term ischæmia being applied to conditions superficially somewhat similar, but due to vascular arrest alone. The term chronic optic neuritis is here retained, not for the consecutive atrophy it has sometimes been confounded with, but rather for the subacute inflammation which precedes the white atrophy. The next two conditions—retinitis and perineuritis—are of great importance Medically, but the two following have an almost equally important bearing on the daily practice of our Profession; these are, consecutive atrophy and primary atrophy, between which the diagnosis is not always easy.

Next are considered the relations of these conditions to intracranial disorders, and the diseased conditions thus considered are—epilepsy, chorea, mania, dementia, meningitis, concussion and fracture, hydrocephalus, tumours and periostitis chronica, atheroma, softening and hæmorrhage, cerebritis, abscess and sclerosis, and, finally, general paralysis. We can hardly refer to all of these conditions, but to some of them we may. Epilepsy during the intervals is marked by a somewhat vascular disc, the vessels being generally larger and fuller than usual. This corresponds with the results of our own observations. In chorea there is no change, as a rule. In acute mania, just after a paroxysm, there is slight hyperæmia or pinkness. In dementia there are many changes, but none very marked. In meningitis, especially the tubercular form, the ophthalmoscope is exceedingly useful in enabling the Physician to come to an early diagnosis—for, long before there may be other symptoms, congestion of the optic papillæ may give warning of the approaching danger. In hydrocephalus, too, we have the ischæmic condition at an early stage, but later on only simple white atrophy. It is, however, with regard to intracranial tumours that most work has been done by the ophthalmoscope—so much, indeed, that we can only refer to the subject here, without entering into the discussion on it, as that would take us farther than we care to go; for though much has been done in this field, very much more requires to be done. In general paralysis of the insane there is a great tendency to simple white atrophy of the discs. Diseases and injuries of the spinal cord are often enough followed by altered conditions of the optic disc to show a connexion between the two, and some interesting facts have been adduced in support of this view; but much remains to be done before the ophthalmoscope can be rendered of much use in the discrimination of these.

There is one morbid condition within the category of internal disorders which in a wonderful way affects the eyes, and consequently from these may frequently be drawn valuable conclusions as to its existence and non-existence. The disease is albuminuria, and the morbid condition of the eye is albuminuric retinitis; this, indeed, may exist in a marked degree

without any appearance of dropsy, and in itself constitutes a sufficient reason why Physicians should cultivate the use of the ophthalmoscope. So, also, there is a leukæmic retinitis, which presents peculiar and characteristic symptoms. Toxic amaurosis we have not time to touch; and though we would fain linger over what might be called the classic story of embolism of the arteria centralis, space and time will not permit—and so we must take leave of Dr. Allbutt. His book, it will be seen, is not a perfect history of the morbid conditions of the retina in all kinds of disease: for such a work no sufficient material exists.

The great merit of this work is, that it clears the way for other workers. By its aid men will no longer be compelled to work for years in the dark—they will have a definite standpoint whence to proceed on their course of observation. And we think it well to say a word on the spirit of the book, which is to us most pleasing. It is not a book of controversy; in it all fellow-workers are spoken of in the most loving spirit. From the kindly dedication to Dr. Hughlings-Jackson to its "Finis," this treatise has only words of encouragement to those workers for whom the author lays bare all his stores—the accumulation of much hard work both in the field of observation and in that of research. Did it not seem unkind, we should be tempted to desire that a new edition might be deferred until these stores had fructified and produced the ample harvest of exact knowledge the labour spent in their acquisition deserves.

NEW BOOKS, WITH SHORT CRITIQUES.

Three Lectures on the Preservation of Sight. By DAVID SMITH, M.D., M.R.C.S.E., Extra-Academical Lecturer on the Eye, Glasgow. London: R. Hardwicke. Pp. 92.

*** These lectures were delivered before a lay audience last May, and are decidedly above the average of such lectures; they give a fairly accurate account of the phenomena of vision. We notice, however, something in the preface which seems like a puff, though quite possibly not so intended.

Food, Water, and Air. Edited by ARTHUR HILL HASSALL, M.D. No. 1, November.

*** This is the first number of a serial edited by Dr. Hassall, which promises to be of much service to the public, and not without interest to the Profession. The chief subjects discussed, and which are treated with much ability, are as follows:—"Has Adulteration Increased or Diminished of Late Years?—Milk and its Adulterations—The Standard of Purity of Water—On the Danger of Reliance on the Permanganate Test for Water—Dr. Sanderson's Experiments on the Growth of Microzymes in Water—On the Utilisation of Sewage." In addition to these there is an article on "Food, Water, and Air," and a *résumé* of miscellaneous intelligence bearing upon the public health. The work is to appear monthly, and is 3d. in price.

THE HAMPSTEAD HOSPITAL INQUIRY.

THIRTY-SECOND DAY.

ON Thursday the evidence of a meat-contractor, Mr. Hughes the nurse, and of Sister Frances, the superintending Sister, in favour of the Management of the Hospital, was taken. Sister Frances gave a full account of the duties she performed—namely, the superintendence of all matters relating to the womanly care of the patients, nursing, charge of linen, laundry-work, and the like. She was taken over the various charges which have been gone over in previous evidence, and she spoke of them as not being in accordance with fact.

On the thirty-third day some other of the ladies who had worked in the Hospital were examined, and gave evidence in favour of the Management. Mr. Collins made a speech in support of the complaints, and the Court afterwards broke up.

VICHY IN 1870.—Although the arrivals took place somewhat later, the visitors were very numerous, and the place was as gay as usual. The total number of visitors amounted to 18,857—16,700 of the number being French and Algerians, 836 British, 197 American, 183 French Colonials, 44 Belgians, 79 Dutch and Belgians, 103 Russians, 215 Spanish and Portuguese, 92 Italians, 41 Poles, 21 Prussians, and 217 Swiss.

IRELAND.

DUBLIN, November 7.

THE INTRODUCTORY LECTURES.

THE opening of the session in the various Hospitals and Medical Schools of our city has this year been marked by comparatively little stir. In fact, before many more sessions have passed by it is more than probable that the time-honoured "introductory" will have, become generally, if not altogether, obsolete. The tendency seems to be to make the close rather than the commencement of the yearly period of study an occasion for advising, and of congratulation. The annual distribution of prizes at our Hospitals and Schools is gradually taking the place of the old-fashioned opening-days. And perhaps this is as it should be. The display at the "introductory" was too often followed by an anti-climax of lessening energy and industry throughout the remainder of the session, and only in exceptional instances was there a goal at the close to which the hard-working student might strive to attain. The Royal College of Surgeons this year took the lead in opening the session, an introductory lecture having been delivered on October 30, by Mr. James Stannus Hughes, Professor of Surgery to the College. The lecturer commenced by alluding in laudatory terms to the late Surgeon Collis, to whom, he said, the Royal College of Surgeons was largely indebted for the high position it had attained. Having referred to the improvements which had been effected in Surgery of late years, and also to the triumphant return of Sir Dominic Corrigan, a leading member of the Profession, as Member of Parliament for the city of Dublin, he entered into a technical statement, containing for the most part advice to young students, as to the books they should study, the companions they should select, and the necessity for unremitting industry in their work. In conclusion, he trusted that all the students would adhere to the declaration they were obliged by Act of Parliament to make before entering the College—namely, by every means in their power to conduct themselves so as to uphold the dignity of the institution.

On the 1st inst., Mr. W. H. O'Leary commenced the courses of lectures at the Ledwich School of Medicine by an address of high merit, its subject matter having reference chiefly to the manner in which young men then entering on the pursuit of a noble Profession should pursue their studies with the best advantage to themselves and their teachers.

At the Adelaide Hospital, a lecture was given on the 3rd inst. by Dr. John Kells Barton, one of the Surgeons. The different members of the staff, a large number of students, and several visitors were present. Of Dr. Barton's address I hope to give some account in a future letter.

On Saturday, the 4th, Dr. Fleming inaugurated the session at Dr. Steevens's Hospital and Medical College. In the course of his remarks, the lecturer congratulated the students on their past success, and expressed a hope that the present session would enable them still further to distinguish themselves. The usual distribution of prizes subsequently took place. To Mr. Frederick Warren was awarded the Senior Medal. The prize of the second year was carried off by Mr. David Bookey, and that of the first year by Mr. Emerson.

On the same day, Mr. Robert Cryan lectured at the School of the Catholic University, Cecilia-street.

The introductory address at the Meath Hospital and County Dublin Infirmary was delivered on Monday morning, the 6th inst., by Dr. Arthur Wynne Foot. Amongst those present were—The Right. Hon. the Lord Mayor; Dr. Hudson, President of the College of Physicians; Dr. Wharton, President of the Royal College of Surgeons; Dr. Stokes, Regius Professor of Physic in the University of Dublin; and G. H. Porter, Esq., Surgeon to the Queen and Senior Surgeon to the Meath Hospital.

Dr. Foot commenced by alluding to the fact that frequently, of late years, the opening sentences of the introductory addresses in this Hospital had consisted of obituary notices, and expressed the general gratification which was felt that on this occasion the prelude was not to be pitched in a minor key. He alluded in graceful and delicate terms to the circumstance that he occupied the post of Junior Physician, vacated by the retirement of Dr. Hudson, now the President of the College of Physicians, rather as his representative than his successor, and regretted that the presence of his predecessor precluded him speaking of him as he could and would. Alluding to the con-

ditions which have led students to regard these annual orations as the capital affliction of human patience, while not expecting that he should escape their criticism in many particulars, he assured them that their ears should not be re-assailed with stock quotations from Bacon and the poets. Declining to handle any topics of intense Professional interest, or even national importance—such as Medical ethics, or State Medicine—he preferred to dedicate the occasion to the interests of the youngest student now beginning to prepare himself by Hospital attendance for the future business of his life. He offered to take him, step by step, over the course he had gone himself, offering, as a guarantee of his sincerity, that, were he in their position, and commencing life, he would, a second time, adopt the plan he now proposed to them. If his food was poisonous he had tasted every dish, and regarded his position there that day as a convincing proof that his method was, at least, worth their trial of it. He advised them to devote themselves at first to the art or practical part of Medicine, which could be learned nowhere but by the bedside of the sick, and nohow but by personal attendance on them, and written narratives of their illness. The courtesies of the sick-room—no mean accomplishment—were to be upheld here as well as in the chambers of the wealthy. High personal character—a most influential circumstance in deciding their future career—if now acquired, would prove a powerful ægis in a life peculiarly assaulted by temptations of various kinds, and would surround them with an atmosphere pure enough to disinfect even the pestilential breath of calumny. "Work" was the password to success, the key to unlock every difficulty, the thread of Ariadne in the maze of life; but work was not to be of an epileptic kind—in convulsive fits, followed by acute attacks of idleness, which did not exhaust their susceptibilities to fresh ones, but, by repetition, left the mind a desert, with no oasis. Their energy was not to be the flare-up of lighted straw, but a banked-up furnace of dull but sleepless determination. He admitted that he was taking his pupil along a toilsome road; the course involved severe labour, unless they commenced it at once, during their first year. If they did that, and would persevere, in the face of utilitarian questions of the *quid utile* and *cui bono* breed, and in spite of the apparent slowness of their progress, they would find that they could do what others had done before them; their knowledge and experience would hourly accumulate around them with the rapidity and silence of thickly falling snow, and their faith in the infallibility of work would soon begin to see some realisation of its hopes. All well-fed active streams of work find their way, sooner or later, to the great sea of knowledge, and, rising again from that sea, rain down such honour, emolument, and rank as the Profession, the public, or the State have it in their power to bestow. The scientific part of Medicine was to be studied as carefully as the art; but later, because the practice of Medicine was the fundamental necessity. Science, as applied to Medicine, meant the physical sciences, and not logics, ethics, and metaphysics. Physical science was striding about in the arena of Medicine, dealing death-blows to quakeries—doing what the art of Medicine could not do; and opposition to the influence of science would be as vain as an attempt to stop the motion of the world, and they would only make a Juggernaut of themselves under the resistless wheels of Progress. Alluding to the necessity of erudition in Medicine, as being a Profession related to all human knowledge, and to the fact that the writings of many Medical men were not properly appreciated in their lifetime, he observed that the brightest epiphanies of intellect were sometimes too strong for the eyes—like comets, they blaze and disappear before we have time to wonder at them; but they leave behind them in their works a glittering train of luminous thoughts, at which men marvel as they read when the dazzling influence of the meteor is withdrawn. The art, the science, and the erudition of Medicine were to be cultivated in due succession, and amalgamated as much as possible; they were thoroughly compatible with each other, although leaders in each section had contrived to bring the three into a seeming collision, as if they were essentially inimical. They should refuse to be representative men in any one of these departments, if they looked forward to the practice of their Profession in its widest usefulness, lest they should become persons of one accomplishment, who, like the *homo unius libri*, were usually disagreeably perfect within their narrow circle, and therefore apt to be gloomily arrogant or testily vain. The purely practical man who looks upon science in its application to Medicine as a modification of the black art, when pressed by the scientific man in one of the unseemly and unprofitable discussions which arise from this sectarianism, runs into his castle of experience, whence nothing

will induce him to sally out. On the other hand, the scientific man, when hot pressed by the practical man, takes refuge in a mist of the technical phraseology of the sciences, and escapes like a cuttlefish, in a cloud of ink. The faith of the pure reader is bibliolatry; an abject slave to venerable tradition, he never ventures to question the correctness of the most fossil dogmas; his independence, parched by the east wind of authority, withers from want of cultivation, and leaves him an unfortunate character, unstable as water, unable to excel. The reconciliation of the three lies in the admission of faults on each side. Practice must acknowledge the utility of science, science must recognise the fundamental importance of practice, and both must allow that erudition is a graceful ornament, and an indispensable accomplishment. Referring to the threefold object of Medicine—the cure, the palliation, and the prevention of disease—he stated his belief that at no very distant time the prevention of disease would occupy the mind of the public and of the Profession in a degree anticipated by few at present. He declined to discuss the question on the present occasion how far preventible diseases are the moral police of the Almighty, and, as such, to be left to work out their own ends; but was not disposed to regard plague, pestilence, and famine as unavoidable tortures inflicted by wrathful Omnipotence upon His helpless handiwork. Our present knowledge of the causes of the propagation of cholera was a striking and solemn illustration that the threat of Rabshakeh enjoys a wider fulfilment than was ever dreamed of by the Assyrian captain. In the midst of luxury and in the centres of civilisation that disease was spread, even among the high and noble, by an unconscious performance of the act which was held out to the Jews as the dire alternative of their refusal to capitulate to Sennacherib. In some concluding remarks addressed to the senior students, he counselled such of them as had great attainments to preserve their lustre by humility, remembering that the great sea of knowledge was unfathomable, and that the wisest of men could not, during his whole lifetime, do more than wet his ankles on its shore; they must be patient if success seemed slow to come, because the crowns of kings would not fit the brows of infant princes. They should scorn every shape and form of humbug, and abhor and dread it as the tunic of Dejanira. They might be sorely tried by the sight of reputation and confidence unfairly withheld, and more unfairly bestowed, and begin to think that there was some truth in the comparison of the world to an old woman who mistook every gilt farthing for a gold coin, and who, finding herself so often cheated, at last made up her mind to trust nothing but the common copper. Malice and Envy were positive agents in this wicked world; Envy moved parallel to Success, and lost no opportunity of stabbing her in the flank. The Medical Profession was not exceptionally free from clashing interests and variety of opinion, and if they struggled for a foremost place they would have to learn that "he makes no friend who never makes a foe." Their own nobleness of character, their instinctive hatred of flattery and intrigue, their very frankness, might throw most unexpected obstacles in their path, and teach them that, though they might deserve success, they might not command it. Whatever their fortune might be, let them endeavour to keep straight in the honourable paths of Medicine, worn by the footsteps of the good and great; never departing from them for the sake of an evanescent popularity—answering the invitations of profit or notoriety with *Retro Satanas!* whenever they were counter to the spirit of their Profession, since it would be better for them, when the wheels ran down, to slip into their graves unnoticed than to have attained to eminence by unworthy means. The address closed with a final appeal to those who were commencing to learn Clinical Medicine at the Hospital this winter, that they would enter on the path of education indicated, and that, cherishing a strong faith in the everlasting power of work, they would persevere until they found their labours crowned with some one or other of the many diadems of success.

BIRMINGHAM.

November 6.

THE LATE MR. LANGSTON PARKER.

THE Profession and the community at large here have just sustained a loss by the death of Mr. Langston Parker, the eminent Surgeon of this town. Mr. Parker had been labouring under enfeebled health for several years past, but at length caught a cold, which carried him off from syncopal asphyxia. An impression has gained ground that he died of apoplexy—owing,

perhaps, to his bodily conformation, which was handsome, but full and thickset, while his cheeks were florid and puffed. He was, however, at the last extremely pale, while his voice was querulous from excessive debility. He did not die in bed, but sitting on the sofa; and his mind was unclouded almost to the very last. He was the son of an old Practitioner here, and succeeded to his father's practice many years ago. He distinguished himself in the literature of his Profession by several papers in the Medical periodicals, and also by works on dyspepsia and cancer; but his chief reputation is based on his work on Syphilis, which has become the text-book on the subject, in which he was most at home, and on which he was largely consulted. The chief characteristics of Mr. Parker's mind were quick perception and decision, along with concentration of thought and purpose. His thoughts were very rapid, and his diagnosis soon made. His memory was remarkably retentive: he could not only remember, after reading a work, the general meaning and expression of the author, but the very words themselves employed, even to the minutest particular. This wonderful faculty of memory he exhibited before a friend a few days before his death in a remarkable manner. With an outward carriage which to strangers might indicate austerity and pride, he was found on acquaintance to be bland, kind, and considerate to a degree; and his exquisite knowledge, taste, and accomplishment in music showed the fine tone of his mind and sentiments, which made him a most delightful companion to those very few who were privileged to enjoy intercourse with him. His reading of both foreign and home Medical literature was very extensive, and it was not confined to Professional subjects only, but embraced general literature too, his favourite subject being the drama, upon which he exhibited a most extensive, accurate, and critical knowledge. He had delivered some lectures in public upon Dreams, Visions, and other Sources of Mental Delusion, which drew great attention. They were published at the time in a periodical, the title of which at present does not occur to us, but we think it would be desirable that they should now reappear in a volume, if his representatives feel so disposed. He was entombed in the family vault at the ancient church of Aston-juxta-Birmingham. The chief mourner was his son and only surviving child, Mr. Adams Parker; and he was borne to the grave chiefly by Birmingham Physicians and Surgeons—namely, Dr. Bell Fletcher, Dr. David Nelson, Dr. George Vernon Blunt; Messrs. Valentine Walshman, Blake, Oliver Pemberton, George Yates, Thomas Thompson, Surgeons; and Mr. Hirnie, of Liverpool, his nephew through marriage. A considerable number of private and Professional friends also attended at the churchyard.

GENERAL CORRESPONDENCE.

CASES AT ST. THOMAS'S HOSPITAL.

LETTER FROM MR. LE GROS CLARK.

[To the Editor of the Medical Times and Gazette.]

SIR,—You referred recently to two cases on which I operated in St. Thomas's Hospital, and it has occurred to me that it may be interesting to insert in your journal the sequel of these cases.

In the elderly man whose penis I amputated, the enlarged inguinal glands have almost disappeared. The wound is healing kindly, and the patient is free from suffering. He has been provided with a short elastic catheter, with a shield, which he is directed to introduce from time to time. The period when contraction of the orifice of the urethra is most to be dreaded, is *after* the stump is actually cicatrised—at least, such is my experience.

The phthisical patient whose thigh I amputated has gone on uninterruptedly well. He scarcely felt the shock of the operation, and had no febrile reaction, but began at once to sleep well and take his food with appetite, and recovered spirits. The stump is now healed, but of course the condition of the lungs is *in statu quo auto*. I am, &c., F. LE GROS CLARK.

St. Thomas's-street, S.E.

PHTHISIS IN AUSTRALIA.

LETTER FROM MR. WILLIAM THOMSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—In a recent number of the *Medical Times and Gazette* it is stated that the statistics given by me on phthisis in Australia were disputed by the *Australian Medical Journal* as greatly

exaggerated. To enable you to satisfy yourself and your readers I send herewith the Registrar-General's return for July last (the latest published), by which you will find that the deaths from phthisis in Melbourne and suburbs during that month were $16\frac{1}{2}$ per cent. of the total deaths from all causes. I also send the *Argus* of this date containing a report of the deaths in the Melbourne Hospital for the past month, in which it is shown that of 29 deaths in that institution from all causes 14, or 50 per cent. were from phthisis.

I may intimate that as the 2126 deaths in five years and a half were taken exception to, because it had not been shown that the patients had not come from the country for Hospital aid, I have now taken *all* the statistics for the whole colony during the same five years and a half, and find that in addition to the 2126 given there have been 2143 more, making over 4200 in all. These will soon be tabulated, published, and forwarded to you as were the former.

South Yarra, Sept. 9.

I am, &c.,

WILLIAM THOMSON.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, OCTOBER 24.

MR. CURLING, F.R.S., President, in the Chair.

MR. LE GROS CLARKE read notes of

A CASE OF LARGE BILIARY CONCRETION IN THE ILEUM.

The author gave the details of a case occurring in a patient, aged 58, who was seized with abdominal pain and bilious vomiting, accompanied by constipation. A hard tumour was to be felt in the right hypochondrium. There was no abdominal tenderness or distension. On the eleventh day the vomiting became stercoraceous. Two days later the bowels were open, and the vomiting ceased until ten days later, when it recurred, and continued at intervals during a week. For three weeks after this time the bowels acted daily, and there was no sickness. The patient was then seized with severe abdominal pain and vomiting; the abdomen was tender, especially over the region of the cæcum, where a hard tumour could be felt. Death took place two months from the commencement of the first attack. At no period of her life had the patient suffered from jaundice. The post-mortem examination revealed the existence of extensive peritonitis. Two large gall-stones occupied the ileum close to the valve. An ulcerated opening in the small intestines had permitted the escape of several small gall-stones into the peritoneum. The gall-bladder was healthy; there were no adhesions between it and any portion of the intestines. There was no trace of any ulceration either in the gall-bladder or in the neighbouring intestines. The concretions measured one inch in length and four inches in circumference. They seemed moulded to the shape of the ileum. On examination, it was found that the stones were composed of 95 per cent. of cholesterine, and that nothing had been added to them in the intestines. The gall-ducts were dilated and thickened. The author drew attention to the singular absence of any proof that these concretions had passed by ulceration from the gall-bladder to the abdomen, though this is the only way in which such large bodies could have entered the intestines.

Mr. DE MÉRIC asked what was the diagnosis as to the cause of the obstruction. He had been consulted in a somewhat similar case, where, however, there was no post-mortem, so that they were left in the dark as to its exact causation.

Dr. A. P. STEWART remembered a patient in Middlesex Hospital with obstinate stercoraceous vomiting. No relief could be obtained, and after death a gall-stone as large as any of those exhibited was found impacted in the ileum. It was smooth and rounded, and constituted a complete barrier to the passage of any matter. There were distinct marks of ulceration in the gall-bladder and duodenum. The year before last he had seen a lady with intense pain; suddenly she obtained rest, but again the pain came on, and again relief followed. Next day she passed a calculus the size of a pigeon's egg. It was almost certain this had passed by the ductus communis.

Dr. HABERSON said such cases were interesting for their rarity and the difficulties of diagnosis. Some years ago he had a somewhat similar case in a lady over 50. She had pain and bilious vomiting, and died in ten days. They found a large

gall-stone in her jejunum. There had been no peritonitis, and no stercoraceous vomiting. There were adhesions between the gall-bladder and duodenum, but no regular cicatrix.

Mr. LE GROS CLARKE said there had been great difficulty in coming to any diagnosis, and that could only be come to by way of exclusion. There were no inflammatory symptoms, and no signs of malignancy, so he considered the obstruction due to scybala, and directed his treatment accordingly.

Mr. J. WARRINGTON HAYWARD read a paper

ON ETHER AND CHLOROFORM AS ANÆSTHETICS.

The paper commenced by stating that, it having been suggested to the author that the statements of Dr. Bigelow and other American Surgeons showed that ether as an anæsthetic had been to our detriment neglected, he had, during the past year, practically investigated the subject, and had arrived at the conclusion that ether was, for several reasons, to be preferred to chloroform. Of these reasons the strongest was the greater safety of ether, for by using it the chief, and in skilled hands, probably the only, cause of fatal cases of chloroform inhalation was excluded—*i.e.*, paralysis of the heart—ether being a stimulant to the heart's action, and uniformly improving the pulse. The second was that ether, from its stimulant quality, was antagonistic to the effects of the shock of an operation, which the author maintained, and quoted cases to show, was not abolished by rendering the patient insensible. A third was the greater liability of chloroform than ether to produce after-sickness. The principles and mode of administering ether were then described, and it was shown that if these were attended to, the production of anæsthesia by ether was as easy and certain as by chloroform, and required but little more expenditure of time or the drug. The only cases to which ether was not so applicable were operations upon the mouth, in which an inhaler could not be used, and where it was necessary to readminister the anæsthetic as rapidly as possible without an inhaler. There were two appendices to the paper: the first consisting of a table of fatal cases from chloroform; the second of a table of ninety-seven cases in which the author had administered ether, including amputations, excisions, perineal section, lithotomy, lithotrity, staphyloscopy, vesico-vaginal fistulæ, ligature of piles, and other operations. Especial note was taken of the occurrence of after-sickness, and the only approach to it was that in one case, after an operation for recto-vesical fistula, the patient vomited once, an hour after the operation.

The PRESIDENT regretted that no notice had been taken of the proposal of the Society's Committee to use the mixed vapours of alcohol, ether, and chloroform.

Mr. SPENCER WELLS said the mixed vapours of ether and chloroform had been employed at Vienna, but it was found that the ether evaporated first, and that after it had gone the patient was drenched with the chloroform. He had long felt the objections to chloroform, especially as regards the vomiting it produced. This was particularly objectionable in many of the operations he had to undertake, especially in the abdomen and vagina. He had tried ether on the advice of Dr. Keith, of Edinburgh, but it was so troublesome that he was glad to take to bichloride of methylene. This he thought the best anæsthetic; after it sickness was rare. Some said it was only a mixture of chloroform and hydrochloric ether; that might be so, but as long as it suited his purpose he did not care what it was chemically. It was best given by Jünker's apparatus.

Dr. DAY said he had frequently given bichloride of methylene for Mr. S. Wells, and was much satisfied with it. He entered at length into its chemical characters, and exhibited the apparatus he used.

Dr. C. KIDD said he had used chloroform, and ether too. He found the latter tedious. It was a good plan to put a patient under the influence of chloroform, and then keep up the anæsthesia by ether. Bichloride of methylene was not so good.

Dr. SANSOM said the data available did not admit of an accurate estimate of the relative danger of chloroform and ether. He differed from the author alike in his estimate of ether and chloroform. He could not call the former safe. Relatively, chloroform was more manageable and less nauseous than ether. He considered the great danger of chloroform lay in its depressing action on the heart; but this could be avoided. It was true ether and chloroform did not go off together, but alcohol acted by restraining them both. By injecting morphia, C. Bernard found that much less chloroform was required to produce anæsthesia. It was best to give morphia subcutaneously first, and chloroform afterwards, or to administer chloroform and alcohol together, or chloroform first and ether next, as he had first proposed some time ago.

Mr. HOLMES said he had tried ether some years ago. It required twice the time chloroform did to produce anæsthesia; but this was an insignificant trouble if it were safer. He tried to favour the escape of the vapour by using a hot sponge, and it blistered the face of the patient. Violent convulsive movements were also induced by it in certain patients. Its relative safety was doubtful, for the statistics were more than suspicious. It was really impossible to avoid danger in the production of anæsthesia.

Mr. BRUDENELL CARTER had tried ether on himself, and the taste of it hung about him a long time. This was an objection to its use.

Dr. HUNTER said if they used other narcotics they must look to the lungs as well as to the heart. In one of these compound cases he had nearly met with a fatal result. It was best, he thought, to use morphia when the effects of the chloroform were passing away.

Mr. CLOVER remembered that sickness followed the use of ether when that anæsthetic was first used in this country. He had been in the habit of giving nitrous oxide first, and then ether, as the great difficulty was to get patients to inhale it freely. As to the giving of chloroform, the modes of giving it were of the utmost importance. He was convinced that a 4 per cent. mixture with one had a totally different effect from a 6 per cent. mixture.

Mr. HAYWARD, in reply, pointed out that he was no special advocate for ether. He had tried it, and he had been struck with the results as being different from those commonly reported. The evidence was rather in favour of its safety. If, therefore, it could be easily employed, it would be well to use it; and he had shown that it could. The pulse really improved under its use. He had seen the combined fluids used; they produced excitement. No peculiar unpleasantness was left behind by ether.

OBITUARY.

WILLIAM DANIEL MOORE, M.D. DUB., M.R.I.A.

IT was with very sincere and deep regret that we, last week, briefly announced the death of this eminent and learned writer and Physician—one of the most persistent and untiring workers of the day. Born in 1813, he followed in the footsteps of his grandfather and father, and so early as 1826 entered on the study of the Medical Profession as the articulated pupil of his grandfather, and afterwards of Dr. Charles Johnson. In 1828 he entered Trinity College, Dublin; but in the year following his University course was interrupted, and not resumed till 1840. He graduated in Arts and in Medicine in 1843, but in 1833 he had passed the examinations of the Apothecaries' Hall of Dublin, and in 1834 became a Licentiate of the Royal College of Surgeons, Edinburgh. In 1835, when only two-and-twenty, he sent to the Chemical Section of the British Association (which met that year in Dublin) a short communication "On a Peculiar Corrosion of Leaden Pipes from Galvanic Action, developed by the Contact of Organic Matter"; and in 1836 he published in the tenth volume of the *Dublin Journal of Medical Science* an interesting paper embodying a "Statistical View of the Principal Medicines prescribed in Dublin during the last sixty years." In 1847 he contributed to the *Dublin Quarterly Journal of Medical Science* a most able and learned "Outline of the History of Pharmacy in Ireland." While collecting materials for this article he "discovered, after much and difficult search, in the possession of the last Master of the then extinguished Corporation of Barber-Surgeons, the records, charters, silver seal, keys, etc., of the Corporation, bearing various dates between 1535 and 1827"; and these interesting historical relics were afterwards, through the kindness of Mr. Farrell, the son of the Master, secured by Dr. Moore for the library of Trinity College, Dublin. In 1849 the same journal contained the results of a series of experiments made by Dr. Moore to settle the dispute as to the coagulability of human milk by heat and acids, the conclusion he arrived at being, "that the casein of human milk forms with most acids two sorts of compounds, one of them soluble in water, the other insoluble, the latter being formed only where the quantity of acid is large in proportion to the casein," and hence the discrepancy of the reports of previous experimenters. In the following year he became a regular contributor to the *Dublin Quarterly*, and for many years not a single number of the journal appeared without some article from his laborious and unwearying pen—his translations and reviews "extending to books in the French,

Italian, Spanish, German, Swedish, Danish, Dutch, English, and Latin languages."

But while possessing sufficient command of this remarkable and formidable list of foreign languages to make them all contribute food for home consumption, he devoted special attention to the Scandinavian and Dutch tongues, and was the chief—almost the only—interpreter between the British Medical world and the Medical writers of Scandinavia and Holland. He thus reviewed for the *Dublin Quarterly Journal* and for the *British and Foreign Medico-Chirurgical Review*—Professor Santesson's work "On Diseases of the Hip-joint;" "The Surgical Instruments of Pompeii and Herculaneum;" "The Endemic Diseases of Sweden;" "Midwifery in England, France, and Germany;" "The Metamorphosis of Tissue;" "Lehrmann on Absorption;" "Schroeder Van der Kolk on Cancer Cells;" "Clemens on Ozone;" "The State of Medical Science in Denmark;" "The Lunatic Asylums of Holland;" and a vast number of other works, his reviews being more analytical than critical, so as to place the opinions of the author well before his readers. He translated for the New Sydenham Society Professor Donders' great work "On the Anomalies of Accommodation and Refraction of the Eye," and Professor Schroeder Van der Kolk's essays on the "Spinal Cord," the "Medulla Oblongata," and "On Atrophy of the Brain"; and he contributed to our own pages, and those of other English and Irish journals, translations of a great number of valuable papers—such as Professor A. Retzius's "Anatomical Observations," Professor Santesson's "Cases in Surgical Practice," Dr. Withusen's paper on "Cachexia Exophthalmica," "Rasmussen on Scleroderma," Fenger's essay "On the Masked Forms of Bright's Disease," Brünniche "On Emboli," and "Donders on the Constituents of Food, and their Relations to Muscular Work and Animal Heat." A list of his original contributions to Medical journals also would occupy a much larger space than we can afford; but we have said enough to show the remarkable and incessant diligence with which he laboured, and the high value of his work is too well known to need mention here. His devotion to science told but too soon and too sadly on his health and strength, and early in 1867 he began to suffer from symptoms of progressive muscular atrophy. For two years the progress of the disease was, happily, slow, but in the latter half of 1869 it took on a more rapid course, and before long he was unable even to stand. For the last seventeen months of his life he was entirely confined to the sofa and his bed, but even during that period he still worked on, and was all through his long illness, as throughout the rest of his life, a noble example of a hardworking, cheerful, learned Christian gentleman.

The value of Dr. Moore's labours was recognised at home and abroad. He was Hon. Fellow of the Swedish Society of Physicians, of the Norwegian Medical Society, and of the Royal Medical Society of Copenhagen. In 1860 he was appointed joint Examiner in Arts in the Apothecaries' Hall of Dublin, and in 1865 the Senate of the Queen's University in Ireland elected him to the office of Examiner in Materia Medica and Medical Jurisprudence in the University. He was a Member of the Royal Irish Academy, a M.D. of the University of Dublin, and M.D. *ad eundem* of the Universities of Oxford and Cambridge.

THE LATE DR. EVANSON.

WE have received the following additional particulars respecting the late Dr. Evanson:—On the Thursday on which he died he had been slightly indisposed in the morning, and determined to remain in bed a few hours longer than usual; but about mid-day it was discovered that he had passed away tranquilly during sleep. Some five-and-twenty years ago Dr. Evanson was one of the most promising of the large circle of rising men who then gave to the Medical School of Dublin a European reputation. Forced to seek health in a different climate, he occupied himself in travelling for several years, during which many English persons of the highest distinction obtained the benefit of his skill in the Continental cities where he occasionally sojourned. Dr. Evanson's conjoint work with Dr. Maunsell on the "Diseases of Children" went through various editions and translations. As a poet his writings show that he was possessed of great kindness of feeling and deep thought, added to a very large scientific and general knowledge. Several of Dr. Evanson's old Irish friends had a last opportunity of seeing him at the meeting of the British Medical Association, held at Plymouth, two or three months since.

LANGSTON PARKER, M.R.C.S.,

DIED at his residence, Paradise-street, Birmingham, on Friday week, in his 66th year. His illness, although it had extended over several months, did not disqualify him for the exercise of his Profession, in the duties of which he was engaged so recently as the day before his death, and its termination was, therefore, somewhat sudden. He was the son of a Medical Practitioner in Birmingham, where, after completing his education at St. Bartholomew's Hospital and at the Hospitals in Paris, he commenced practice in 1830. Besides taking an active part in the affairs of the Philosophical Institution, to the members of which he delivered a very able course of lectures on "Dreams," he co-operated zealously with Mr. Sands Cox in the establishment of the Queen's College and Hospital. In the former institution he filled the chair of Anatomy for a quarter of a century, and was Honorary Surgeon to the latter for an equally long period, at the termination of which he was appointed Consulting Surgeon. Among his published writings may be mentioned a work on "Comparative Anatomy," another on "Diseases of the Stomach," and one on "Cancer." His best known work was on "Syphilitic Diseases." In private life Mr. Parker was of a most genial and kindly disposition; and, being a well-known and highly esteemed member of the Profession, his loss will be greatly deplored by a numerous circle of friends and others.

FRANCIS F. SEARLE, M.R.C.S.,

DIED at Exeter on Monday week, at the age of 32. He survived his wife only a few weeks. He was a Fellow of the Geographical Society, and was formerly in the service of the Peruvian Government. In 1865 he took charge of an expedition sent to explore the Upper Amazon, which he penetrated farther than any other European had done before. His conviction was that the new country visited by him offered a healthier climate than any other tropical country, and greater advantages to European immigrants. Last year Mr. Searle read a paper before the Exeter Naturalists' Club, describing incidents of his voyages, the appearance of the places he visited, and the manners and customs of the people. Whilst in South America, Mr. Searle suffered greatly from an attack of fever, and did not recover his strength after his return to England; but his premature and somewhat sudden death was not anticipated.

LEGAL INTELLIGENCE.

TESTAMENTARY CAPACITY—A MEDICAL MAN TAKING INSTRUCTIONS FOR A WILL.

THE case of *Winstone v. Owen* was decided at the Court of Probate, on November 4, before Lord Penzance. The will of the testator, Thomas Winstone, late of Bayswater, was propounded by the defendant as executor and universal legatee. The will bore date September 5, 1870. The testator was not on friendly terms with his relatives, and there was no question as to his intention to leave his property to Mr. Owen, who was an old and very intimate friend; but he deferred making his will until he was on his death-bed, and the question was whether he was, at the time he executed it, sufficiently conscious to be able to understand what he was doing.

The principal witness in favour of the will was Dr. Baker, his Medical attendant, who took his instructions shortly before the will was prepared, at the time when the testator was perfectly conscious. The solicitor who prepared the will from the written instructions of Dr. Baker, was of opinion that he was quite unconscious at the time when his hand was guided to make the signature. Dr. Baker, however, was of a contrary opinion, although the testator was then unable to speak, and the Doctor and the solicitor attested the will. The testator never rallied after signing the will, and died the same evening.

The nurse was examined in favour of the will; and the landlady of the lodging, and several other witnesses, were examined against it.

Lord Penzance said that this was one of those cases which required to be carefully watched, and there was a great difference between instructing to make a will in a person's favour and actually making such an one. In this case there was an entire absence of any evidence from which the Court could come to the conclusion that the testator was of testamentary capacity at the time when the will was signed. In the opinion of some of the witnesses he was conscious; but the law required, not only that he should be conscious, but that he

should have a sound and disposing mind. That party propounding the will was bound to establish that he had a sound and disposing mind; and having failed to do so, the Court must pronounce against the will. But it was a peculiar feature in the case, that the defendant, in whose favour the will was made, took no part whatever in preparing it or procuring its execution. He was a stranger both to the Medical man and the solicitor, and he took no step whatever to obtain the will. Under these circumstances it was just that the defendant should not be condemned in costs.

NEW INVENTIONS.

MR. GARDNER BROWN'S SELF-ACTING DISINFECTOR.

THE Self-acting Disinfector is a reservoir containing a disinfectant, and communicating with the water-pipe in some part of its course from the cistern to the closet-pan. Whenever water passes down this pipe, it draws over and becomes commingled with a certain portion of the disinfectant. The measuring, effected by a regulator within the apparatus, prevents anyone drawing off more than his due share of the fluid.

The "Disinfector" is easily fixed by a plumber at a small cost, or by the "ready method," which only requires a slight knowledge of the use of a gimlet and screwdriver.

Condy's fluid or carbolic acid used with this apparatus are "safe, efficient, extremely economical," and placed entirely beyond the control of anyone using the closet.

The capacity of the "Disinfector" varies from a quart to two gallons, and one charge of a disinfectant will last from a fortnight to several months, according to the frequency with which the closet is used and the capacity of the apparatus. Chloralum, chlorinated lime, and Burnett's fluid must not be used at present with these "Disinfectors"; but experiments are now being made to meet the difficulties arising from their energetic action on metal, without using fragile substances like glass.

A, The patent self-acting "Disinfector" (3 in. by 12 in.); B, supply-pipe to water-closet; C, funnel for charging; E, union with outlet-pipe to supply-pipe.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, held on Monday, November 6, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President in the chair, Sir John Conroy, Bart., Dr. J. Hall Davis, Ralph Henry Christopher Nevile, Esq., and Henry Rigg, Esq., were elected Members of the Royal Institution.

MEETING OF THE FRENCH MEDICAL ASSOCIATION.—The first general meeting of this body since the recent disasters, took place last week, and was numerous attended, although some of the local societies affiliated to it have seceded, either on account of the derangement which they have been subjected to during late events, or because they have been disappointed in the expectations that they entertained when they joined the Association, that it would be enabled to protect them from the rivalry of illegal practitioners. It was determined that in future the President should be elected by universal suffrage, and also that the three local societies of the annexed departments (whose representatives at the meeting were received with enthusiasm) should still continue to form part of the Association. Indeed, one of their presidents was chosen to supply a vacancy in the Council of the Association.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examination in Anatomy and Physiology at a meeting of the Court of Examiners on the 8th inst., and when eligible will be admitted to the Pass Examination:—

Alliott, Alexander J., student of St. Thomas's Hospital.
 Banham, Henry French, B.A. Cantab., of St. Thomas's Hospital.
 Bennett, H. Selve, of St. Thomas's Hospital.
 Bevan, Adolphus, of Guy's Hospital.
 Brady, John C., of the Charing-cross Hospital.
 Collinson, A. Cockburn, of St. Mary's Hospital.
 Elliott, C. Bolton, of Guy's Hospital.
 Harbinson, Alexander, of the Belfast School.
 Harvey, Charles W., of University College.
 Haslam, Thomas H., of St. Thomas's Hospital.
 Hutchinson, Charles F., of the Edinburgh School.
 Hyatt, James Taylor, of the Westminster School.
 Ivens, A. Somers, of St. Bartholomew's Hospital.
 Lloyd, C. Ayliffe, of St. Bartholomew's Hospital.
 Magill, James, M.D. Queen's Univ. Ireland, of the Cork School.
 May, W. Allan, of Guy's Hospital.
 Owen, Charles W., of St. Thomas's Hospital.
 Ramsay, Ebenezer J., of University College.
 Ross, W. Graham, of the Montreal School.
 Sawdon, Frederick J., of the Edinburgh School.
 Sloane, Ebenezer E., of the Belfast School.
 Spencer, Lawrence W., of King's College.
 Piers, Charles E., of the Dublin School.

Ten candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their anatomical and physiological studies for three months. The pass examinations for the diploma of Member commence this day (Friday), and, owing to the large number of candidates, will be continued throughout the ensuing week. The following were the questions on anatomy and physiology submitted to the candidates on the above occasion, viz.:—"1. Describe the anatomy of the colon, including its minute structure. State its position in reference to the exterior of the abdomen; and mention the internal parts and structures with which it is in close relation. 2. State how the first act of breathing is induced in the new-born infant, and explain the physiological effects of respiration. 3. Describe the dissection required to expose the internal maxillary artery; then give its course, relations, and branches in the order in which they arise, and their distribution. 4. Give the position, attachments, and function of the ciliary muscle. Describe its microscopic structure. 5. Describe the os hyoides, and mention the muscles and ligaments connected with it, and state the nerves by which the former are respectively supplied. 6. Enumerate the various excretions. Give the principal constituents of each, their mean amount in the healthy adult subject in twenty-four hours, and the sources whence each of these constituents is derived."

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, November 2, 1871:—

Bethell, Alfred, Pelton, Shepton Mallet.
 Davies, Arthur Evelyn, Penner House, near Newbridge.
 Lang, John Messiter, Thatcham, Berks.
 Thompson, Henry, Hull.

The following gentlemen also on the same day passed their first Professional examination:—

Emms, Alfred Wilson, Guy's Hospital.
 Kenyon, George Simpson, Liverpool School of Medicine.
 Townend, Joseph Henry, Guy's Hospital.

At the recent examination for the Prizes in Materia Medica and Pharmaceutical Chemistry the successful candidates were—

First.—Thomas Johnston English, of St. George's Hospital (Gold Medal).
 Second.—Sydney Howard Vines, of Guy's Hospital (Silver Medal and Book).

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALDERSON, FREDERICK HENRY, M.R.C.S. Eng., L.S.A. Lond., L.M.—Medical Officer and Public Vaccinator for No. 5 District of the Fulham Union.

COOPER, GEORGE JOSEPH, M.R.C.S. and L.S.A.—Resident Medical Officer of Poplar Hospital (for Accidents), 303, East India-road.

HODGES, FRANK H., M.R.C.S., L.S.A., and L.R.C.P. Edin.—House-Surgeon to the York County Hospital, *vice* Oswald Baker, L.R.C.S., L.R.C.P. Edin., resigned.

HOWSE, H. GREENWAY, M.S. Lond., F.R.C.S. Eng., Assistant-Surgeon and Lecturer on Anatomy to Guy's Hospital—Surgeon to the Evelina Hospital for Sick Children, *vice* Alfred Willett, F.R.C.S. Eng., resigned.

MILLIGAN, JOHN, M.R.C.S.E., L.S.A.—Medical Officer to the Keighley Local Board of Health.

NEAL, B., L.R.C.P., L.F.P. & S., L.M.—Assistant Medical Officer to the Cornwall Lunatic Asylum, *vice* B. G. Derry, L.R.C.P. Lond., M.R.C.S. Eng., appointed Medical Officer for District No. 3 of the Bodmin Union.

BIRTHS.

GARMAN.—On November 4, at 1, Clarendon-terrace, Bow-road, Middlesex, the wife of Cornelius E. Garmau, Surgeon, of a daughter.

HARLING.—On October 30, at 16, Seymour-street, Portman-square, the wife of R. D. Harling, M.D., of a son.

HARRIS.—On October 31, at Marles-hill House, Godstone, the wife of Arthur G. R. Harris, L.R.C.P.L., M.R.C.S.E., of a daughter.

MARRIAGES.

ALLFREY—HOLT.—On November 7, at St. Mary's, Stoke Newington, George Allfrey, eldest son of the late George Allfrey, Esq., of Stamford-hill, to Catherine Emily, second daughter of Joseph Rose Holt, M.D., M.R.C.S., Uckington, Gloucestershire.

HEATH—LEWIS.—On October 17, at St. Mark's, North Audley-street, R. E. Heath, M.D., 88th Connaught Rangers, to Catherine Maria, only child of the late Edward Lewis, Esq., of Battlesfield.

HOOD—FLOWER.—On November 2, at St. Matthew's Church, Croydon, Donald William Charles Hood, Esq., of Caius College, Cambridge, eldest son of the late Sir William Charles Hood, M.D., to Alice, third daughter of John Wickham Flower, Esq., of Park-hill, Croydon.

LUKE—PEARCE.—Walter Rochford Luke, Esq., of 65, Bramah-road, London, to Ann Elizabeth, eldest daughter of the late Francis Drake Pearce, Surgeon, of Kingsbridge.

OTTERBOURG—COHEN.—On November 6, at the Synagogue, Northampton-street, Dover, Solomon Otterbourg, M.D., Chevalier of the Legion of Honour, Commander of the Order of Francis Joseph, etc., of 10, Rue Lafayette, Chaussée d'Antin, Paris, to Theresa, daughter of the late Rev. R. J. Cohen, of Sussex House, Dover.

DEATHS.

BARROW, HERBERT WILLIAM, youngest son of the late John Barrow, Surgeon, Newton-le-Willows, Lancashire, at the residence of his brother, at Golborne, on October 30, aged 28.

BUTLER, WILLIAM, M.R.C.S.E., at the residence of his father, Sheffield Court, on November 1, aged 23.

HAWKINS, JOHN, M.D., formerly of Langharne, Carmarthenshire, at Woodstock, on November 3, in his 88th year.

REES, MARY ANNE, eldest daughter of the late David Rees, Staff Surgeon, Antigua, and formerly Surgeon 81st Regiment, at Dawlish-road, Teignmouth, Devon, on October 29.

RUSSELL, ELEANOR, eldest daughter of the late Dr. Rutherford Russell, at 94, Earl's-court-road, Kensington, on November 3, aged 25.

WALLER, LUCY, third surviving daughter of the late Thomas Waller, Surgeon, of Luton, Bedfordshire, at Devonshire-place, Brighton, on November 3.

WILLIAMS, CALEB, M.D., at Micklegate, York, on November 5, aged 73.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

COUNTY OF WICKLOW INFIRMARY.—Apothecary. Must be duly qualified. Applications and testimonials to Mr. H. Rooke, Secretary, on or before November 13.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Assistant-Physician. Must be M.R.C.P.L., or pledged to become so within twelve months. Applications and testimonials to the Secretary, on or before November 11.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Clinical Assistant. Gentlemen applying for this appointment must possess at least one qualification. Applications and testimonials to the Secretary, on or before November 11.

KENT AND CANTERBURY HOSPITAL.—House-Surgeon. Gentlemen applying for this appointment are required to possess qualifications in Medicine and Surgery. Applications and testimonials to Mr. T. Southee, Secretary, on or before November 24. The duties commence on January 1, 1872.

LINDSEY, LINCOLNSHIRE.—Medical Officer for the County Gaol and House of Correction. Candidates for this appointment must be duly qualified and registered. Applications and testimonials to the Deputy Clerk of the Peace, Lindsey, on or before November 18. The duties will commence about the end of March, 1872.

LIVERPOOL INFIRMARY FOR CHILDREN.—House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to the Chairman of the Committee, on November 11.

MIDDLESEX HOSPITAL MEDICAL COLLEGE.—Lectureship on Materia Medica. Applications to the Dean, on or before November 11.

ROYAL FREE HOSPITAL, GRAY'S-INN-ROAD.—Junior House-Surgeon. Must be M.R.C.S. Applications and testimonials to the Secretary, on or before the 16th inst.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. The following qualifications are required:—Member of one of the Colleges of Surgeons of the United Kingdom, also L.S.A.; or possess a Licence to practise Medicine. Applications and testimonials to Dr. J. C. Hall, on or before November 15.

SOUTH STAFFORDSHIRE GENERAL HOSPITAL, WOLVERHAMPTON.—Physician's Assistant. Candidates must be graduates in Medicine of a British University. Applications and testimonials to the Chairman of the Medical Committee, on or before November 27.

SUSSEX COUNTY HOSPITAL, BRIGHTON.—Surgeon. Must be M.R.C.S.E. Edin. or Dub. The office of Assistant-Surgeon is also vacant; the qualifications required are the same as for the appointment of Surgeon. Applications and testimonials to Mr. A. Vesey, on or before December 6.

TEIGNMOUTH, DAWLISH, AND NEWTON DISPENSARY AND INFIRMARY.—House-Surgeon. Must be duly qualified and registered. Applications and testimonials to the Chairman of the Committee, on or before November 16.

VICTORIA HOSPITAL FOR SICK CHILDREN, GOUGH HOUSE, QUEEN'S-ROAD WEST, CHELSEA.—House-Surgeon. Must possess at least one qualification to practise. Applications and testimonials to Mr. St. John H. Young, on or before November 27.

WESTHAMPTON UNION.—Medical Officer for the Rumboldswyke District. Candidates must have both Medical and Surgical qualifications. Applications and testimonials to Mr. R. G. Raper, West-street, Chichester, on or before November 19.

UNION AND PAROCHIAL MEDICAL SERVICE.

*• The area of each district is stated in acres. The population is computed according to the census of 1871.

RESIGNATIONS.

Acminster Union.—The Colyton District is vacant; area 9378; population 2939; salary £64 18s. 10d. per annum. The Shute District is vacant; area 2450; population 609; salary £18 4s. per annum.

Bishop Stortford Union.—Mr. A. K. Packman has resigned the Braughing District; area 4300; population 1180; salary £35 per annum.

Chorlton Union.—Mr. Henry Webster, Assistant Medical Officer at the Workhouse, has resigned; salary £125 per annum.

St. Marylebone Parish.—Mr. Alfred Elkins has resigned the St. Mary's District; salary £100 per annum; no fees.

Portsea Island Union.—Dr. Way has resigned the Landport District; area 1000; population 15,800; salary £70 per annum.

APPOINTMENTS.

Ellesmere Union.—Richard S. Perkins, M.R.C.S., L.S.A., to the Overton District.

Glendale Union.—James Lambie, M.B. Glasg. Univ., L.F.P. and S. Glasg., to the Lowick District.

Thorne Union.—Alexander Cameron, M.D. and M.C. Univ. Glasg., to the Epworth District.

Walsall Union.—John Burton, L.R.C.P. Edin., L.R.C.S. Edin., to the Workhouse.

MR. ELKINS has resigned the office of Medical Officer of St. Mary's District, Marylebone.

WE regret to hear that Dr. Dalrymple, M.P., has been suffering since his arrival in the United States from intermittent fever.

DR. BARCLAY reports the health of the parish of Chelsea to be in a very satisfactory state.

THERE were 637 deaths in Paris last week.

IN the neighbourhood of Calcutta, in the Hooghly district, fever is raging with unusual virulence.

A MOVEMENT is on foot in Birmingham to purchase the house of Dr. Priestley, at Fairhill, and preserve it as a memorial to the "Father of pneumatic chemistry."

THE extension of the Queen's Hospital, Birmingham, is to be commenced about the latter end of this month, by the erection of an out-patient department, which will include accommodation for the resident Medical staff and nurses, and also the dead-house, post-mortem rooms, etc.

A CONFERENCE of the Governors and Medical officers of Hospitals and Dispensaries is to be called by the Charity Organisation Society, to consider the expediency of converting free Dispensaries into provident institutions.

THE Professors of the Medical College of San Carlos, in Madrid, have mostly resigned, in consequence of the steps which the Ministers have taken to suppress them, as they represent sinecures. A demonstration in favour of one of the Professors was made by 150 students.

A FAREWELL banquet, and a diamond ring and a gold snuff-box, were given to Dr. Robinson, L.R.C.S.I., by the inhabitants of Chenes, Victoria, on his departure for Europe, as a mark of the esteem and affectionate respect in which he is held by the people among whom he has practised for the past fourteen years.

THE Totnes Board of Guardians very properly resolved, a few days ago, to prosecute a lady who caused her servant, who was suffering from small-pox, to be driven to the workhouse porch and there left. The girl had caught the disease from her mistress's son.

THE *Torquay Directory* informs us that a Medical Officer is required for that town. He is to attend all meetings of the local board, make reports on all sanitary matters, be a competent analyst, and is to receive a salary of £50 a year! Mr. Wilkinson, an active member of the local board, denounced the salary as "totally inconsistent" with the duties, and succeeded in getting the subject referred back to the committee.

PHTHISIS AND DEATHS IN THE MELBOURNE HOSPITAL.—During the four weeks ending on August 11 last, thirty deaths (exclusive of those of natives) took place in the Melbourne Hospital. Seven, or 23 per cent., of the deaths were occasioned by consumption. The persons who died of phthisis had respectively resided 9, 9, 6, 1, 14, 12, and 13 years in the colony, or an average of nine years each.

THE ROYAL ACADEMY.—Professor Partridge, F.R.S., commenced his annual course of lectures on Anatomy, in the new theatre, at Burlington House, on Monday last, and will continue them every Monday evening at eight o'clock until the 11th proximo, inclusive.

CITY OF LONDON TRUSS SOCIETY, 35, FINSBURY-SQUARE.—The number of patients relieved during the month of October was 686, to whom 688 instruments were supplied.

MORTALITY OF EUROPEAN TROOPS.—The total number of European troops in India who died or were invalided during the nine years 1861-69 was 34,916; the average number employed during the same period was 67,363—so that rather more than half died or were invalided.

ON Tuesday, the 14th inst., "The Erratics" will give a dramatic performance in St. George's Hall, Langham-place, W., for the benefit of the Great Northern Hospital. *Won at Last*, followed by *Charles the Second*, will be played.

NERVOUS FEVER IN SWITZERLAND.—From the time that the French Army of the East passed through Neuchâtel, nervous fever has been raging in the village of Travers, where, out of seventy or eighty persons attacked with this epidemic, seventeen have died. It is believed that this temporary insalubrity is entirely attributable to the passage of the numerous French soldiers, who have left in this village, more than elsewhere, the germ of the "typhus of armies"—a malady which follows in the wake of troops, especially during the cold and damp season, and when the houses and other places insufficiently ventilated have been crowded with soldiers and horses.

ICE IN ACUTE RHEUMATISM.—Professor Esmarch, in a communication to the Berlin Medical Society, related instances of the great benefit which he had derived from the continuous application of ice to joints affected with acute rheumatism. The general temperature becomes lowered, the pain abated, and the course of the disease abbreviated to an extent procurable by no other means. So far from fearing the induction of cerebral affection by repelling the articular inflammation—the *phrenopathia rheumatica* being here, as in typhus, dependent upon the increased temperature—ice is especially indicated for its prevention or removal.—*Berlin Woch.*, No. 35.

BIRMINGHAM MIDLAND MEDICAL SOCIETY'S CONVERSAZIONE.—LECTURE BY DR. LIONEL BEALE.—On the evening of November 8 a *conversazione*, attended by a large number of the members of the Midland Medical Society, was held in the Assembly-room at the Royal Hotel, Birmingham. Surgical instruments were shown by Messrs. Salt and Son, and microscopes and specimens were lent by Mr. Parsons, Mr. Wells, Dr. Russell, Dr. Sawyer, Dr. Underhill, and others. At eight o'clock Mr. West, President, took the chair, and called upon Dr. Lionel Beale, F.R.S., to deliver a lecture upon "The Nature and Origin of Contagious Disease Germs." Dr. Beale said: It would be agreed, by most observers, that some material passed in all cases of contagion from the diseased to the healthy organism. Experiments had demonstrated that, though it might remain suspended in the air, it could not strictly be called volatile, though it might be described as impalpable. It can be separated by filtering the air through cotton-wool, and must, therefore, consist of actual particles of matter. Contagion germs once introduced into the human system, multiplied themselves, and there was no chemical substance of which this could be said. Actual contact was not necessary for the spread of a contagious disease, for the contagion would hang in clothes; but the carrying of an actual particle was still necessary to contagion, and he did not think that any of these germs would retain their poisonous properties for a twelve-month. The quantity necessary for infection was extremely small, and an object no larger than a fly's foot might carry enough contagious matter to infect many persons. The almost impalpable nature of these fine particles had led many people to the erroneous belief that they could not be measured, weighed, nor in any way made appreciable by sense. So small were they that a single fragment of hair, or a starch globule, would afford space for thousands of them, any one of which would be infectious. They might exist in an atmosphere without the dust, and dust without the germs. Offensive odours, again, were not in all cases necessarily associated with contagion, and there were evil smells in which the germs of disease existed in no greater quantity than in an atmosphere free from odour. The fact appeared to be that all infection arose from diseased living organism, and no matter which was not derived from living sources could grow and multiply as these germs did, converting as they did whatever other living organism with which they came in contact to their own nature. Contagious diseases were

not due to the presence of bacteria or vibrios in the blood. The existence of these was not the cause, but the concomitant or consequence, of the changes induced in the course of the disease. The germs of these bacteria existed in healthy subjects in almost incalculable numbers, and when the tissues of the frame were damaged, these microzymes—as they were also called—developed. When the contagious material was perfectly fresh, there were no microzymes in it; but if it were left exposed to the air for a time, it became filled. Hence, in the case of vaccine lymph, it would be seen that it was quite an error to suppose that the microzymes gave it its power of infection; for exactly in proportion as the effect of the lymph decayed, the microzymes increased in number. For any particle to have infectious property it must have life. In the pus taken from an ordinary abscess there were movements which the lecturer had known to continue for so long a time as four-and-twenty hours, and which could only belong to life. Pus was derived from the normal living matter of the tissue of the body, and, living much faster than any healthy part, it generated, as only living matter could, other matter of its own nature. It had been contended by some that pus corpuscles were the white corpuscles of the blood, but the fallacy of this was readily shown by the fact that there were not enough white blood-corpuscles in the whole system to create the pus corpuscles which would appear in one abscess in a single day. In case of fevers and inflammations the same changes were observed in the germinal matter of the tissues and blood. The fever might be considered a general inflammation, and the inflammation regarded as a local fever. All contagious diseases, then, were the result of the growth of degraded living matter, and the history of infectious disease seemed to point to the rise of various new types.

THE anti-opium pills we make are composed of extract of hyoscyamus and gentian, camphor, quinine, Cayenne pepper, ginger, cinnamon, with Castile soap and syrup to form the mass, and liquorice-powder to form the coating. We have had abundant testimony to their efficacy in overcoming the habit, or "yin," and preventing the evil consequences which too often follow on giving up opium without medicine, or by means of purely native prescriptions. Many are deterred from giving it up on account of the inefficiency of the native nostrums, the danger of producing other and worse diseases, and the fact, only too patent, that it is as difficult to get weaned from the medicine as from the drug itself. This is owing to the fact that all native remedies contain opium in some form, most frequently ashes of opium already smoked. As many as 5000 are sold monthly at the rate of ten pills, to satisfy a yin of one mace, at a cost of about four candareens.—*Report of the Peking Hospital, by Dr. John Dudgeon.*

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

Dr. L. J. Martin.—Your letter containing enclosure has come safely to hand.

Paris.—A translation of Dr. Fort's letter shall appear next week.

A Colonial Hospital Surgeon.—At a recent discussion on the advantages of being Honorary Surgeon to the Kyneton Hospital, Melbourne, Dr. Rigby said—"There is neither honour nor profit connected with the office. Do you think, if I was sending a report of a case to one of the Medical journals, I would sign myself Honorary Surgeon to the Kyneton Hospital?"

Worcester.—We have perused the report of the meeting of the Worcester Board of Guardians on Thursday week, contained in the *Worcestershire Chronicle*. We think that the guardians were not justified in passing a vote of censure on Dr. Woodward. Certainly, there was no proof of negligence, even according to the showing of the only witness brought against him. Votes of the kind referred to are not only unjust, but injurious to the best interests of the poor.

STRYCHNINE AND MORPHINE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—When experimenting upon animals with morphine and strychnine, the one appeared to neutralise the action of the other. I therefore instituted a series of experiments, and found that, given together, strychnine and morphine neutralise each other's action; also, that the one is a perfect antidote for the other, as the three following experiments, selected from a large number, will prove:—

A brown horse was given, subcutaneously, morphine gr. viij., strychnine gr. j.; and the only effect produced was a very slight dilatation of the pupils. Again, the same horse was given, subcutaneously, at 3.10 p.m., strychnine gr. js., and at four o'clock the whole of his muscles were quite rigid; at 4.5 morphine gr. x. was given; at 4.10 the rigidity of muscles was subsiding; and at 4.30 the horse had quite recovered, with the exception of a slight restlessness, and increased flow of saliva from the effect of the morphine.

A black pointer dog was given, subcutaneously, at 4.50 p.m., morphine gr. ss.; at 6.50 he was sleeping soundly; the saliva was running from his mouth, and when roused he was unable to use hind legs, and quickly subsided into a sound sleep. He then had given strychnine gr. $\frac{1}{32}$. At seven o'clock the flow of saliva had ceased; at 7.5 the sleepiness had gone, and the dog was able to walk; at 7.30 he had quite recovered.

Now, as the action of morphine has precisely the same effect on the dog as it has upon man, it is fair to infer that the like result would be the case in poisoning with opium in man.

I am, &c.,
FREDK. JOS. MAON, M.R.C.V.S.

CORRIGENDUM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you kindly, in your next issue, correct two errors which appear in your pages to-day. First, our entry of students is much larger this year than last, our total being nearly 100. Second, "Queen's College" is the name of our school, not "School of Medicine," or "Royal School of Medicine." I am, &c.,
FURNEAUX JORDAN.

22, Colmore-row, Birmingham, November 5.

LAST SUNDAY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Stained glass windows have recently been added to our handsome church, the vocal cords of the organ renovated, new anthems rehearsed, and a ladylike lovely young curate (an Honourable), who shaves his head and wears the best of clothes, will shortly arrive. Quite oblivious of the handsome hunting men sprinkled about, pretty girls in winter bonnets and seal-skin jackets bend demurely over ivory prayer-books, and old ladies, prone to respirators and gold-headed smelling-bottles, severely worship. Here and there are sables of woe; but those griefs burn most which gail in secret, and too often the widower whose loss appeared irreparable finds out another mate within the twelve months.

The Liturgy never palls. Reverentially—poor miserable sinners—we pray for true repentance, that "we shall be forgiven all our sins, negligences, and ignorances, and be endued with the grace of God's holy spirit to amend our wretched lives according to His holy word." During the sermon attention flags. Whinyates is not one of those enterprising clergymen who thunder out the newest discourses procured regardless of expense; his *forte* lies in hard, earnest parochial work, not in oratorical display.

The red-hot Medical student in the next pew wonders what complaints David and Job suffered from—if Calabar bean, condurango-root, skin-grafting, and the sulpho-carbolates had each fair trial; whether Luke was fully qualified, or with unexceptionable references *sine* diploma.

We brood over the smashed carriage—£12 10s. 6d. (with respectful compliments) to repair the result of a collision when rushing to a ease of croup in Lypiatt-terrace—Rebecca dead lame, Sir Roger Tichborne gone in the wind. Sadly we think of Ned, his mother's favourite, who promised so well at the Proprietary College, only to turn out a cruel thorn; and about Ada, our headstrong daughter, engaged to a scrofulous dandy with Dunderbush whiskers, who, always loitering about the promenade or Montpellier-gardens, is wonderful at billiards, but too proud for business.

In the chancel sits a lady in deep and bitter sorrow; possibly, if we had been more skilful, she would not be here a widow in rusty mourning, her daughters, accustomed to every luxury, going out as governesses. Though not in mortals to command success, it is our duty to leave no stone unturned in the pursuit of practical knowledge. "Neither shall the wave which has passed over ever be recalled, nor can the hour which has once fled by ever return again." Trying to the utmost, we may benefit ourselves as well as others. It is a glorious triumph from the jaws of death to restore the father to his family. Thus earning our bread, it is a fine thing honestly to gain money, name, and position, and to feel that those we love best will be provided for, and not turned out of the old home to meet poverty, and privation, and the world's cold shoulder when we are gone. No Profession is more taken advantage of and defrauded than ours, often by people of wealth and status, who forget the rent of houses, the cost of carriages and horses, and the expense of living in London.

Physicians and Surgeons gain European reputation, but die before reaping well-earned harvests, and leave but little money behind. Every Medical man—no matter how small his present income—ought to insure his life. None know better than ourselves the precarious tenure of that life: the frail quality of the sword-suspending hair, how readily the silver cord is loosened, and how easily the golden bowl is broken. A sudden silence in the church—Whinyates has closed his book; and I conclude a prosy sermon on the propriety of
MEDICAL INSURANCE.

SULPHUR IN PLEURO-PNEUMONIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Twelve months ago I mentioned to you that I was watching with deep interest a sudden outbreak of pleuro-pneumonia which had made its appearance in a small lot of cattle which I myself was feeding with the view of testing an experiment. They were ten in number, and for about seven weeks all went well with them. The locality of their stable was unfortunately seven miles from Kirkcaldy, so that their superintendence was committed virtually to the fidelity of a servant, who was charged to fumigate the byre at least twice a day, and to be careful to report anything being amiss. Instead of this, however, I found two of the animals sick when I visited them incidentally, as also that the fumigation had been interrupted, because his supply of sulphur had run short. As to the nature of the disease there speedily appeared abundant proof, and the premises were "proclaimed," and placed under the control of the official veterinary. The fumigation was renewed and kept up night and day during the remainder of the time whilst the epidemic lingered; but from its spread to one animal after another—numbering seven in all—I thought it essential that some auxiliary should be had recourse to, and accordingly I commenced the internal administration of sulphurous acid in large doses—viz., 2 ozs. every second hour in a quart of gruel—and I think that my after-experience warrants my having used to you the word "unparalleled." Out of the seven cases, two proved fatal; one of these, however, died before the "bottle" was put into use, and the other was labouring under effusion into the pleura before the treatment was begun. The effect of the remedy upon the others was very striking; for although all were in their turn certified officially as "affected," they began to improve within a few hours after getting the medicine. Three of the ten still remain to be accounted for, and they escaped infection, notwithstanding that I shifted them into the diseased stalls, and several times saw them licking the noses of those that ultimately died. I may mention that the blood-meal upon which these cattle were throughout fed seemed to come in most appropriately to suit

ORIGINAL LECTURES.

CLINICAL
LECTURES ON OPHTHALMOLOGY,

DELIVERED AT

St. Thomas's Hospital,

By R. LIEBREICH,

Ophthalmic Surgeon and Lecturer to the Hospital.

LECTURE IV.

ATROPHY OF THE OPTIC DISC.

GENTLEMEN,—We have studied the fundus of the eye in its normal aspect, and shall now proceed to examine its pathological conditions, and begin with the atrophy of the optic disc.

I would not have done so were I to deliver a systematic course of ophthalmology; but here we have to accommodate the course of our studies to the cases as they present themselves. You must not be astonished to see a comparatively large number of cases of amaurosis; you would find just the same in every other newly opened Hospital or Dispensary. Hopeless cases, having already been treated in various other places without benefit, are always the first to flock to a new establishment, and to try a new method and a new Surgeon.

Such cases, though of little therapeutic interest, are nevertheless very important for diagnostic studies, not only from an ophthalmological, but also from a general Medical point of view.

To draw diagnostic conclusions from ophthalmological aspects, it is not sufficient to state mere atrophy, but to distinguish between the different forms of atrophy. In fact, the atrophy of the optic disc may be the consequence of a variety of affections of the retina, of the optic nerve, of the brain, of the spinal cord; and I need scarcely mention how important it is to recognise the nature and the course of the disease which gave rise to the atrophy of the papilla.

To obtain a general survey of the different forms of atrophy, let us look at the cases depicted in my "Atlas." We find there (Plate IV., Fig. 2) a most complete atrophy of the papilla after syphilitic retino-choroiditis. It is, no doubt, a very exceptional case, on account of the nearly complete disappearance of the vessels of the retina, Plate VI., Fig. 1, "Atrophy in a case of retinitis pigmentosa."—Plate VII., Fig. 5, shows the atrophy following an embolism of the central artery of the retina. The comparison between this figure and Fig. 4, which gives the state of the same eye immediately after the formation of the embolism, demonstrates the changes in the colour of the papilla and in the vessels of the retina. The papilla has acquired a white colour, the arteries have become extremely thin—in some places empty, in others filled with the darker coagulated blood. There is some similarity with the cases just described in Fig. 1. of the same plate, where the partial atrophy of the optic disc with its empty vessels is due to very extensive hæmorrhage in the retina.—Plate IX., Figs. 3, 4, 5, 6, 10, and 12, give instances of the different appearances of partial or complete atrophy of the optic disc after different affections—viz., of the retina (Fig. 3), of the sheath of the optic nerve (Fig. 4), of the spinal cord (Fig. 6), of the glaucoma (Fig. 10), after neuritis optici (Fig. 12).

These drawings appear so different that you can scarcely designate the general characters of the atrophy otherwise than vaguely as a diminution of redness in the colour of the papilla, with a smaller diameter of the vessels. You may perhaps be astonished not to hear me speak of a diminished diameter of the papilla itself. This supposed symptom is, indeed, indicated in many handbooks on ophthalmology, but I have very often taken quite exact measures of the diameter of the optic disc in the living eye as well as in anatomical preparations, and never could state any diminution in cases even of the most absolute atrophy of the optic nerve. There is, in fact, a loss of substance produced by the disappearance of the nerve-fibres. The mechanical changes caused by this loss are to be found in a plane which passes through the axis of the optic nerve, and you will easily observe this circumstance by the flat, atrophic excavation seen either with the ophthalmoscope or under the microscope in a longitudinal section of the nerve. The plane perpendicular to the axis of the optic nerve, which, with an ophthalmoscope, we distinguish as the optic disc, remains in form and size unchanged even after a complete atrophy of the nerve-fibres. If the border of the papilla—that is, the hole within the choroid (choroid limit) and the

edge formed by the transition of the sclerotic and the nerve-sheath (sclerotic limit)—remains in the same place after the disappearance of the nervous substance surrounded by these limits, it is, *à priori*, necessary to suppose that some new substance vicariously fills up the empty space. This is, indeed, the case, and it is the nature of this new substance which determines chiefly the difference in the aspect of the papilla. In all cases in which the atrophy of the nerve-fibres is produced without any preceding disturbances in the retina or in the papilla, it is the vitreous body which fills up the excavation. This body, being much more transparent than the nervous substance of the papilla, allows us to distinguish, with much more clearness than in the normal eye, the white network of the lamina cribrosa, which now appears not only in the centre, but throughout the whole extent of the optic disc. For the same reason, the sclerotic limit and the border of the choroid appear too sharply delineated. If, on the contrary, the atrophy of the optic disc is preceded by an inflammatory process of the retina and the papilla, or the latter alone, the disappearing nerve-fibres are replaced by substance of new formation. This substance is more opaque than the nerve-fibres, and consequently covers the lamina cribrosa, which disappears more or less completely, whilst the contours of the papilla, also more or less covered, appear weaker, undecided, and irregular. These conditions will furnish you with the most important points on which you will have to rely for your diagnosis, especially if you also consider the state of the bloodvessels.

To obtain these observations it is necessary to examine the direct image. For that purpose you must be placed close to the eye of the patient, adapting behind the mirror concave glasses of such a power as is required by the shortsightedness of the eye of the patient, or of that of your own.

In order to be able to examine the direct image without artificial dilatation of the pupil, it is necessary to use a mirror with a sufficiently small and carefully worked hole in the centre. If the hole is nearly as large as the pupil of the patient, it is impossible to throw light enough into his eye. If the margin is irregular, containing little scratches, or if it forms a channel instead of a sharp ring, the reflex of light proceeding from this border puzzles the observer by producing entoptic phenomena in his own eye.

A very small part of the mirror only throws light into the pupil—namely, that which immediately surrounds the hole. It is therefore quite useless to use very large mirrors, which are tiresome to the patient, without giving a stronger light to the part of the fundus under observation.

Since I gave these explanations, the diminution of the mirror and its central hole has often been made too great. If the mirror is too small, it cannot well be put against the supra-orbital margin, and insufficiently protects the observer against the flame. Too small a hole has two great inconveniences; at first it diminishes the intensity of the light, allowing only too small a pencil of light to pass from the observed to the observer; secondly, it acts as a stenopaic apparatus, and deprives us of our judgment on the refraction of the patient by suppressing the circles of dispersion.

I therefore propose to make the hole not smaller than two millimetres, and the mirror not smaller than three centimetres, and to use in preference a thin silvered glass mirror, the centre of which is not perforated, but only deprived of the silver covering. The focus of the mirror may be of eight or ten inches.

THE
DISCUSSION ON PURULENT INFECTION

AT THE
PARIS ACADEMY OF MEDICINE.

By Professor VERNEUIL.

(Concluded from page 583.)

You will find it quite natural, Gentlemen, that after this recital of experimental researches, the exactitude of which you cannot deny, I again turn to the definition of the so-called pyohæmia; but reassure yourselves—I shall be brief, and only replace the long list of denominations given to that disease by the one of *septicæmie embolique*.

Shaken, perhaps, but still hesitating, my adversaries will doubtless seek a last refuge. The experiments, they will say, seem convincing, but experiments have more than once led Practitioners astray; and, more than that, we must not conclude from animals to man. Generally speaking, I care but little for that kind of argument. To show, however, that

my theory does not fear controversy upon any ground, I shall turn to that of human practice. But, first of all, I hasten to say that I recognise several notable differences between the pyohæmia of the laboratory and that observed at the bedside. The first sets in suddenly; the two phases of the disease are confounded into one. The infection of the blood and the profound intravascular inoculation are simultaneous, or, at least, contemporaneous. The proper symptoms of each of them work and arise parallelly, and take a conjoint part in the fatal issue. Things go on quite differently in man. The pyohæmia scarcely ever begins the same day as the wound, but only after one, two, or three weeks, and sometimes even later still. This tardy apparition is easily explained; a few days, at least, are indispensable to develop in the wound or in the neighbouring tissues—firstly, the necessary conditions for the formation, and secondly, the migration of the toxic emboli; but from the moment that this migration begins, man is in every respect alike to the animal under experiment.

Second Difference.—The pyohæmia of the laboratory begins at a precise and well-known moment. It surprises the animal in full health, and has neither antecedents, prodromes, nor predisposing causes. The pyohæmia in man surely begins at a given time—the very moment that the first embolus stops in the capillary network. But there is no symptom which announces this beginning. We only know that, in case a man in perfect health is wounded, a certain lapse of time always occurs between the date of the injury and the invasion of the disease. But, if the wounded man is already febricitant, if the pyohæmia declares itself in a patient suffering from a more or less chronic spontaneous affection, it is very difficult to know the exact hour of its commencement. Let us take the most simple example: A wounded person is seized with pyohæmia towards the third week. What has taken place during the fortnight between the accident and the invasion of the disease? An attentive observation of the symptoms and the curves of the thermometer shows that the organism has been invaded by some serious general trouble—by an inevitable attack of fever. I do not believe that we can prove the existence of pyohæmia showing itself suddenly in a wounded person, otherwise perfectly well, and without fever. If the fact exists, I avow, at least, never to have met with it. We may then ask, What is that serious general trouble—what is the nature of this fever? It might be said that one and the other form the prodromic phases of pyohæmia. Infectious diseases, it is true, are not generally characterised from the first day; a certain *cortège* of equivocal symptoms precedes the apparition of the pathognomonic phenomena. But, in order to apply this reasoning to pyohæmia, we should have to forget that the established infectious diseases, in spite of the uncertainties of the first few days, have none the less a perfectly regulated evolution, and a chronologically determined progress. The incubation presents but very slight oscillations.

Pyohæmia, for a specific disease, we must own, would have strange ways to be able to remain latent for from five to six days to two and three months. All difficulties vanish, on the contrary, if we consider it as a complication. And, moreover, when the general symptoms set in a few hours after the wound, and cause death before the end of the second day, before supuration has even commenced or emboli had time to form themselves—as is sometimes observed after the crushing of a limb or after wounds from large projectiles, when, at the post-mortem examination, visceral abscesses are wanting—must we then attribute death to the prodromes of pyohæmia alone? Are we here, again, to make use of an hypothesis formerly so much abused, and accept a pyohæmia without emboli, infarctus, or visceral abscesses, just as was once admitted a variola without variola, an erysipelas without erysipelas, etc.? To attribute the precursory fever and the general trouble to ordinary septicæmia, seems to me more simple, more logical, and especially more in conformity with the truth. This disease, which, as already shown, is solely governed by the variable production, absorption, and elimination of the sepsine, presents no regular type, and suffers every possible anomaly as to apparition and duration. Thus it may, without violating its laws of existence, last indifferently twenty-four hours or a year.

According to the present state of science we can perfectly well diagnosticate a traumatic fever, but we are unable to say if this fever will terminate in pyohæmia or not—which means to say, that this latter disease has no universal precursory phenomena. I go further than that, and affirm that the differential diagnosis between grave septicæmia and commencing pyohæmia is frequently impossible, because the characteristic phenomena of this latter disease are developed in the inaccessible depths of the organism; that the incertitude of the

diagnosis may sometimes continue during the entire duration of the disease, and, in a large number of cases, only cease to exist in the autopsy-room.

I do not find, therefore, that Billroth is wrong in saying—“It is as difficult to determine the exact moment when the patient is taken with pyohæmia as it is troublesome to indicate the transition from the primitive traumatic fever to septicæmia;” and I should like to ask my colleagues to show me, *at the bedside*, by what sure sign they can know the invasion of pyohæmia, and how in certain cases it is possible even to affirm its existence before death. All our serious previsions are limited to this. Pyohæmia being always preceded by septicæmia, the first will be the more to be feared, as the second has been more favoured by the nature of the wound, the constitution of the patient, and by the composition of the surroundings.

Third Difference.—In the experiments *in anima vili*, the introduction of the sepsine and the embolus is brought about by a very simple mechanism—violence. There is, consequently, no necessity for taxing our minds in trying to discover the mysterious route followed by the generating agents of this pyohæmia. In man, on the contrary, we must inquire into the manner in which the sepsine is introduced—into the origin, and, finally, the means of transport of the emboli.

The septic poison insinuates itself through the closed or open lymphatics, or through the arterial and venous capillaries of small calibre; it doubtless sometimes traverses their parietes when intact, but will surely find itself arrested by the clots which fill the cavities of those vessels. These same clots which stop up the gaping orifices of the open vessels, would, according to theory, form an obstacle to the introduction of the poison; but it is now well known that these clots are permeable to putrid liquids, which traverse or pervade them without difficulty, and afterwards reach the fluid blood bathing their central extremity.

As to the embolus, it varies in its nature, and is of various origin. At a time when the development of pyohæmia was always attributed to pus, the greatest efforts were made to bring the pus of the wound, or that arising from the phlebitis of the open veins, into the blood. All theories were able to explain certain cases, but failed with many, until at last Virchow's researches on the blood-clots and the so-called phlebitis destroyed the whole; and we now know that the pus is not the indispensable element of the septic embolus. The puriform substance arising from the *ramollissement* of the thrombus—and even the fragments of the latter—the leucocytes which abound in the permeable vessels around the inflamed tissues, and the very droplets of fat—all can become matter for toxic emboli, provided these diverse solid particles have imbibed the septic liquid of the morbid focus.

As to the migration of the emboli, it finds its agents in the blood itself, in various mechanical actions—the contraction of muscles and other numerous causes—which I need not discuss at this moment. I shall finish, therefore, believing I have sufficiently proved that, though incontestable differences exist between experimental researches and clinical facts, these differences do not prevent us from recognising, in the pyohæmia of the laboratory and that following Surgical accidents, one and the same process; and which, furthermore, permits us to apply to the latter the precise and clear conclusions furnished by the study of the former. We should leave off, then, I think, for ever, the provoking opposition which Surgeons have too often made to experimenters and pure Practitioners—to the book-learned theorists or *chercheurs*. But be this as it may, anatomy, physiology, vivisection, and other so-called accessory means, remain, and will ever remain, the least uncertain guides to the Physician.

One thing, Gentlemen, surprises me greatly. I cannot imagine why Surgeons have not followed the broad road opened to them by Obstetricians, and for what theoretical or practical purpose they have arbitrarily divided the uninterrupted and indivisible series of traumatic fevers.

Puerperal fever has been perfectly well described many years ago; the greatest differences have been observed in the symptoms, progress, termination, and even in the post-mortem lesions, from one lying-in woman to another, from one ward to another, from one Hospital to another, from one city to another, and from one season to another. Death has been known to take place suddenly or tardily, the putrid infection rapidly or slowly, the classical purulent infection, the absence of post-mortem lesions, and the extreme variability of these isolated or associated lesions—metritis, peritonitis, lymphangitis, phlebitis, putrilaginous state of the uterus, diffuse purulent infiltration into the subperitoneal cellular tissue—all, and more than these, have been observed.

Well, notwithstanding these dissemblances, and in spite of the obstinate efforts of the separatists, the serious Practitioners have never consented to the parcelling of puerperal fever: they have always, to use rather an antiquated expression, recognised the *unity in the variety*.

What obstetricians have done for the accidents of puerperal fever should be repeated by Surgeons for pyohæmia, and they should show that in spite of these various origins of the disease the causes, evolution, and nature are the same. We all know that pyohæmia is most often consecutive to wounds or Surgical operations which expose an open focus; but it is equally certain that it also complicates and causes a fatal termination in a number of non-traumatic diseases, as well as after slight wounds already cicatrised for some length of time. I shall enumerate a few of them:—Furuncle, anthrax, malignant pustule, spontaneous erysipelas without a wound, typhoid fever, variola, cow-pox, perhaps scarlatina, pneumonia, ulcerous endocarditis, arthritis, osteo-myelitis, acute diaphysal and epiphysal osteo-periostitis without incision of the focus, spontaneous varicose phlebitis or that provoked by the simple pricking with the Pravaz syringe, ligature of tumours, and especially hæmorrhoids, subcutaneous fractures, abscess of the prostate gland, profound urethral scarifications, simple catheterism of the urethra or œsophagus, lithotripsy, etc.

I am ready to justify this list by bringing observations to support it, and show that its members, however dissimilar they may appear, enter into the theory without difficulty; for in nearly all of them the preparatory septicæmia, the formation and the migration of various emboli, have been perfectly demonstrated. Thus we find again, and in our own turn, the unity in the variety. These developments, for which I hold myself at the disposal of the Academy, would also throw some light upon a truth as yet imperfectly known—namely, that there exist no truly traumatic diseases, accidents, and complications, but only diseases, accidents, or complications which either appear from spontaneous genesis or follow a traumatism, and belong to both the two great sections of pathology—Medical and Surgical.

At the time when exclusive theories had their sway, it was successively held that there could be no pyohæmia without previous suppuration; afterwards, that there was no pyohæmia without an open wound; and, finally, that there was no pyohæmia without phlebitis. The present formula—may it be the last!—is this: No pyohæmia without sepsine and emboli.

ORIGINAL COMMUNICATIONS.

PHTHISIS AS A NEUROSIS. (a)

By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.L.S.,
Physician to the Leeds General Infirmary, etc.

If I say that for many years past my own thoughts have been busily occupied with those phenomena of several orders which of late have been mixed together under the indefinite name of phthisis, I shall probably be showing only that I am engaged as all my brethren are. If the terrible scourge of phthisis be rife in Leeds, where are the few favoured places which can boast of their freedom? and if my own colleagues are, like myself, incessantly on the watch against this fatal disease, or class of diseases, where is the Doctor whose days are not saddened by its pitiless inroads, and by the abiding sense of his own helplessness? The teaching of Laennec and his followers, which in my student days had as unquestioned a hold upon the schools as an article of orthodox theology at a clerical seminary, had never a firm hold upon my own mind; and ten years ago I wrote in the *British and Foreign Medico-Chirurgical Review* to urge the inflammatory and non-tubercular nature of the disease now known as caseous pneumonia, and to prove that the cheesy masses in this disease were not specific, but of the nature of cold or dry abscesses. These essays have now lost their value, as my opinions have been overshadowed by the rapid advance of similar ones, more thoroughly reasoned out and elaborated, by Niemeyer, Waldenburg, Villemin, Burdon-Sanderson, Williams, and others. I cannot doubt, for my own part, that in many cases of phthisis we have no such thing as tubercle in the strict sense of the term. As a blow upon the knee in one person passes off without farther heed, while in another the lack of rapid repair allows of the initiation

of a white swelling—as a scratched pimple, again, within the nose of a vigorous person a scratched pimple is to him and nothing more, while in another it becomes the starting-point of a spreading ulceration, which in months gains ground so far that alæ, septum, and soft palate are threatened, and ere long fall away, destroyed by what is too often called lupus, and therefore left to ravage undelayed—so in the like habit a catarrh may, and unquestionably often does, extend from the lining membrane of the larger bronchial tubes to the smaller, from the smaller to the alveoli, and there develops into caseous broncho-pneumonia, a disease very commonly fatal, without one grain of tubercle in its composition; or, upon this, tubercle may be superinduced by secondary infection; or, finally, we may have the phthisis of miliary tubercle, taking its rise either in some forgotten cheesy gland, or tending to arise in some constitutions, as it would seem, without any previous pyoid infection. All this, and much more, is now so familiar to the Profession, that I feel it would be unfair to the editor of this journal and to his readers were I, in accordance with a promise which he gave me long ago, to publish some lectures embodying these views at large. One species of phthisis there is, however, which I describe in my lectures which is not uncommon, which is quite unexplained by the theories already named, but which has not, I think, been clearly distinguished by any author. The cases have been seen, no doubt, and described often enough, but I think no one has detected their peculiarity as a class, nor has offered any explanation of the mode of their initiation. Under the head of “Phthisis as a Neurosis,” I propose, therefore, in the present short essay, to publish that portion only of my intended series of lectures which deals with the classification of this variety of phthisis, and which endeavours to make out its relation to other disorders. Let me begin by reminding the reader that there is a class of phthisical cases which in the explanations of Niemeyer are entirely omitted, as, on the one hand, they are—in the outset, at least—non-tubercular, and on the other hand, they are no extension of catarrh. For example, a young lady has had, let us say, some disappointment in love, or has suffered from some other such external cause of depression. She droops and becomes languid; other changes also are seen in the digestive system and elsewhere; her friends are “anxious about her;” and her Medical adviser examines her chest repeatedly, but without detecting any mischief. Then, however, she begins to complain of cold of afternoons, perhaps has even a slight shivering fit on one or two days, and when she is next seen by a Doctor her temperature is 102°, and consolidation of the upper lobe of one lung is found, or both are involved. There is, perhaps, little or no cough at the time, but this gradually sets in, and the case thenceforth pursues the usual course of consumption, often in a severe form. On a post-mortem examination there may not be a vestige of tubercle, or tubercle may be found abundantly; but that tubercle is not essentially concerned in these cases is evident from the fact that such patients, if taken in time, may entirely recover, and very often do recover, the consolidation slowly melting away without breaking up the organ. Now, a case of this kind, which is too common to need longer description at present, if in all probability it is not tubercular at the outset, on the other hand it certainly is no result of creeping catarrh. Having thus indicated the kind of disease I have under consideration, let me go on to make out its characteristics more clearly. Let me endeavour to ascertain with what other diseases and morbid tendencies this kind of phthisis is associated, and thus, finally, we may be enabled to hazard some guess at its essential nature or immediate causation. In my ideal case I have assumed some depressing passion to have disposed a young lady to this phthisis; but whether such an additional cause be required or not, depends much upon the constitution of the person liable. If the innate tendency to this phthisis be strong, it will come on either in man or woman without any such antecedent depression from without. It is generally seen in young adult life, and not so often like other forms of phthisis seen also in boys and girls on the one hand, and in the middle-aged on the other. Nevertheless, I have two cases of the kind in my note-book, in which the invasion occurred so late in life as 38 and 43 years respectively. The period of the later “teens” is, however, the most dangerous, and the years onward from 20 to 30 in decreasing degree. One of the earliest symptoms, and one seldom wanting, is anæmia. For months or even years a young girl or young man will lose colour, and this waning will increase to actual pallor. Beyond the anæmia there will be little else to lay hold of, save that in the girl amenorrhœa will probably be present also in some degree. For this anæmia all kinds of

(a) The materials for the present essay are taken from the Course of Lectures on Practice of Medicine at the Leeds School.

treatment will be put in force; the patient will show a little bundle of prescriptions from various Medical men, which all contain steel in some form or other, and, if circumstances permit, the chalybeate springs of England or Germany will also have been sought, and not perhaps without some decided, though too often temporary, advantage. During all this time the patient will declare that there is nothing the matter, and the anxious mother will reluctantly admit that she cannot pronounce definitely upon any symptom except a certain degree of transient languor, debility, or petulance, especially in hot weather. In a while, however, the appetite begins to fail somewhat, and the tongue takes on a red, irritable appearance, coated sometimes, also, in the middle, with a light white fur. This is a sign of the coming mischief—of the onset of fever, of consolidation in the upper lobe of one or both lungs, and the rather sudden declaration of marked phthisis with local mischief. This form of phthisis is, so far as my small experience as a traveller goes, not uncommon in hot countries, and even in England the hotter weather seems decidedly injurious to the sufferer. If the mischief goes on, menorrhagia and hæmoptysis are often present, the latter symptom being especially frequent; while amenorrhœa may replace the former, even in the earlier stages, and always subsequently. The temperatures present a continued fever, with rather sharp remissions between 100° and 103°. With great care in nursing, *morale*, climate, and Medical treatment, these cases may, and often do, recover; but, on the whole, the prognosis is unfavourable—it lies between catarrhal pneumonia and true tubercle, being less dangerous than the latter, but more dangerous than the former. I think I need not pursue this part of my subject, as the kind of consumption intended is familiar enough; let us next inquire in what sort of persons such attacks take place. I think they will be found in persons closely allied to, if not actually contained in, the class which I have called “neurotic.” (b) They would probably be described by their friends as being of a “nervous temperament”—as being vivacious, or even irritable; energetic also, but often in a fitful kind of way—and they are very commonly frank, high-spirited young men, and charming lively girls in society. They often have that kind of good looks which Sir William Jenner attributes to the “tuberculous diathesis” in its narrow sense—in the sense of silky-haired, thin-skinned, slimly built, mobile persons; and I think that they are persons in whom tubercle itself is not unlikely to arise, and that they resemble these more than they resemble the heavier and more sluggish victims of “scrofulous” or broncho-pneumonic phthisis. But of this more hereafter.

If we turn to the diseases found in their relatives, we find a marked tendency to neurotic forms of disease—to chorea, stammering, epilepsy, asthma, bed-wetting, neuralgia, insanity, and the like—we find, also, a tendency to that irritability of the mucous membranes, and to those forms of skin affection which I have ventured to associate with the neurotic phases of disease. (c) Among the diseases more closely allied to the lung disease, I may refer once more to true tubercle, and also to a liability to the more ordinary acute pneumonia of the apices with great constitutional depression, which is no doubt an occurrence of the same kind as my special form of phthisis. If the pneumonia runs an acute course, as it sometimes does with implications of both lungs, we have the phthisis itself in a galloping form. About a year ago I attended a refined lady belonging to a highly neurotic family, and whose children presented the like characters; she had been a nervous, irritable, neuralgic woman all her life, but never actually ill in any serious way. She was worn down by nursing one who was very dear to her, and whose death, which followed, shocked and prostrated her still more. She took to her bed with consolidation of the apex of the right lung, then of the left; in both the mischief spread rapidly, hectic fever ran high, and in three weeks she was dead. Her age was about 43. On the autopsy, which was made in consequence of her death appearing to the family to be very sudden, we could not find a single tubercle in the body; but the apices of the lungs were almost destroyed, and lesser degrees of mischief were found below. I had seen another case a few years before, in which such a galloping consumption occurred after nervous depression in a highly neurotic subject. The son of nervous parents on both sides, the father being odd and eccentric, and the mother actually insane, he was himself one of those heady, impressionable, gay fellows who make our charming prodigals—and a very pretty prodigal he was. Ruined in purse and character, and terribly depressed, though I do not think in any great degree worn out by actual

vice, he arrived at home to meet with the reception such parents (or, at any rate, one of them) were likely to give him. A few days later he began to feel more and more exhausted, his pulse and temperature ran up, his right lung solidified and broke down, the left lung followed, and after five weeks of distressing illness he was dead. Here, again, I believe, there was no tubercle, but we neither sought nor obtained an autopsy. This case was the first which impressed me strongly with its probable neurotic origin. Take, on the other hand, a less painful case. A gentleman of highly nervous temperament—and a local preacher, I believe—at any rate, a man of high religious susceptibility, meets with losses in business. His brother, the only relative he knows anything much about, is a rambling, queer fellow, who has been twice in an asylum. My patient loses appetite and strength for a few days, feels shivery, and takes to bed with sudden consolidation of the upper third of the left lung. This consolidation took place in a night, but did not advance farther. The result was a happier one, for the patient recovered in a few weeks, after a period of crepitation, without a bad symptom remaining; but the case was one, I cannot doubt, of the same nature as the preceding, and differed only in severity. In no one of these cases was there any history whatever of “taking cold,” or of any undue exposure. Were I to enumerate the cases of phthisis belonging to the same category, I should soon fill many columns; but none of them is more remarkable, from the present point of view, than that which occurred in the family of a dear friend of my own. His father, a fine man and a ripe scholar, lived to a long old age. His wife died early of “consumption,” leaving four or five children, the heirs to a very large estate. The eldest brother became, and I think died, insane. The second, a man of highly nervous temperament, of refined æsthetic tastes, and much personal charm, died of the very kind of phthisis I have endeavoured to describe—a phthisis commencing in sudden consolidation, with some preceding anæmia and nervous dyspepsia, and without preceding catarrh or concomitant tubercle. The third son, my own friend, a fine scholar in a college of scholars, became epileptic in early life; he was likewise asthmatic. Two other children survive, whom I do not personally know.

Again, I have seen a tendency to this neurotic phthisis in the children of parents not especially neurotic themselves, who have, one or both, married late in life. The children of such parents always show a marked delicacy; they have thin, transparent skins, and they are passionate and difficult to rear on account of the caprice of their temper, stomach, and bowels. They decline food, or they vomit it by spasmodic regurgitations, or they shoot it from their bowels; and it is in the later life of such children that I have seen more than once a sudden consolidation of one or both apices usher in the final act of a frail existence. On the other hand, I have been astonished and pleased to see how successful judicious management, both of body and soul, has been in warding off such a catastrophe, and in fortifying the delicate frame, where not only love, but an equal degree of steadfast good sense also, have distinguished the parents. These qualities we are more likely to meet with in parents whose constitutional fault lies in their age rather than in their diathesis. Having, then, cases of phthisis presenting the exact features already described, and having also many cases of catarrhal broncho-pneumonic phthisis, and, more strictly, tubercular phthisis, presenting like characters intercurrently with others of their own, I felt that neither the catarrhal theory nor the tubercular theory would account for all instances. For some time I felt annoyed with these cases, and with the characters like them which cut in upon other cases, because they refused to allow me to rest in the neat hypothesis of (1) catarrhal phthisis, (2) catarrhal phthisis complicated with secondary tubercle, and (3) miliary tubercle. So they were to me for some years, until I began to find, in my own practice and in the writings of alienists, how large a part phthisis plays in neurotic families. Even then, however, it did not occur to me to associate any particular form of phthisis with neurotic disorders, until a few striking cases of my unclassable variety occurred in neurotic families under circumstances which spoke too eloquently to be overlooked. Since that time I have recognised that the kind of phthisis associated with other marked neuroses is in some measure true tubercle, (d) but is in a much greater measure that which I have described. To put it in other words, the members of neurotic families are liable to sudden inflammatory consolidations of the upper lobes of the lungs, not due to

(b) *Vide* Introductory Address, *Lancet*, October 14, 1871.

(c) *Vide Lancet*, *loc. cit.*

(d) I am satisfied that there is a strong tendency to miliary tuberculosis also in neurotic families, but I have not yet satisfied myself of the precise relation which this bears in them to the phthisis I am now describing.

catarrhs or to tubercles, but which present alarming consumptive tendencies; also, that phthisis occurring in persons not highly neurotic, but subjected to depressing causes, may take a like form; also, again, that pneumonias occurring in neurotic persons, or in persons anxious or depressed in mind, prefer the apices of the lungs, and tend to cross the indefinite line which professes to separate such pneumonias from acute or "galloping" consumption.

If we try to go a step farther, and ask for a pathological explanation of these facts, we approach a land of darkness. The more, however, I study the relations of the disease, the more I am satisfied that the lung mischief is also a neurosis: by which I mean that the lesion is one not originating in the local tissues, but originating in the nervous system, and probably in the nervous centres. The profound antecedent deterioration of the blood and the interference with menstruation point to some such origin also; for these anæmias obstinately decline to be cured by good food and iron, and yield but grudgingly to these allies when to them is added a liberal help of stimulants, both alcoholic and medicinal. By this addition—one in itself, however, peculiarly dangerous to neurotic temperaments—we can sometimes gain our point for a time; but the recovery is partial in too many cases, and the full mischief may appear in spite of our seeming success. I regard the apices of the lungs, therefore, as liable, in certain persons, to take on somewhat sudden consolidation under the influence of nervous causes; but whether the nervous influence be irritative or paralytic it is hard to say. To use Dr. Laycock's convenient word, it is a "trophesy," by which word he would signify a palsy of nutrition. If it be denied that nerve changes can set up such extensive nutritive mischiefs, I can only say that in the present state of our knowledge my opponent is scarcely in a safer position when he denies this possibility than am I when I assert it. On my side I have to point to the sudden invasion of disease without any apparent local cause, but always under circumstances which point forcibly to the nervous system, and in persons whose hereditary tendencies are neurotic; also to many analogies, as, for instance, the sudden erysipeloid attacks in such persons, and their liability to swollen face on the shortest notice.^(e) To this let me add that in highly organised beings their farther complexity is gained by subordinating all processes, both "animal" and nutritive, more and more to a co-ordinating central system, which centre acts as a great distributor and equaliser of tension—that is, among other things, of nutritive activity—throughout the body. Moreover, evidence is accumulating to show that this governance of nutrition is not exercised merely by the so-called "vaso-motor" nerves indirectly, but directly through some undetected spinal filaments, having central as well as peripheral connexions. Finally, those disorders and diseases which seem to arise as neuroses are very generally found to have, among other characters, that of suddenness and caprice in their occurrence. It would be difficult to quote a better example of this than the sudden and capricious coryzas to which neurotic persons are liable. These catarrhs are in them a phenomenon of the same order as their neuralgias, and they come and go with the same unaccountable activity. A neurotic person will awake in the morning, will begin soon afterwards to sneeze violently; in a few hours the conjunctivæ are injected, the eyes are filled with tears, the sinuses are tense, and the Schneiderian membrane is hot and full—a phenomenon of palsy no doubt due to some chance chill upon the terminal expansions of the fifth nerve, and showing itself in trophic rather than in sensory change. At other times the two sets of events, pain and inflammation, may occur together, and alone or together they vanish—perhaps in half a day—as suddenly as they came.^(f)

One word as to treatment; not only because all our work

(e) For an estimate of the importance I would give to hereditary history in elucidating all disease, see a paper on "Classification of Disease," in the second volume of St. George's Hospital Reports, 1867.

(f) There are few more curious instances of the way in which words, like logs, may barricade the gates of knowledge, than the impediment caused to true conceptions by the words "motor nerve," "sensory nerve," etc. The qualifying word "motor" fixes a belief that the nerve itself has some property of massive motion, and keeps out the true idea that nerves are mere equalisers of tension or propagators of its disturbance. What the result of disturbance so propagated may be, or what the result of interference with its equalisation, depends solely on the things to which the nerves are tied. Why, then, the recent bewilderment of some worthy physiologists, who are obliged to admit that "trophic nerves" are closely allied to motor nerves? Rightly looked at, every nerve is a trophic nerve—is the medium, that is, of molecular change, being extended from point to point. Whether this molecular change result in massive contraction of the attached tissue, or otherwise, is a matter of the quality of the tissue affected.

must be carried on with the definite object of relieving disease, but also because by the key of treatment I obtained some farther insight into the doctrine I have ventured to propose. About five years ago, in the old Leeds Infirmary, I drew up some careful tables upon which the course of phthisis was noted in a large number of cases. One of the incidental results of this tabulation was to disclose to me the great value of arsenic in some forms of the disease, and, as farther experience showed, in that kind of the disease which I have ventured to distinguish now as neurotic phthisis. The red irritable mucous membrane of these cases, so far from being a bar to the administration of the drug, was actually an indication for its use; and, allowance being made for the disappointment which inevitably follows the treatment of a large percentage of consumptive cases, I am able to speak very favourably of its effects. I think I had seen arsenic recommended in phthisis by a writer in one of the Medical journals, but the chief impulse to its use in my own practice was derived from its happy effects in the case of a lady who was herself phthisical, and who had borne four highly neurotic children—children in whom herpes, nocturnal enuresis, epilepsy, neuralgia (occurring in the first branch of the fifth of the right side, and only relieved by the local use of aconitine ointment) had occurred, and whose temperaments were all excitable. Here arsenic, empirically given, benefited in a striking manner; and from this experience as a commencement I was led to its use from that time (about half-a-dozen years ago) to the present. The more I have seen of the results of arsenical treatment, the more have I been led to confine its use to the cases of phthisis which in this essay I have called neurotic; and thus the more have I been led by an empirical result to the establishment of my general conception, that this peculiar form of phthisis is one phase in the changes of the neurotic cycle, and that it should be classified, therefore, with insanity (also of certain definite kinds, of which more hereafter, and requiring arsenic in its earlier stages at least, if not throughout), with epilepsy, with certain definite kinds of skin diseases,^(g) with peculiar irritative catarrhs and other fluxes, with asthma, with neuralgia, stammering, and with other neuroses too numerous now to repeat. All this bears out a belief which I have often published before, and which forces itself upon me more and more year by year, that arsenic is not a specific for skin diseases in any wider sense than this: namely, that it supplies something required in that large class of persons who present these various signs of one diathesis—the neurotic—and that of these it relieves not their skin diseases only, but their other neuroses also, including even their phthisis and their anæmia, against which iron itself is often powerless. In giving this sketch of the effects of arsenic, however, I must add in conclusion that, without the mental and moral treatment required in these patients, all drugs may fail. Above all things they must be made calm, and perhaps even happy, if success is to crown our efforts. It is the duty of the Physician to point this out clearly to the patient and to those about him, but in the lack of it too often his failure is involved. *Sic anceps varios rotat alea casus.*

Postscript.—When this manuscript was ready for the printer, and after the delivery of my Address in Medicine,^(h) in which I also allude to the neurotic diathesis, I received Dr. Anstie's work on Neuralgia, and heard his discourse on hereditary neuroses, at Wakefield, on October 17. The views therein expressed by Dr. Anstie have a very deep interest for me, in that they support so strongly the views which I have set forth. I have regarded the matter somewhat differently from Dr. Anstie, but I hope there is nothing in my observations which his own will contradict.

GOVERNMENT has granted £300 from the Royal Bounty to the children of Dr. Livingstone.

NATURAL SCIENCE SCHOLARSHIPS AT CAMBRIDGE.—Trinity College, Cambridge, offers one or more Foundation Scholarships, of the value of £80 a year, for proficiency in the Natural Sciences. The examination will commence on April 5, and be open to all undergraduates of Cambridge and Oxford and persons under 21 who are not members of the Universities. St. John's College, Cambridge, offers an Exhibition of the value of £50. The examination in Chemistry, Physics, and Physiology will commence on April 12, and be open to persons under 20, not members of the University, and to undergraduates in their first term. Further information may be obtained on application to the tutors of the respective colleges.

ON LIGATURE OF THE SUBCLAVIAN ARTERY.

By H. H. A. BEACH, M.D.

ASSISTANT-SURGEON F. P. STAPLES, Medical Staff, published in the *Medical Times and Gazette* for July 22, 1871, an article entitled "Observations on Ligature of the Subclavian Artery—A New Incision suggested," in which he advocated the employment of a method different from the one usually practised. He has performed it for some time, and brings it before the notice of Surgeons with the hope of overcoming the difficulties of tying that vessel in the third stage. He calls the posterior belly of the omo-hyoid muscle the true guide to the artery, and pronounces it far more reliable than the anterior scalenus muscle and tubercle of the first rib. The first steps of the operation are devoted to the display of the posterior belly of the omo-hyoid. This having been accomplished, it is directed that "the edges of the wound should now be retracted, and the superior retractor should carry with it the omo-hyoideus; and when this has been done, the white cords of the plexus, with the artery inferior and internal to them, will be observed to occupy the bottom of the wound." The details of the operation proposed by Surgeon Staples certainly convey the impression that it would not be difficult in its execution; that, as a rule, it could be performed with ease in any case requiring that treatment. The value of the operation as compared with others rests upon the theory that the posterior belly of the omo-hyoid muscle is the true guide to the artery. This is claimed by Surgeon Staples, and believed by him to be corroborated by his experience. Opposed to this are the well-known facts that the posterior belly of the omo-hyoid is occasionally wanting, and that anomalies of the muscle are not infrequent. "The muscle occasionally is attached to the clavicle instead of the scapula, arising from the former bone about its middle; and in such a case the posterior belly is absent." One instance has been recorded (R. Quain) in which the posterior belly alone was present, and was connected to the hyoid bone by a band of fascia. The muscle has likewise been observed double, one slip being attached to the clavicle, and the other to the normal place of origin on the scapula. (a)

"The omo-hyoid is in some instances immediately over the artery." (b)

"In a case operated on by Professor Todd, this muscle (omo-hyoid) lay below the clavicle, and it became necessary to draw it up and divide it before the artery could be exposed." (c)

In some remarks made by Sir William Fergusson after performing the operation, which were published in the *London Medical Times and Gazette* for February 25, 1871, he stated that "many attempts had been made in the ward to determine the precise position of the omo-hyoid muscle, but without success, and during the operation there was some little trouble in making out this point." He considers it a better guide than the scalenus, but said that he had performed the operation twice only.

In dissections of the neck, I have observed that the posterior belly of the omo-hyoid was wanting in two instances; and I once found an anomalous muscular slip—passing from a point on the scapula in front of the origin of the omo-hyoid, forward and upward, crossing the subclavian artery, vein, and brachial plexus—to be inserted by a small well-rounded tendon into a prominence of the clavicle, just behind the insertion of the subclavius muscle and outside of the scalenus anticus.

It is not difficult to imagine that the case requiring operation may be the occasional one, where the posterior belly of the omo-hyoid is wanting, or where some of the anomalies of that muscle are present; yet these contingencies are not provided for by Surgeon Staples. The results from the use of any method must depend upon the facilities which it offers for the finding of the guide to the vessel, and any innovation upon what has been proved to be reliable as such should, after careful consideration, be found to possess stronger claims than those presented by the method of Surgeon Staples. Without doubt, success has followed the performance of the new operation, but it offers chances for embarrassment to the Surgeon, and consequently increased risks to the patient, beyond the methods now in use.

With these chances before him, I doubt if a Surgeon is

justified in changing his practice from what is established as safe and sure to what promises little beyond uncertainty. Boston, U.S.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

GUY'S HOSPITAL.

THE following cases are of interest as forms of disease affecting the buccal cavity of children. The cases of ranula indicate that this kind of tumour of the mouth is often congenital, and may, in the first days of life, be of danger by preventing the infant suckling. They would seem to negative the general truth of the explanation frequently given of their origin as being due to dilatation of Wharton's duct; for it is difficult to conceive how so small a tube can expand into cysts of this size. They prove, too, that in the treatment of ranula it is not always necessary to excise a portion of the cyst-wall or to promote contraction by setons, but that recovery will follow from merely evacuating the contents of the cyst by means of a free incision.

CONGENITAL RANULA.

(Under the care of Mr. BRYANT.)

Mary B., aged 4 days, was brought to Mr. Bryant for a transparent swelling, the size of a large almond, beneath the tongue. It had existed from birth, and by its gradual increase had prevented the child suckling. It was clearly a ranula. It was opened freely; the ordinary mucoid fluid escaped. A good recovery followed.

Mr. Bryant had operated upon a brother of this child, aged 4 days, eighteen months previously, for the same form of congenital tumour, with the like result. The tumour was so large as entirely to prevent suckling.

Eliza K., aged 7 weeks, was brought to Mr. Bryant at this Hospital for a double ranula of a congenital nature, which prevented suckling. The cysts pressed the tongue upwards, and were above the level of the gums. They were both opened freely from end to end, and a good recovery followed.

William S., aged 3 months, came under notice with a congenital ranula on the left side of the tongue. Its increase had been gradual. It was opened freely, and a good recovery took place.

WARTY GROWTH ON TONGUE OF CHILD.

(Under the care of Mr. BRYANT.)

Alice B., aged 14, applied at Guy's Hospital with a warty growth on the posterior part of the tongue. It had been accidentally discovered three weeks previously on looking into the mouth for a sore-throat. The wart was about the size of a sixpence. Nitrate of silver was freely applied to its surface, and a good recovery followed in about one month.

SALIVARY CALCULUS IN DUCT OF SUBLINGUAL GLAND.

(Under the care of Mr. BRYANT.)

Eliza S., aged 22, came under treatment for a painful swelling situated beneath the tongue. It had been felt for many months, and was more painful and much increased in size after eating, the pain passing up the side of the jaws. It gradually subsided between meals. On examination, a small calculus was clearly to be felt occupying the orifice of the duct of the left sublingual salivary gland. With the nail it was readily picked out. In one week all symptoms had disappeared. The calculus was about the size of a hempseed.

INFIRMARY FOR EPILEPSY AND PARALYSIS.

ON NEURO-SYPHILITIC AFFECTIONS.

(Cases under the care of Dr. ALTHAUS.)

THE proportion of syphilitic to idiopathic affections of the nervous system, which have for the last five years been treated at this Infirmary under the care of Dr. Althaus, has shown a singular constancy, as it has in each twelvemonth been very nearly 5 per cent. of the total number of cases which have come under observation. On further analysing the nature of these affections, another curious fact was elicited—viz., that

(a) Quain's "Elements of Anatomy," seventh edition, p. 193. London, 1837.

(b) *Ibid.*, p. 366.

(c) Power's "Surgical Anatomy of the Arteries," p. 160.

the number of cases of syphilitic paralysis and palsy from non-specific disease bore a constant relation, as, out of 100 cases of paralytic affections of all kinds, in twenty a syphilitic origin could be clearly traced. Without attaching undue importance to these numbers, comprising as they do but a limited area of observation, Dr. Althaus thinks it well to put them on record, as showing a much more frequent occurrence of neuro-syphilis than is believed in by many Practitioners. On the other hand, syphilitic epilepsy appeared to be rare, unless all cases of neuro-syphilis in which convulsive attacks occurred were put down as epilepsy, which would obviously be wrong. Amongst paralytic affections, palsies of some of the cerebral nerves ranked first in frequency; then followed hemiplegia and paraplegia. Local palsies of spinal plexuses or nerves were of rare occurrence; but a more or less considerable impairment of the memory and intellect was present in no less than 60 per cent. of the cases treated at the institution.

The diagnosis of neuro-syphilis is not always easy, and requires an intimate knowledge of the peculiar clinical features and phases of the distemper. In many cases, of course, the connexion between cause and effect is so evident, that the patient himself makes a correct diagnosis before the Physician has time to do so. There has been a hard chancre, an indolent bubo, early affections of the skin and throat, and perhaps a painful node on the shin-bone; then the patient, who lives in constant dread of something more and worse to follow, finds some morning on awaking that one of his eyelids droops, or that he has sensations of pins and needles in the feet, and has lost the power of walking to a more or less considerable extent. This he at once attributes to the same dread cause which has given rise to all his previous sufferings, and the diagnosis is therefore "cut and dried" for the Doctor. But this is by no means the rule. Although it seems absurd, yet there are patients to be found who strongly deny having caught infection from an impure source, and ascribe all their ailments to overwork, anxiety, mental shock, etc.—circumstances which probably act occasionally as exciting causes, but are not at the real bottom of the malady. We must, therefore, when the symptoms are suspicious, never be satisfied with the denial of a primary syphilitic affection by the patient, but take such denial for what it is worth. Sometimes, in the further course of the treatment, a tardy confession is obtained. Again, in other cases, the primary affection has been so slight that it escaped notice at the time, or has been really forgotten; or an unsuspecting husband is infected by a faithless wife, or an illicit lover by his indiscriminating mistress, the vehicle of contagion being sometimes poisoned leucorrhoeal mucus, primary affections being and having been absent. In all such cases we have to trust entirely to the clinical features of the case as a guide to our diagnosis.

What, then, are the peculiar features of neuropathy from venereal disease in contradistinction to idiopathic nerve-disease? They are—

1st. *The great variety of symptoms* which are observed in neuro-syphilis, while in other non-specific nerve-disease the range of symptoms is more limited. In this particular, neuro-syphilis resembles hysteria, for we find all kinds of paralysis, spasm, hyperæsthesia, and anæsthesia occurring together, or succeeding each other rapidly. If this is observed in men, or in unimpressible women, it affords considerable suspicion of syphilis.

2nd. *The irregular or intermittent course* of neuro-syphilitic affections distinguishes them from their idiopathic namesakes. Thus, for instance, a non-syphilitic patient affected with aphasia only improves slowly or not at all under the best treatment; a syphilitic patient may have aphasia for half an hour, a day, or three days, and then completely recover his language. Cases of this kind of intermittent aphasia have been described by Dr. Hughlings-Jackson as epileptic aphasia; but Dr. Althaus has never seen them excepting in syphilitic subjects, and does not think them in any way connected with the true epileptic condition. Intermittent amblyopia and amaurosis also occur in neuro-syphilis, but we cannot claim these as epileptic affections any more than attacks of neuralgia or ague.

3rd. *Mental symptoms*, which in a large number of idiopathic nerve-diseases are absent, are very frequent in neuro-syphilis. The memory is more apt to suffer than the intellect, but the latter is also often impaired.

4th. *The general appearance* of neuro-syphilitic patients is mostly sallow and miserable, while patients with idiopathic neuropathy often look the very picture of health. In fact, a frequent complaint of the latter is, that their friends and relations do not believe in their complaints because they look so well. The peculiar fusty smell of syphilitic patients, which

was mentioned as characteristic by Dr. Gull, at a recent meeting of the Clinical Society, has several times been most strikingly present in Dr. Althaus' patients.

5th. *The results of treatment* are in the majority of cases quicker and apparently more satisfactory in neuro-syphilis than in non-specific nerve-disease; but relapses are more frequent in the former than in the latter.

We now proceed to give a few cases of neuro-syphilis which have been recently under observation at the Infirmary.

Case 1.—Intermittent Aphasia and Paralysis—Later on, Syphilitic Hemiplegia of the Right Side.

A carpenter, aged 42, admitted October 31, 1870; has had gonorrhœa several times, and had a hard chancre five years ago. There have been slight secondary symptoms off and on, affecting chiefly the fauces and the skin. Two years ago he suddenly lost his speech for about fifteen minutes; but, as he then completely regained it, nothing was thought about it at the time. Since then, however, he had again lost his speech on several occasions for an hour or two, but underwent no special treatment. In July last he began to have intermittent attacks of paralysis, which always affected the right side, but only lasted for a few hours at a time, after which he again felt quite well. After having had about a dozen such attacks, he at last, on August 30, had a real apoplectic seizure, accompanied with loss of speech and consciousness, and total paralysis of the right side. His consciousness returned in about three hours, his speech, to some extent, at the end of the first week. The distortion of the face lasted only a day or two, and the leg also began to improve after about a fortnight. The arm only improved to a slight extent during the first month, and has lately been quite stationary, so that he is thoroughly disabled from working.

Patient looks wretchedly out of health—in fact, thoroughly broken down. Tongue deviated to the left side and fissured. No affection of the cerebral nerves; but he complains of a constant aching pain at the back of the head, and frequent flushes of the face, which make him feel restless and miserable. Memory has been gradually getting worse; speech is thick and somewhat hesitating. The attention is apt to wander from one thing to another, and since the paralytic attack "he has said and done foolish things." Arm is to a great extent useless, through a semi-paralytic condition of the deltoid, serratus, trapezius, triceps, and extensor digitorum communis muscles. There is slight contraction of the biceps, and flexors of the hand and fingers, and a certain amount of pain at the insertion of the deltoid. Slight anæsthesia and coldness of the whole upper extremity. Thigh and leg are weak; slight contraction of hamstring muscles. Digestion tolerably good; bowels regular; no disorder of the chest or genito-urinary organs. A small and tender node is on the left shin-bone, and at the right hip there is a rather large cicatrix from a syphilitic ulcer, which healed about two years ago. Ordered potass. iodidi gr. v., ter. die.

November 7.—No change in the patient's condition. He takes the iodide well; this was, therefore, increased to ten grains thrice daily.

14th.—No change in the paralysis; no iodism. Fifteen grains ter. die.

21st.—Same report. Scruple doses of potassic iodide.

28th.—Slight epiphora and coryza; no improvement in paralysis; on the contrary, the contractions, both in the arm and leg, are increasing. Continue iodide.

December 5.—Contractions still increasing; iodism is getting troublesome. The iodide was therefore given up, and an indifferent mixture substituted for it; at the same time galvanisation of the cervical sympathetic and of the suffering nerves of the arm and leg was ordered three times a week.

12th.—First application of the constant current to the sympathetic removed the pain from the back of the head; arm and leg feel a little stronger; immediately after the application the paralysed side is warmer than the healthy one.

January 30, 1871.—Patient has had seventeen applications of the constant current. He is able to use arm and leg so well that he wishes to be discharged, as he feels able to return to his work. Has not attended since.

The foregoing is one out of a number of cases of syphilitic hemiplegia which show that *iodide of potassium* has no curative effects in syphilitic hemiplegia, and that, if the patients do not recover by the reparative process of nature, we must have recourse to the same agent, which is the only one of real use in idiopathic hemiplegia—viz., the constant galvanic current.

SATURDAY, NOVEMBER 18, 1871.

THE TRIAL OF KELLY FOR THE MURDER OF TALBOT.

On the evening of July 11 last, Thomas Talbot, who had been in the Irish constabulary, and had greatly distinguished himself in the suppression of Fenianism, was making his way home through the streets of Dublin. A man—Kelly—came up to him, and shot him in the open street. This man fled, but was never lost sight of until captured, which he was forthwith, after shooting a constable through the thigh with the revolver he had in his hand. Talbot walked, with some help, to the Richmond Surgical Hospital, where he came under the care of Dr. Stokes, junior, who first saw him about two or three o'clock on the morning of the 12th. It was then seen that a bullet had entered a little behind the mastoid process, and by probing it was found to have passed inwards towards the spine. Dr. Stokes imagined he could detect the bullet, and proceeded to enlarge the wound, so as to remove it, but failed to do so. At this time Talbot was perfectly conscious; his pulse was good, and his voice strong, but he was very pale. He had not been sick, but there had been some bleeding from the wound. He was put to bed, and next morning he was examined by Dr. Stokes, Professor Smith, Mr. Hamilton, Mr. Tufnell, Dr. M'Donnell, and Dr. Baxter. The wound was again probed, and it was resolved, *nemine dissentiente*, to try to remove the bullet. In the probing, Nélaton's porcelain probe was used, without any decided result. The wound was again enlarged; in doing so, two arteries were cut, one of considerable size; the latter was secured by a tenaculum and ligature, both of which were left in the wound. No bullet could be found, and the man was put to bed. Next day the only bad symptom was a tremulous tongue. On Friday he had severe rigors. On Saturday evening he was much excited. On Sunday morning, his brother, who was with him, noticed some bleeding from the wound: this was promptly stopped. Later in the morning he was raving; in the afternoon he required half a dozen people to keep him in bed. Finally, he became comatose, his pupils widely expanded, his breathing diaphragmatic, and he died the same evening. An inquest was held, and a post-mortem examination ordered. This was made by Dr. Stokes, who discovered some particles of lead embedded in the lambdoid suture. A portion of the atlas was broken to pieces, and some particles of lead were found in the neighbouring textures, which were in an inflamed condition, bathed in pus. The membranes of the spinal cord were also covered with pus.

Most unfortunately, the bullet itself was not traced. There were some indications (post-mortem), according to Mr. Tufnell, that it had lodged under the scapula.

If ever a case looked clear, this is surely one. The law of England is still as laid down by Hale—"If a man give another a stroke, which it may be is not in itself so mortal but that with good care he may be cured, yet, if he dies of the wound within a year and a day, it is homicide or murder, as the case is." In another case—Queen v. Pym—Mr. Justice Erle said—"I am of opinion that when a dangerous wound is inflicted, and the best advice taken, and an operation performed on that advice, which is the immediate cause of death, the party giving the wound is criminally responsible."

Now, here is a case in point. A man is shot in the street; he is not killed on the spot, but taken to a Hospital; the Surgeon who sees him thinks it best to attempt to extract the bullet he has reason to believe is in the wound, but fails to do so; the propriety of the attempt is supported by some of the best reputations in Dublin—no mean school of Surgery; and according to these men, the operation is skilfully, if unsuccessfully, performed. Next day the patient is well enough, beyond a slightly tremulous condition of the tongue, which, as the patient had been a confirmed spirit-drinker, was by no means astonishing. On Friday we have rigors, the mark of commencing suppuration. On Saturday, the inflammation had extended further; the coverings of the nervous system were affected; and from this date the sequence is rapid. No great amount of change is needed to cause death in the vicinity of the medulla oblongata, and so violent delirium soon gave way to coma, and coma to death.

The chain could hardly be clearer, and yet we have audacious men coming forward boldly in open court to say, "This man's death lies not at the door of his assassin, but of his Surgeon." We have read all the evidence in this case with the utmost care. We have read what has little pleased us—the browbeating of witnesses and the reckless use of indefensible language. The wrangling of barristers, if common, is not pleasant; but to hear of one barrister declaring that his opponent shall answer for his words elsewhere, is something unheard of except on this trial, at the present day. Still worse were the altercations between judges, jurymen, and barristers; worst of all, the outside abuse of one of the most honourable and independent judges on the bench. But it needed a combination of all these things, with a verdict of acquittal to follow, to render this trial of Kelly one of the greatest legal scandals of modern times.

Of all the features in this trial, however, there is none so interesting to our Profession as the audacious charge advanced by the counsel for the prisoner of *mala fides* on the part of Dr. Stokes. According to the law of the land, if a man has suffered an injury at the hands of another, such as to require Medical aid, and yet perish in spite of it, it is not necessary to show that that Medical aid was administered with more than ordinary skill to enable a verdict of murder to be brought in. It is enough that he should have been attended by a properly qualified Medical Practitioner who has done what he could, honestly, altogether apart from the fact that men of greater skill in their Profession might have been called in. When, therefore, the question of skill was imported into the case, the counsel for the prosecution promptly objected to such a line of defence, and it was ruled by the Lord Chief Justice to be inadmissible. Unfortunately, the Lord Chief Baron did not take the same view, whereupon Mr. Buttmost unwarrantably entered the plea that Dr. Stokes had in his treatment of Talbot behaved most recklessly and with no *bonâ fide* intent of procuring his recovery. This is the first time such a plea has been entered, and we should have expected, especially when a reputation like that of Dr. Stokes, jun., was in question, that it would have been supported by a formidable array of skilled witnesses. Yet how did it end?—By not one tittle of evidence being produced to

warrant such an assertion. Nevertheless, by this time it had suited Mr. Butt's purpose. He had been enabled to throw dust in the eyes of the jury, and it was nothing to him though a meritorious young Surgeon should be ruined, provided he procured the acquittal of his interesting client and the applause of Ribbonmen and Fenians, even though coupled with the execrations of all good citizens.

It is true that in his summing-up the Judge cleared away all these cobwebs regarding alleged malpractice. He told the jury plainly that the question of good treatment, bad treatment, or no treatment at all was not before them; but the indignant virtue of Mr. Butt, the audacious insinuations of Mr. Falkiner, and the scornful laughter of Mr. Keogh had been too much for them, though unsupported by a tittle of evidence. There had been unusual difficulty in procuring a jury to try this case—men shirked attendance on every possible excuse; for they feared, if they found Kelly guilty, that they too might share the fate of Talbot. And so, this quibble being raised, and evidence as to treatment being admitted, they eagerly embraced it—what is most wonderful, unanimously—and acquitted the prisoner of a crime for which his advocates did not venture to defend him. It was not even contended that Kelly did not fire the shot that killed Talbot; the contention was that Dr. Stokes was guilty of his death. Usually much latitude is allowed to counsel in defending a prisoner, and people are not greatly accustomed to care much for what they say; but it is too much for a man to defile another's character as Mr. Butt did that of Dr. Stokes, and that the latter should have no remedy.

Doubtless it will be gratifying to Dr. Stokes to see the opinion of our highest Surgical authorities as given in the *Times* of November 16, and appended to this article, and how thoroughly they clear his character. Nevertheless, it is a shame that such an opinion should have been required in such a case, and we cannot help feeling that the ruling of the Lord Chief Baron is at the root of the evil. Unfortunately, this rule now holds good until annulled by higher authority; so that this is probably not the last time we shall hear of the plea of recklessness and *mala fides*—only we hope it will be raised next time in England.

With a view to such an occurrence, it may not be amiss to point out one or two salutary lessons to be drawn from this unfortunate case. The first is, the necessity, when one has to do with a case likely to come before a court of law, of taking the very greatest care in coming to a diagnosis, and adopting a line of treatment. Above all, nothing hazardous should be attempted, provided the exigencies of the case do not demand it. Let the Practitioner think that he may have to stand in a witness-box and justify his acts to the nation at large, and not to his own mind only. Such a reflection will, at all events, teach him caution.

Next—and what, perhaps, is more important, because more likely to be overlooked—is the advisability of taking note of everything as it occurs. The senior resident pupil on this occasion, Mr. Vesey, was most unmercifully bullied by Mr. Butt because he had made two sets of notes—one at the time each occurrence took place, the other later—and the two varied somewhat. They differed in this respect: the former consisted of facts and inferences mixed up together, mainly the result of his own observation; the latter contained the experience of others also, to which, of course, he could not swear. The grand rule is this: take as copious notes as you please of everything that passes around you, but avoid all inferences—either keep them apart or, better still, in your own mind. The very first note Mr. Vesey made involved this mistake, and gave Mr. Butt abundant material for bullying him. He stated in his notes that when Talbot came in he was pale from loss of blood. No doubt he was pale, and no doubt he had lost blood; the mistake was, connecting the two as cause and effect. Fright, shock, or half a dozen things, might have made the man pale. But Mr. Butt promptly seized the handle thus afforded him.

Here was a man, said he, pale and weak from loss of blood, and yet Dr. Stokes sets to work at once to operate on him, and thus, in one way, was guilty of recklessness. Other portions of these notes erred in the same way, and so their well-meaning and intelligent author was put to shame before the Court, partly through his own mistake, partly through Mr. Butt's violence.

We should be glad to sink the whole miserable transaction in oblivion, but we fear its memory will live for many a day, and prove fruitful in other deeds of violence and injustice.

P.S.—The last thing we hear of this extraordinary case, just before going to press, is, that the jury acquitted Kelly *because a gunsmith examined the particles of lead found in Talbot's skull microscopically, and found they were part of a slug, and not of a ball such as Kelly used.* This bangs Banagher! We are bewildered, and ask what it all means? Who was this wonderful microscopist, and what were the means of identification he used?

We have much pleasure in publishing the following statement:—

"The undersigned, having carefully considered the evidence in the recent trial for the murder of Police-constable Talbot, and believing that certain statements made during the trial are likely to affect very injuriously the Professional reputation of Mr. William Stokes and the Surgeons who acted with him, desire to record their opinion that the bullet-wound in the neck of Police-constable Talbot was the direct and sole cause of his death, and that no blame can be justly assigned to any of those by whom the wound was treated.

THE BROWN INSTITUTION.

MANY of the most zealous pathologists of this country, and especially such of them as have studied in the great Continental schools, have for the last few years felt with increasing regret that England is totally unsupplied with means for the study of experimental pathology. It is true that even in Germany laboratories specially instituted for the study of this branch of scientific Medicine can scarcely be said to exist: under the professors of pathological anatomy and physiology, however, one is always able to make any investigations he may wish on disease induced in the living animal. In this country, on the other hand, it is only within a year or two that even physiological laboratories have been built; and meanwhile, many of the experiments in pathology which have been undertaken have been performed, we are afraid, with too imperfect resources of every kind to be of much scientific value in their results.

Every true student of pathology, therefore, must have hailed with extreme satisfaction the announcement made, now many months ago, that the Brown trustees had resolved, in conformity with their obligations, to erect an institution "for the study of the diseases of animals, and, if possible, for their cure." And many seem to have even allowed themselves to be carried away by this feeling; for it is a fact, that the prevailing idea in London at the present moment is that the Brown Institution will be simply a laboratory for experimental pathology on a very large scale. This is quite a misunderstanding, for there will be found in it just as extensive provisions for the cure of the sick animal as for the experimental investigation of morbid processes. The Institution will be, in fulfilment of the desire of its benevolent founder, not only a pathological institute, but a veterinary Hospital. And that what we have said is true may be learned from the following description of the place:—

The Brown Institution buildings are situated in a piece of ground of about an acre and a half in Wandsworth-road, Nine Elms. Occupying the front part of this space, and separated

from the road by a garden, are the houses of the resident officers, behind which the rest of the ground may be described as a garden in which the buildings proper have been erected. Extending along one side of this garden for half its length is the stable for large animals; flanking this is a smaller erection for dogs, etc.; while situated almost in the middle line of the back half is the laboratory. Thus the two departments are quite distinct from each other; and a row of trees running from the dwelling-house to the laboratory will make this division of the premises still more complete. At either end of the dwelling-house, also, there is a small building; one is intended for a post-mortem theatre, the other is a small stable, etc.

Of the wards for the animals we need not speak at length. There are stalls for at least seven large animals, besides accommodation for a great number of sheep, dogs, etc. The furnishings are all of the most recent and most substantial kind; every room and every stall will be warmed by hot-water pipes; and in respect of the sewage and ventilation we have only to mention that the arrangements for their perfection have been carried out under the superintendence of Professor Burdon-Sanderson himself. Light, also—so necessary for health—has been abundantly admitted by large ventilating windows.

The laboratory is a single large building, with one floor of rooms above the level of the ground, and a second partly under it. The former of these rooms are intended for working-rooms or laboratory proper, and are five in number. One is the Professor's apartment, one is for the Resident Superintendent, and a third for the more ordinary apparatus; while the fourth and fifth are being fitted up as general laboratories for experiment and microscopy respectively. In these, although they are not yet completed, one may see the general arrangements of the fixtures and furniture. Along the back and front wall of each runs a fixed table, conveniently high for the student working at it, either in the sitting or in the standing posture. The front benches are well lighted by large windows with a northern aspect, and furnished with plain glass. At these benches there will be allotted to each student a definite place, and there he will find a supply of water and gas for his special use. In the centre of each room is a square movable table; and several cupboards for apparatus, etc., complete the more fixed furniture of the place. All these rooms will be heated by warm-water pipes, and by these only. The private rooms of the officers have very much the same arrangement.

The lower floor is reached from the upper by a trap in the apparatus-chamber. It contains four rooms, which will be used chiefly for chemical purposes. They are furnished with warm-water and cold-water pipes; while in one will be fitted up a chemical hearth, and in another arrangements for organic analysis. The fifth room on the lower floor is entered by a separate door at the side of the building; it is fitted up in a careful manner as a stable for small animals belonging to the laboratory.

No apparatus are yet to be seen; but in respect of these we understand that there will be no lack of whatever is required for operation, injection, cultivation, chemical and microscopic investigation, and so on. The particular microscope used will probably be Hartnack's, and gas will be employed when artificial light is required.

In regard to the working of the Institution, there are three special offices connected with it, and these have been already filled up in a most satisfactory manner. The Professor-Superintendent is Dr. Burdon-Sanderson; Dr. Klein, from Vienna, is the Resident Superintendent of the laboratory; and Mr. Duguid holds a similar post in the Hospital. The election of such a staff reflects the greatest credit upon the trustees, and is an assurance that the work of the place will be most earnestly and fully carried on.

Attendance will be given daily by the Veterinary Surgeon for the admission of animals, and his time will be otherwise

occupied in the post-mortem room and in the museum, which will be fitted up in the dwelling-house.

In the laboratory will be done all kinds of work of an experimental nature relating to pathology, whether pure or with the aid of chemistry and the microscope; for both these last there will be especially complete provision.

The Institution will be ready certainly before Christmas, and, we understand, will be open to pupils the whole day. It is easily reached, either by river, rail, or omnibus.

THE WEEK.

TOPICS OF THE DAY.

WE are glad to see that a timely protest has been raised by a Fellow of the Royal College of Physicians, in the *Times* of Wednesday, against the attempt which is being made to obtain funds for a new "Women's Hospital," "to enable the Medical staff (the working part of which is to consist of women) to deal effectively with cases requiring Surgical treatment, and with the more serious class of cases generally." The writer of the protest urges that already many of the best Hospitals in London are languishing for want of funds; that already there are the Samaritan Free and the Soho-square Hospitals, where the Surgical diseases of women are especially treated; and that there is not a woman in England who has ever performed the operations which ought to be done weekly in such an institution. We do not know what may be the success of this monstrous appeal; the more absurd and unnecessary the object, the more likely it is that some silly partisans will be found to subscribe money to it. But in the interest of the women-patients, if not of the women-Doctors, it is to be hoped that some check will be given to the undertaking by the letter of the Fellow of the Royal College of Physicians. He writes:—

"Where have these ladies acquired their training for such operations as are here indicated? It is well known to the Profession that the cases here alluded to are among the triumphs of modern Surgery, and that the conservative results which have crowned a few well-known names with European reputation are the product of immense opportunities for practice, operations repeated on hundreds, precautions founded on a long experience, and costly preparations to seclude the sufferer from every fluctuation of temperature, and from every chance of contagion."

We have little to add to this, but cannot refrain from strengthening the case of the "Fellow of the College of Physicians" by some facts from the "Manchester Medical and Surgical Reports" just issued. We find there that in the Provincial Hospitals of Manchester, Leeds, and several other large towns, thirty-six cases of ovariectomy were observed in the year 1870. Of these patients, twenty-one died, and only fifteen recovered. In the Samaritan Hospital, Mr. Spencer Wells can show that, of thirty-six cases, only ten would die, and twenty-six recover. He can show still better results in private practice, and so can Dr. Keith, of Edinburgh—the two operators who have the largest experience in Great Britain. If, then, there is such a fearful difference between two Surgeons of very large experience and very able Surgeons of large experience in general Surgery, what an awful mortality may be expected if this operation is to be practised by women who have no experience whatever in any Surgical operation!

The inquiry for the missing child from the Hampstead Small-pox Hospital has proved abortive. We should think it more than likely that the child died, and was buried under another name. Although the matter may be explained on the supposition that the features of the child were disfigured by the disease, and that the nurse neglected to change the bed-card, it constitutes by far the most serious charge yet brought against the Hospital.

Mr. Disraeli has been elected Lord Rector in the University of Glasgow by a majority in all the four nations, and by a large total majority.

Sir William Stirling Maxwell has been elected Lord Rector of the University of Edinburgh. His opponent, Sir Roundell Palmer, was beaten by a majority of 92.

We can sympathise with the opposition which has been raised by the inhabitants of Hampstead to the erection of a permanent Small-pox Hospital there. Mr. Stansfeld seemed to hold out but little hope to the deputation that waited on him early in the week of any interference on the part of the Local Government Board to induce the Metropolitan Asylums Board to seek another site. It certainly does seem a mistake to have fixed a Small-pox Hospital in one of the chief health-resorts of North London. A member of the deputation to Mr. Stansfeld said that the inhabitants of Hampstead would be willing to incur the expense of removing the Hospital. If this be the case, the Asylums Board should undoubtedly find a site in a less popular situation.

At a special meeting of the Senatus Academicus of the University of Edinburgh, held on Saturday last, the following motion was proposed and carried by a majority of 14 to 13:—"That the Senatus represent to the University Court the propriety of rescinding their resolution and regulations in reference to the admission of women to Medical education in the University; without prejudice, however, to the rights and interests of those ladies who have already entered upon a course of study in pursuance thereof, and without prejudice to the right of Professors to give separate instruction to ladies in such classes as the University Court may from time to time think fit and approve." This shows that at least a majority of the Senatus are beginning to be alive to the bad effects which their false liberalism is having upon the fortunes and reputation of their University as a Medical school for men. As we have on a previous occasion remarked, the University has made no real or implied compact with the women-students to admit them to graduation; and we hope that the Professors of the University will strenuously resist the inroad which a party of foolish Scotch Presbyterian clergymen, lawyers, and women are endeavouring to make upon the decency and standing of the Edinburgh Medical School. The friends of the women-students endeavoured to get an amendment substituted for the original motion, but they were out-voted. The amendment was to the effect—"That, without asking the University Court to rescind their resolution, the Senatus should authorise an intimation to be put into the *Calendar*, that it was for the present impossible for ladies to obtain a Medical education in the University, notwithstanding the resolution and regulations of the University Court." We notice from the report of their recent meeting that the Association for Securing a Complete Medical Education for Women in Edinburgh are crying out for more funds. Mr. McLaren, M.P., who seems to have been the chief speaker on the occasion, boasted that he and his wife had been the means of procuring one-fourth of the funds from England for the defence of Miss Jex Blake—an assertion which does not raise our idea of the intellectual *status* of the acquaintance of Mr. McLaren. For ourselves, we have only pity for a man who sees no reason why men and women should not sit together in Medical classes in a Medical school as they sit together in church. We can say this, however, to Mr. McLaren, that the sitting together to any good purpose in church would be fatal to any idea of their sitting together at anatomical and physiological demonstrations.

An attempt to simplify the present complicated and continually changing chemical nomenclature has been recently made by Mr. Metcalfe Johnson, of Lancaster. In the number of the *English Mechanic* for November 3 appears a letter from Mr. Johnson, announcing his proposal, which is simply this—"To use the Greek terminal *ov* for all substances, whether element or compound, and to indicate the number of atoms of

each *element* by the Greek numerals, and of each *compound* by the Latin numerals, one to five." Thus, one terminal and five prefixes are made to identify each element or compound, and to indicate the exact chemical composition of the substance. Thus, water composed of OH_2 would be oxo-dihydron; nitrous oxide, N_2O , would be oxo-dinitron; nitric oxide, N_2O_2 , binitroxon; and so on. Some of the words so produced are rather long, and not very euphonious—*e.g.*, bisulphate of soda, natro doxo-bi-sulfotroxon; but the plan has the advantage of being uniform, and it certainly would not be much more difficult for the student than the perplexing phraseology at present in vogue.

The Shoreditch parochial authorities have recently made themselves notorious by passing a resolution that a wooden shed, lately used as a small-pox ward, should be broken up and sold for £27 10s. The Local Government Board and the Metropolitan Asylums Board have had their attention called to the matter, and the Shoreditch authorities will probably be prevented realising the worth of the boards at the expense of the health of the metropolis.

THE MEDICAL SOCIETY.

At the Medical Society, last Monday, the proceedings were unusually interesting: the subjects were numerous and varied. After the minutes were read, the secretaries brought forward an amended report on Thermometers. The reporters advise that a standard thermometer, and also an approved clinical thermometer, should be kept at the Society's room. Next, Dr. Tilbury Fox made very brief but interesting remarks on an Extensive Outbreak of Ringworm. The novelty was his discovery of epithelial scales containing fungi in the air of the workrooms. They were deposited on glass slides exposed in the room. Then, Dr. Carpenter, of Croydon, read a very methodical paper on two cases of what he believed to be Muscular Anæsthesia. He exhibited his two patients, and to show the difference betwixt their gait and that of locomotor ataxy, he presented also a patient who was the subject of that disease. This paper excited great interest, and led to valuable remarks by Dr. Lockhart Clarke on the subject of muscular anæsthesia, and on the symptoms and pathology of locomotor ataxy. Dr. Lockhart Clarke, Dr. B. W. Richardson, and Dr. Hughlings-Jackson were requested to join Dr. Carpenter in investigating the cases, and to furnish a report on the condition of the muscles. A short paper on "Endocarditis complicating Phthisis" was then read by Dr. Sansom, who showed pathological specimens from the case. After this paper was discussed, Mr. Brudenell Carter also showed some pathological specimens—this phrase meaning, that he demonstrated certain abnormal conditions of the fundus oculi. With the reflecting ophthalmoscope the optic disc could be seen easily and very clearly by anyone who put his eye to a hole in one of the properly adjusted mirrors; no further "skill" being required of the observer. If the demonstration had had no other value than that it convinced any novice in ophthalmology of the value of the ophthalmoscope as a practical instrument of research, it did good service. Perhaps there is not to be found, nowadays, anyone so incredulous as to require to have actually demonstrated to him that the optic disc, with its arteries and veins, is really to be seen. But there are, we believe, some who have not a clear notion of the great definiteness of ophthalmoscopic appearance. We advise anyone in this state of mind to attend further demonstrations Mr. Carter is announced to give. But the cases—or, as we have said, pathological specimens—were in themselves of great practical value, and that not to the ophthalmologist only, but to Medical observers in general. One case was a specimen of cinbolism of the right arteria centralis retinæ. Besides the importance of the case from a directly utilitarian point of view, as showing one rare and yet definite way in which "amaurosis" is caused,

it was most instructive, for the earliest stage of the embolic process was there to be looked at. It was on this point that Mr. Carter laid most stress—not dwelling with exaggeration on the phenomena resulting from sudden blocking of one important artery, but speaking *from* this particular case with reference to the results of plugging of arteries in general. In this case, besides better known appearances, blood could be seen upon the optic disc itself. With all this abundance of material there was, thanks to the courteous management of the President, no confusion in the proceedings of the Society. The evening was both pleasant and profitable.

THE HUNTERIAN SOCIETY.

At a meeting of this Society, held on Wednesday, November 8, Mr. Bryant brought under the notice of the members some interesting cases bearing on the subject of Insuperable Constipation and its Treatment. The object of his remarks was to show that in a large number of cases of chronic constipation colotomy is a sure and proper mode of treatment, that its performance ought not to be too long delayed—so long, indeed, as often is the case—and that the objection to the operation, that it causes the after-life of the patient to be one of discomfort and annoyance, was not true, in fact. He alluded to two patients on whom he had performed colotomy for fistulous communication between rectum and bladder, who at this time were enjoying very comfortable existence, and who say they would not undergo an operation for closing the artificial opening even if they could with safety. As a curative mode of treatment in some cases of severe simple, or syphilitic ulceration, the operation ought to be performed early, for healing is either very prolonged or out of the question altogether until a chance is thus given for its repair. He also referred to the occasional occurrence, especially in persons advanced in life, of insuperable constipation from loss of power of the large intestine, and without any actual or positive cause of obstruction. Such cases sometimes prove fatal, and, when occurring, should be treated, not by severe and frequent purgatives, but by means of enemata.

The first case described as illustrating the relief afforded by colotomy was that of a lady who was supposed to have some tumour connected with the uterus or ovary, but who, when seen by Mr. Bryant, was suffering severely from the results of obstruction of the bowel—"of a chronic blockade of the intestine," as Mr. Bryant termed it. Colotomy was performed, and immediate and considerable relief was given; but death subsequently occurred from the rupture into the peritoneal cavity of a cyst, of creamy fluid contents, growing near the sacrum.

Another case bearing on the first was a female who had for seven weeks suffered from obstruction. She had been treated with opium, and with mild and powerful aperients, before colotomy was performed. This was done on the right side, and a quantity of feces was evacuated, and on the sixth day after the operation the patient was well. In this instance the uterus was prolapsed, being pressed down by something which gave to the finger in the rectum, when passed above the uterus, the same sensation as a fibroid tumour of that organ gives to the finger in the vagina. A quantity of wax-like material was also felt in the rectum; on withdrawing some of it, it presented much the appearance of fine wax, and was, no doubt, Mr. Bryant thought, an accumulation of soap which had been thrown into the bowel with the previous frequent injections. This patient is still living, so that the nature of the growth causing the obstruction has not yet been ascertained.

Mr. Bryant also referred to another case of considerable interest in the person of a young woman who had had colotomy performed on the right side in 1867 for obstinate constipation and faecal vomiting. The patient is now in Guy's Hospital, in order to have the artificial opening closed. This Mr. Bryant has partly succeeded in doing; but before completely doing so he is

gradually accustoming the colon to take on its long-suspended functions by passing into it injections of warm water.

The paper altogether was one of considerable interest.

Dr. Pye-Smith gave an account of a case of Cystic Enlargement of the Pelvis of the Kidney, brought on, as he very plausibly assumed, by traumatic stricture of the ureter a few inches from the kidney. The cyst subsequently suppurated, and a fistulous communication between it and the bowel resulted. Dr. Pye-Smith raised the question as to the advisability of laying open such a cyst when suppurating, by a free incision into its posterior part through the abdominal wall—a view which was supported by one or two of the members who took part in the discussion.

THE MIDDLESEX HOSPITAL MEDICAL SOCIETY.

The first meeting of the season of this Society was held on November 2, in the Board-room of the Hospital, when Mr. Langmore, M.B., read a paper "On the Hygienic and Medical Management of Infants." At a special general meeting held on November 9, the President (Mr. Morris) in the chair, the mode of Instructing Deaf Mutes by Lip-movements was the subject brought before the Society. Dr. John Murray commenced by giving a brief outline of the history, results, and prospects of lip-reading. Mr. Van Praagh then described the means by which the education of the dumb by this method was effected, and afterwards held a conversation with Mr. Polano, the son of the Professor of Surgery at Leiden. Mr. Polano was born deaf, and has been educated by lip-movements; he is now able to converse in his own language with entire strangers, and can also read aloud in the English tongue, although he has not been sufficiently long in this country to understand the language. Mr. Dalby, Aural Surgeon to St. George's Hospital, afterwards made some remarks, in the course of which he said that, though he was not so sanguine of this method for teaching the deaf and dumb as were some of its friends—owing to the opposition it would receive from ignorance and prejudice—he, however, considered it the best. It was, too, a method by which not only those who were born deaf, and were in consequence dumb, could learn to read and articulate, but one by which children who have talked naturally, and have subsequently become quite deaf, can be prevented, if taught early, from becoming dumb; and, further, that children who have once spoken, and, as a result of extreme deafness, have become dumb, may be more easily taught than those children who have never heard.

DR. ROSE CORMACK'S SERVICES DURING THE TWO SIEGES OF PARIS RECOGNISED BY THE FRENCH GOVERNMENT.

So far as we know, it has not yet been stated in any of our Medical journals that, by decree of July 11, Dr. Rose Cormack, of Paris, received from the French Government the cross of Chevalier of the Legion of Honour. There was sent along with the decree and insignia of the Order a "protocole," dated "Ministere des Affaires Etrangères," and signed "Jules Favre," in which the following sentences occur:—"Je me félicite d'avoir été à même de faire connaître au Président du Conseil le savoir et le dénouement avec lesquels vous avez donné vos soins aux blessés Français recueillis dans l'Ambulance Anglaise de la Rue d'Aguessseau. Vous vous êtes montré un digne collaborateur de Sir Richard Wallace et le Gouvernement Français s'est plu à le reconnaître." In addition to this recognition, Dr. Cormack has received the war medal and the cross of the Société Française de Secours aux Blessés.

JOTTINGS ABOUT CHOLERA.

The disease continues undiminished in Constantinople. Thirty-three out of the 708 inhabitants of Haskeni, who compose the English colony, have died of the complaint. It continues to rage in various parts of Arabia.

UNAUTHORISED EXAMINATION OF DEAD BODIES.

GREAT dissatisfaction has been caused of late in several cases where post-mortem examinations have been made in the Hospitals of London without the sanction, and in one or more cases against the expressed wish, of the friends of the persons deceased. It is to be regretted that these misunderstandings should occur; more particularly as, in the vast majority of instances, the consent of friends could be obtained if proper means were resorted to for that purpose. The last case which has occurred, and which has caused considerable excitement at the East-end of London, was at the Children's Hospital at Ratcliff-cross. An inquest was held last week, before Mr. Richards, the Deputy Coroner, on the body of a child, 6 years of age. It appeared by the evidence that the child had been in the Hospital since August 16 last; that the parents were told a few days since by the House-Surgeon, Baron P. von. Sadilitz, that the child would not live, and they, fearing a post-mortem examination would be made, forbade it. Mr. R. N. Phillips, Police Surgeon, said that, by order of the Coroner, he made a re-examination of the body, which had previously been opened. The heart had been removed from the body, and was missing. The lungs were diseased and congested. He believed that the child had died from disease of the heart. The Coroner said that the Hospital Doctor had no right to cut open the body. It was a punishable crime. A juror said a magistrate should be at once applied to, and the whole case made public. Ultimately a verdict of "Death from disease of the heart" was recorded. It was stated that criminal proceedings would be taken in connexion with the case.

TRAFFICKING IN DEGREES.

It was generally supposed that the trafficking in degrees had ceased, now that the "Medical Register" is published annually, and the Council of Medical Registration refuse to place on the Register the names of those persons who have obtained licences, diplomas, or degrees in an irregular manner; but the traffic still proceeds. Whatever may be its results so far as other professions are concerned, we must conclude that with reference to Medicine it is an unprofitable pursuit. Anyway, the pursuit is followed, as witness the following advertisement which appeared a few days since in the *Times* newspaper:—

"DEGREES.—Gentlemen of ability and position can obtain promotion to learned degrees in theology, law, arts, Medicine, music, and other recognised orders. Strict confidence assured. Address, M.A., etc.—"

The *Weekly Review*, in order to ascertain the real meaning of the above advertisement, sent a letter to the address, purporting to be written by a Presbyterian clergyman, and a reply has been received which brings clearly to light a system which is in the highest degree objectionable both as respects the givers and receivers. It is high time that so abominable a system should be put a stop to.

MEDICAL STUDIES AT CAMBRIDGE.

At a meeting of the Senate of the University of Cambridge, held on Saturday last, the Vice-Chancellor presiding, the proposed additional requirements prior to the third examination for the M.B. degree, referred to in our last issue, were considered. Dr. Paget and Professor Liveing were present. In answer to a question, Professor Liveing said that the requirements of the regulations could be met at the hands of the Professor of Experimental Physics. Dr. Paget urged, however, that the proposed regulations would have the effect of materially reducing the term of study at present required—viz., four years. Though he had signed the report as a whole, he would suggest that an alteration be made in the second clause of regulations. At the present time, four years' study was necessary to qualify a student for entering into the Medical Profession, and he thought that system should still obtain.

THE LORD CHIEF BARON ON THE PRESERVATION OF THE PUBLIC HEALTH.

It is seldom that the City authorities are reminded by those in position above them of the duties appertaining to their offices. The Lord Mayor, on presenting himself, on the 9th inst., before the Lord Chief Baron of the Court of Exchequer, was reminded of the imperative necessity, before another session of Parliament passed over, of promoting measures for the preservation of the health of the people. It was of the utmost importance, said his Lordship, that public bodies charged with municipal duties should be reminded of the responsibilities devolving upon them. It is to be hoped that the "gentle reminder" of the learned judge will not be lost sight of by those to whom it was addressed.

INCREASE OF SMALL-POX IN LONDON.

THE lull in the epidemic of small-pox appears to have ceased. The report of the Committee of Hampstead Small-pox Hospital, on Saturday last, stated that during the past fortnight 126 fresh cases of small-pox had been admitted; 16 had died, and 61 were discharged, leaving 190 under treatment, as against 140 at the date of the last report. The total number treated up to the present time has been 5822, of whom 1099 died, and 4543 have been discharged. It will be seen that the number of fresh cases has been 80 per cent. higher during the past fortnight than in that preceding, and has exceeded the vacancies caused by discharges and deaths by 49. This has rendered necessary the immediate reappointment of a second Assistant Medical Officer. It is feared, from present appearances, that the whole of the accommodation that can be afforded will be required during the forthcoming winter.

FOOT AND MOUTH DISEASE IN CHILDREN.

SOME weeks since we stated, on the authority of the Chairman of the Hertford Chamber of Agriculture, that children fed on the milk from diseased cows had suffered from a complaint similar to the "mouth disease." Since then Dr. Alfred Packman, of Puckeridge, has treated several cases of this complaint, and states in a certificate that the patient "suffered from a peculiar eruption of the mouth, nose, and face, accompanied by sore tongue and throat, and salivation. I have no sort of doubt that the affection was caused by drinking milk from cows suffering from foot and mouth disease."

REVACCINATION IN THE ARMY.

It is probable that revaccination may be made compulsory throughout the English army and the families of married soldiers. It is well known that the influence of revaccination in the Prussian army has been most beneficial. An order has just been issued by the Medical Department of the Army, directing that the whole of the married women and their children above 10 years of age, belonging to the depôts attached to the general dépôt battalion at Chatham, are to be vaccinated.

JURYMEN AND CONTAGIOUS DISEASES.

A SHORT time since Dr. Lankester, at an inquest held by him on a person who had died from a contagious disease, suggested that in all such cases a pane of glass should be placed on the lid of the coffin of any person on whom an inquest was to be held, so that the body might be "viewed" without danger. The jury, in the case of an inquest on a person who died of small-pox in Bloomsbury, where the plan was carried out, expressed their gratitude to Dr. Lankester for the suggestion.

DISTRICT MEDICAL OFFICERS.

THE following notice of motion has been given by Mr. C. N. Cook, one of the Guardians of the Poor of Lambeth, to be discussed at the next meeting of the Board:—

"That the existing system under which the District Medical Officers are appointed, and required to give both Professional

attendance and medicines out of their allowance, is wrong in principle and objectionable in practice; and that it will be advantageous to the ratepayer, satisfactory to the Medical officer, and beneficial to the class of people seeking relief if the system be placed on a totally different footing.

CHOLERA ON SHIPBOARD.

ADVICES from New York state that forty-one deaths from cholera occurred on board the steamer *Franklin* on her voyage from Stettin to New York.

FROM ABROAD.—M. LE FORT ON FRENCH MEDICAL MILITARY SERVICE—EDUCATION OF PARIS MEDICAL STUDENTS.

IN the *Révue des Deux Mondes* for November 1 is an important paper from the pen of M. Léon Le Fort, on "Military Surgery in Modern Armies." Few are more competent to speak on the subject, for he has seen service in more than one important campaign, and has made it, as well as the cognate subject of Hospital arrangement, the matter of study in most European countries. In the recent war, too, he was engaged in active ambulance service, and, indeed, it is the teaching derived from this that constitutes the most pressing interest of the present paper. This teaching, however, is only a reiteration of impressive warnings as to the faulty condition of the French Medical Military Service, which have been repeatedly addressed in vain by himself, Dr. Chenu, and others, to a heedless Administration; and we fear that there is now as little likelihood as ever of the radical changes which he considers as essential being adopted. It is but another chapter of the now often told story of the defective condition of French organisation, and of the vast scale on which reforms, to be of utility, will have to be conducted. M. Le Fort writes with a singular absence of prejudice and animosity, considering the scenes he has of late been witness to, and describes at length, for the benefit of his countrymen, the system of organisation which prevails in the Medical service of the Austrian and German armies. The necessity of closely imitating this he strongly urges; but here we think he, in common with his countrymen in their search for remedies at the present crisis, is somewhat too indiscriminate in his recommendations, as if mere imitation of Prussian procedures would necessarily be followed by satisfactory results. Indeed, as far as military Medicine is concerned, much that prevails in Prussia is of comparatively recent adoption, and admits of considerable amendment; for the arrangements for the treatment of the sick and wounded (with the exception of those for their prompt removal from the battle-field, and for their rapid—sometimes too rapid—transport to distant Hospitals) were very meagre, and far too much dependent on the volunteer aid of a large force of civil Practitioners, many of whom were quite inexperienced in the duties they had undertaken to perform.

M. Le Fort forcibly demonstrates, as he and others have so often done, that the Intendance is the incubus and curse of the French Medical Service, and that any essential improvement is impossible until it is liberated from the trammels of that department. From highest to lowest, the French Medical officer is entirely deprived of all power of action or initiative, and scarcely can be said to have a consultative voice, being, in the words of Chenu, a "mere instrument for amputating, bleeding, and purging." The position and disposition of Hospitals, and the number of their inmates, or the period of the stay or discharge of these, are matters placed beyond his control; while the Intendance is so overwhelmed by the amount and diversity of its duties as to be utterly unable to fulfil them, even if possessed of the necessary knowledge, of which, as regards Medical matters, it is entirely destitute. The *personnel* of the French Medical Service ought, at the beginning of 1870, to have consisted of 1147 individuals, but even this inadequate force did not exist, the number really mustered being only 1020, leaving a deficiency

of 11 per cent., the *pharmaciens* also being in a deficiency of 15 per cent. This state of things had arisen from the increasing number of resignations and the difficulty of reeruiting new candidates. In the face of the increasing attractions of private practice, the degraded position of the military Medical service in relation to the Intendance and to the other branches of the service, together with the poorness of the pay, men cannot be tempted into it in sufficient numbers, and those who have entered are incessantly leaving it. With the proposed increase of the army—bringing it up, inclusive of reserves, to a million men—this condition of things will be much aggravated; and M. Le Fort considers, at some length, the various means that can be had recourse to, even after the indispensable emancipation from subserviency to the Intendance. That his recommendations do not carry the matter very far may be seen from the fact that one mode which he suggests for supplying the deficiency which will still exist even after their adoption is, that a stipulation should be made in future diplomas, in consideration of the exclusive right to practise which these confer, that their holders should be liable, until the age of 40, to military Medical service on all occasions when the defensive reserve may be called out.

M. Le Fort, who saw during the late war much of its operations, emphatically condemns the Geneva Convention—at all events, in its present undefined condition. His statements are most temperate upon the subject, and plainly show that many of the alleged German violations of its provisions arose from the ignorance which prevailed among the French concerning the nature of these. So little pains had been taken to make them known in the army, that when the war broke out the Intendance was entirely ignorant of their character. In the hands of volunteers the badge was most grossly abused. Volunteer societies, he observes, under strict submission to military order, and with limited objects in view, did admirable service for the German armies; while when these were left, as on the French side, to spontaneous action, their operations were often of very questionable utility, when not positively mischievous. With few exceptions, the *infirmiers volontaires* were drunkards or idlers, and were in many instances more occupied in pillaging the dead than tending the living; while the conversion of private houses into ambulances, under the protection of the Geneva Flag, where it was not, as it often was, a sham to escape quarterings, became not infrequently, through mistaken benevolence, a source of mischief, many of the wounded dying in these who might have been saved had the Surgeons been aware of their existence.

"The war of 1870 has superabundantly shown that the International Society did mischief by diverting from military service, in order to employ them itself, those civil Surgeons, who would have willingly entered the ranks of the army temporarily in order to devote themselves to the care of the wounded—thus in part rendering sterile individual efforts, which, under the immediate direction of military Surgeons might have proved far more useful. Maintaining for individuals all the respect which pure intentions deserve, can we say that the intoxication of devotion which covered France with little private ambulances, and converted so many persons, not only into Hospital sisters and nurses (which, perhaps, was a benefit, in spite of their inexperience), but even improvised them into Doctors (which was certainly an evil), has not contributed to increase the mortality, destroy what remains there were of discipline, and keep from the ranks soldiers well fitted for service? However this may be, we may say with M. Lucas-Championnière, Surgeon to the 5th Ambulance—'We might point out improvements that every kind of voluntary ambulance is susceptible of, but we shall furnish no details on the subject, because we believe that civil ambulances have played out their part, and that that part is terminated.'"

Some time since Mr. Simon, when President of the Medical Teachers' Association, somewhat startled the non-imaginative and less advanced portion of the Medical world by his suggestion that Medical curricula should be abandoned, and that the assurance that candidates possessed the amount of Medical and

scientific knowledge requisite for their being trusted with their future important duties should be ascertained by more efficient examination. Those who were aware of how much the bulk of Medical students stand in need of all the aid that can be given them in directing the proper course of their studies, and what waste of time and neglect of objects of importance would ensue, and who were somewhat sceptical as to the possibility of constituting an Examining Board of the assumed perfection, naturally regarded such a proposal as rather visionary; and, in fact, so little was it likely to be assented to by those who would be responsible for its results, that it excited but little discussion. It may not, however, be amiss to refer to what others think of such a line of procedure where it has been to some extent adopted:—

In commenting upon the reopening of the Medical Faculty of Paris, the *Union Médicale* of last Saturday forcibly deplores the procedure which allows the French students to pick up their knowledge when, how, and where they can, and actually proposes a course of lectures in order to teach them what might be so easily and advantageously authoritatively laid down for them.

"Truly it was pleasant to see and feel this animation where last year all was so silent and so sad. Last Monday the Quartier de l'École de Médecine resumed all the appearances of old times. Judging from the great amphitheatre, which overflowed at the Introductory Lecture on General Pathology, by M. Chauffard, the number of students must be considerable. Whether the new ones are more numerous than in former years can only be known when the register is closed. Nothing, in the meantime, indicates that our Faculty has in any way modified its habits or its programme of instruction. Everything seems as if it is to go on as heretofore—that is, the theatre is opened and lectures are to be delivered, the students frequenting those of them they please, providing they present themselves for examination. Of method, direction, advice, not a shadow is to be seen. If liberty of teaching does not exist absolutely for those who teach, the liberty of study is certainly complete enough for those who are taught. They do just as they please—attend what courses they like, without rendering account to anyone (except at the examinations) of the employment of their time or the direction of their studies. That is how it is; and for many years past has this cruel and dangerous abandonment of the student on entering our Faculties been pointed out. Nothing has been done—nothing has been changed. Amidst all the desiderata which the teaching of the Faculty stands in need of, one is almost afraid of being accused of rashness in pointing out two others, which, however, are not of minor importance. We could wish, then, that two new courses of lectures were established, the one for students commencing, which might be termed 'Methodology of Medical Studies,' and the other for those finishing, and designated as 'Medical Deontology.' For the student who is beginning his career, would it not be serviceable to indicate the order and method, if he would not go astray and lose precious time, in which he ought to commence and pursue his studies; teach him how to avoid false routes; preserve him from a perplexity of choice, and exhibit to him that bond which unites all portions of science, so as to preserve his mind from confusion by enabling him to perceive the concordance and harmony of biological science? And for the student who has completed his studies, should we not be performing an excellent office in instructing him in the duties and the rights of the Physician towards himself, towards his *confrères*, towards society, and towards Government, cautioning him against the dangers, embarrassments, perfidies, and the thousand little hurtful incidents which await the young Practitioner upon his entrance on his career?"

APOTHECARIES' HALL, DUBLIN.—The Governor and Council have announced as the subject for the prize examination next year the "British Pharmacopœia." This was also the subject of examination last May. The prize, which is five guineas, will be competed for by apprentices on the first Monday and Tuesday in May, 1872.

A RETIRING PENSION of £550 per annum has been granted to Surgeon-Major J. P. Brougham, of the Indian Medical Service.

MISS NIGHTINGALE ON "LYING-IN INSTITUTIONS."

MISS NIGHTINGALE has just published a small volume of "Introductory Notes on Lying-in Institutions," together with a proposal for organising an institution for training midwives and midwifery nurses. The name of the author, and her long and well-known connexion with sanitary questions, will no doubt attract a large share of public attention to the work. At the outset of her inquiry as to what is the real normal death-rate of lying-in women, Miss Nightingale admits that midwifery statistics are in an unsatisfactory condition. She refers to Dr. Matthews Duncan's suggestions for the improvement of the records of obstetric practice, but without attempting to explain the enormous variance between the conclusions of that gentleman and of Dr. Evory Kennedy on the influence of aggregation on the mortality of lying-in women—the latter, from the statistics of the Rotunda Lying-in Hospital in Dublin, having, as our readers must be aware, formed the opinion that aggregation immensely increases the mortality; and the former, from the same records, treated in a different way, having drawn exactly the opposite inference—that the mortality in the Rotunda Hospital was lowest during the periods in which the greatest number of women were delivered. She virtually adopts the opinions of Dr. Evory Kennedy. She, however, neither mentions his name nor alludes in any way to the remarkable paper "On Zymotic Diseases, as more especially illustrated by Puerperal Fever," read by him before the Dublin Obstetrical Society in 1869, or to the subsequent discussion. She is, nevertheless, strongly in favour of small "lying-in institutions," as distinguished from large special "lying-in Hospitals." She objects to the name and idea of "Hospital"—so long as that means a place for the reception of diseases and accidents, from which a certain death-rate is inseparable—being applied to a building intended for the reception of lying-in women. "Lying-in," she asserts, is neither a disease nor an accident at all; and she maintains that, from causes unconnected with the puerperal state, no woman ought to die in her lying-in, that there ought in a "lying-in institution" to be no death-rate at all, and that a death in childbed is almost a subject for an inquest. She further assures her readers in another place that parturition is neither infectious nor contagious; for which we most sincerely say, "*Deo reddantur gratiæ!*"

With regard to special lying-in Hospitals, she asks—Does not the whole evidence point to the one conclusion, that, unless it can be clearly shown that the enormous death-rates which prevail in them can be abated, or are altogether inevitable, such establishments should be closed? She sums up the results of her inquiries into obstetric statistics with the remark that a woman in ordinary health, subject to the ordinary social conditions of her station, will not, if delivered at home, be exposed to any special disadvantages likely to diminish her chances of recovery; but, if she be received into an ordinary lying-in ward, together with others in the puerperal state, she will from that very fact become subject to risks not necessarily incident to that state. Without vouching for the entire accuracy of Le Fort's data, she still considers them to show approximately the penalty which is being paid for the supposed advantages of these institutions—viz., that for every two women who would die if delivered at home, fifteen must die if delivered in lying-in Hospitals—a statement which differs but slightly from that made by Dr. Evory Kennedy, that, in all the deaths that have occurred in the Rotunda Lying-in Hospital, Dublin, for the last seven years, in parturition, out of every nine deaths seven and a half women have died who would in all human probability be at this moment alive had they been confined in their own homes or in isolated cottage Hospitals. The usefulness of lying-in Hospitals as training-schools for midwives and students can also hardly be maintained, when, as Miss Nightingale observes, we thereby "ensure killing a certain number of mothers for the sake of training a certain number of midwives." If we are to have a training-school at all, she maintains we must, above all things, make it as safe to enter it as to be delivered at home; and, having made up our minds as to what is necessary for this purpose, we must pay for it.

The results of the experiment tried in King's College Hospital, of having a lying-in institution and training-school for midwives, in connexion with that establishment, from 1862 till

1867, were so unfortunate, that the wards were closed, and the experiment abandoned. Miss Nightingale illustrates by a plan the structural defects of the part of the building told off for the purpose, and details various objections on hygienic principles to the site, and to the admission of students from the general to the lying-in wards. She also describes the Maternité, and the Hôpital de la Clinique, Paris, and Queen Charlotte's Lying-in Hospital, London, showing the defects in each, and giving plans of the two last named. She also details the very favourable results attained in the lying-in wards of the Liverpool Workhouse, and in the Waterford Lying-in Hospital.

The experience of the Liverpool Workhouse lying-in wards is very remarkable, as having, although working under many singular disadvantages, escaped the usual fatality of special lying-in Hospitals. During thirteen years, in 6396 deliveries there were 58 deaths, giving a total death-rate of 9.06 per 1000. The deaths from puerperal diseases were 22, equal to 3.4 per 1000; from accidents of child-birth, 14, or 2.2 per 1000; the aggregate death-rate from puerperal diseases being 5.6 per 1000. These deaths are said to include all among puerperal women delivered in these wards, whether occurring within or without the maternity division. To this Mr. Barnes, the Medical officer of the establishment, can answer with certainty for the last five years; also that, as no puerperal woman is discharged from the workhouse unless in perfect health, no puerperal death can have happened after discharge. In 1868, 1869, and 1870 there were 1416 deliveries, including twenty premature. Six mothers died from all causes, of which three at least were non-puerperal. The total death-rate was only 4.2 per 1000.

In the delivery ward are seven beds, with nearly 1200 cubic feet per bed; the number of beds occupied at a time rarely exceeds four or five. The lying-in ward contains 14 beds, at 900 cubic feet per bed, and of these all or most are generally occupied. In the convalescent ward there are 11 beds, at 762 cubic feet to each; these also are generally all full. In the wards for pregnant women are 24 double beds, generally full, accommodating 48 women, at 345 cubic feet per inmate; but as these women are engaged during the day in various occupations within the workhouse, they only inhabit the wards at night. The wards are so divided off by partitions that each has windows on only one side, but the wing of the Hospital in which they are situated has windows at both sides, and at one end. The water-closets are between the wards, in a very objectionable position. The floors are washed daily. The bedclothes are changed after each delivery, and the beds, which are of straw, after every third delivery. The patients are for the most part unmarried women: during the three years from 1868 till 1870, out of 1401 deliveries, 936, or two-thirds, were those of unmarried women, among whom only 6 deaths, or 4.2 per 1000, occurred.

Until recently, the whole of the deliveries, averaging 500 a year, were under the charge of one paid officer and a pauper, who, without any payment or extra diet, delivered nearly every case, and worked both night and day. The high and well-ventilated site, the absence of connexion with a general Hospital or Medical school, the constant change of wards, frequent cleansing and limewashing, short detention of women in the lying-in division, the deliveries being attended by a woman specially attached to the delivery ward, no part of whose duty it is to attend sick, the immediate isolation or removal of cases exhibiting feverish symptoms, and the reduction of intercommunication between the lying-in and Hospital divisions to the smallest possible degree on the part of Medical officers and nurses—are the points of management to which, in spite of defects, Miss Nightingale attributes the favourable results. But in these respects the Liverpool Workhouse lying-in wards are surely not so singular as to account for the marvellously low death-bed mortality observed during the three years from 1868 till 1870—not higher than in the healthy districts of England.

As instances of the results of improved lying-in ward construction, Miss Nightingale refers to military female Hospitals, in which the death-rates have been comparatively low. Excluding Aldershot Hospital, as being unfit for childbirth cases, the total mortality in the other seven Hospitals referred to, for periods varying from two to twelve years, was 7.4 per 1000. The mortality from puerperal diseases was 2.7, from accidents of childbirth 2.7, and from the two combined 5.4 per 1000. At Shorncliffe and Colchester, two camp Hospitals for lying-in cases, consisting only of wooden huts, have yielded very important experience. At the former, up to December, 1869, in 702 deliveries, there occurred one death from scarlet

fever, one from hæmorrhage, and two following craniotomy. There was no death from puerperal disease. At the latter, which has been in use for a considerable number of years, there have been altogether 500 or 600 deliveries. The matron states that during the whole time no death has occurred in it. But statistics have only been kept from 1865 till 1870, during which period, in 252 registered deliveries, there were no deaths. There have thus been 954 registered deliveries in the two huts, and four deaths, of which three were due to puerperal accidents, and none to puerperal diseases. They are both detached buildings, or rather huts, having no connexion with any general Hospital. They contain very few beds; that at Colchester only four, each in a small separate room. The beds are seldom or never occupied all at one time—and, indeed, at Colchester there is seldom more than one, or, at most, two beds constantly occupied throughout the year—and the woman rarely remains more than ten or twelve days in Hospital.

Taking these hut Hospitals as the pattern, Miss Nightingale gives a full description of her ideal of what the "lying-in institutions" of the future should be. She gives a series of illustrative plans, designed by Lieutenant Ommaney, of the Royal Engineers, of the "ward-unit" in such institutions. The maximum number of beds should be four; in one plan the beds are all in the same room, but in the other in separate compartments, as at Colchester; and this, she states, is to be the plan on which in future all military female Hospitals are to be constructed. She fixes the minimum of ward cubic space for a lying-in woman, even when the delivery-ward is, as it ought always to be, separate, at 2300 cubic feet in a single-bed ward, and 1900 cubic feet in a four-bed ward. Each "ward-unit" has its own offices perfectly distinct: these offices include scullery, with a fireplace, dresser, linen-press, and sink; another small room containing stove, bath, slop-sink, and water-closet. A corridor nine feet wide, and thoroughly ventilated, separates the ward from the offices. The wards have opposite windows, fireplace, foul air outlets, and fresh air inlets, and, besides the beds, should contain as little furniture as possible. A further design is given by Lieutenant Ommaney for the combination of a number of such wards into a building designed as a training institution for midwives, comprising also quarters for the matron and other officers, as also for the pupil midwives. The design appears to us admirably suited for the purpose; it obviates completely the possibility of overcrowding, and provides, as far as can be done, for a completely separate atmosphere for each pavilion. There are four delivery-pavilions—two in each wing, on two floors—each containing three beds; one pavilion only is to be used at a time. There are three wards in each wing on the ground-floor, and two in each wing on the second-floor, each containing four beds. There will be six delivery beds and four or eight lying-in beds always unoccupied, and there will remain accommodation for six simultaneous deliveries, and for thirty-two or thirty-six lying-in women. There will be a special detached ward for febrile cases, behind the building.

The plan is admirable; but the difficulty as to the nursing and administrative staff at once arises. As Miss Nightingale observes, no charity or institution could bear the expense of a single-bed ward or even a four-bed ward lying-in establishment for a pretty constant succession of thirty-two patients unless there were a training-school. Even with a training-school the first year would be one of great difficulty, as the first batch must necessarily be all fresh hands. Miss Nightingale only attempts a guess at the amount of nursing accommodation for so completely new an experiment as a lying-in institution of forty beds in single-bed or four-bed pavilions. One matron, one head midwife, one assistant-midwife, one deputy assistant-midwife, and thirty pupil midwives, a cook, a housemaid, and one or two other female servants would, she says, be necessary. Two experienced nurses might be required in addition during the first year. The expense of all this would be very great; but, as Miss Nightingale's design is to train ladies as scientific Physician-Accoucheuses—not, she observes, as Medical men—the fees from pupils of that class should be considerable. The experiment of such an institution certainly deserves trial. She addresses, in the appendix, those ladies who desire the education of Medical men as her "dear sisters," or, with characteristic irony, "*chers et très-honorés confrères*." We will not enter into any argument with her on the question of Midwifery as a career for educated women. Her statement that all women would prefer the attendance of educated Physician-Accoucheuses to that of male obstetric attendants appears to us rather too general. But if ladies devote themselves to the necessary preliminary studies—including, as Miss Nightingale tells them, dissections and

post-mortem examinations—and acquire in such an establishment as Miss Nightingale has described a thorough knowledge of the obstetric art, and if they prove themselves physically fit, we see no reason why they should not practise it among those who prefer them to male attendants. The course of education, Miss Nightingale says, must certainly be not less than two years. All the Professors must at first be men, but probably in time all or nearly all would be women.

Whatever Miss Nightingale undertakes she works at with a zeal and devotion which long-continued bad health has not impaired. Whatever she says attracts and deserves public attention; and she says it in a manner peculiarly her own, with a dash of harmless exaggeration, just enough to give piquancy to her observations. We have no doubt that the present work will have numerous readers, both in and out of the Profession.

To all who are interested in the welfare of our poorer classes, and particularly to those engaged in the construction of cottage Hospitals, the work now before us will supply most valuable information and many most suggestive hints.

The book is dedicated, "without permission," to the shade of Socrates' mother, who in life had been herself a midwife, and the questioning shade of the philosopher himself is invoked for assistance. We hope that the spiritualists may not, on the strength of this classical allusion, claim Miss Nightingale as a medium.

REVIEWS.

Lehrbuch der Ohrenheilkunde, mit besondere rücksicht auf Anatomie und Physiologie. Von Dr. JOSEF GRUBER. Wiener: Carl Gerold's Sohn. 1870.

Manual of the Treatment of Ear Diseases, with special reference to Anatomy and Physiology. By Dr. JOSEPH GRUBER. Vienna. 1870.

ALTHOUGH Great Britain may justly claim to have taken the lead in establishing Aural Surgery (and many other branches of Medicine) on a truly scientific and practical basis, yet in recent years no work of real importance, or anything like the one under review, has appeared (Toynbee's work must of course be excepted).

Wilde and Toynbee are names of which we may justly feel proud, and it may safely be said that England is not, even now, without aurists of deservedly good reputation; nevertheless, as a nation, we are very much behind the Germans in our scientific knowledge of the healthy and diseased states of the ear, and, consequently, in our practice. The chief reason for this is probably the ignorant and misguided belief which prevails with many, that little or nothing can be done for ear diseases, that they do not admit of scientific study, or that they are very difficult to diagnose. There is, no doubt, some truth in the first and last statements, but the second is utterly untenable, and no one in the least conversant with the laws of acoustics and their practical application to the ear would uphold such a view. And here is one great blank in all English works on the subject—viz., that they take no heed of physiological acoustics. The ear can no more be thoroughly understood without a previous good elementary knowledge of acoustics than can the eye be profitably studied without a moderate foundation of optical knowledge. If the acquisition of a modicum of acoustic principles were to precede the practical study of the ear, many of the alleged difficulties would vanish, and there would be good hope that not only the comprehension of Aural Surgery, but also its advancement, would be promoted. As in the eye, so in the ear, scientific principles applied to its diagnosis and treatment cannot fail to yield good results.

Another reason for the neglect of Aural Surgery in England is, that, until recently, no special provision for the treatment of ear cases, and the instruction of students and Practitioners in this branch of study, has been made. It really is astonishing that the Medical staffs of the various metropolitan and provincial Hospitals, who must, or should be, cognisant of the general bearings of Aural Surgery, have not earlier seen the necessity of appointing either a member of their own body or a specialist to the charge of this department. We have long thought, and still continue to think, that for many reasons it is, perhaps, better to appoint a general Physician or Surgeon to superintend a special department, as it is more probable that one who is in the habit of looking at the system generally runs less risk of becoming "groovy" or merging into the mere specialist. However, let this be as it may, the necessity of supplying this want in Medical education is still urgent, and must be met. The demand

exists, and the supply must be forthcoming; and we hope that, by this means, before many years, quacks will be driven from the field. But now to Gruber. The first 151 pages are occupied with an account of the anatomy and physiology of the organ; they contain the substance of recent researches on the subjects, and a few original observations, and are altogether excellent. On pages 150-1 are some brief but interesting remarks on Helmholtz's theory of sound-sensation and perception, and of the irritation-action of the auditory nerve.

The "general part" of the work deals, in its first chapter, with the Examination of Patients, and the description of the mode of using the various aural instruments for diagnostic purposes. In the second chapter he treats of the General Pathology of Ear Diseases, and in the third of their General Therapeutics. We will consider them briefly in their order, touching only on noteworthy points. At pages 186-7, etc., he describes the mode of examining the posterior nares and fauces with the rhinoscope, and also with Türk's tongue spatula. It would be well if English Surgeons practised themselves more in the use of these aids to diagnosis. There can be no doubt of their value in skilled hands, and the detractors of this mode of examination must be classed among those who cannot or will not employ it.

When describing Politzer's method, he enters into a controversy respecting the priority of discovery and application of it, and claims to have originated and used it before Politzer. Much credit is, no doubt, due to Gruber, as having been among the first to use this method, and possibly to discover it; but to Politzer, nevertheless, is due—in our opinion—the praise of having reduced scientific principles to intelligent practice. We quite agree with our author in the opinion that this proceeding is inapplicable to the production of diagnostic auscultatory sounds, and are, further, of opinion that it frequently complicates instead of clearing up matters.

When treating of the introduction of liquids through the Eustachian tube, he makes no mention of his own paper in the *Wochenschrift der K.K. Gesellschaft der Aerzte*, No 9, 1862, p. 72, by which it would appear that he was one of the earliest to employ this manner of treatment, especially with reference to the prevention of the collection of free secretions in the tympanum.

We ought to have noticed before, that when discussing (at page 231, etc.) the use of the tuning-fork, he puts more faith in the diagnostic value of the instrument than Aural Surgeons of experience are inclined to accord to it. We regret to find that no sufficient notice is taken of the writings of Lucae and Politzer on physiological sound-conduction and propagation.

The author strongly recommends (at page 261, etc.) the use of his method of syringing through the Eustachian tube without the aid of the catheter, especially in cases of nasopharyngeal catarrh. It is, doubtless, a useful and safe method, and should be generally adopted in such cases. We find no mention of T. Weber's nasal douche, which is a useful instrument, though not without its dangers. See *Archives für Ophthalmologie und Otologie*, Band 1.

In the special part the author describes the Malformations, Symptoms, Prognosis, and Treatment of the various affections of the three divisions of the ear. We will just draw the reader's attention to the description of fibrous tumour of the lobule after puncturing it, and the accounts, with references to the original papers, of such growths in negroes; also to the notices of the ear fungus of Wreden, the *Aspurgillus glaucus*. Schwartz pointed out that the relapses so common in some inflammations of the external auditory meatus are due to the presence of this fungus. We look on *aspurgillus* as much more frequently the result of the external inflammation and suppuration than as its cause, and we presume this is the view of Schwartz. In the severer forms of otitis and periostitis, the author mentions the possibility of the inflammation extending to the membranes—a matter worthy of the serious attention of general Practitioners. The treatment recommended is incisions down to the bone. The sections treating of Myringitis and the Lesions of the Tympanum due to Injury are excellent, and well worthy of careful reading. In the portions treating of Otitis Media, the author rejects the classification of Von Tröltzsch, and adopts his own—viz., otitis catarrhalis, purulenta and hypertrophica. He gives a *résumé* of what has already been done, without, however, sufficiently separating those evidences which belong to the acute inflammations from those which appertain to the chronic. He points out that the purulent form may end fatally, and recommends paracentesis of the membrana tympani, without giving any particular time at which to perform it. We should have liked more definite information on this

point, as Aural Surgeons are, in our opinion, inclined to delay this operation longer than the severity of the disease justifies; and considering that the proceeding, though rather painful, is not difficult, and very rarely serious, we think that the operation should be performed, and that the approximative time for interference is between thirty and fifty hours from the onset of active symptoms. The difficulty is to keep the opening patent, but this might be effected by a piece of perforated lamina. The author recommends astringent injections; but, knowing the frequent obstinacy of the disease in its later stages, we should in these cases resort to the caustic treatment of Schwartz where circumstances did not contraindicate it. The hypertrophic form, in the author's opinion, frequently ends in complete deafness. His treatment of this and the other forms of median otitis does not come up to what we expected of him; and considering that these affections are among the commonest of those to which the ear is liable, we anticipated a much more full, explicit, and satisfactory section on this subject. The sections on Etiology, Nosology, and Symptomatology are almost all that can be desired; but we must be pardoned for saying that in our comparative inexperience we looked to so deservedly high an authority for more complete information on a matter of such practical moment, and were disappointed. Both the general Surgeon and aurist will do well to peruse the sections on Caries and Necrosis of the Temporal Bone, and on Perforation and Trepanning of the Mastoid Process. They contain valuable practical information.

In the chapter on the General Pathology of Ear Diseases the author dwells on the necessity of Aural Surgeons being men of good general Medical education, and in this we fully agree. This observation should apply to all specialists; but we would go further, and lay stress on the absolute need for gentlemen devoting themselves to special studies to keep themselves *au courant* with the advances in *general Medical knowledge*. General Surgeons and Physicians should also be well informed in the practice and lore of special departments. In this way they would be enabled more readily to perceive the mutual actions and relations of the general and constitutional on the local, and *vice versa*; and they would be able, each in his own department, to further the great body of Professional knowledge. Specialists have done much for their specialities, and general Surgeons and Physicians would do well to obtain a moderate knowledge of them if they wish to prosecute their Profession in its entirety and to their own satisfaction and advancement.

As an illustration of the neglect (as we suppose) of being conversant with recent literature on other subjects, we need only draw attention to the statement of the author, in the fourteenth chapter, that statistics of the operation of iridectomy in glaucoma show that in the majority of cases it proved unsuccessful! Surely this is against all experience, and such an assertion could hardly have been made by anyone who had studied ophthalmology and was familiar with its recent developments.

The sections on "Myringotomy and Myringectomy" are valuable, and in them the author describes and illustrates by engravings instruments which he has devised for these purposes, and explains his method of operating—they will well repay perusal. But in this connexion, and with reference to the treatment of growths in other parts of the ear, we should have been pleased to see recorded the experience of the author on the value of the galvanic cautery. He gives indications for the operations above mentioned, and speaks well of his results in cases of obstructed Eustachian tube and tinnitus.

The fifteenth chapter, treating of New Growths in the Middle Ear, is most excellent, and far superior to anything of the kind in other works with which we are acquainted. In polypi the author advises early removal, which no doubt is essential to prevent accumulation of pus behind the growth, and its consequences. Chapter 16 deals with Affections of the Internal Ear, and is on the whole instructive; but it may be questioned if the author be correct in considering the pigment found in the cochlea as always a pathological product. Lucae and Kölliker have observed it both in normal and diseased ears of adults. The author further thinks that inflammations of the middle ear are usually complicated with hyperæmia of the labyrinth. We cannot speak at all positively on this point, and should like more evidence before giving an unqualified adhesion to this view. We look in vain for any account of the relation between nervous diseases and ear affections, and think that Vienna could supply numerous opportunities for observation in this matter. The engravings and chromo-lithographs are good, but there is no index, an omission which we hope to see rectified in another edition. We must now take leave of Gruber; and when

we say that the work is not quite a complete or exhaustive one, and that its style is sometimes obscure, we do not for a moment mean that otherwise it is not most excellent. Gruber has done good and lasting service to Aural Surgery by this publication, and we heartily recommend all interested in the subject to procure and study the work.

Germany and Austria can boast of Politzer, Tröltzsch, Schwartze, Lucae, Moos, Helmholtz, Rüdinger, Voltolini, and others; France, of Bonnafont, Itard, Triquet, Menière; and England of Tyndall, Toynbee, Wilde, and Hinton; but we have yet much to do before Aural Surgery in Great Britain can vie with that of its Continental *confrères*. We want *scientific* as well as practical workers, and require that to this end the subject should be well taught in the schools.

Text-book of Skin Diseases. By DR. ISIDOR NEUMANN, Lecturer on Dermatology in the Imperial University of Vienna. Translated from the Second German Edition, by special permission of the author, by ALFRED PULLAR, M.D. Edin., Physician to the East London Hospital for Children. London: Hardwicke. Pp. 329.

OF late years it may have been fairly said that the French and English schools of dermatology, eminent though they be, have been fairly eclipsed by that of Vienna; for, just as Von Graefe made Berlin the first school of ophthalmology in the world, so Hebra has acquired for Vienna a similar reputation as regards skin diseases. And the onward impulse has not stopped with him alone, for in this book of Neumann's, though we can see traces of the influence of Hebra's master-mind, nevertheless we can also see the results of abundant work on the part of the author.

The English system of grouping skin diseases has long seemed to us most trivial; accustomed as we have been to have paltry distinctions drawn between blebs of different sizes and swellings in different situations, the whole overlaid with a heathenish jargon of bad Greek terms, it was not to be wondered at that the study of skin diseases speedily palled on the mental appetite, insomuch that it was a positive relief to escape to the somewhat illusory and vapourish doctrines of the French as to darts and other diatheses. For these reasons we gladly welcome an admirable translation of a book which tends to place skin diseases on a level with others which have been the subject of rational study. The basis of modern Medicine is pathology, using the word in its widest sense; and of the two great methods of investigation which have been instrumental in its advance, the histological has far outstripped the chemical. It is, therefore, satisfactory to have before us a pathology of skin diseases elucidated in similar fashion; and in this it seems to us that Neumann has been eminently successful. The book is not a very large one, yet in it we have a careful account of all the normal and abnormal conditions of the skin, with some very excellent illustrations of the same. These are mostly new to us, and, as Dr. Pullar has been favoured with casts of Neumann's blocks, we have copies quite equal to the originals. To those to whom this portion of the subject is new, these illustrations will be objects of much interest, for it is not always easy to procure microscopic sections of diseased skin, especially in England, where there is no grand centre for their study, like the Allgemeine Krankenhaus in Vienna.

Neumann's book can well afford to stand on its own merits; it remains to say a word as to the translation. As aforesaid, this is most carefully done. In the first place, Dr. Pullar qualified himself for his self-imposed task by a residence of some duration in Vienna, and by study of the subject under both Hebra and Neumann; and in the second, his translation is the work of years instead of months. The rendering is good, and the book—in spite of a somewhat awkward size of page, necessitated by the size of Neumann's blocks, and some printer's errors—is a most convenient one. We cordially commend it alike to those who have and those who have not studied skin diseases in this country.

Notes on the Treatment of Skin Diseases. By ROBERT LIVEING, A.M. and M.D. Cantab., Demonstrator on Diseases of the Skin, and Senior Assistant-Physician to the Middlesex Hospital. Second Edition, with additions. London: Longmans, Green, and Co. 1871.

The rapid sale of the first edition of this most useful little book is sufficient evidence that our first warm commendation was well merited. The writer has very wisely refrained from increasing the bulk of the volume by more than a few pages in this new edition, so that it is still a *bona fide* "pocket com-

panion." At the same time, some important additions have been made, of which the chief are hyperidrosis, vaccinia, varicella, and diseases of the nails, with some further valuable suggestions for the treatment of some of the more obstinate forms of eczema, and other skin affections. We are sure that students and practitioners alike will feel grateful to Dr. Living for providing them with such a complete manual in so convenient a form.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

EDINBURGH, November 13.

THE news that the Queen has been pleased to confer on Dr. Christison the honour of baronetcy, has been received by the Medical Profession and the public generally with the greatest satisfaction. It is the universal feeling that Dr. Christison has long been well deserving of such a distinction. It is also highly creditable to Scotland, to Edinburgh, and to the Medical Profession in this city, that a second time within a few years this high honour has been bestowed upon a Medical Professor in our University.

Dr. Christison's career is as well known as it has been distinguished. He was born in 1797, is the son of the late Alexander Christison, Professor of Humanity in the University of Edinburgh, and twin brother of the Rev. Alexander Christison, of Foulden, Berwick, a well-known scholar and man of taste. At the early age of 25, Dr. Christison was appointed Professor of Medical Jurisprudence, and ten years later was transferred to the more important chair of *Materia Medica*. Dr. Christison's writings on both of these subjects are many and important. His "Treatise on Poisons" is a standard work, well known throughout Europe. More than any other living man, he represents the Medical Profession of Scotland. Since the passing of the University Act in 1858 he has been the representative of the Senatus in the University Court. He has sat as one of the Crown nominees in the General Medical Council of Education and Registration since its commencement. At the present moment he is President of the Royal Society of Scotland. He is also Physician-in-Ordinary to the Queen for Scotland. All who know Sir Robert Christison will heartily unite in the desire that he may long be spared, not only to enjoy his new honour, but also to be—as assuredly he will be—an honour to the baronetcy.

The election of a Lord Rector of the University took place on Saturday last. This was preceded by the usual biddings of youthful eloquence and genius, and accompanied by the ordinary amount of peas, cabbages, and crackers. The latest and most effective missile was a little bag of thin paper filled with flour, which abounded like a snow-storm. It was an important feature in this election that the majority of the Medical students were disposed to make the question of female Medical education a vital one.

At a meeting which they held on the night of Wednesday last, in reference to this contest, Mr. Aitchison moved that the meeting should pledge itself to vote for no candidate who was not known to be opposed to mixed classes. He stated that he had asked Sir William Stirling Maxwell his opinion on this subject, and that Sir William had answered that he had not considered the question, and that, if he had, he would not state his opinion. He said, further, that Sir Roundell Palmer had been asked—"Is your opinion favourable to mixed Medical classes?" To which he had replied by telegram—"My opinion is not favourable to the education of male and female students in the same Medical classes." Mr. Cunningham Craig moved an amendment in favour of Sir William Stirling Maxwell, stating that he thought no man of honour would give such an opinion as that asked by Mr. Aitchison. The motion and amendment were put to the meeting, when upwards of 250 voted for the motion, and only 8 for the amendment.

At the election on Saturday, Sir W. Stirling Maxwell was returned at the head of the poll with a majority of 92 votes, 594 having voted for him, and 502 for Sir Roundell Palmer.

I have mentioned the fact of the importance attached in this election by the Medical students to the female Medical question. Let it not, however, be supposed that the result is therefore in favour of the ladies; for, although Sir William Stirling Maxwell refused to give any pledge on the matter, it was generally believed that he was opposed to mixed classes. The fol-

lowing is from a leading article in the *Courant* of Thursday last:—"We confess that we should indeed be very much surprised to find that Sir William Stirling Maxwell was in the least degree favourable to Medical classes for the joint and simultaneous instruction of male and female students, nor have we the slightest doubt that he is quite opposed to them." So that, while the opinion of the Medical students came out strongly in the election, the result of the election cannot be said to prove anything in this matter. Indeed, we know that many of the students who are strongly opposed to female Medical education voted without fear or hesitation for Sir William Stirling Maxwell.

At last the Senatus have done the right thing. At a meeting held on Saturday they resolved by a majority of 14 votes to 13 to rescind the existing regulations for the admission of female students to the University. It will be remembered that all that was at first promised was that an experiment should be made. The experiment has been made to the extent promised, and the results have not proved encouraging. If the University authorities can escape from the awkward predicament into which they have allowed themselves to be decoyed, it may not be altogether a matter of regret that the experiment has been made.

In the meantime the moral of the story is surely this. It is not always safe to let in the small end of a wedge, be that small end ever so polished and apparently harmless. A little farther on in the side of the wedge may come a trap, in which even University authorities—Medical Faculty, Senatus, University Court, General Council, and Chancellor—may find themselves caught, and perhaps painfully constrained to drag in after their entangled limbs the whole unknown creature with all its incalculable consequences.

IRELAND.

DUBLIN, November 13.

ON the 6th inst. an introductory lecture was delivered in the theatre of Jervis-street Hospital by Mr. Kelly, one of the Surgeons of the institution. The lecturer, in the course of a very able address, gave an interesting historical sketch of the Hospital, from its foundation, in the year 1726, to the present time. He stated that the Managing Committee had determined to erect a new Hospital, in consequence of the inadequate accommodation afforded by the present structure to the daily increasing wants of the suffering poor. From the situation of Jervis-street Hospital, in the immediate neighbourhood of a densely populated and poverty-stricken district of the city, in which severe accidents are of frequent occurrence, the philanthropic design of the Committee is well worthy of public support.

At the Adelaide Hospital the session was inaugurated, as I mentioned briefly in my last letter, on Monday week, by an address from Dr. Barton. The lecturer said that public Hospitals fulfilled a twofold object. They provided relief for human suffering, and they afforded a school for the technical instruction of students in the wards, this clinical training being the very fountain-head of Medical knowledge. The primary object of Medical skill was, and should ever be, the alleviation of actual bodily affliction, the prolongation of human life, and the prevention of deformity. The secondary purpose of Medical study was little lower than this, its chief aim—namely, to discover the sources and causes of disease, to suggest the means by which they might be prevented, and to obtain methods by which the various forms of external injury might be rectified. In this light, Medical Practitioners were divided, by an obvious distribution of labour, into Physicians and Surgeons; one of these classes was concerned with the nature of natural and organic disorders, and the other with external injuries. He referred to further subdivisions of Medical science—to the branches concerned with ophthalmic, auricular, obstetric, and other diseases—and remarked that such subdivisions had been already carried as far as was expedient. Excessive splitting up of the highways of Medicine into too minute branches might tend to obscure the main features of broad natural laws, and to lead to all bodily disarrangement being referred to the same cause. The Physician should care for the whole human race, without distinction of race, religion, or complexion; and he trusted that when it came to the turn of those whom he was addressing to apply their acquirements, they would never allow such distinctions as these to interfere with their anxiety to assist the afflicted and soothe the weary. When their sympathies were touched by application for relief, they should remember to place pecuniary reward as a purely secondary

matter in their consideration. These exalted motives they should never lose sight of in executing the noble work of their Profession. They should ever keep in check all unworthy impulses, and place recompense beyond their immediate calculation, no matter what case they should be called on to visit. He would now address them with respect to a subject known as Medical ethics, which might be defined as the code by which the immediate intercourse of Medical men with their patients and with one another should be regulated. With regard to patients, the Medical man was always bound, as he had already said, to give the best advice in his power, irrespective of what the position of the sufferer might be, making the diagnosis carefully, and treating accordingly. While he paid all due deference to any little prejudices of the patient, the Physician should never make any compromise with quackery, nor allow his regard for the opinion of some old woman to permit any nostrum to be tried upon a patient in his charge. If there was danger to the life of a patient, should the Medical man tell him so, or encourage him by holding out hopes of recovery which were unlikely to be realised? When death was imminent, it would certainly be false mercy to deceive a patient; but as long as there was no immediate danger, and a hope of recovery, it was better to cheer him forward. There were many instances in which people who laboured under organic disease of the heart lived well for many years. If those persons had been informed of their actual condition their lives would have been rendered miserable, and their deaths would, in all probability, have been hastened. The friends of the patient, however, should be honestly made acquainted with the true state of the case, although there were times when it was even more prudent to express to them a quiet doubt than to give a decisive opinion one way or the other. When they had to deal with cases which had been previously under the care of another Medical man, the most generous care should be taken to say nothing to damage his reputation, even when they had to differ from him and adopt a different course of treatment. The Army Medical Service now afforded fine openings to young Medical men. The dispensary Doctors of this country were still, however, for the most part, placed in an unsatisfactory position. The position they occupied had not sufficient official inducement to attract the best men, nor were the prospects of private practice much more encouraging. The institution of local village Hospitals, containing half-a-dozen beds, with a good, well-trained nurse to attend each, was one of the greatest desiderata in this country at present. Very great advantages would be afforded by them. In minor cases, patients would be spared the humiliation of going to the workhouse Hospitals; in more complicated ones, the delay, inconvenience, and danger of travelling fifteen or twenty miles to the county infirmary; while, at the same time, the local Surgeon would have his experience largely improved by having them from the outset under his own supervision. Institutions of the kind were to some extent established in England. They would cost very little; and he trusted that some gentlemen of property in Ireland would soon make a move in that direction.

In my letter of September 12 last, I alluded to the low death-rate of Dublin during the summer months of this year, and to the comparative immunity from small-pox enjoyed by our city up to that date. I regret to say that we can no longer congratulate ourselves on either a low mortality or an epidemic of variola disarmed of all its terrors. The death-rate, which for nine weeks from the beginning of July had averaged only 18 per thousand inhabitants annually, has risen to an average of 24.4 for the eight weeks commencing September 10 and ending November 4. The actual rates per week have been 24, 23, 23, 22, 31, 24, 24, and 24 respectively. The very exceptional (for Dublin) mortality of 31, which characterised the week ending October 14, was due to a large extent to the unusually severe weather of the last ten days of September and first week of October. The result of this was to raise the mortality from bronchitis to almost its winter level; for no less than twenty deaths were referred to this cause in the week in question. Diarrhoea, again, still continued to be prevalent, for it proved fatal in thirteen instances. In the same week ten deaths resulted from fever, and seven deaths from small-pox were registered. With the return of mild weather in the middle of October the mortality from pulmonary affections again declined.

The small-pox epidemic is assuming much more formidable proportions than was generally anticipated some time ago. Looking at the mere numbers of fatal cases published from week to week by the Registrar-General, we find that they are by no means inconsiderable; but, when we remember that in a population so protected by vaccination as is that of Dublin the mortality percent. of persons attacked must be low, we obtain a clearer

idea of the prevalence of the epidemic. In the six months ending September 2, the total number of deaths was 20. In the two months ending November 4, 51 persons died of the disease. The number per week of fatal cases registered has been, since September 2—2, 4, 4, 0, 5, 7, 7, 8, and 14 respectively. The increasing prevalence of the epidemic has caused some amount of panic among the lower classes, and the thronged waiting-rooms at the different city Dispensaries on "vaccination days" bear witness to the unpopularity of vaccinophobia in Ireland.

I may mention that the Poor-law Guardians of the North and South City Unions have proved themselves equal to the occasion, and have not only entered into arrangements with several Hospitals for the reception of small-pox patients, but also taken steps to open wards in sheds especially adapted to the purpose.

At the risk of exhausting your patience by the length of this letter, I would refer to the fact that on Saturday, the 11th. inst., the presiding magistrate at the Northern Divisional Police-court made an order for the absolute closing, after the lapse of a fortnight, of several houses in Church-street and its vicinity—one of the filthiest, most fever-stricken parts of the city. The landlords of the condemned houses had been repeatedly summoned and fined; but this was apparently without effect, for the Corporation Inspector described the basement story of these human habitations as presenting a most horrible appearance—a sea of filth covering the ground, and even oozing up through the floor, when it was walked upon. The same houses have long been hotbeds of fever, and in one of them an outbreak of small-pox has lately taken place.

GENERAL CORRESPONDENCE.

ON THE RELATION OF OSTEO-MYELITIS TO PURULENT INFECTION.

LETTER FROM DR. FORT.

[To the Editor of the Medical Times and Gazette.]

SIR,—You have probably received some account of the reading of the memoir, which M. Demarquay has presented, before the Academy of Medicine. Will you allow me to note a single point with regard to it concerning histology.

In his memoir M. Demarquay has said that osteo-myelitis often coincides with purulent infection, and that this inflammation is one of the most frequent causes of purulent infection. In anatomy and physiology it is admitted that the marrow of bone is gifted with a very energetic power of absorption, of which M. Demarquay has wished to take advantage in his experiments on rabbits. He drills through the lower extremity of the femur of the animal with a gimlet. Thus the medullary canal is reached; into this he injects some drops (from 60 to 100) of pus, and the animal dies some time after with all the lesions of purulent infection—visceral congestion, metastatic abscess, etc. These experiments recall to mind those of M. Sédillot, of Strasburg; their only object here was to demonstrate the vascular absorption of the medullary canal of bone.

At the Academy, the greater part of the members who took part in the discussion after the reading of the memoir contended that M. Demarquay had injected the pus directly into the veins opened by the perforating instrument. On his side, the experimenter contended for the contrary, admitting only an exceedingly active absorption on the part of the osseous vessels.

On which side lies the truth? It is difficult to say.

A priori, it seems more logical to admit a rupture of the veins, and the penetration of the purulent matter into their cavities. There is, however, another explanation possible, which I will try to make clear.

To understand this it is indispensable to recall some histologic ideas founded on the researches of Cohnheim, Neumann, and Bizzozero.

The treatment of tissues by nitrate of silver solution has shown to Cohnheim and Recklinghausen, as well as to other microscopical observers, that the true capillaries supposed heretofore to be possessed of an amorphous homogeneous wall, are in reality formed by epithelial cells in close juxtaposition (the endothelium of His), exactly as if they were formed by a single layer of epithelium rolled round on itself.

The remarkable researches of Cohnheim on suppuration seem to prove that pus corpuscles encountered without the capillaries are only the white blood-corpuscles which have made their way through the vessel's wall. These corpuscles, as

everyone knows, are endowed with amœboid movements of a very active kind.(a)

Thus, Cohnheim has been able several times to make out amœboid elongations of the white corpuscles of the blood, introducing themselves into the little interspaces which separate the epithelial cells forming the wall of the capillary.

On the other hand, Noumann and Bizzozero assert the foregoing phenomena, saying that the bony marrow is a blood-forming tissue. According to Bizzozero, the young medullary cells, gifted with energetic amœboid movements, penetrated the capillaries, elongating themselves between the epithelial cells of the capillaries, and went to form white blood-corpuscles which in turn transformed themselves into red corpuscles.

If the observations of Bizzozero are exact, I do not see why they cannot explain M. Demarquay's experiments. It is quite possible that pus introduced into the medullary canal of the femur should determine inflammation and suppuration of the marrow. The medullary cells give birth by proliferation to pus corpuscles; but these, above all other young corpuscles, exhibit many amœboid prolongations. These phenomena being granted (and I do not see why they should be rejected), it is logical to admit that, in the experiments of M. Demarquay, the pus corpuscles penetrated the capillaries through their epithelial covering.

I am, &c.,

Dr. FORT,

Professeur libéré d'Anatomie
à l'Ecole Pratique de Paris.

Paris, November 2.

* * * We have long been familiar with the facts alleged by Dr. Fort; and three years ago we gave an account of the researches of Neumann and Bizzozero, and shortly after had occasion to point out the important bearing they had on pyæmia. We have also repeatedly pointed out the close connexion between osteo-myelitis and pyæmia. In the American war this was especially noticed, and our esteemed contributor, Professor Fayrer, has long insisted upon their essential relationship. No doubt whatever the bony marrow consists of elements not greatly different from leucocytes, in which rapid proliferation may be set up and the wide-mouthed veins severed in operations on bone, and, unable to retract owing to their connexion with the hard bony tissue, offer them only too easy access to the current of the circulation. But this is not everything in pyæmia—much yet requires explanation.

GLOUCESTERSHIRE MEDICAL AND SURGICAL ASSOCIATION.

LETTER FROM Mr. JOHN P. WILTON.

[To the Editor of the Medical Times and Gazette.]

SIR,—I enclose a copy of a resolution and amendment which were discussed at a special meeting of the above Association, called to consider the Report of the Royal Commission on the Contagious Diseases Acts (human). The attendance at the meeting was small, the number of members present being sixteen. Many other gentlemen had expressed their intention of attending, but were prevented doing so by Professional engagements at the last moment. Of the numbers present seven voted in favour of the resolution and eight supported the amendment. In accordance with the rules of the Association, such members as were unable to attend the meeting were invited to express their views by letter. Three absent members supported the amendment and two the resolution.

I am, &c., JOHN P. WILTON, Hon. Sec.

Gloucester, November 13.

Resolution proposed by Dr. Washbourn, Gloucester; seconded by Dr. Paine, Stroud—"That, in the opinion of this Association, the Report of the Royal Commission upon the administration and operation of the Contagious Diseases Acts, conclusively proves that in all localities in which the provisions of the Acts have been enforced, great advantages, both moral and physical, have been the result. This Association therefore believes that the extension of the provisions of the Acts to all sea and inland ports of the United Kingdom would be productive of similar benefit—namely, a marked and progressive diminution both of prostitution and disease."

Amendment proposed by Dr. Morley Rooke, Cheltenham; seconded by Dr. Davey, Northwoods, near Bristol—"That, in

the opinion of this Association, the Report of the Royal Commissioners upon the administration and operation of the Contagious Diseases Acts, tends to show that whilst some physical advantages may have resulted from these Acts, the Commissioners have very grave doubts as to their moral effects and bearings, and in the face of recommendations by the Commissioners for such amendments of these Acts, as would do away with the principal objections of their opponents, it is highly inopportune for this Association to urge an extension of these Acts in an unmodified form to other parts of the kingdom."

HUTCHINSON v. WATSON.—AN APPEAL TO THE MEDICAL PROFESSION.

LETTER FROM Mr. G. S. BANHAM.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your very opportune and just remarks on the above case render it almost unnecessary for me to refer to the monstrous injustice to which Dr. Watson has been subjected. After successfully repelling a groundless attack on his reputation, by most convincing evidence, and after undergoing many months of anxious suspense, with a heavy and unwarrantable charge of improper, negligent, and unskilful treatment hanging over him—unable the meanwhile to offer one word of defence—he is called upon, after obtaining his triumph of justice, to discharge all pecuniary liability, amounting to £150, the plaintiff being unable to pay costs. The danger which every Medical man incurs in encountering actions of this unjust character is a personal one. No one can regard himself safe from such a calamity, which may involve him in ruin. It is, therefore, the duty of every Medical man to be true to the interests of our Profession—to help to the utmost every brother Practitioner who has the great misfortune of being a victim of a cruel and groundless charge of negligence and unskilfulness. In this case there was scarcely any evidence in support of the plaintiff, even if that of the plaintiff herself be included—a hysterical woman undergoing the pains of labour. The evidence in support of defendant's case was overwhelming, Dr. Keiller and other eminent Practitioners exonerating the defendant from the serious charge brought against his reputation. Where is the remedy for the injustice which Dr. Watson is called upon to bear? There is, indeed, no remedy, except it be the partial one which his Professional brethren may render him—the tangible support by which they may assist to bear the burden which has fallen so heavily on him. I need scarcely insist on the hardship of such a case. It is an injustice against the whole Profession. The Medical men of the district, who are fully acquainted with the facts, have generously supported Dr. Watson, and voluntarily came forward at the trial to give evidence in his behalf. Subscriptions will be thankfully received by Dr. G. H. Hume, 55, Westgate-street, Newcastle-on-Tyne; Mr. William Berry, 27, Steven-street, Glasgow; or by

Mr. G. S. BANHAM, Secretary.

9, Russell-street, Stockton-on-Tees.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, NOVEMBER 7.

Mr. HILTON, President, in the Chair.

THE PRESIDENT, on taking the chair, expressed his regret at having been compelled, by his duty as Examiner at the College of Surgeons, to be so frequently absent. He trusted that this year the meetings would fall more fortunately for him.

Dr. PYE-SMITH exhibited a specimen of what he termed Cystic Kidney from a young male subject. He had been suffering from diarrhoea, when, one morning, he noticed his abdomen swollen, and when examined it turned out that his left side was occupied by a large, smooth, solid mass, dull, and somewhat elastic. He had several times been kicked by horses, being a farrier by trade, and on one occasion, some years before, he had passed blood. His urine was healthy. The swelling was tapped by a small trocar, and several pints of blood and pus came away. The tapping had to be repeated more than once, and he left the Hospital. After a time he died, when it was found that the left lung was adherent to the diaphragm, and there were many peritoneal adhesions. The tumour turned out to be a large cystic kidney. The ureter was healthy, but

(a) In histology they now admit that the pus corpuscles and the white blood-corpuscles are identical (Cohnheim, Robin, Virchow).

blocked at one spot. The other kidney was swollen. Some food was found in the tumour, showing a communication with the bowel—probably the descending colon. He thought that when the man passed blood the ureter had been torn, that it had imperfectly re-united, and, finally, completely contracted.

Dr. GIBBON asked what was the cause of death.

Dr. DICKINSON thought the case might be explained otherwise. The blow to have caused rupture of the ureter must have been very severe, and would have caused great local disturbance, of which there was no history. The origin was much more probably a calculus, which had escaped gradually, and constriction of the ureter followed, which, in its turn, would cause enlargement of the kidney.

Dr. HARE objected to the term "cystic" being applied to simple dilatation of the kidney. A blow could not give rise to cystic disease. In this instance all the sacculi communicated with the pelvis of the kidney, which was not the case in cystic disease. He thought they might have this condition without any calculus, merely by a twist of the ureter, as in hydronephrosis.

Dr. THOROWGOOD was glad to hear that there might be occlusion of the ureter without a calculus, as in a similar case he had reported it was suggested that the calculus had been missed.

Dr. MURCHISON said Mr. Stanley had reported a number of cases of occlusion of the ureter from injury. He had done so, also. He thought it very improbable that there had been a calculus in this case.

Mr. HULKE did not think the traumatic origin of the dilatation untenable, as severe internal injuries were often unaccompanied by external marks.

Dr. PYE-SMITH, in reply, stated that he had no idea of confounding cystic degeneration with dilatation. He did not understand the twisting of the ureter suggested, and he did not think there had been any calculus.

Mr. SQUIRE exhibited a specimen of Ulcerated Intestine and Enlarged Kidney from a boy aged 13. Two years ago he had suffered from pulmonary tubercle, but he got better. This autumn he got diarrhoea, but he recovered somewhat, when anasarca set in. This, however, left in its turn, and he died of diarrhoea. His urine had been plentiful, of high specific gravity, and containing much albumen. There were signs of peritonitis, and ulcers in the intestine extending to the serous coat. There were grey tubercles in the lung.

Dr. POWELL asked the date of the lung disease, and the kind of kidney disease.

Mr. SQUIRE replied that the lung was affected three years ago.

Mr. HULKE said the extinction of tubercle in one part need not imply its extension in another part. This was well seen in bone operations.

The specimen of lung was referred to Drs. Powell and Whipham.

Dr. KING showed the Heart and Spleen of a patient who six years ago had Rheumatic Fever. Not long ago he complained of dyspnoea, palpitation, etc. Some time elapsed, and he complained of violent pain in the region of the spleen. A month after signs of apoplexy came on; he recovered for the time, but afterwards sank. Emboli existed in the brain and spleen. There were vegetations on the mitral valve, and a pouch projecting from the ventricle into the auricle.

Dr. MURCHISON asked the nature of the mass in the brain.

Dr. KING said there was no embolus in the anterior cerebral artery, but in its neighbourhood a cheesy mass. Nothing was elsewhere to be seen.

Dr. LEARED had that afternoon examined a somewhat similar case, the details of which he hoped to bring before the Society on another occasion. The brain was affected on the left side.

Dr. BAÜMLER asked if plugs had been found in the spleen; but the organ had not been cut up.

Dr. MURCHISON explained that these masses found in the brain are really independent of emboli, as they are often found in fevers where there has been no heart disease. In a specimen he had exhibited, the spleen had been like this, so had the kidneys and femoral arteries, the patient finally dying from brain disease, induced in the same way. There was a tendency to a deposit from the blood in these cases. Perhaps there was a similar tendency in rheumatic fever.

Dr. CAYLEY said that in heart disease the lung was thus affected by early coagulation of blood in the heart, extending to the lung. In these the coagula were formed weeks before, and after death the blood was found fluid in the heart.

Dr. PYE-SMITH suggested that these were venous thrombi carried round to the arterial system.

Dr. GIBBON objected that such would be stopped in the lung.

Mr. HULKE exhibited a number of specimens of Epithelioma, in none of which was there any family history of cancer. 1. Epithelioma occurred in the forearm in a man aged 64. Early in life his arm was crippled, and his hand remained stiff. One spot in the scar was thin. Ten years ago it grew irritable, and a wart grew, which he pared from time to time. Two years before the present date it began to enlarge much, but the axillary glands were unaffected. He amputated the arm, and the man did well. 2. This also originated in a scar on the scapula. The patient had been burned when seven years old, and the sore was three years in healing. It remained irritable in the centre. Here she received a blow; the scar broke and bled, and a warty mass grew. There was no gland enlargement. The mass was excised, and chloride of zinc applied. She did well. 3. Epithelioma of the tongue occurred in a man who had long suffered from what had been called ichthyosis of the tongue, consisting of hypertrophied papillæ. He used to pare this with his knife. Epithelioma came on. A great part of the organ was removed, but the disease returned, and he died. 4. This also was a case where the patient had suffered from leathery patches on the tongue. A knot formed in it, but a great part of the tongue had been removed by the écraseur, and the patient had done well.

Dr. EDIS said that from observations on the uterus he was inclined to think such maladies were distinctly local. When, however, they were not interfered with, three years was their general term. In one instance, where he had been able fairly to remove the disease, the patient had done well. In two others he had used the actual cautery to remove all traces of the disease, and those also had done well. In one, what was two years ago a rapidly extending epithelioma, was now practically a sound uterus. In another, the operation came too late to save life.

CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 27, 1871.

Dr. W. W. GULL, F.R.S., President, in the Chair.

Mr. HULKE exhibited a blacksmith, from whom, in August, 1870, he had removed, in the Middlesex Hospital, by excision and cauterisation, a very large Rodent Cancer of the left side of the face. It had eaten away the whole lower eyelid and part of the upper one; it had also invaded the orbit and destroyed the eyeball, and opened the frontal sinus and nasal passages. The patient returned in August last with two small growths of the size of a threepenny-piece. These were destroyed with zinc paste, and the whole surface now seemed perfectly healthy. There was now a large hollow, lined with healthy mucous membrane, showing the lower and middle turbinated bones, the openings into the frontal sinuses and nasal passages, and the antrum. This chasm could be hidden by a mask. Mr. Hulke said that the danger of operating in these advanced stages was over-estimated, and that with care the actual cautery and a chloride of zinc paste could be safely used, even to the roof of the orbit.

Mr. G. LAWSON exhibited a patient from the Middlesex Hospital on whom he had operated successfully for a Rodent Cancerous Ulceration, involving the upper eyelid and extending into the orbit and on to the side of the nose. On account of the extent of the disease the eye was first excised, and then the whole of the diseased structure was removed with a scalpel. The bleeding having been arrested by the actual cautery, the chloride of zinc paste, spread on pieces of lint, was freely applied to the cut surface; a layer of cotton-wool was then laid over the parts, and the whole was kept *in situ* by a turn of a bandage round the head. The patient suffered comparatively little from the operation. The pain which she had was relieved by a subcutaneous injection of morphia. Large sloughs soon came away, and portions of the bony walls of the orbit exfoliated, and ultimately the granulating surface of the wound cicatrised. There was now a large gap, showing the upper portion of the nasal cavity and some of the ethmoidal and frontal cells; but the parts were all healthy and cicatrised, and there was reason to hope there would be no recurrence of the cancerous ulceration.

The PRESIDENT suggested that the patients should be photographed, with a view to representation in the *Transactions*.

Dr. MOXON asked the structure of the growth removed.

Mr. HULKE said it consisted, as far as the indurated edges were concerned, almost wholly of small round cells, with no intercellular substance.

The PRESIDENT asked how the chloride of zinc paste was made, and

Mr. HULKE replied that it was made by mixing chloride of zinc and boiled starch, to which a little laudanum was added, till it reached the consistence of honey.

Dr. MOXON asked whether such cells would be sufficient to characterise the growth clinically.

Mr. HULKE said he accepted Virchow's definition of cancer. These were really specimens of ulcerated cancer to which he thought the definition would apply.

Mr. BERKELEY HILL said one marked feature of rodent ulcer was its tendency to return. He had one now under his care, which had returned again and again. He had arrested it for a time by nitrate of zinc and glycerine, but it returned.

Mr. HULKE would not deny the possibility of recurrence even again and again, but that depended mainly on defective eradication; and by this method, when it recurred it could be easily removed.

Dr. LEONARD SEDGWICK had found zinc and glycerine to run and increase the discharge. He had added tannin to the compound.

Mr. GEORGE LAWSON said a good powder was formed by mixing chloride of zinc with the oxide, which could be easily employed. Many cases treated this way remained long unaffected.

Mr. DE MORGAN said zinc paste does not run, and this is its great convenience. He thought Dr. Moxon's question important. He thought they could not deny the alliance of rodent ulcer with epithelioma, which was truly cancerous. These two would represent the two least infecting forms of cancer. When the surface was destroyed at once, and the antiseptic applied, very little constitutional disturbance followed. He had seen a case of epithelioma in a gentleman, aged 84. The diseased parts were cut out, the hot iron applied, after which chloride of zinc was put on, and he recovered without a single bad symptom.

Mr. HULKE said they could easily regulate the depth to which the caustic should eat, by the thickness of the layer on the lint. It had hardly any tendency to run. In a case where the whole upper maxilla was removed, he applied chloride of zinc to an enormous surface, but it did not run in the slightest.

Dr. C. THEODORE WILLIAMS related three cases of Phthisis, in which contraction and rapid obliteration of cavities had taken place. The patients were two females and one male, and their respective ages were 15, 53, and 27. They had symptoms of phthisis for periods varying from six to twelve months; the disease being for the most part limited to the upper lobe of one lung, where unequivocal signs of a cavity had appeared. The first was a case of caseous pneumonia, where the cavity became obliterated in two months, and the patient has since remained free from cough for more than one year. In the second case, which, from the great prostration, excessive night-sweats, and aphthous state of the mouth, was regarded as unfavourable, the disease followed pleuro-pneumonia, and closure of the cavity was complete in three months. In the third case the patient had fistula, followed by scrofulous pneumonia; and a large tinkling cavity, involving the whole upper lobe of the right lung, formed, which became obliterated in two months, cavernous sounds being no longer detected. All three patients were free from family predisposition. They took cod-liver oil, with tonics, and enjoyed a liberal diet. Dr. C. T. Williams remarked that contraction had taken place with unusual rapidity in these cases; and the remarkable feature was, that it gave rise to little or no displacement of the neighbouring organs, and to no marked collapse of the chest. He therefore concluded that the vacuum created by the shrinking of the cavities must have been supplied by an expansion of the lung tissue round the cicatrix. The obliteration in two months of a cavity sufficiently large to give tinkling sounds was an exceedingly rare occurrence.

Dr. HABERSHON considered the diagnosis of a cavity in phthisis far from easy. No ordinary physical signs sufficed. Everyone must have seen cases with dulness, loud breathing- and voice-sounds, where there was only local consolidation, and they soon got well. He remembered a case where blood was extravasated and condensation existed, yet the patient soon got well. In two of the instances adduced it was doubtful whether the signs were not due to local pleuro-pneumonia.

Dr. C. J. B. WILLIAMS said that he had seen one of the cases, and could confirm the diagnosis. In one metallic tinkling existed, and there could be no doubt of the existence of a cavity, and a large one. He did not remember seeing such another case. In the first instance there were signs of consolidation, afterwards softening and a cavity. The voice-sounds were

quite distinct from bronchophony. The puffing breathing was also characteristic. The cracked-pot sound was present in two, and that was a tolerably certain mark. Dr. Addison, who advanced the opinions uttered by Dr. Habershon, was very sceptical.

Dr. Moxon considered the difficulty not altogether removed by Dr. Williams's speech. An incorrect diagnosis was not very infrequent in his experience, especially when only one examination had been made. The first case he did not consider conclusive. The words "cavernous croak" made use of were partly inferential. Often at the post-mortem they found the parts solid they expected to find cavernous. As to one case a single observation only was recorded. There was often a large accumulation of mucus blocking up a tube leading to a cavity. As to the evidence of filling up, there was a little shrinking where he would have expected much. There was neither evidence of the existence of a cavity nor of its cure.

Dr. POWELL said there was no doubt in his mind of the existence of a cavity. They often found evidences of a closed cavity such as enlargement of the opposite lung; also, sometimes, a cavity empty and flattened. Lung disease often extended by inflammation of the interior of a cavity, with ulceration, and perhaps hæmorrhage. Sometimes there was sphacelus, which gave rise to pneumonia.

Dr. Moxon said he had no doubt of the contraction of cavities; that was not the question in hand.

The PRESIDENT said the real point at issue was—Can you make an absolute diagnosis of a cavity? He did not think one could. He remembered a case of pleuro-pneumonia where there were all the signs of a cavity at one particular spot. They marked it, and when the man died they carefully examined, and found it solid. There were all the signs of a cavity, including pectoriloquy unmistakably.

Dr. C. J. B. WILLIAMS replied that if they relied on intensity of sound they would be deceived, as that might be produced by tracheal resonance if the lung apex was solid. The point was, the existence of an island where voice-sounds were heard. They might have cavernous sounds from the bronchi. The history of these cases was totally different from those adduced in opposition. By a cavernous croak he meant the sudden entrance of air into a cavity.

Dr. C. T. WILLIAMS, in reply, admitted the difficulty of a diagnosis; still, here all the facts pointed one way. Several observations, not one only, had been made.

OBITUARY.

CALEB WILLIAMS, M.D., F.R.C.S.

ON Sunday, November 5, after an increased illness of a few days, died Dr. Caleb Williams, in the 73rd year of his age, the oldest member of the Medical Profession in York. His early Professional education was under Dr. Travis, of Scarborough, with whom he remained till he was 21. He afterwards attended Guy's and St. Thomas's Schools in London, and spent a short time in those of Paris. At the age of 25 he commenced practice in York; in the same year he was chosen as Visiting Medical Officer to the Friends' Retreat. On the ground of declining health he resigned this appointment in April, 1871, after having filled it uninterruptedly for nearly fifty years. In 1864 he succeeded Dr. Thomas Simpson as Consulting Physician to the York County Asylum.

In 1832 that terrible epidemic, the cholera, broke out in York. In common with some of his fellow-Practitioners, he was faithful to his trust in this severe visitation. In addition to Medical skill and care, he was enabled, as the almoner of some of his friends, to minister to the wants of the poor and destitute, by providing the means of additional food and other necessaries for the sick. For twenty years he occupied the chair of Materia Medica and Therapeutics in the York School of Medicine. This post he resigned in 1858. The School has since been closed.

In addition to his connexion with the two institutions already mentioned, Dr. Williams was Visiting Medical Officer to two private asylums in the neighbourhood of York. His large experience in the treatment of the insane gave him a wide-spread reputation, and his aid was sought for from far and near by the friends of this unhappy class.

Fifteen years ago Dr. Williams appeared as the advocate of a wider range of the plea of insanity in criminal cases than judges or jurors or public opinion were then prepared to admit. In 1856 he made known his opinions, the results of long and careful observation, in a work on "The Criminal Responsibility

of the Insane." Recent events have shown that public opinion now adopts wiser and more humane views on this subject.

Dr. Williams's course as a Practitioner was one of constantly increasing reputation. His skill and judgment in his Medical career, of which his success is some guarantee, was united with refinement, courtesy, and gentleness of manner, that made him a favourite with his patients and their friends. His well-known character as a Christian gentleman gave him opportunities of speaking words of comfort by many a bedside, so that, whilst alleviating physical suffering, he was often enabled to minister to and to soothe the anxious or troubled spirit.

Dr. Williams took no part in politics. He cordially united with his fellow-citizens of every denomination in the support of the numerous philanthropic, benevolent, and educational institutions in the city. The County Hospital, the Dispensary, and the Penitentiary were especial objects of his interest and care. For forty years he was an esteemed minister of the Gospel in the Society of Friends.

On Thursday, November 9, his remains were deposited in a vault in the Friends' Cemetery, Heslington-road. The funeral was attended by many members of the Medical Profession, by many of his fellow-citizens, and his friends from far and near.

MR. A. MULLAN, M.R.C.S.

WE regret to record the death, on board the *City of Antwerp* steamer, on the 5th inst., of Mr. Andrew Mullan, Surgeon R.N., invalidated from the *Sparrowhawk*, on the Pacific station. He died from aneurism of the aorta. Mr. Mullan's remains were landed at Haulbowline Hospital.

NEW INVENTIONS.

DUNN AND HEWETT'S BROMATINE.

THIS is described as a "cocoa deprived of its superfluous butter." It belongs to the class of preparations soluble in boiling water, although improved if made to boil for a time. It has the agreeable, sub-astringent, clean taste of the cocoa, and nothing luscious or dyspeptic. It seems a good and economic preparation. Daniel Dunn is asserted to be the inventor and earliest manufacturer of soluble preparations of cocoa.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on November 14:—

Adams, Robert, Gunnislake, near Tavistock, North Devon, student of University College.
Atkins, Francis Grant, Barbadoes, of St. Mary's Hospital.
Baber, Edwd. Cresswell, Thorloe-sq., Brompton, of St. George's Hospital.
Barlow, Thomas, Greenthorne, near Manchester, of the Manchester School.
Biggs, Moses George, L.S.A., Welford, Northampton, of University College.
Davis, Arthur Evelyn, L.S.A., Newport, Mon., of University College.
Davoren, John Lucius, B.A. and M.B. Dub., Wandsworth, of the Dublin School.
Giffard, Douglas William, Guernsey, of St. Bartholomew's Hospital.
Godrich, Alfred, Fulham-road, of St. George's Hospital.
Hammond, Robt. Edwd., St. Helens, Manchester, of the Manchester School.
Hayes, Aylmer Ellis, Tavistock-crescent, of St. Mary's Hospital.
Hill, Thomas Wood, L.R.C.P. Edin., South Kensington, of St. George's Hospital.
Hodson, William Edward, L.R.C.P. Edin., Bishops Stortford, of the Charing-cross Hospital.
Jackson, James, L.S.A., Wootton Bassett, of St. Thomas's Hospital.
James, William Dale, Yonge-park, Islington, of the Sheffield School.
Lang, John Messiter, L.S.A., Thatcham, Berks, of St. George's Hospital.
Lawrence, Henry, Clifton, Somerset, of the Bristol School.
Lyth, John Burdsall, Sheffield, of the Liverpool School.
Maisey, Frederick Thomas, L.S.A., Cheltenham, of Guy's Hospital.
Marshall, John, L.S.A., Bolney, Sussex, of Guy's Hospital.
More, James Huson, L.R.C.P. Edin., Manchester, of the Manchester School.
Newberry, William John, L.S.A., Liverpool-road, of St. Bartholomew's Hospital.
Price, Charles Williams, Merthyr Tydfil, of University College.
Raines, Charles, L.S.A., Hull, of the Hull School.
Randolph, Charles, Milverton, Somerset, of the Bristol School.
Seymour, Francis, L.S.A., Odiham, Hants, of Guy's Hospital.
Sinclair, Daniel Archibald, M.D. Victoria College, Toronto, London, Canada West, of the Toronto School.
Thompson, Henry, L.S.A., Hull, of the Hull School.
Tims, Thos. Lamb, L.R.C.P. Edin and L.S.A., Warwick, of Guy's Hospital.
Turner, Francis Charwood, M.A. Cantab., of Guy's Hospital.
Wacher, Frank, L.S.A., Underdown, Kent, of Guy's Hospital.
Walker, Robert, Melbourne, Australia, of St. George's Hospital.
Webb, Charles Frere, L.R.C.P. Edin., Basingstoke, of King's College.

The following gentlemen were admitted Members on November 15:—

Baily, Thomas, Birmingham, student of the Birmingham School.
Beech, Lionel, Grays, Essex, of the London Hospital.
Bridgman, Henry Edward, Torcross, Kingsbridge, Devon, of St. Bartholomew's Hospital.
Cockburn, John Alexander, Birkbeck-road, of King's College.
Coulter, William, M.D. Queen's University, Ireland, Belfast, of the Belfast School.
Coupland, Sidney, Streatham, Surrey, of University College.
Duke, Douglas William, Upper Norwood, of Guy's Hospital.
Dustan, Henry, Jersey, of University College.
Elliott, Frederick William, Turnham-green, of University College.
Hosking, Ethelbert, Woburn-square, of King's College.
Jackson, Thomas William, L.S.A., Leyland, Lancashire, of Guy's Hospital.
Kilner, Walter John, B.A. Cantab., Bury St. Edmunds, of St. Thomas's Hospital.
Mackenzie, Lewis, *Dreadnought* Hospital Ship, Deptford, of the London Hospital.
Meredith, William Henry, L.S.A., Netherton, near Dudley, of the Birmingham School.
Parnell, Gerald Crecy, Sussex-place, Regent's-park, of St. Bartholomew's Hospital.
Richmond, Onslow Robert, Hornsey, of King's College.
Thane, George Dancer, jun., Montague-street, of University College.
Wall, William Barrow, L.R.C.P. Lond., Wedmore, Somerset, of University College.
Wesley, William Ken, Gloucester, of St. Bartholomew's Hospital.
Wheeler, Daniel Martin Bonniwell, L.S.A., Chelmsford, of Guy's Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, November 9, 1871:—

Graham, George William, Winchester.
Mayne, Thomas, Devonport.
Seymour, Francis, Odiham.

As an Assistant in compounding and dispensing medicines—
Wolff, Edward Parker, Evelina Hospital, Borough.

The following gentlemen also on the same day passed their first Professional examination:—

Edwards, Alfred, University College.
Griffith, William Edwin, Middlesex Hospital.
Hawthorn, William Thomas, London Hospital.
Woodward, George, St. George's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALLAN, JAMES, M.B. Glasg., L.R.C.S. Edin.—Medical Officer for the Newmilus District of Londoun Parish, *vice* J. Davidson, Surgeon, resigned.
CAYLEY, W., M.R.C.P.—Physician to the London Fever Hospital, *vice* Dr. Harley, resigned.
FRY, J. B., M.R.C.S.E., L.S.A.—Medical Officer for the Third District of the Highworth and Swindon Union.
GARTON, WILLIAM, M.R.C.S., etc.—Resident Clinical Assistant at the Hospital for Consumption, Brompton, S.W.
KEYS, ROBERT ATCHISON, L.R.C.P., L.R.C.S. Edin., etc.—Assistant Medical Officer at the Toxteth-park Township Workhouse.
LOMAS, WM., M.D., M.R.C.P. Lond.—Physician to the Finsbury Dispensary, *vice* Dr. Wm. Abbotts Smith, M.R.C.P. Lond., resigned.
MATTERSON, WILLIAM, M.D., M.R.C.P.L.—Consulting Physician to the Asylum, Bootham, York.
NEAL, BLEWARD, L.R.C.P. Edin., etc.—Assistant Medical Officer to the Cornwall County Asylum, *vice* W. G. Derry, M.R.C.S., resigned.
PHILLIPS, ALFRED, M.R.C.S. Eng., L.S.A.—Resident Medical Officer, *vice* G. L. May, M.R.C.S., L.S.A., resigned.
WILLIAMS, ISAAC M., M.R.C.S.E., L.M., L.S.A.—Visiting Medical Officer to the Lawrence House Asylum, *vice* Caleb Williams, M.D., F.R.C.S., deceased.

BIRTHS.

CURREY.—On November 7, at Lismore, co. Waterford, Ireland, the wife of J. E. Currey, M.D. St. And., M.R.C.S., of a son.
ELLIOTT.—On November 13, at Manor-road, Forest-hill, the wife of John W. Elliott, M.R.C.S. Eng., of a daughter.
INGLES.—On November 13, at The Shamrocks, Weymouth, the wife of J. Chamberlayne Ingles, Staff Surgeon H.M.S. *Achilles*, prematurely of a son, stillborn.
MAY.—On November 2, at Tottenham, the wife of Edward Hooper May, M.D., of a daughter.
OLDNIXON.—On November 4, at Talfourd-place, Denman-road, Peckham, the wife of Dr. George Scott Oldnixon, of a daughter.
SHONE.—On November 7, at Great Marlow, Bucks, the wife of W. J. Shone, Surgeon, of a son.
THOMAS.—On November 13, the wife of William Thomas, F.R.C.S., of 97, Bradford-street, Birmingham, of a son.

MARRIAGES.

ATKINSON—DALY.—On November 8, at Holy Trinity Church, Hull, the Rev. H. Sadgrove Atkinson, B.A., to Elizabeth Francis (Lily), eldest daughter of Dr. Owen Daly, F.R.C.P. Lond., and J.P. for the East of Yorkshire.
AVERILL—GOODWYN.—On November 8, at the parish church, Tetbury, Alfred Averill, Surgeon, Tetbury, to Maria Anne Goodwyn, third daughter of J. G. Goodwyn, Retreat House, Tetbury.

BERTRAM—HORLOCK.—On November 9, at the parish church, Shorwell, Isle of Wight, William, youngest son of the late James Bertram, Esq., of Corve, Chale, Isle of Wight, to Lucy Grimes, youngest daughter of the late Robert Horlock, Surgeon, of Newport, Isle of Wight.

MASSEY—HOLLAND.—On October 28, at St. Peter and Paul Catholic church, Joseph Francis Massey, Esq., to Hannah Alloysia, eldest daughter of the late Dr. R. G. Holland, of Highgate, Middlesex, and Sheffield, Yorkshire.

PERKINS—BANNISTER.—On November 7, at All Saints', Hessle, East Yorkshire, Thomas Perkins, Surgeon, Snaith, to Polly, daughter of Anthony Bannister, J.P., Kingston Lodge, Hessle.

DEATHS.

ALLEN, FRANCES ROSE, infant daughter of W. E. Allen, F.R.C.S., H.M.'s Bengal Army, at Chittagong, East Indies, on October 8, aged 3 weeks.

BULLEN, GEORGE, F.R.C.S., at Carr-street, Ipswich, on November 11, aged 80.

FRITH, CLARA, widow of the late Dr. Frith, of Calcutta, on November 7, aged 73.

KEENBYSIDE, SIBELLA, wife of Richard Headlam Keenbyside, M.D., Vernon House, Surbiton, on November 13, aged 67.

PRICHARD, PHILLIPPA, widow of the late Thomas Prichard, Surgeon, of Sidcup, Kent, at 18, Palace-road, Lambeth, on October 27, in her 62nd year.

ROWLAND, HENRY ORFORD, Surgeon, second son of the late Mr. Samuel Rowland, of Akenham Hall, Suffolk, at his residence, Claydon, on November 8.

WETHERHEAD, THOMAS, Surgeon, at his residence, Prees, Shropshire, on November 2, aged 55.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BIRMINGHAM GENERAL HOSPITAL.—House-Governor and Secretary. Applications and testimonials to Mr. Francis Fowke, on or before November 30.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House-Surgeon. The gentleman appointed must be a Member of one of the Colleges of Surgeons of the United Kingdom. Applications and testimonials to the Secretary, on or before December 4. Election on the 12th.

BRADFORD FEVER HOSPITAL.—Honorary Medical Officer. Must be duly qualified under the "Medical Act" of 1858. Applications and testimonials to Mr. C. Woodcock, on or before November 27. Election on December 12.

CHARING-CROSS HOSPITAL, WEST STRAND.—Surgeon-Dentist, who must be a Fellow or Member of the Royal College of Surgeons of England. Applications and testimonials to the Secretary, on or before November 29.

DERBY COUNTY LUNATIC ASYLUM.—Superintendent Physician. Applications and testimonials to Mr. John Barber, on or before November 28.

EDINBURGH ROYAL INFIRMARY.—General Superintendent. Applications and testimonials to Mr. Bell, Clerk to the Corporation, on or before December 1.

EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK-BRIDGE-ROAD, S.E.—Medical Registrar. Candidates must possess a recognised qualification. Applications and testimonials to the Committee of Management, on or before November 23.

KENT AND CANTERBURY HOSPITAL.—House-Surgeon. Gentlemen applying for this appointment are required to possess qualifications in Medicine and Surgery. Applications and testimonials to Mr. T. Southee, Secretary, on or before November 24. The duties commence on January 1, 1872.

LINSEY, LINCOLNSHIRE.—Medical Officer for the County Gaol and House of Correction. Candidates for this appointment must be duly qualified and registered. Applications and testimonials to the Deputy Clerk of the Peace, Lindsey, on or before November 18. The duties will commence about the end of March, 1872.

LIVERPOOL ROYAL INFIRMARY.—Physician. Must be F. or M.R.C.P.L., or a Graduate in Medicine of one of the following Universities—namely, Oxford, Cambridge, Dublin, Edinburgh, Glasgow, or London. Applications and testimonials to Mr. E. Gibbon, on or before December 1.

REETH UNION.—Medical Officer for the Muker District. Candidates are required to possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. James R. Tomlin, Richmond, Yorkshire, on or before December 1.

ST. MARY'S HOSPITAL AND DISPENSARY FOR WOMEN AND CHILDREN, QUAY-STREET, MANCHESTER.—Medical Officer for Out-patients. Must have Medical and Surgical qualifications. Applications and testimonials to Mr. J. Barber, on or before December 2.

SOUTH STAFFORDSHIRE GENERAL HOSPITAL, WOLVERHAMPTON.—Physician's Assistant. Candidates must be graduates in Medicine of a British University. Applications and testimonials to the Chairman of the Medical Committee, on or before November 27.

STOCKPORT INFIRMARY.—Assistant-Surgeon. Qualifications in Medicine and Surgery required. Applications and testimonials to the Honorary Secretary, on or before November 30.

SUSSEX COUNTY HOSPITAL, BRIGHTON.—Surgeon. Must be M.R.C.S.E. Edin. or Dub. The office of Assistant-Surgeon is also vacant; the qualifications required are the same as for the appointment of Surgeon. Applications and testimonials to Mr. A. Vesey, on or before December 6.

VICTORIA HOSPITAL FOR SICK CHILDREN, GOUGH HOUSE, QUEEN'S-ROAD WEST, CHELSEA.—House-Surgeon. Must possess at least one qualification to practise. Applications and testimonials to Mr. St. John H. Young, on or before November 27.

WANDSWORTH AND CLAPHAM UNION.—Medical Officer to the Workhouse and Infirmary. Candidates must be duly qualified and registered. Applications and testimonials to Mr. John Sanders, on or before November 27. Election on the 28th.

WESTHAMPTON UNION.—Medical Officer for the Rumboldswyke District. Candidates must have both Medical and Surgical qualifications. Applications and testimonials to Mr. R. G. Raper, West-street, Chichester, on or before November 19.

UNION AND PAROCHIAL MEDICAL SERVICE.
 ** The area of each district is stated in acres. The population is computed according to the census of 1871.

RESIGNATIONS.

Blything Union.—Mr. H. J. Horton has resigned the Eighth District; area 11,089; population 2590; salary £43 per annum.

Grantham Union.—Dr. Ferneley has resigned the Grantham District; area 11,834; population 9462; salary £96 per annum.

Hezham Union.—Mr. Thomas Stainthorpe has resigned the Western Division of the Third District; area 9952; population 731; salary £5 per annum.

Honiton Union.—The Eighth District is vacant; area 2130; population 331; salary £9 per annum.

APPOINTMENTS.

Fullam Union.—Frederick H. Alderson, M.R.C.S.E., L.S.A., to the Fifth District.

Glandford Brigg Union.—Robert Bruce Low, M.D. Edin., M.C. Edin., to the Mersingham District.

Goole Union.—Matthew Shirley, L.F.P. & S. Glasg., L.R.C.P. Edin., to the Swinefleet District.

Great Ouseburn Union.—Norman McCaskie, M.B. and C.M. Univ. Edin., to the Great Ouseburn District and the Workhouse.

Lutterworth Union.—William Sharples, M.R.C.S., L.S.A., to the Second District.

Pocklington Union.—Alfred Jackson, L.R.C.P. Edin., L.R.C.S. Edin., to the Second Pocklington District and the Workhouse.

Portsea Island Union.—William Johnston, M.D. Edin., L.R.C.S. Edin., to the Southsea District.

Wimborne and Cranborne Union.—Charles H. W. Parkinson, M.R.C.S., L.S.A., to the Second District and the Workhouse.

UNIVERSITY INTELLIGENCE.—CAMBRIDGE, NOVEMBER 10.—The report of the Board of Medical Studies, which recommended that candidates for the Third M.B. Examination be required on and after the Easter Term, 1872, to produce a certificate of having been clinical clerk for six months at least at a recognised Hospital; or of having, subsequently to the completion of his attendance on Hospital practice, attended to practical Medicine with special charge of patients, in a Hospital, Dispensary, or parochial union, under superintendence of a qualified Practitioner, unless he himself be duly qualified, and that Experimental Physics be added to the list of courses of lectures in Section 10 of Regulations for Degrees in Medicine, came on for discussion this afternoon in the Arts School. The first recommendation passed without opposition; but the proposal to include Experimental Physics in the course of lectures to be attended by Medical students as part of the requirements of keeping a Medical term was opposed by Dr. Paget, upon the ground that it required modification. He did not object to Medical students attending lectures on Experimental Physics, but objected to add it to the list of subjects, attendance upon a course of lectures being part of the requirements of a Medical term. It could not be called studying Medicine to attend a course of lectures on magnetism or botany, however desirable it might be that Medical students should have a knowledge of those subjects. He thought the time required for Medical study—four years—was the least possible period which could be allowed, and he doubted whether it was not too short. One could not maintain that attending lectures on Experimental Physics was studying Medicine, and unless the proposed regulation were modified that would be the effect. It would not be right for the University to introduce a regulation which might run the risk of external criticism as tending to make the University examinations for a degree in Medicine less stringent, and the time of study in effect shorter. They had a deserved reputation for their Medical degrees, and he should lament if any of their *prestige* was lost. He suggested that lectures on Experimental Physics should only be counted when at the same time attendance was given by the students to some of the other subjects named in the schedule more intimately connected with the study of Medicine. The Vice-Chancellor thought the proper plan would be to refer the second part of the report again to the consideration of the Board of Medical Studies, for it to make the alteration suggested by Dr. Paget. This course was assented to, and the first part of the report only was passed.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The next meeting will be held on Saturday, November 18, at 7.30 p.m., at the Scottish Corporation Hall, Crane-court, Fleet-street. Professor W. H. Corfield, Medical Officer of Health for Islington, and Mr. J. J. Skegg, Medical Officer of Health for St. Martin-in-the-Fields, will be balloted for as ordinary members. Dr. J. Mouat, Athenæum Club, Pall-mall, late Inspector of Prisons, Bengal, and Dr. A. Fergus, Glasgow, President of the Sanitary and Social Section of the Philosophical Society, will be balloted for as associated members. The President, Dr. R. Druitt, will deliver an address "On the Present Position of Medical Officers of Health; their Work and Prospects."

MISS ELLEN P. DOWNING, a past student of the Ladies' Medical College, has passed the Arts Examination at Apothecaries' Hall, London.

WE hear there are 599 matriculated Medical students in the University of Edinburgh at this date, of whom 209 are registered as first-year students.

SMALL-POX IN OXFORD.—In the past week there have been three new cases, and one death—unvaccinated. There are twenty-two cases under treatment.

ANTI-VACCINATIONISTS.—The Manchester Board of Guardians, on Thursday last, refused, very properly, to receive a deputation from a meeting held at Harparhey protesting against the enforcement of the Vaccination Act. The Guardians stated they had nothing to do but to enforce the law.

THE Report on the Sanitary Condition of St. Mary, Islington, for October, 1871, states that the total number of deaths (263) during this month has been remarkably low—lower than in any October since the census of 1861 was taken, if due allowance be made for the increase of the population—and absolutely lower than that of any year since 1862, with the exception of 1864 with 216, and 1867 with 260 deaths. This small number is partly due to the fact that miasmatic diseases have caused only 58 deaths during the month, while in the same month of the last three years they caused 72, 98, and 96 deaths. Measles and scarlatina are on the increase as compared with last month, but the latter has not as yet assumed the serious proportions of an epidemic that it did in the October of 1869 and 1870. It is, however, necessary to point out that it is especially by contagion that these diseases spread, and that strict attention to the separation of persons attacked from healthy persons, and also of families where one member is attacked from other families (thus, children from families where one member is ill should not be sent to school, as they may convey the contagion, although unattacked themselves), and to the proper, and especially the thorough ventilation of sleeping- and living-rooms, are the great means by which their spread must be sought to be prevented; the use of disinfectants as auxiliary agents not being omitted. Diarrhoea has much abated, only fifteen deaths from it being recorded, as against eighty-five during the five weeks of September. Small-pox has only caused four deaths during the month, the smallest number recorded since October, 1870.

EXAMINATION QUESTIONS.—At the examinations on the 10th and 11th inst. for the Diploma of Membership of the Royal College of Surgeons, the following were the questions on Surgical Anatomy and the Principles and Practice of Surgery which were submitted to the ninety-seven candidates, viz. :—

1. Describe the action of a ligature and of torsion in arresting hæmorrhage from a severed artery; and state what is the effect of a ligature upon an undivided artery as in an operation for aneurism, and how the continuity of the artery is permanently interrupted after the separation of the ligature.
2. Give the Surgical anatomy of the ulnar artery as far as the wrist, and describe the operation for its ligature in the middle of the forearm, indicating the precise relations of the vessel at the point at which it is tied.
3. Describe the symptoms, consequences, and treatment of chronic enlargement of the prostate gland.
4. Mention the different tissues and localities in which the formation of pus causes the greatest local pain and constitutional disturbance. State (giving examples) the circumstances that would induce you to open an abscess early, and those in which delay or non-interference would be preferable.
5. Describe the deformity produced by simple dislocation of the foot outwards at the ankle; mention the structures which are necessarily broken or lacerated in this accident; state the mode of reduction and the means you would have recourse to under circumstances of unusual difficulty.
6. Mention the various kinds of cataract; give the diagnostic characters of each, and state the usual conditions under which the different forms occur; and describe the operation of extraction.

The following were the questions on the Principles and Practice of Medicine, for which there were forty-nine candidates, viz. :—

1. A day or two after exposure to cold, a patient is taken with feverishness, difficulty of breathing, and uneasiness at the chest. What are the different forms of disease which may probably be commencing, and how would you severally distinguish them?
2. What are the chief deposits which may be found in the urine, under what circumstances do they severally occur, and how would you recognise each form?
3. Mention the remedies which are commonly described as nervine tonics, and state in what cases you would use them, and the doses in which they may be given. Write a prescription for the exhibition of one of these medicines."

A COTTAGE HOSPITAL is to be erected at Ledbury.

FINE FOR ILLEGALLY USING "M.D."—A complaint was recently heard before Sheriff Comrie Thomson, at Aberdeen, at the instance of John A. Forbes, chemist, West North-street, against John H. Boyd, 14, Marischal-street, to the effect that he had wilfully and falsely pretended to be a Doctor of Medicine. It was stated in the complaint that this had been done by means of the respondent advertising in an Aberdeen paper of October 7, and being entered in the "Aberdeen Directory" of 1871-2 as a Doctor, while he is not registered as such under the Medical Act of 1858, and is not recognised as such by law. The respondent failed to appear. The evidence of the witnesses examined went to show that the advertisement founded upon had been inserted by order of the respondent, and that with his knowledge he had been entered in the "Directory" as John H. Boyd, M.D. The Sheriff found the charge embodied in the complaint proven. He said it was impossible at any time to have much sympathy with anyone who committed such an offence against the law, and, in the present case, any sympathy which might have been felt was greatly lessened, if not altogether destroyed, by the open and daring manner in which the crime had been committed. He could do nothing less than impose a fine of £10, with £2 2s. of expenses; failing payment, forty days' imprisonment.

CONVERSAZIONE OF THE EDINBURGH OBSTETRICAL SOCIETY.—The opening of the thirty-first session of this Society on the 8th inst. was inaugurated by a *conversazione* in its Hall, 5, St. Andrew's-square. The invitations issued by the President and Fellows included the names of the Practitioners in the city and county, and most of the Corresponding Fellows in Scotland. In addition to the Fellows of the Society present, we observed Professors MacLagan, Lister, Spence, Sanders, Balfour, etc.; Drs. Littlejohn, Thomas Keith, Dycer, J. Smith, Hogue, Black, Cadell, Inglis, Hislop, Orphoot, Roberts, John Duncan, Thomson, Wight, etc.; Messrs. Aytoun, Ainslie, Gardner, Gilman, Hepburn, J. W. Hogue, McKay, Nicol, Swanson, Tait, Wilson, Hilliard, Young, McGregor, etc.; and amongst those from a distance were—Drs. P. A. Young (Portobello), Fowler (Corstorphine), Brodie (Liberton), Hope (West Calder), Carmichael (Burntisland), Carruthers (Crimond), Fergusson (Peebles), Professor Wilson (Glasgow), Drs. Kerr, R.N. (Bonnyriggs), McArthur (Anstruther), Macfarlane (Polmont), Parker (Nova Scotia), Robertson (Lauder), Thomson (Inveresk), Thorburn (Loanhead), Turnbull (Coldstream), McLeod (Ben Rhydding), Ballantyne (Dalkeith), Forrest (Stirling), Monro (Glasgow), Black (Cockburnspath), Whiteford (Greenock), Laurence (Montrose), Brotherstone (Alloa), etc. The guests were received by the President, Dr. Charles Bell, who opened the proceedings by introducing Dr. Keiller to the meeting, as a former President of the Society, who had been selected by the Council to deliver an address. The subject chosen by Dr. Keiller was the "Progress of Obstetrics," the time of the great subject, dwelling occasionally on some of the more important steps in the progress of Obstetrical Science. He also referred to the dangers the Accoucheur and Surgeon were occasionally exposed to in the exercise of their duties from actions being raised against them for malpractice; but time did not permit him entering upon the merits of the recent case at Stockton-on-Tees, in which he gave evidence for the defendant. Referring to the success of ovariectomy, he alluded in complimentary terms to the grand results of our Edinburgh operator, Dr. Thomas Keith, and, before concluding, paid a tribute of respect to the memory of Simpson—a name ever well received in this Society. On the motion of Professor MacLagan, seconded by Dr. Turnbull, of Coldstream, a cordial vote of thanks was awarded to Dr. Keiller for his interesting address. The company then adjourned to another room, where refreshments were provided, and instruments and preparations exhibited. Amongst the exhibitors connected with the Society were Professor Simpson, Dr. Keiller, Dr. Matthews Duncan, Dr. Macdonald, Dr. Young, Professor Inglis (Aberdeen), and Dr. Ritchie. Professors Sanders and Turner exhibited a series of preparations of injected uteri and placenta of the lower animals. Mr. Archibald Young exhibited the utero-abdominal support and pessary of Dr. Charles Bell; a new midwifery forceps with one solid blade, by Dr. Hamilton, of Falkirk; Dr. Cappie's bayonet-jointed forceps with long and short handles; a new hysterotome by Dr. Coghill; Professor Inglis's short-handled forceps; Dr. Matthews Duncan's cephalotribe, and also his hollow sound and syringe for injecting the uterus, etc. Mr. Mackenzie exhibited Dr. Gordon's new forceps with locked handles and movable blades. Mr. Hilliard exhibited a variety of obstetrical instruments and apparatus. Mr. Gardner

exhibited Simpson's, Churchill's, Duncan's, Cappie's, Keiller's, Barnes's, Campbell's, Oldham's, Greenhalgh's, Murphy's, Blondell's, Robertson's, Graily Hewitt's, Davis's, Ramsbotham's, and Denman's forceps; Simpson's, Weiss's, Holmes's, Lee's perforators; Simpson's, Murphy's, Conquest's, Holmes's, Churchill's cranioclasts; and Simpson's, Duncan's, Barnes's, and Charles's cephalotribes, etc. After a very pleasant evening, the company separated about ten o'clock.

HEALTH OF SCOTLAND.—The deaths of 2476 persons were registered in the eight principal towns during the month of October, of whom 1186 were males and 1290 females. This is the greatest number recorded during any month of October since the Registration Act came into operation in 1855. Previous to this month the greatest number in October was in 1868, when 2298 deaths were registered. Allowing for increase of population, the present number is 199 above the average for the corresponding month of the last ten years. A comparison of the deaths registered in the eight principal towns shows that during October the annual rate of mortality was 16 deaths per 1000 persons in Aberdeen, 23 in Leith and in Perth, 28 in Edinburgh, 29 in Glasgow, 30 in Dundee, 31 in Greenock, and 32 in Paisley. Of the 2476 deaths registered, 1079, or 43 per cent., were of children under 5 years of age. In Perth, 28 per cent. of the persons who died were under 5 years of age; in Paisley, 34 per cent.; in Edinburgh, 35; in Dundee, 40; in Aberdeen, 43; in Leith, 44; in Greenock, 45; and in Glasgow, 49 per cent. The zymotic (epidemic and contagious) class of diseases proved fatal to 654 persons, thus constituting 26 per cent. of the mortality. This rate was greatly exceeded in Dundee (43.5 per cent.) from the prevalence of small-pox, and in a less degree from that of diarrhoea and fever; and in Leith (39.5 per cent.) from the prevalence of small-pox and scarlatina.

VARIOLA IN PREGNANCY.—In his report on the diseases prevalent in Paris during September, M. Besnier relates the case of a woman, aged 22, who was admitted into Lariboisière suffering from "coherent" variola. During the stage of desiccation she was delivered of a full-timed, healthy child, which did not exhibit on its body any trace of the disease. The patient, during her convalescence, suffered from numerous disseminated abscesses situated on all parts of her body, which obliged her to remain with her infant for more than a month in the ward, into which were admitted new cases of small-pox. The infant was vaccinated about a month after its birth with some of the same lymph which succeeded in all the other cases in which it was employed. In this infant, however, it failed, as did two other vaccinations subsequently practised also with good lymph. It is suggested that the fœtus may have been preserved from variola during its intra-uterine life by means of the maternal blood.—*Gaz. des Hôp.*, November 11.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN OCTOBER, 1871.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases but the following, when it was turbid—viz., in those of the Chelsea and the Grand Junction Companies.

The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 114,354,087 gallons; and the number of houses supplied was 490,332. This is at the rate of 35.3 gallons per head of the population daily.

DIPHTHERIA.—For the last three years we have had, each year, to report the progress of this deadly affection. It is called here by such names as *nao sang tse, heu pi, heu yung*, all signifying more or less malignant sorethroat, or narrowing to

suffocation of the air-passages. The former is the popular expression for it. It is said to be a new disease, and to have been known only for the last fifty years. It seems almost entirely to be confined to Peking. It is said not to be known even at Tien-tsin. No cases are reported from the Hospitals of Central and Southern China. If this be so, what reason can be assigned for it? Do the same conditions not exist in other parts of China? Most of the adult cases seen early have recovered; almost all seen after the fourth or fifth day have died. All classes and ages are affected; but it proves speedily fatal among children, some of whom are reported to have died after one day's illness. Its insidious and almost painless character makes it dangerous. Pain, which drives us all to seek for help, is a less prominent symptom than difficult deglutition. The Chinese, so generally indifferent to everything, are less prompt in applying for relief in such instances, probably from the fact that they are rather subject to throat affections. Their universal remedy is counter-irritation by chafing with copper cash, pinching the skin between the fore finger and thumb, and sometimes by lancing the tonsils with their long finger-nails. Lunar caustic, a gargle of chloride of calcium, nourishing diet, fomentations, dilute and concentrated muriatic and carbolic acids, have been found serviceable.—*Report of the Peking Hospital, by Dr. John Dudgeon.*

NOTES, QUERIES, AND REPLIES.

Be that questioner much shall learn much.—*Bacon.*

R. E. Power, Dartmoor.—Write to Dr. Farr, Somerset House. We do not think the returns are yet published.

A Constant Reader.—Try a well-regulated hydropathic institution, such as that at Ben Rhydding or Forres.

M. D.—The title of Doctor of Medicine was first bestowed upon William Gordenio, who received it from the College of Asti, in 1329.

E. C.—Liebig's beef-tea is described in his "Researches on the Chemistry of Food," translated by W. Gregory (London, Taylor and Walton, 1847), page 122, *et seq.* The illustrious author proves, by scientific research, what empirical observation had taught cooks—viz., the importance of the soluble constituents of muscular fibre, both to the palate, the stomach, and the system at large. He thus describes the method of making beef-tea:—"When one pound of lean beef, free from fat, and separated from the bones and finely chopped, is mixed with its own weight of cold water, slowly heated to boiling, and the liquid, after boiling briskly for a minute or two, is strained through a towel—for the coagulated albumen and the fibrine now become hard and horny—we obtain an equal weight of the most aromatic soup, of such strength as cannot be obtained even by boiling for hours from a piece of flesh. When mixed with salt and the other usual additions by which soup is usually seasoned, and tinged somewhat darker by means of roasted onions or burnt sugar, it forms the very best soup which can in any way be prepared from one pound of flesh." Liebig goes on to describe the extract, prepared by evaporating the above, which has since obtained so much celebrity as "Liebig's Extract." There is no doubt but that the "extract of meat" is the most valuable and costly ingredient in soup; but as little doubt, for practical purposes, that the albumen which is strained off coagulated, the gelatine which is extracted from the bony and tendinous parts, and the finer and tenderer parts of the muscular fibre ought to be added to make a perfect soup. We would call E. C.'s attention to the following passage, in which the illustrious Liebig enounces a proposition that cannot be overturned:—"It is obvious that if flesh employed as food is again to become flesh in the body, if it is to retain the power of reproducing itself in its original condition, none of the constituents of raw flesh ought to be withdrawn from it during its preparation for food."—*Op. cit.*, p. 122.

INFANT MORTALITY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.
 SIR,—The death-rate among infants is proved from statistics to be large, and, consequently, it should be the aim of those entrusted with the care of the health of the community to employ all legitimate means in their power to lessen this enormous loss. My object in addressing you is to draw the attention of those interested in this matter to a point which I consider greatly neglected. Among the working-classes a great proportion of the women are attended during labour by old women, whose only qualification (if it be such) for undertaking the responsible duties of an accoucheur is their age. Their presumption is at times so great that they are even bold enough to prescribe for the various ailments of the little sufferer, and after death to give the parents the cause of the sad termination! I shall give you a short account of the case which induced me to write this note, and I may safely suppose that many of your readers have met with similar instances in the course of their practice.

This morning I was consulted by a woman who stated that she "altered" during the second, third, and fourth months of pregnancy. In inquiring into her previous history I ascertained that she had been pregnant seven times. Of these one had been a miscarriage. It was only when she was

conceive for the fourth time that she began to suffer from this peculiarity, and I may state that it is not a monthly, but a continuous flow, with only a few free days during the three months; this has occurred with all her subsequent pregnancies. Of the six children born alive, three have died. Of the latter two were attended by a Medical Practitioner, and the third by the woman "who brought the child home." I was also informed that those treated by the Doctor "died of measles and lumps in the belly"; and that by the midwife "from bull-hives and want of gums when only a few days old"! According to the woman's statement, it seems the Registrar was satisfied with this cause of death when it was given in by the father. Now, I am of opinion that had this midwife been taken to task when this occurred, it would have deterred her as well as others from playing at Doctor for the future. For aught we know many other infants in her estimation may have died of "bull-hives and want of gums," but would have been saved from an untimely death had proper Medical treatment been employed. Apologising for having encroached on so much of your valuable space, and trusting that efficient means may, through your influence, be enforced to suppress this evil, I am, &c.,
November 13. AN UNQUALIFIED ASSISTANT.

Philologicus.—These points refer to custom and taste, which have been settled for many centuries, and which have quite as much in their favour as the innovations have. The whole of Western Europe used to represent Greek characters by certain Roman ones: the thing was conventional, and we do not see the use of a change. If, nevertheless, it be judged more "philological" to write "Herakles" than "Hercules," or "ekzema" than "eczema," be it so. "It pleases she, and don't hurt he." But with regard to such a word as "upodermic," instead of "hypodermic," it is a barbarism. The "y" is the living representative of the Greek γ —the same letter, in fact; and anyone who will turn to a French grammar may see that it is called *ygrec*, showing its identity with the Greek γ . Every word in which γ occurred in Greek was represented in Latin from time immemorial by Y. Thus, when the mediæval Churchmen transcribed the Greek $\Delta\omicron\varsigma\alpha$ *en* $\acute{\alpha}\nu\theta\rho\omega\pi\omicron\iota\varsigma$, they wrote it *Doxa in hysistis*. The long α in Latin is the representative of the Greek diphthong $\omicron\upsilon$, as in the well-known word *Heautontimorūmenos*. We therefore plead still for the words "hypogastric," "hypodermic," and the rest.

A *Wine Drinker* sends us a quotation from *Ridley and Co.'s Wine and Spirit Trade Circular*, November 11, 1871, relative to some "learned Doctor, who was accredited to a Xeres firm with full power to exert his skill for their benefit in making wine by his own process." It is said that "he had been duly put in communication with the grapes, and it is understood that he superintended the making of 100 butts," which proved a failure so absolute as to be useless even for distillation. It was supposed that the learned Doctor was to transmute low-class sherry into old Solera Amontillado. We believe that the search for the philosopher's stone, so as to get gold without industry, was not more useless and pernicious to humanity than are attempts to substitute chemical tinkering, for the careful selection of plant, well-cultivated vineyard, warm sun, and most watchful skilful care in gathering, pressing, tending, and maturing the genuine grape-juice, which is necessary to make good wine. As is shoddy to good broadcloth, so are these miserable imitations to good wine.

"PROFESSIONAL ETIQUETTE IN BAYSWATER."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I observe that certain gentlemen in Bayswater complain that a *confrère* has attracted (or endeavoured to do so), by means of a prospectus, some of their patients to himself, and that on the prospectus appear only the names of the Surgeon and secretary to the "Society," which provides medicine and attendance to members for 10s. per annum. Now, what are we to think of the "Medical etiquette" in another part of London, as shown in the enclosed two advertisements? In "Bayswater etiquette," the Surgeon of the Society will attend patients for 10s. a year; in the other case the Surgeon will attend patients for *nothing at all*, and, according to the advertisement, he absolutely does attend, on these terms, 1000 weekly. To come nearer home, what are we to think of the "Westbourne-grove Provident Dispensary," whose prospectus was, I believe, sent to me? The terms of this Society are very moderate—something between the 10s. and nothing per annum. I am, &c.,
A BAYSWATER M.D.

*. The following are the advertisements referred to by our correspondent:—
"National Institution for Diseases of the Skin, Gray's-inn-road and Mitre-street. Physician, Dr. Barr Meadows, 49, Dover-street, Piccadilly. Average number of patients under treatment, 1000 weekly. Free letters are available for necessitous applicants.—Thomas Robinson, Hon. Sec."

"Western Dispensary for Diseases of the Skin, 17, Duke-street, Manchester-square. Instituted 1851. Mr. Hunt attends every morning, from 9 till 10, and on Saturdays from 3 to 4 also."

M.D. calls our attention to the report of an inquest, held at Stratford-upon-Avon, upon the body of a boy of 8, who had both legs torn off by a ploughing machine, and sank from exhaustion after amputation of the stumps. "M.D." calls attention to a practice adopted by Mr. Le Sage, the Surgeon to the Union, who deposed as follows:—

"I found the right foot entirely separated from the leg, about four inches above the ankle, and the left foot was severed with the exception of the muscles of the calf of the leg. Deceased was much exhausted. I had a consultation with Mr. Rice, and we considered amputation necessary. Every possible effort was used to keep deceased alive, by stimulants, heat, etc., and he was wrapped in a sheepskin—Mr. Bruce having slaughtered an animal on purpose to provide one, and the deceased was put in it as it was, reeking from the carcase. Death was caused by the great shock to the system."

This remedy is an unusual one in this country, but it has the sanction of the highest authority and antiquity. It is commended by Baron Larrey, in his "Chirurgie Militaire," and was put in practice, with excellent effect, in the case of Marshal Lannes, Due de Montebello, after a

severe injury met with in the French invasion of the Peninsula. It is like wrapping a patient in cotton-wool, plus warmth and moisture; and some people believe that a degree of "vitality" may adhere to the skin of the recently killed animal. This may or may not be true; but if not true, is a very old error: *Vide* case of King David and Abishag; Cope-land's Dictionary—On Young People sleeping with the Old; The Popular Practice of ripping up a Live Kitten or Puppy and applying it to Ulcers and Abscesses, etc.

URTICARIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Sidney Smith, Swift, or Lionel Beale—*non mi ricordo* which—has ably pointed out the diuretic effect of the bag-pipe on the Scotchman. The scraping of slate-pencil, the sight of a snake, the smell of onions, the taste of physic, and the receipt of Christmas bills, sensibly annoy the majority of mankind.

James I. could not endure the sight of a drawn sword; coincidentally, Rizzio was killed at the feet of Queen Mary when pregnant with him. A cat concealed in a room has been known to produce a feeling of agonising tremor in a person who has not perceived it by any one sense, and has been in no other way informed of its presence. Equally unpleasant is that instantaneous serous infiltration of the papillæ of the skin occurring in nervous susceptible subjects, commonly termed nettle-rash, caused either by the stings of insects or plants, local irritation, or by mental emotion, influenced by certain conditions of body at particular seasons—for instance, infantile dentition, else dyspepsia, dysmenorrhœa, pregnancy, or lactation. These tingling, transient, erythematous red-and-white wheals may directly be induced by indulgence in shell-fish (mussels), cucumbers, pickles, pork-sausages, pepper, tea, almonds, and certain fruits, or by taking such medicines as copaiba, turpentine, chloral hydrate, or quinine. Cold, heat of the fire, the warmth of bedclothes, or indulgence in wine will develop this peculiar cuticular hyperæmia, which, associated with vomiting and diarrhœa, will produce such febrile disturbance, amounting to delirium in certain cases, as to lead to a faulty diagnosis of scarlet fever, measles, or variola. The disease suggests its own treatment; the advice of *Punch* to people about to get married—"Don't." And the old proverb of the burnt child avoiding the fire should caution those susceptible as to diet and hygiene.

Not long ago, at a pleasant dinner party, after talking over Sir Charles Dilke's vulgarity, the doleful prospect of doing away with bands and messes, the disgraceful treatment of Medical witnesses by barristers, specially in the late Irish trial, Denne talked cricket, and Lyon said hunting was the sport of kings, the image of war, without its guilt and five-and-twenty per cent. of its danger.

Mrs. Rotten Rowe, a fine woman, whose white skin, jet-black hair, splendid bust, and magnificent diamond ear-rings created admiration in the men, envy in the women, became so absorbed in the fascinating conversation of a certain Medical editor (who was enlarging on the appalling world-wide circulation of his journal) as inadvertently to take strawberry cream. Horror! instantaneously her face became the colour of her cherry-coloured silk dress, for out burst the
NETTLE-RASH.

Traveller.—1. No. 2. "Yasva" is one of the local maladies of Siberia. It is an epidemic which suddenly makes its appearance, one knows not whence or how. The person attacked is at once struck helpless, and a swelling about the size of a walnut appears on the side of the head, or some other part of the body. Unless assistance is at once afforded, death almost immediately follows. Men are not often attacked by this strange disease, but horses and cattle are very subject to it.

Disease and Death.—Dr. Lankester, in his Report of the Health of St. James's, Westminster, for 1870, after enumerating the various causes of disease which are preventible, says—

"I might have extended these general remarks, but I hope I have said enough to show you the nature of one set of enemies with which we have to deal. When we consider their insidious nature, their extensive existence, and the ease with which they are diffused, we may, perhaps, congratulate ourselves that they are not more destructive than they are. At the same time it should be recollected that our knowledge of the laws of the nature of these diseases is much more accurate than formerly, and that we now know enough to show us that more active and intelligent sanitary legislation would be of the greatest possible benefit. What we want is imperial and compulsory Acts of Parliament for the removal of the sources of disease and death, and not local and permissive measures. At the same time, it is quite useless to pass Acts of Parliament unless people are prepared to employ them and act under them. This can only be done by teaching the people, both high and low, the laws by which health and strength may be secured, and disease prevented from laying low the youth and strength of the country. It is not for me to show you, but it is for everyone to calculate, the wealth of health, and the enormous loss sustained by preventible disease and death."

Infant Mortality from June to September, 1871.—In the Registrar-General's Quarterly Report, it is stated—

"The 121,236 deaths registered from all causes in England and Wales during last quarter included 37,367 or 30.8 per cent. of infants under 1 year of age, and 23,536 or 19.4 per cent. of persons aged 60 years and upwards. In the corresponding quarter of 1870 these proportions were almost identical—30.9 and 19.4 per cent. respectively. Infant mortality, measured by the proportion of deaths of children under 1 year, to births registered, was 20.0 per cent. in 1870, and 19.4 in the third quarter of the present year. Infant mortality calculated in this manner was 27.6 per cent. in the seventeen largest English towns, 23.4 in the entire urban population, and only 16.0 in the remaining or rural districts. Among the seventeen largest towns, the proportion of deaths under 1 to births registered ranged from 16.9 and 18.8 per cent. in Wolverhampton and Portsmouth, to 35.1 in Leeds, 35.2 in Liverpool, 37.3 in Manchester, and 46.2 in Leicester. This difference between the average proportion of 16 per cent. among the ten millions of persons living in the rural districts, and the 46 per cent. shown in the borough of Leicester, is so remarkable that an exhaustive inquiry into the cause of this terrible infant mortality seemed imperatively called for. The inhabitants of Leicester, and of other large towns, should know the cause of this waste of life, the reason why their infants more readily fall victims to diarrhœa and other infantile complaints."

COMMUNICATIONS have been received from—

Dr. J. WILLIAMS; Mr. R. S. HILL; Mr. LE NEVE FOSTER; Mr. KITTO; Mr. METCALFE JOHNSON; Mr. EDWARD WILSON; Dr. WOODWARD; Mr. TEEVAN; Dr. R. T. MASSY; Mr. BOSTOCK; NETTLE-RASH; Dr. BEACH; Dr. D. W. DAVIES; Mr. G. WILMOT; Dr. DUDFIELD; Mr. C. FINN; Mr. B. NEAL; Mr. KARKEEK; Mr. BRADFORD; Mr. TOMBS; M.D.; Mr. CHARTERS WHITE; A BAYSWATER M.D.; AN UNQUALIFIED ASSISTANT; Mr. LAWSON; Mr. WILTON; Mr. R. E. POWER; A CONSTANT READER; Mr. I. M. HOGG.

BOOKS RECEIVED—

Ruppaner's Contributions to Practical Laryngoscopy—Cutter's Contribution to the Treatment of the Versions and Flexions of the Unimpregnated Uterus—Reynolds's Lectures on the Clinical Uses of Electricity—Bennet on the Treatment of Pulmonary Consumption by Hygiene, Climate, and Medicine—Living on the Treatment of Skin Diseases—Murray on Smoking—Grainger Stewart on Bright's Disease of the Kidney, 2nd edition—Hamilton on Fractures and Dislocations—Hartshorne's Essentials of Practical Medicine—Madden on Puerperal Mania.

PERIODICALS AND NEWSPAPERS RECEIVED—

Nature—Pharmaceutical Journal—English Mechanic—New York Medical Journal—Philadelphia Medical Times—American Journal of Medical Sciences, October—L'Union Médicale—Medical Press and Circular—Dublin Quarterly Journal of Medical Science.

APPOINTMENTS FOR THE WEEK.

November 18. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, 7½ p.m. Dr. R. Druitt (President), "On the Present Position of Medical Officers of Health: their Work and Prospects."

20. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.

MEDICAL SOCIETY OF LONDON, 8 p.m. Dr. Prosser James, "On Ozena." Adjourned Discussion on Dr. Alfred Carpenter's Paper "On Two Cases of Muscular Anæsthesia." Casual Communication by Dr. Wiltshire. Mr. Spencer Watson, "A Case of Skin-grafting under Continuous Irrigation, by Mr. J. D. Harris (Shrewsbury)."

21. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited:—Dr. Dickinson, "Intracranial Aneurism the Cause of Sudden Death." Dr. Bäumlner, "Aneurism of the Innominate Artery, compressing the Pneumogastric Nerve." Dr. Hawkes, "Horse-shoe Kidney." Mr. Spencer Watson, "Ulcer of the Lower Eyelid, removed by Dr. Swift Walker." Mr. H. Arnott, "Results of Excision of the Elbow-joint."

22. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

SOETY OF ARTS, 8 p.m. Mr. Hyde Clarke, "On the Present State of the Through Railway Communication to India."

23. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

24. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Papers by Dr. Anstie and Dr. J. W. Ogle. Dr. Glover, "A Case of Uncomplicated Aphasia." Dr. Moxon, "On Symptoms of Cranial Tumours destroying Nerves cured by Iodide of Potassium." Dr. Habershon, "On Cases of Heart Disease."

QUEKETT MICROSCOPICAL CLUB, 8 p.m. Mr. M. C. Cooke, M.A., "On the Tremelloid Uredines."

VITAL STATISTICS OF LONDON.

Week ending Saturday, November 11, 1871.

BIRTHS.

Births of Boys, 1091; Girls, 1115; Total, 2206.

Average of 10 corresponding weeks, 1861-70, 2078'4.

DEATHS.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29'57 in. The highest was 29'97 in. on Sunday morning, and the lowest 29'29 in. on Wednesday morning.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

FLUID MEAT.

A New Preparation containing all the constituents of Lean Meat in a soluble form.

Messrs. DARBY and GOSDEN respectfully call the attention of the Profession to this important and valuable improvement in a soluble animal food. The necessity for such a food in the treatment of diseases and during convalescence is fully recognised by the Profession, and even by the public, as is clearly manifested in the ready acceptance and extensive employment of Liebig's Extractum Carnis.

Whilst the public are unable to appreciate the fact, yet physiologists are well aware of the objection to an extract of meat consisting, for the most part, of the elements of nutrition in a state of retrograde metamorphosis: taking from animal flesh what is soluble in cold water, subjecting the solution to a boiling-heat and evaporation—*i.e.*, making an extract—excludes all the fibrine, albumen, and gelatine, the very substances which give meat its superiority as an article of diet over all others. These constituents are those most needed to supply the waste from wear and tear, and to restore the tissues after the rapid destruction caused by fevers, inflammations, and other exhausting diseases.

Baron Liebig himself recognises the inefficiency of his "Extractum Carnis." He has remarked ("Lancet," 1865)—"Were it possible to furnish the market at a reasonable price with a preparation of meat containing in itself the albuminous together with the extractive principles, such a preparation would have to be preferred to the Extractum Carnis, for it would contain the nutrient constituents of meat."

This is exactly what is accomplished in our FLUID MEAT. Fibrine, albumen, gelatine, together with all the saline constituents and extractive matters, exist as in meat and its tissues, but that they are brought into a soluble state—*i.e.*, the first step in stomach-digestion—by means of pepsin and hydrochloric acid, an artificial gastric juice. It will therefore be obvious how well adapted this Fluid Meat must be for all cases of weakened digestion, irritable stomach, insufficient nutrition, and convalescence from diseases which, like fever, consume the various tissues. It must also be equally acceptable as a concentrated form of food to persons in health, when subjected, by exercise or otherwise, to temporary exhaustion and wear and tear.

We may state that, before making our preparation thus public, it has been submitted to trial in a variety of cases—some of them of a very exceptional character—in each of which most satisfactory results of its value as a nutritive and restorative agent have been obtained.

For further information, see Pamphlet on "Fluid Meat," published by Messrs. J. & A. Churchill, New Burlington-street.

FLUID MEAT is sold in Jars at 10s. 6d., 5s. 6d., & 3s. each, by
DARBY & GOSDEN, Practical Pharmacutists,
 140, LEADENHALL-STREET, LONDON.

THE LONDON HOSPITALS
 USE
WHITEHEAD'S SOLID ESSENCE OF BEEF
 AND
SOLIDIFIED SOUP SQUARES.

1 lb. of the Essence equals 42 lbs. of Butchers' Meat; each SOLIDIFIED SOUP SQUARE MAKING 1½ pints of delicious Soup. See Leaders in "Telegraph," "Pall-mall," &c.

Wholesale of Copland & Co., Travers & Sons, Preston & Sons, Crosse & Blackwell, E. Lazenby & Sons, &c., and of the Manufacturers, at 8 and 9, Lime-street-square, London.

MELBOURNE MEAT-PRESERVING COMPANY (LIMITED).
COOKED BEEF AND MUTTON, IN TINS,
 With full Instructions for use. PRIME QUALITIES AND FREE FROM BONE.
 Sold Retail by Grocers and Provision Dealers throughout the Kingdom. Wholesale by

Fox's "palatable" Castor Oil

Natural Mineral Waters of Vals, Vichy, Carlsbad, Seltzer, Kissengen, Homburg,
 PULLNA, FRIEDRICHSHALL, &c., direct from the Springs; also the Artificial Mineral Waters prepared by Dr. Struve and Co. at the Royal German Spa, Brighton, and the Natural Bromo-Iodine Water of Woodhall Spa, Lincolnshire.—Agents, W. BEST and SONS, 22, Henrietta-street, Cavendish-square, London, W.

**WESTERTON'S PATENT
 ZYMOTIC DISINFECTING FLUID**

Prevents the spread of infection; protects the nurse and those about the sick-room. Sponging over the body with the Fluid disinfects the emanations from the skin and (being volatile) exhalations from the lungs of the sufferer. Destroys the noxious properties of the excretions, and purifies the atmosphere.

PREPARED BY

W. C. WESTERTON, 85, Abingdon-villas, Kensington, London;
 and may be had of all Chemists, in bottles, 1s., 1s. 9d., and 3s. 6d.; 10s. per gall.

ORIGINAL LECTURES.

CLINICAL LECTURE ON PERIOSTITIS OF THE TEMPORAL BONE.

By JONATHAN HUTCHINSON, F.R.C.S.,

Surgeon to the London Hospital, and Lecturer on Surgery at the Medical School.

GENTLEMEN,—A few months ago an old man, aged 64 years, was admitted under my care into Mellish Ward, on account of various symptoms connected with his ears. He was extremely deaf, and it was difficult on that account to get a good account from him of the history of his illness. It appeared that his symptoms began about two months before admission, with pain in the left ear. This pain was attributed by him to "a cold." There was no history of other disease or injury likely to lead to earache or discharge from the ear. The pain persisted until about three weeks before admission, when he first noticed a discharge from the meatus. The earache on the left side then subsided, but about a week before admission he was attacked by a similar pain in the right ear, and this still remained. When first seen, besides the deafness, which was such that he could not hear a watch when in contact with either ear, the following symptoms were noticed:—There was a copious, fetid, brownish, purulent discharge from his left ear. There was no marked tenderness on pressing the region of the temporal bone on this side, if we excepted the articulation of the lower jaw, where he flinched slightly. On the right side, however, considerable pain was caused by very slight pressure over the seat of the articulation, and around it for some distance in all directions, especially over the front part of the mastoid process, just behind the ascending ramus of the jaw. The movements of his lower jaw were much impeded, and he could open his mouth only just enough to put out his tongue; it was quite impossible to examine the back of his mouth and throat. He had paresis of the left facial nerve; he could not shut the left eye so well as the right; and when the other facial muscles were in action the face was decidedly drawn to the right side. The man was perfectly conscious, but "stupid," answered questions slowly, and performed muscular acts tardily; he seemed inclined to become drowsy when not interfered with. He was not feverish, his temperature being only 99° F., and there was no history of rigors.

The symptoms presented by this man pointed to abscess from periostitis of the temporal bones. The abscess on the left side had broken, but probably another was forming on the right side, and accounted for the extreme tenderness over the corresponding temporal bone. Periostitis of the temporal bone presents several points of difference from periostitis elsewhere; and it is, moreover, a disease of very grave import to the patient. I think, therefore, that we may with profit study the subject, as illustrated by the case before us, a little more in detail. You will do well to bear in mind that the temporal bone, unlike the bones of the trunk, is not covered on its opposite surfaces by the same periosteal membrane, the dura mater not being continuous with the periosteum covering the extra-cranial surfaces of the bone. You are well aware that necrosis and exfoliation of the portion of bone beneath an inflamed periosteum is a very common occurrence in the long bones; but necrosis of the temporal bone is comparatively rare. We may have periostitis of this bone accompanied by considerable supuration, and yet followed by complete recovery without the death of any portion of bone. This result is probably to be ascribed to the copious supply of blood which the temporal, in common with the other cranial bones, obtains through its double nutritive membrane, and in addition from the lining membrane of the meatus and tympanum. If, as is commonly the case, the inflammation begins in the external periosteum or in the lining membrane of the meatus, it may extend through the bone until, sooner or later, it reaches the dura mater, the internal periosteum. When this occurs, it will probably cause death. This fatal extension of the disease does not usually occur rapidly, many weeks often intervening between the first symptoms and the death. It does not, however, by any means follow that because a patient has periostitis of his temporal bone he will therefore have meningitis; for, as I have before mentioned, cases not unfrequently happen in which recovery takes place after the formation of an abscess in connexion with circumscribed inflammation of the external periosteum. Possibly we may attribute this comparative immunity of the inner surface of the bone to the absence of continuity between

the dura mater and the external periosteum. In the patient above referred to, there was reason to fear, from the deafness and weakness of the facial nerve, that the disease had already extended at least into the tympanum, if not to the internal ear and the cranial surface of the bone.

With regard to *cause*, it seems probable that exposure to cold is frequently the starting-point of the disease. The exposure to cold wind is followed by severe persistent earache and the other symptoms which have been mentioned.

The treatment of periostitis of the temporal bone resolves itself mainly into the possibility or impossibility of opening the abscesses which form in connexion with the inflamed periosteum. If there be a collection of matter over the mastoid process, it can, of course, be readily enough got rid of by a free incision; but if the abscess point in the meatus, and especially in some part of the pharynx, then opening it may be difficult, or even impossible.

In our patient, the impediment to opening the mouth was quite enough to prevent any examination of the back of the throat.

ORIGINAL COMMUNICATIONS.

FATAL PENETRATING WOUNDS OF ABDOMEN AND THORAX INFLICTED BY AN ASSASSIN ON AN INDIAN JUDGE.

By J. FAYRER, M.D., C.S.I.,

Professor of Surgery, and Senior Surgeon, Medical College Hospital, Calcutta.

At about 11.15 a.m. on September 20, 1871, I was suddenly summoned to see the Hon. J. P. N., Officiating Chief Justice, who had been stabbed, on entering the High Court, by an assassin, who rushed on him, and wounded him with a knife in the back and abdomen. He had been taken to a neighbouring house, and Dr. W. Palmer, of the General Hospital, who happened to be passing, had been requested to see him. I found the patient lying on a couch in a lower room; he was pale, agitated, and exhausted; his respiration was hurried, and his pulse was quick and feeble; his hands were cold, and bedewed with moisture. His clothes had been partially removed; those that remained were stained with blood, and other blood-stained clothes were about him. Dr. Palmer informed me that Mr. N. had been stabbed in the abdomen and thorax, but that he had not yet ascertained the depth of the wounds. There had been, it was said, considerable loss of blood; his appearance confirmed that statement, and it also evinced the shock of a severe injury.

On examining the wounds, I found one directly through the umbilicus, passing into the abdominal cavity; but there was not, nor had there been, any protrusion of the contents of the abdomen. Blood was trickling freely from the wound, but there was no appearance of any alvine fluid with it. The wound was three-limbed (Y), evidently having been caused by first stabbing and then withdrawing the weapon with a wrench of the wrist. It was a little more than an inch in length. A compress and bandage had been applied. I introduced a silver-wire suture to prevent gaping and protrusion, and over it a fold of lint and a bandage soaked in carbolic acid lotion. There was a slight abrasion on the inner and palmar aspect of two fingers of one hand, as though, in attempting to seize the knife, they had been grazed. There was also a wound entering the posterior border of the left axilla, a little more than an inch from its margin, and penetrating deeply downwards, inwards, and forwards, through the muscles and between the ribs, one of which could be felt to descend into the thorax. It did not appear to me that the lung had been wounded, though the pleural cavity was certainly opened. The depth of penetration beyond this could not, of course, be then ascertained. The bleeding from this wound was trifling, and easily arrested by slight pressure. The wound was of the same shape as that in the abdomen; a suture was similarly applied, with dressing and a bandage. Respiratory sounds were audible all over the left side of the thorax. No air came from the wound. There was no hæmoptysis. At one time I imagined I heard a somewhat cavernous sound; this may have been due to the hernia of the stomach through the diaphragm, discovered after death. The result proved that no pneumothorax had occurred. He was very restless, tossing about, complaining much of cold, notwithstanding the heat of the weather. His face was pinched and anxious, and the lips pallid. There was constant thirst; nausea and retching soon

supervened, and continued more or less until the end. Shortly he began to complain of a sense of distension of the bladder, and an intense desire to empty it; he was unable to do so voluntarily. A catheter was passed, and only a few ounces of clear urine withdrawn. He was very much depressed, but stimulants were very sparingly administered, with the view of not interfering with the formation of clots; iced water and gallic acid were administered. Towards 1 p.m., when restlessness, pain, and distressing irritability of the stomach increased, opium was given, and repeated at intervals of two or three hours with the greatest relief to his suffering. He retained consciousness until about midnight, and ceased to breathe at 1.20 a.m. of September 21, or about fourteen hours and a half from the time when the wound was inflicted. He sank from exhaustion and shock. The retching, vomiting, and desire to void urine continued throughout, but they were much allayed, as was the distressing restlessness, by the opiates.^(a) Towards midnight his pulse gradually failed, he became exhausted and unconscious, and sank at 1.20 a.m.

The post-mortem examination was conducted (in my unavoidable absence) by Dr. J. Ewart, in the presence of Dr. Woodford, Police Surgeon, and Dr. W. Palmer, of the General Hospital. The report is appended.

M. N. was a robust, muscular, and very powerful man in the prime of health and life, aged 52, when he was mortally wounded. The assassin was a Mahomedan, of 40 to 45 years of age, of middle size, but vigorous and powerful frame. He was seized on the spot, has been tried, and capitally sentenced. As yet his motives for committing the crime are undiscovered. He is probably from the North-west of India, and the knife he used was a long sharp-pointed weapon, with a white bone or ivory handle, bound with brass. The blade was very sharp, and at both edges near the point (which was slightly broken—probably against the spinal column), triangular in shape, and about a foot in length—just such a knife as one sees in the Punjaub and North-west of India. Throughout the treatment of the case I received most valuable aid from Professor N. Chevers, Dr. J. Ewart, and Dr. W. Palmer.

Dr. Joseph Ewart, Surgeon Bengal Army, made the following statement with regard to the post-mortem examination:—"In company with Dr. Woodford and Dr. Palmer, I examined the body of the late Chief Justice N., at the house of Messrs. Thacker, Spink, and Co., at 6 a.m., on September 21, or four hours and forty minutes after death. The body was found to be well nourished, the general appearance being that of a powerfully built and well-made man of average height. Exactly at the umbilicus there was a wound, of a somewhat triangular shape, and about an inch in its longest diameter. Its direction, for about a couple of inches through the abdominal wall, was obliquely downwards and backwards, and then almost straight backwards towards the spinal column. The external opening of this wound was partially filled by coagulum, and the dressings covering the same were soaked in semi-fluid dark-coloured blood. On following this wound inwards, it was found to pass through a fold of the small intestine, severing fully three-fourths of its calibre. The contents of the bowel had escaped in quantity through this opening into the cavity of the peritoneum. The wound then passed through several folds of the mesentery, thus wounding several mesenteric vessels, but without injuring the corresponding divisions of the intestines. Considerable bleeding had taken place from these wounded vessels, and upwards of a pound of fluid and coagulated blood was found extravasated, and gravitating towards and pressing upon the bladder. The peritoneum covering the intestines, omentum, and mesentery was of a vividly pink hue, and in the first stage of acute inflammation. No lymph had been exuded, sufficient time to allow of its formation not having elapsed between the occurrence of the injuries aforesaid and death. About an inch and a half from the posterior fold of the left arm-pit, and on a level with the same, posteriorly, another wound was observed a couple of inches long, also of a triangular form, with one of its angles extended, apparently from the withdrawal of the weapon employed by the assassin. This wound passed downwards, forwards, and inwards, eventually penetrating the walls of the chest, and entering the pleural cavity between the seventh and eighth ribs, about four inches anterior to their attachment to the vertebrae. On opening the chest, it was found that the weapon had grazed and indented the inferior margin of the seventh rib, dividing the intercostal

artery, and actually incised cleanly the upper part of the eighth rib to the extent of fully three-fourths of its substance, the remainder having been fractured transversely. The broken end of the rib next the spine was split longitudinally. On further prosecuting a search for the course of this wound, it was discovered that it passed through the diaphragm, without, however, injuring the pulmonary pleura or lung, and without damaging any of the abdominal organs. The opening in the diaphragm was tightly plugged by a portion of omentum with a knuckle of the left division of the stomach, which were lying in the pleural cavity. Both these protrusions were intensely congested, the peritoneum covering them being in the primary stage of inflammation. There was a very small quantity of bloody serum in the cavity of the pleura. The stomach, kidneys, liver, spleen, pancreas, heart, lungs, and the muscular and nervous systems were perfectly healthy. Death was caused by a combination of mortal injuries—(1) A large wound of the intestine with escape of its contents into the cavity of the peritoneum, and consequent peritonitis (first stage); (2) hæmorrhage from several wounded mesenteric vessels; (3) traumatic hernia of the omentum and stomach through a wounded diaphragm; (4) the severe shock of the general nervous system sustained by these serious injuries to vitally important parts." Calcutta.

AUTOPSY OF A CENTENARIAN.

By R. TUTHILL MASSY, M.D.

DEATH has at length overtaken Thomas Geeran, at his reputed age of 105 years and 6 months, but not before he desired death—bearing out that belief of Hufeland, Foderé, Barhez, and others, that old people have the power by will to prolong life, making man the more exalted and accountable. It is now four years since I first prescribed for Geeran during an attack of pleurisy in the left side, and although at that time I had but a slight hope of his recovery, yet he expressed no wish for relief by death. Recently it was otherwise; three weeks before his last illness he said, "I wish God would take me away." On October 21 he was taken to the Brighton Workhouse Infirmary in a state of insensibility, from which he rallied for a few days, when he again became unconscious and continued so until his death on the following Saturday, October 28, at 8.30 p.m. The immediate cause of death was "serous apoplexy," according to the opinions of Drs. Ross and Richards. Not until about three hours before his burial on Wednesday, November 1, did the event become known to me, when I instantly drove to the Infirmary and was fortunate in meeting Surgeon Richards, who, with his usual courtesy, gave his consent for a post-mortem examination, and helped in procuring through the master that of Geeran's widow. Thus armed I entered the dead-house; in it lay three bodies, one that of Geeran, in a black coffin, with his name written in white chalk on the cover. The Infirmary porter removed the lid and raised the clean white shroud. Geeran looked calm, and as if still in the act of breathing his last. His hair and beard have recently become scanty; the old sabre-cut could be distinctly felt along the left parietal bone; but time would not allow me to examine the brain. His gums were hard and toothless, the last (left eye-tooth) having fallen out about two years since, and, as he could not find it, he believed he must have swallowed it.

The body appeared well proportioned, thin; skin clean and white, without any appearance of hair (so different from Old Parr); the abdomen sunken and changing into a greenish tinge; limbs strong and extended; skin adhering closely to the sternum and ribs; pectoral muscles were of a bright pink; bony chest, elastic, the knife running readily through the cartilages. Seeing this, the old porter remarked—"Your knife,^(a) sir, cuts ribs better than skin." The ensiform cartilage was elastic and prominent. There was some difficulty in raising the breast-bone, on account of close attachments by dry cellular tissue to the anterior mediastinum. After a very careful dissection through a thick membrane, the heart was found firmly encased in the pericardium—the result of some former inflammation; the lung on the left side adhered to the ribs and pericardium. The heart appeared small and felt firm in texture; valves healthy; columnæ carneæ dense and of a bright red. The pulmonary artery had a thick bluish-black clot of crassamentum

(a) The vomiting and peculiarly pinched expression of face were no doubt due to the diaphragmatic wound and hernia of the stomach. The urgent desire to micturate is accounted for by pressure of the blood-clot on the bladder.

(a) Not having a dissecting-knife with me, nor any preparation, I borrowed a pocket-knife from the head nurse and a common darning-needle threaded with pack-twine, which for the emergency answered well.

occupying its circumference from the semilunar valves; no osseous formation visible or to be felt; lungs were of the dark mottled grey of old age, otherwise healthy and elastic.

Surgeon Richards arrived during my examination of the liver, for we both felt most anxious to see its appearance, on account of the old man's reputed love for his morning glass of rum(b) during the last seventy or eighty years. The liver was not of the usual hepatic colour; in this case it presented a deep purple-black, with a smooth shining surface, to the touch more elastic, and, if anything, slightly enlarged. It did not cut like ordinary liver, for all the structure and the vessels gave me more the idea of the black carbonised lung of the coal-miner, except that here the colour was due to coal-black blood, thick as black-currant jelly, which oozed out. The thin edge of the liver had a dull leaden hue, due to the change since death, now the fourth day. The gall-bladder contained some dark-coloured bile. The duodenum and pyloric end of the stomach felt hard and irregular; I therefore passed the knife through their coats, and found the structure changed to the extent of three or four inches into carcinoma, with one ulcerated patch. This discovery led me at once to forgive that craving for stimulants for which he was so much blamed during his lifetime, even by those who were themselves contributors. There were no traces of fat in any part. The stomach contained from six to eight ounces of a coffee-coloured fluid. His diet while in the Infirmary consisted of beef-tea, milk, and farinaceous food, with one gill of gin a day.

The genito-urinary organs were healthy, and, it is said on good evidence, exhibited functional activity up to two years ago. Old Thomas Parr, at 105, did penance in a white sheet in Aldersbury Church for an illicit amour with fair Catherine Milton, on which the poet Taylor wrote—

"Should all that so offend such penance do,
Oh! what a price would linen rise unto!"

Had we not made this examination, it would have been concluded that death resulted from old age or serous effusion on the brain, caused by a worn-out constitution. But here we are led to think that length of years did not lead to his death so much as force of will; for is it not remarkable that, with two such diseases as those of the pericardium and stomach, neither appeared to contribute to that end?—more remarkable still, that he went out in all weathers, ascended the heights around Brighton, only occasionally stopping to rest, had no marked difficulty in breathing, had a remarkably quick blue eye, without a trace of the *arcus senilis*, and no ossific deposit in his cartilages! He was exceedingly fond of reading history and translations from the ancient classical authors; from "Xenophon" he could speak on the fortunes of "the ten thousand." He had all the punctuality of a soldier to the day and hour within a mile of his lodgings, and was truthful.

A new edition of his eventful life is in the press, and will be out the end of this month(c). He enlisted in Waterford; was present at the capture of Seringapatam, in 1799; at Corunna, in 1809, he received two gunshot wounds below the left knee; at Vittoria, in 1813, a severe sabre cut in the head. He escaped through Waterloo, and entered Paris with the victorious army; was discharged, invalided, from the 71st Highlanders, in 1819, with 114 days' pay, *but without any pension!*

Brighton.

MIDWIFERY NOTES FROM BRITISH KAFFRARIA, SOUTH AFRICA.

By CHARLES JAMES EGAN, A.B., M.R.C.S.E.,
Assistant-Surgeon to Guy's Hospital, and District Surgeon,
King William Town, Kaffraria.

As your paper appears always to be open to correspondence from abroad, you may perhaps feel willing to publish the following notes of midwifery practice in the frontier part of the colony of the Cape of Good Hope.

I will commence by stating that midwifery and the diseases of women and children form the most important branches of Medical practice in this place; and, judging from my own experience in this colony, I should say that any Medical Practitioner intending to settle in a colony should make these branches of the Profession his especial study.

(b) A manufacturer of rum, from Jamaica, has informed me that rum prepared from the scum off the boiling sugar-cane and that from the drainings of the casks containing the molasses, mixed, has the reputation of "preserving the liver" in that hot climate. "The oldest inhabitants are rum-drinkers."

(c) Published by the St. James's Library Company, 80, King's-road, Brighton.

From my practice in this place I have brought together the following notes and statistics of 400 cases of midwifery attended by me among the European population, thinking they may be interesting to some of your readers, and may be compared with similar statistics of home practice. But in such comparison it must be borne in mind that many of these cases were not seen by me until the labour was far advanced, and by the time I arrived the fate of mother and child was hanging in a very doubtful balance. Not being called in to see a case until labour has lasted over twenty-four hours; having to ride twenty or thirty miles in a temperature of 80° in the shade and 120° in the sun; having no nurse or assistance of any kind, except a neighbour called in for the occasion, make a midwifery operation of any kind difficult, and throw a great responsibility on the Medical attendant. Yet in practice here one must be prepared for all such emergencies.

Deaths of children 18

Some of the cases placed in this table as natural labour should perhaps more properly be classed as complicated labour; for, although the labour itself was short and natural, it was followed by pelvic cellulitis, phlegmasia dolens, or fever. Thus, the death of a primipara in the class of natural labour was caused by puerperal peritonitis. The details of the case were as follows:—Mrs. F., a fat, florid woman, aged 24 years, taken in labour of her first child. Vertex presentation; first stage lasted about six hours; second stage four hours, delayed by inertia; ergot was administered, and also an enema of salt-and-water; a male child born alive; placenta expelled in about ten minutes; discharge natural. This lady was very feverish for two days previous to her labour, suffering from a severe attack of influenza. In the morning, ten hours after her confinement, she appeared well, but the pulse was very quick—120. There was no tenderness over the abdomen; the lochia natural. On the succeeding day there was high fever—pulse 140; she was suffering from a slight attack of bronchitis, great tenderness over the lower part of the abdomen, and suppression of the lochia. From this day regular puerperal peritonitis set in, terminating in death on the eleventh day. The case of death in a primipara, after the use of forceps (see table), should also be placed in the class of complicated labour. Here death resulted from an attack of typhoid fever. The following are short notes of the case. Mrs. J., aged 21 years, in labour of her first child; vertex presentation. First stage lasted twenty-five hours; second stage, three hours. During the first hour of the second stage the head entered the pelvis, but the pains gradually became weak, and no advance was made. Ergot of rye was administered, and an enema of salt-and-water, but without any good effect. Forceps was applied, and a live male child extracted. She apparently progressed favourably until the third day, when fever came on; pulse 100; no tenderness over the womb; and the discharge remained natural. Two days after, diarrhoea came on, with tenderness and crepitus in the right iliac region. On the fifteenth day, rose-coloured maculae appeared over the chest and abdomen, and death occurred on the twenty-first day after delivery, from congestion

of the lungs. This lady was the only person in the family that was affected by the fever, although all were exposed to the same source of the disease. The fever poison was, in my opinion, derived from the water used for household purposes. The water was taken from a large tank, excavated in the back yard, built round with single brick and plaster. About eight feet from this tank there was a large cesspool beneath a privy, which had become so full that the level of the faeces collected in it was two feet higher than the water in the tank. The soil between the two was of a sandy, porous nature, and I consider there must have been a percolation of matter from the cesspool into the tank. The tank was filled with rain-water, collected off a galvanised iron roof. The water looked beautifully clear, but, on being tested with permanganate of potash, it showed the presence of a considerable quantity of organic matter. What surprised me here was that no other person in the house became infected with the fever. But I think this can be explained. So long as the persons using the water had sufficient out-door exercise and fresh air, they were able to eliminate the poison; but when Mrs. J. was unable to go about so much as usual, and then was laid up in bed, and being from the puerperal state more susceptible to the action of the poison, it developed itself. This water has not been used for household purposes since, and no other cases of typhoid fever have appeared.

I have accurately noted the duration of labour in 160 of these cases, and I find that the average was nine hours. Of these, thirty-seven were primiparæ, in whom the average was thirteen and a half hours; six were delivered by forceps, and one by turning. The longest case lasted thirty-six hours, the shortest three hours. In the remaining 123 cases of multiparæ, I find the average to be seven and a half hours; two of these were delivered by forceps, and one by turning. The longest of this class lasted twenty-four hours, and the shortest only one hour.

I have seldom met with rigidity of the os uteri as a cause of lingering labour, and none which did not readily yield to a few doses of tartar emetic; but I frequently have met with a cause of delay in that period of the labour just between the first and second stage—and that is, the anterior lip of the os uteri coming down in front of the child's head, forming a fold between the child's head and the os pubis, all the rest of the os being fully dilated. In these cases I have passed two fingers of the right hand into the vagina, and in the interval between the pains pressing the lip of the os upwards, and keeping it with my fingers in that position during a pain; and I have found this practice most successful, the head coming down, and the lip of the os receding above it. I have not met with any notice of this in any standard works on midwifery; but if it has been mentioned by occasional writers in the Medical journals, you must excuse my ignorance, and make allowance for colonial life. In the class of lingering labour I have placed two cases which should belong to cases of obstructed labour—viz., one in which the distended bladder was protruded external to the vulva by the child's head. The other case was one in which a pedunculated polypus of the uterus entered the pelvis, and prevented the passage of the head.

I have remarked that there is generally a very free discharge of blood in childbirth in this country, probably owing to the great heat; but I have only placed under the head of flooding those cases in which the hæmorrhage threatened life. I invariably follow the practice taught by Dr. McClintock (who was Master of the Dublin Lying-in Infirmary when I was a student), of keeping steady pressure of the hand on the uterus, after the birth of the child, until the placenta is expelled, and not putting on a binder until the third stage is completed. In some cases I have used injections of vinegar and water into the womb, and in others the tinctura ferri muriatis. In one case in which I used the latter, slight metritis followed. In three different cases in which, at previous confinements, not attended by me, dangerous hæmorrhage had occurred, I administered three-grain doses of gallic acid, twice daily, for six weeks previous to parturition, and in all these cases no more than ordinary discharge took place after the birth of the child. Whether this was the result of the use of gallic acid, or from more care being taken in making pressure over the uterus than was done on previous occasions, I leave for others to form their own opinion; but I certainly intend to try the same practice in any other case of the kind that may come under my care. To obviate as much as possible the constipating effects of the gallic acid, I had it made into pills with the extract of rhubarb.

The induction of premature labour was performed on account of deformity of the pelvis. I twice performed the operation on the same person. At the commencement of the eighth month of gestation the pelvis was barely three inches in the antero-posterior diameter of the brim, the sacrum being greatly

curved, and the promontory protruding into the brim. The first time I operated by perforating the membranes and evacuating the liquor amnii; labour came on in forty-eight hours, the child presenting with the breech. The second time I only separated the membranes from the uterus with a sound; labour came on in about eighty hours, the child also presenting with the breech. This woman had had four previous labours, in all of which the child had to be taken away with instruments. After her first confinement, which occurred in London, the Doctor attending her recommended her to have premature labour brought on.

I will finish this letter by giving details of a case which, though unusual, is not unknown:—

Mrs. B., aged about 35 years, at the time when she supposed herself to be two months pregnant, suffered from what she supposed to be a miscarriage—lumps and clots coming from her, with much hæmorrhage. From this time she had not any menstrual discharge; the abdomen increasing in size, though very slowly, and a tumour being perceptible. This state lasted for seven months, when she was taken with labour-pains and profuse hæmorrhage. I was then called in to see her. I found the abdomen about the size of the fifth month of pregnancy, of an ovoid form, the long diameter of the ovoid lying across the pelvis. The pains were regular and strong—like labour-pains. On making a vaginal examination, I found the os uteri partially dilated, and a presentation resembling placenta prævia. The hæmorrhage was so profuse that I plugged the vagina, and administered ten-grain doses of *secalis cornuti* every half-hour. After the third dose, a placenta was expelled of the same size and appearance as it would be at the natural termination of pregnancy, with this exception, that where the funis should have been there was only a withered membrane, and on the surface of the placenta were numerous hydatiform tumours, like large white grapes, full of clear fluid. This must have been a case of separation of the embryo from the placenta at the second month of gestation, the placenta not coming away, but remaining attached to the uterus, and increasing to the normal size it should be of at the termination of pregnancy, and at that period being naturally expelled.

Should you consider these few notes on midwifery practice among the European population of any value, I can follow this communication by some cases taken from the native population.

King William Town.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

ST. GEORGE'S HOSPITAL.

At a recent visit to the operating theatre of this Hospital, we saw, besides operations for harelip and nævus of the scalp, three cases of epithelioma treated by excision. These were of considerable interest—the first as arising from a well-ascertained blow, and growing rapidly, in a young man; the second as recurring for the second time in the situation of the original disease, without glandular affection; and the third as also being due to irritation upon a part much exposed to undue pressure from deformity.

EPITHELIOMA OF FACE.

(Under the care of Mr. POLLOCK.)

A young man, of good general health; he received a blow on the left side of his nose, from a cricket-ball, six or seven weeks before, and about three weeks later, on applying to Mr. Pollock, there was noticed in this situation a small vascular-looking nævoid growth. A fortnight later it had still a nævoid aspect; but presented also a suspicious appearance of malignancy. He was admitted into the Hospital, and in a day or two suffered from a slight attack of erysipelas of the face; the small tumour partly sloughed away, and there was left an oval-shaped warty excrescence, tuberculated on its surface and dark in colour. This was seized with forceps, and dissected away wide of the disease. The edges of the wound were brought together by means of the continuous suture, and covered with collodion. Mr. Pollock, alluding to the possibility of its recurrence, said that such was much more likely to be the case in a young than in an old person. If it returned, he should apply some strong escharotic, such as chloride of zinc, to it. Mr. Pollock recom-

mended the continuous suture in wounds of the face, as they are less likely to be followed by scars if so treated.

EPITHELIOMA OF SCALP.

(Under the care of Mr. POLLOCK.)

This growth was different in appearance, but similar in structure, to the first case. It was seated on the top and side of the head, was of the size of a small fist, and irregularly nodulated and ulcerated on the surface. It projected from the level of the surrounding parts, and was of a reddish colour. An epithelial growth had been removed from the same situation twice previously. The second operation was performed in January, 1867, and the first only a short time before the second. It was now excised by an incision through the healthy parts wide of the diseased tissues, and one or two suspicious tubercles, which could be felt in the skin on one side of the large mass, were dissected out. It was expected before the operation that considerable hæmorrhage would follow the removal of so large a tumour from the scalp, and that some trouble was to be expected in controlling the hæmorrhage, from the numerous vessels which anastomose on the scalp, and which were supplying the tumour. This, however, was not the case, and the edges of the wound were brought together without delay by means of needles and twisted sutures. This was not done with the hope of getting immediate union—for the needles would require to be soon removed, owing to the pressure they were exerting on the edges of the wound—but with the intention of controlling hæmorrhage should there be a tendency towards bleeding during or after recovery from the effects of chloroform.

EPITHELIOMA ON THE SOLE OF THE FOOT.

(Under the care of Mr. PICK.)

This was a red, granulated, fleshy-looking growth, the size of a large walnut, along the outer edge of the sole of the foot, associated with talipes equino-varus, in an elderly man. It was removed by dissecting it, with the skin around it, off from the fascia beneath. Mr. Pick remarked that in all probability the constant irritation from pressure had been the cause of the disease; for, as the patient was deformed by talipes, the portion of the foot on which it occurred was that which received the weight and pressure of the body in walking. Should the disease recur, amputation would be the treatment to resort to.

Mr. Pollock also operated on two other cases. One a hare-lip, associated with cleft palate, both hard and soft. The operation was performed without chloroform. Mr. Pollock stated his objection to operating on cases of cleft palate before the third or fourth year, because, as children are very intolerant of loss of blood, the quantity (even though very small) lost at the operation might be attended with fatal consequences.

The other case was a nævus, the size of a cherry, in the course of the parietal suture of an infant. This Mr. Pollock tied, after transfixing the base of the tumour by means of two needles passed at right angles to each other. Mr. Pollock has never known any ill-consequences follow from ligaturing a nævus in the neighbourhood of or over the fontanelles.

INFIRMARY FOR EPILEPSY AND PARALYSIS.

ON NEURO-SYPHILITIC AFFECTIONS.

(Cases under the care of Dr. ALTHAUS.)

(Continued from page 617.)

Case 2.—Recent Syphilitic Paraplegia.

A PAPER-STAINER, aged 32, had a chancre three years ago, and secondary symptoms affecting the skin and fauces at intervals. He was first seen on May 17, 1869, when he was suffering from complete paraplegia, which had come on rather suddenly about ten days previously. He had been apparently well, when he began one evening to complain of sensations of "pins and needles" in the feet; next morning he felt numbness in the lower extremities, and staggered in walking. As the day wore on he got worse, and towards evening was perfectly helpless. He was carried into the consulting-room of the Infirmary, being quite unable to move his legs. There was complete anæsthesia from the waist downwards; the bladder and rectum were not affected. The paralysed muscles responded well to both the induced and continuous current. The legs were much colder than the arms. There was a slight degree of ptosis of the left eyelid, and incomplete palsy of the rectus externus of the same eye. This patient emitted a most disagreeable smell from the surface of his body, and this was quite as bad when the patient's back

was turned as when one faced him. It was not the peculiar "poor-man's smell" which is so often noticed in out-patients of Hospitals, and which arises chiefly from filthy shirts and underclothing, nor was it the well-known unpleasant smell which is owing to foulness of the stomach; but it was a smell *sui generis*. Ordered gr. xv. of potass. iod. thrice daily.

May 24.—Patient reports himself somewhat better; the numbness is not so great, and he can move his legs a little when he is sitting on a chair. Gr. xx. of potass. iod. thrice daily.

31st.—Patient takes the iodide well. Can stand when supported by one person's arm; moves his legs more freely.

August 2.—The iodide has been continued without ever disagreeing. He can now walk pretty well for about a mile with the aid of a stick; anæsthesia completely gone.

October 18.—Patient presents himself, apparently quite well. The smell has completely disappeared. Discharged.

This is one of a class of cases showing that *in recent cases of syphilitic paraplegia large doses of potassic iodide are sufficient for a cure.*

Case 3.—Syphilitic Paraplegia of Three Years' Duration.

A cabinet-maker, aged 39, married, of wretched appearance and sallow complexion, applied at the Infirmary on February 27, 1871, complaining of inability to walk. It appeared that he had long suffered from shooting pains in the head and limbs, a feeling of faintness, and weak sight. A twelvemonth ago he occasionally lost his sight completely for a few hours, after which it would return. He is deaf in the right ear. At the commencement of 1868 he began to suffer from "pins and needles" in the feet, and gradually lost power over the lower extremities. There had never been complete paralysis; the patient could turn in bed, and walked slowly and in a jerky manner with the aid of a stick and another person's arm. He cannot stand with his eyes closed for more than a few seconds, finds it difficult to put his foot on a chair, and has scarcely any command over the ankle-joint. There is difficulty of micturition and defæcation. The patient, who seems to be a truthful and religious man, denies having had any sexual relations out of wedlock, and says he had never had any sore on the penis. His wife, who accompanies him, has the appearance and bearing of a woman of the town, and has a copper-coloured eruption on the forehead and neck, and swollen cervical glands. On being questioned, she complains of a "nasty discharge from the womb," which she has had for a long time. Patient was ordered potassic iodide, in ten-grain doses *ter die*, and a table-spoonful of cod-liver oil twice a day.

March 6.—Feels rather better in himself, but is still very poorly on his feet. Dose of potassic iodide increased to fifteen grains.

13th.—Much the same as before. To take twenty grains of the iodide thrice daily.

April 3.—Symptoms of iodism; the dose is reduced to ten grains *ter die*. There being no improvement, the constant galvanic current was ordered to be applied to the spine three times a week.

June 26.—Patient, who lives at a considerable distance from the Infirmary, has only been able to attend once a week for the application of galvanism. The general aspect of the case remains unchanged, although considerable doses of the iodide salt have been taken for four months. Patient ceased attendance.

This is one of a class of cases showing that *in syphilitic paraplegia of long standing, iodide of potassium produces little if any benefit.*

Case 4.—Neuro-Syphilis of Nineteen Years' Standing.

A carpenter, aged 54, a very intelligent man, applied at the Infirmary on April 1, 1870. He had had a chancre in 1851, followed by rash and sorethroat. Three months had scarcely elapsed after the primary affection when cerebral symptoms began to make their appearance. He lost his memory to a great extent, had difficulty in speaking, and gradually became very weak in his legs. He applied at a general Hospital, and, after two months' treatment, was apparently quite recovered. Two years afterwards he had several convulsive fits, in which he lost his consciousness; and some years later he was out of his mind for a few days, and very violent. He is a total abstainer, but occasionally feels now as if he were drunk and would fall; but he can by an effort rouse himself, "without going off." His speech is now tolerably distinct, although articulation seems troublesome; his memory is better than it was ten years ago; he feels no diminution of his intellectual capacity; he has slight ptosis of the left eyelid, and numbness in the third and little-finger of the right hand. He applied at the Infirmary chiefly on account of his walking so badly—indeed, he walked like a man suffering from locomotor

ataxy. As it appeared that the man had already taken large quantities of mercury and potassic iodide, no medicine was given. The constant current was applied continuously to the spine, and intermittently to the nerves of the legs. After twenty applications the patient walked very much better than before, and ceased attendance.

This is one of a class of cases showing that in syphilitic paraplegia of long standing the constant galvanic current is an excellent remedy, which should always be employed where iodide of potassium fails to do good.

Case 5.—Syphilitic Affection of Cerebral Nerves.

A shoemaker, aged 35, had for the last three years suffered from "venereal." He now (May 8, 1871) complains chiefly of drooping of the right eyelid, and the rectus internus of the same eye appeared to be paralysed. Nocturnal headaches were likewise complained of. Potassic iodide was given in ten-grain doses, and the constant current was applied to the levator palpebræ superioris and rectus. After a few weeks of this treatment the patient was apparently quite well. That the ocular muscles were beneficially affected by the constant current, and not so much, if at all, by the iodide, became clear from the circumstance that there was immediate improvement after each application, and that no progress was made in the interval between two applications.

It is of importance that in cases of this kind the constant current should be used early, as when ptosis has existed for many months or years it often resists treatment which would almost certainly have cured it in the commencement of the affection.

On analysing the symptoms of neuro-syphilis, we cannot experience any real difficulty to bring them into accordance with the teachings of recent physiological pathology. During the last ten years we have evidently been too much under the influence of the writings of Engelsted, Gros, and Lanceraux, who, in a number of cases of fatal neuro-syphilis, did not discover any anatomical lesions; from which it was concluded that neuro-syphilis was probably always a merely functional disease. We are surprised to find that even so recent a writer as Dr. Beyer (*New York Medical Journal*, 1870) admits this now completely untenable view. Indeed, it may be fairly said that we may always discover structural changes in the nervous centres of syphilitic persons who have died with striking nervous symptoms, if we only know how to look for them. It appears from the observations of Virchow, Moxon, Heubner, and others that too little attention has been given to the examination of the cerebral arteries. On the other hand, it would plainly be a mistake to ascribe all nervous sufferings of syphilitic patients to coarse structural lesions. Some symptoms, although apparently formidable, disappear so rapidly—with or without treatment—that they must be looked upon as owing to temporary vascular disturbance within the cranium—viz., sudden changes in the diameter of the bloodvessels, and consequent variations in the amount of blood contained in them. Slight serous effusions, the absorption of which under proper treatment is easily effected, probably occur likewise. But where the symptoms are of slow growth, and an exceedingly gradual change in the physical and mental constitution of the patient is brought about, the pathological lesion is most probably external or internal pachymeningitis, which is most frequently found in autopsies. We may fairly assume that the severe headache from which so many syphilitic patients suffer is referable to such inflammation. It is found that either purulent, or sanguineous, or caseous exudation-products accumulate between the tabula vitrea and the dura mater (external pachymeningitis); or that the dura mater, arachnoid, and pia mater coalesce amongst each other and with the surface of the brain, forming thick grey fibrous callosities (internal pachymeningitis). Such formations necessarily cause pressure on both nerves and arteries in the neighbourhood of which they occur. If nerves are thus compressed they lose their function, and may gradually become atrophied. The coats of arteries coursing between these exudation-products undergo degeneration—the width of the bloodvessels is diminished, and at last complete occlusion occurs by thrombosis. Whether plugging of arteries also occurs spontaneously without previous meningitis, is at present not settled. Other pathological processes which may give rise to nervous disturbance are, gummatous tumours of the cerebral substance, and osteo-periostitis of the bones of the skull, chiefly on their inner surface; but such lesions are far more rare than those previously described. A succession of apoplectic seizures can only be explained by thrombosis in consequence of multiple circumscribed disease of the cerebral arteries, the direct result of which is softening of the corre-

sponding district of cerebral matter. When the patient recovers for a time without special treatment, the improvement is due to the establishment of collateral circulation in the brain, which is becoming gradually satisfied with a less abundant and more circuitously yielded supply of blood.

Dr. Altbaus believes that the constant galvanic current acts beneficially in neuro-syphilis, not so much by repairing the damage done to individual bloodvessels by thrombosis as by powerfully promoting collateral cerebral circulation, whereby the progress of softening is prevented, the nutrition of already softened matter improved, and thus function gradually restored, either completely or partially. Potassic iodide cannot do this; it may be able to neutralise in, or eliminate from, the system all or most of the syphilitic poison, which causes the arterial disease that in its turn gives rise to softening and hemiplegia; but it cannot cure the softening, where this has proceeded to any considerable extent. This is the reason why the constant galvanic current must be looked upon as the necessary complement of potassic iodide in the treatment of most forms of neuro-syphilis.

SATURDAY, NOVEMBER 25, 1871.

SANITARY ORGANISATION.

WHEN the Royal Sanitary Commission recommended, in their Report, that steps should be taken to "consolidate the present fragmentary and confused sanitary legislation," they were only pointing to what had long been a crying evil; but everyone rejoiced that the urgent and imperative necessity for reform in that direction had at last been given voice by so high and weighty a body as a Royal Commission. And still more lively was the satisfaction felt when the first actual step towards carrying out the recommendations of the Commission was taken by the passing of an Act, "for constituting a Local Government Board, and vesting therein certain functions of the Secretary of State and Privy Council concerning the public health and Local Government, together with the powers and duties of the Poor-law Board."

We have so repeatedly had to point out in these pages the difficulties with which Medical Officers of Health had to contend, the various, and but too often conflicting, authorities under whom they had to act, the confused and fragmentary Acts by which those authorities were appointed, and the uncertainties that attended attempts to set them in action, that we need not now dwell on the immense advantage of having a great central authority, such as is the new "Local Government Board," which combines into one all the various authorities which had hitherto looked after the Public Health, the Relief of the Poor, and Local Government. The need, and the

largeness of the concentration of powers thus gained, cannot be better pointed out than by quoting a few words from the paper, which we elsewhere publish, read by the President of the Association of Medical Officers of Health at their last meeting. Describing the new Act, to which we have referred, Dr. Druitt said—"The Poor-law Board, *eo nomine*, is abolished, so is the Medical Department of the Privy Council. All the powers and duties of the Secretary of State relating to registration, public health, local Government, drainage, sanitary matters, baths and washhouses, public improvements, towns' improvements, artisans' and labourers' dwellings, and local taxation, and all the powers and duties of the Privy Council relating to vaccination, and the prevention of disease, are made over to this new Local Government Board." This is a very important and valuable commencement of a reform which, as Dr. Druitt observes, should be extended, according to the recommendation of the Royal Sanitary Commission, "to the smallest areas of authority." Anyone who has happily had no experience of the annoyances and bitter vexations too often arising out of the present state of sanitary legislation, and who is in a state of blissful ignorance of its imperfections, will find them very clearly set forth by Dr. Druitt; but the most valuable part of his able and excellent paper is that which deals with the reforms needed in the organisation of sanitary districts and local health authorities. The Royal Sanitary Commission recommends that there shall be "one local health authority in every district, and not more than one; and that every local authority shall have a Medical Officer of Health, and it is suggested that the Poor-law Medical Officer shall be that Medical Officer of Health in rural districts; and that every such officer should have the power of an Inspector of Nuisances." Dr. Druitt offers some very important and, as we think, valuable suggestions as to the way in which the reforms recommended by the Royal Commission should be worked out. First, that "as the Poor-law Board has been abolished, so should be Poor-law Surgeons;" and that, instead of that title, something more attractive should be adopted, as "Civil Surgeon," or "Civil Curative Officer"; then that this officer should have preventive and sanitary duties added to his present ones; that he should therefore, of course, have an increase of status and pay; and that he should work with and under a Medical Inspecting Officer of Health. To this Curative Officer, or Civil Surgeon, Dr. Druitt would give a portion of preventive work—he should have the duty of reporting on local insanitary conditions; of reporting, of course, all cases of fever or cholera, and of, at the same time, accounting for them, if possible; and if insanitary conditions exist, of reporting whether proper notices have been served, and if not, why not—acting thus as Health Officer "of the first instance"; and the whole of the work, preventive and curative, of these officers, Dr. Druitt would make subject to the inspection and criticism of the superior Medical Health Officer, or "Civil Inspecting Practitioner." This latter officer should be possessed of higher and wider qualifications, and would therefore have to perform wider and higher duties. To him would the public look "for statistical information as to sickness and death, and their causes, over the area of his jurisdiction; for initiating and carrying out legal proceedings against nuisances; for inquiring into cases of uncertified deaths. Moreover, he should conduct post-mortems, make analyses, test adulterated food, determine the purity of water, act as coadjutor or substitute for the coroner," and so on. In this way we should have a combined curative and sanitary Medical organisation. The superior Inspecting Medical Officer would be provided by the Curative Officer, or Civil Surgeon, with all the information he would need as to the sanitary condition of his district, and the Civil Surgeon would be relieved from the possibly invidious duties of initiating law proceedings, and of the embarrassment of perhaps offending his friends and patients, while he would gain the support and help of having a superior officer at his

back. And we need not, surely, point out that there could not rightly be any feeling of jealousy on the part of the Civil Surgeon as to the higher status of the Civil Medical Inspector—there must necessarily be differences of rank in every organised service.

The plan thus suggested by Dr. Druitt is, we think, well worthy of attention. It is, of course, more fully developed in his paper, and to that we refer our readers. The exact way in which it should be carried out, the titles to be given to the two classes of officers, and other details, may be open to alteration or improvement; but, as it is, it is a valuable contribution towards the mode of working out one of the most important problems of the day. The Inspecting Medical Officers must be highly educated men, and would have very many and onerous duties to perform; but we incline to think, with Dr. Druitt, that they should not be debarred from private practice. There is much force in his remark that "the greatest possible inducement to keep pace with the day is responsibility of attendance on the sick; and that it would be limiting the choice of officers unduly if all degrees of private practice were disqualifications."

Dr. Druitt notices that the kind of system he advocates was some thirty years ago "foreshadowed by the arrangements in some rich and liberal London parishes. For instance, the parish of St. George, Hanover-square, used to employ a Physician and Surgeon, with handsome salaries, besides the general Practitioners." Sir James Clark (then Dr. Clark) and Mr. Howship were the last holders of these offices, and "the parochial Infirmary had a status equal to that of any Hospital." We may be certain that, under such a system, there never would have arisen the need of the "Hampstead Hospital Inquiry." All such institutions must, for due efficiency, have responsible salaried Visiting Physicians; and the kind of organisation recommended by Dr. Druitt would provide the necessary inspection and supervision.

HOW ARE WE TO CHECK INTEMPERANCE?

It is now generally admitted that some sensational articles which lately appeared in an influential review, respecting the increase of secret drinking amongst women in the upper and middle classes, were founded on most imperfect data, and that the alleged evil was gravely exaggerated. The writer, assuming his facts to be correct, launched out into an eloquent denunciation of the "growing vice." It is not denied that secret drinking is the most dangerous form of intoxication, most difficult to cure, and fraught with incalculable mischief. No one knows this better than the Physician. But no one knows better than the Physician that the charge brought against our countrywomen is without any such foundation as is worthy of serious consideration. In times past it was the custom of women of the better classes to stimulate and intoxicate themselves with certain quack medicines, the staple of which was strong alcohol. Drugs, too, such as opium and sal volatile, were extensively used by them. Pope refers to this practice in his memorable distich on "Simo's Mate"—

"Who in sweet vicissitude appears
Of mirth and opium, ratafie and tears."

The practice referred to continued long into the present century; but it must be remembered that an excuse might be offered for it in the hard drinking of the men of the period. The debauchery which prevailed amongst the higher and middle classes of men in the first quarter of this century was never exceeded, if equalled, at any time in the history of civilisation. Unquestionably, the current literature did much to favour the orgies which prevailed; and notably the "Noctes Ambrosianæ"—the most fascinating and graphic account of convivial meetings, as also nearly the last—had a marvellous effect on the imaginations and habits of the people. Happily, this has all passed away, and the man who, in the time of "the Regent," was considered a brilliant boon

companion, and who was known as a "two-bottle man," would not now be tolerated in decent society. One of the chief causes of this improvement in the habits of this class of men, was undoubtedly the cessation of their meetings at taverns, at which they carried on drinking to excess, to hours of the morning at which the present generation are asleep. Whatever a man's proclivities may be in respect to drinking, it is certain that in the presence of his wife and family he would be less likely to indulge in habits of drunkenness than if he were surrounded by his tavern friends, each of whom vied with the others in stimulating him to excess. Can it be denied that the great prevalence of intemperance amongst the lower orders is due to the congregation of men at gin-shops and taverns? We think not. This practice, now all but obsolete amongst the better classes, has of late, we fear, been greatly on the increase amongst mechanics and artisans. Hence an accession of crime, disease, and poverty. In the splendidly lighted and comfortable "gin-shop" the frequenter with his fellows forgets all the duties of home, and indulges to an extent to which, whatever his "home" might be, he would not there resort. This vice reacts on his wife and children, and they "retaliate" upon him by drinking strong liquors, and making the home he had made wretched still more miserable. The guardians of one of our most important western metropolitan unions tell us that this kind of intemperance is one with which they find the greatest difficulty to cope. They have found by long experience that the "pauper," who comes to them for either out-door relief or for admission into the workhouse, no sooner becomes independent of their assistance than he immediately repairs to his old haunt—the public-house—and returns to his habits of intemperance, which never fail to bring him back a recipient of their relief. The "licensing system" is one of the most important questions, which must be fairly met in the next session of Parliament. The ratepayers demand that some revision of it should be made; the health of the population cries out imperatively for some remedy for its deficiencies. Those best acquainted with the question are the foremost to admit its difficulty. But wherein lies the difficulty? Clearly in the extreme views which are entertained by the opposing parties in the discussion. Speaking for the Profession—not for that small number of them who would close public-houses altogether, nor for those, still fewer, who would let things remain as they are—we ask, Is there no middle course to be pursued? Is it impossible to preserve the "vested rights" of a large and influential class—the "licensed victuallers"—and at the same time give a check to the present unbridled course of a malignant intemperance? We think not. Mr. Gladstone has done infinite service to the cause of temperance by his reduction of the duties on foreign wines. He may yet place his countrymen in the position of owing him a deeper debt of gratitude, if, in any modification of the "Licensing Act," he shall make it possible for any seller of wines and spirits to hand over to the purchaser a sealed bottle, the contents of which cannot be consumed on the premises, but must be carried away for home consumption. Let it be possible to procure in every town of the United Kingdom, great or small, a bottle of wine or spirits pure and of moderate price. If a man wants to drink, let him share it with his family.

VOLUMETRIC ANALYSIS.(a)

To many to whom the phrase Volumetric Analysis is well known, the process itself is something mysterious and unintelligible; so that we hail with pleasure the appearance of Mr. Sutton's valuable treatise, as affording an opportunity of saying a word on this exceedingly useful invention.

(a) "A Systematic Handbook of Volumetric Analysis; or, the Quantitative Estimation of Chemical Substances by Measure, applied to Liquids, Solids, and Gases, etc." By Francis Sutton, F.C.S., Norwich, 2nd edition. London: J. and A. Churchill. Pp. 377.

There are two modes of ascertaining the exact constitution of a substance subjected to chemical analysis. One is by separating all its elements or ingredients in simple known forms and weighing them. This is gravimetric analysis or quantitative analysis by weight. The other process is founded, not on reducing a substance to its simplest constituents and weighing them, but by subjecting it to certain well-defined and well-known reactions, using for this purpose a solution capable, let us say, of neutralising a given quantity of the kind of material submitted for examination. In this way the quantity of the material submitted for examination neutralised may be exactly ascertained by knowing the quantity of the solution required to neutralise it. This is volumetric analysis, which, though it was mainly developed abroad, speedily acquired a well-recognised importance at home, especially among manufacturers. It had its first development among alkali manufacturers, the so-called process of alkalimetry having been invented long ago by Gay-Lussac. The object of the manufacturer was to ascertain the quantity of soda available in a given specimen of soda-ash, and for this purpose they compared the ash with a solution of soda of a known strength. If, now, ten drops of sulphuric acid exactly neutralised ten drops of the solution the exact constitution of which was known, but it required twenty drops of acid to neutralise a similar quantity of the solution being tested, it was quite plain that the latter contained twice as much soda as the former. Of course the exact point of neutrality would be easily ascertained by the behaviour of the solutions to test-paper.

Now, this is exceedingly simple and exceedingly easy; but the process implies three things. It implies a substance in solution whose power with regard to the substance to be estimated is exactly known. This solution must be of known strength. In the instance just cited the sulphuric acid would practically be known to be capable of neutralising so much carbonate of soda per cubic centimetre; so that, to know the quantity of soda in the specimen undergoing examination, one had only to know the number of cubic centimetres of sulphuric acid expended in neutralising a measured quantity of it. Another thing requisite is an accurate measure, such as is commonly called a "burette." Thirdly, the substances employed must react on each other in such a way that the completion of the reaction is easily recognised. In the instance cited the exact point of neutralisation would be indicated by litmus. But if the process be useful to manufacturers, it is not less so to Medical men, who by it can easily ascertain the composition of any specimen of urine submitted to them—at all events, as to its most important ingredients. Let us take two instances, either of some importance, which will further exemplify the two modes of making the standard solutions employed in practice.

It is well known that in many forms of acute disease the chlorides are remarkably deficient in the urine, whilst in others urea is equally so; the danger of this last condition is known to all.

Now, to estimate the chlorides in a specimen of urine, we take a given quantity of filtered urine, and into this is let fall, drop by drop, a solution of nitrate of silver, until a precipitate ceases to form. The silver solution is thus formed:—108 is the atomic weight of silver; but it would be too much to make a solution containing 108 grammes of pure silver, so the tenth of that is taken—viz., 10.8 grammes of pure silver—dissolved in nitric acid, and the solution made up to one litre by distilled water. (In these estimations the metric system is almost universally used.) Each cubic centimetre of this solution will contain $\frac{1}{10000}$ th of the atomic weight of silver in grammes, = 0.0108 gramme, and will precipitate exactly $\frac{1}{10000}$ th of the atomic weight of chlorine (35.5) in grammes, = 0.00355 gramme, as chloride of silver. The number of cubic centimetres required, therefore, to complete the precipitation in urine need only be multiplied into the last number to

give the exact quantity of chlorides in it. In this case the standard solution has been made on the atomic system; but there is another and (for the Practitioner) more convenient way, which we shall next illustrate.

To estimate urea, a solution is made, as in the case of the silver, but is of such a strength that .772 gramme of the red oxide of mercury dissolved in nitric acid and diluted is contained in 10 cubic centimetres of the solution. Next, let 40 cubic centimetres of filtered urine be mixed with 20 of a solution of baryta (= two volumes of urine to one of baryta), which will precipitate all the phosphates and sulphates, which would otherwise interfere with the reaction. The mixture is filtered, and 15 cubic centimetres, containing 10 of urine, are retained for examination. Into it is carefully dropped the mercurial solution, until turbidity is noticed from that point the reaction begins, so the quantity of mercurial solution in the burette must be carefully noted. The two must now be mixed and stirred freely, until a drop of the solution let fall into a drop of carbonate of soda solution turns yellow, when the reaction is complete. Here is the explanation of the process. The mercury unites with the urea to form an insoluble compound, but only after the chlorides are decomposed; so that the first drops do not count. As long as urea is being precipitated the carbonate of soda has no effect on the mercury, but as soon as all of the urea is thrown down the mercury solution is decomposed, and the red oxide precipitated. That is the meaning of the yellow colour. Now, by looking at the burette, the number of cubic centimetres required to produce this reaction may be known, and each cubic centimetre of the mercurial solution is equivalent to 0.01 gramme (0.154 grain) of urea. Of course, 10 cubic centimetres would contain ten times that amount, or 0.01 gramme, = 1.54 grain, of urea, from which, the total quantity of urine passed being known, the total urea excreted may be readily calculated. The solutions in this case are what are called empiric solutions; they are difficult to prepare, but easy to work with, (b) and in this way an analysis can readily be made, which otherwise would be exceedingly difficult or barely possible. We have used the metric system of weights throughout, while Mr. Sutton in that portion of his book which refers to urinary analysis—which, though short, is very good—makes use of the grain standard. This to Englishmen is very convenient, but for regular work we strongly commend the other.

THE WEEK.

TOPICS OF THE DAY.

THE announcement in the *Times*, on Thursday, that the indisposition of the Prince of Wales appeared to be the commencement of an attack of typhoid fever, and the paragraph confirming the report of the nature of the illness, which appeared in some of the evening papers, are calculated to awaken serious apprehension. Sir William Jenner arrived at Sandringham on Thursday, where Dr. Gull and Mr. Oscar Clayton were already in attendance. It is satisfactory, however, to learn that at present no unfavourable symptoms have appeared. That the late Prince Consort and the Prince of Wales should both be attacked by typhoid fever is, to say the least, an extraordinary coincidence, the more so as persons in so exalted a station should be, it may be supposed, shielded to a great extent from the attacks of preventible disease. But who can guard against the danger of the modern water-closet system? Dr. John Lowe, of King's Lynn, is also in attendance on the Prince.

A correspondent of the *Times*, writing from Constantinople on November 7, discusses the measures adopted by the Medical Board appointed by the Turkish Government for combating cholera and preventing its spread. The disease, after lingering about a month on the shores of the Bosphorus, broke out with

(b) Nobody need trouble himself with the preparation of these solutions; they are much more easily and economically got ready-made from Griffin, in Garrick-street, or the author of the book above referred to, at Norwich.

some intensity in the quarter of Kassim Pasha, an integral part of Constantinople, and afterwards at Hasskeuy, a populous village or suburb. Sanitary cordons were immediately established, and the isolation of the affected districts rigorously enforced. A large colony of English workmen is located within one of the isolated districts. Our countrymen have remonstrated with characteristic fervour against measures which they maintain are unjustifiable, and worse than useless. The Medical Board replies that its action is justified by the principles laid down by the International Sanitary Conference held in 1866, although the remonstrants maintain that the course taken is the exact opposite of that enjoined by the Conference. The following are the recommendations of the Conference, which certainly seem to favour the conclusion of the remonstrants:—

“1. The Conference is of opinion that sanitary cordons established in the midst of a crowded and dense population, are of uncertain effect, and often dangerous; that, on the contrary, established in limited localities, or places thinly populated, like some Asiatic countries, cordons may be expected to render great service against the propagation of the disease.

“2. The Conference is of opinion—first, that isolation, whenever it can be applied to the first cases which mark the outset of an epidemic, is a prudent measure, which no country should neglect for its safety; secondly, that the isolation of a locality attacked by cholera is all the more practical and useful where the country is thinly populated, and the sequestration applied close upon the outset of the epidemic; thirdly, that the isolation of the initiatory focus is the capital prophylactic measure against the invasion of cholera.

“The Conference is of opinion that interruption of communication is the best method of isolating choleraic foci, and should consequently be employed whenever circumstances admit of its being rigorously enforced; but that this measure, applicable only to circumscribed localities, becomes impracticable and inefficient when the epidemic has been propagated over a large space.”

The *Times* correspondent adds, however, that the results obtained seem to favour the doctrine of sanitary cordons; for cholera had not appeared elsewhere in the city in a virulent form.

The Porbeagle shark, caught off Rye a few days ago has been purchased for the Museum of the Royal College of Surgeons.

Dr. Ellis, of St. Pancras Workhouse, after having been acquitted by the Local Government Board of the charges brought against him, has been nevertheless called on to resign his office by the same authority, in order to “promote harmony amongst the Guardians.”

The Pauper Inmates' Discharge and Regulation Act, 1871, contains a useful and much needed provision with regard to any pauper escaping from or leaving a workhouse or asylum before he is entitled to do so. If such person is suffering from any bodily disease of an infectious or contagious character, the justice convicting him of the offence is empowered to suspend the warrant of commitment, and order him to be taken back to the workhouse or asylum, where he is to remain until he shall be cured, or otherwise lawfully discharged, when the warrant of commitment shall be put in execution. The necessity for this proviso arose from several patients having absconded from the Small-pox Hospital at Stockwell when in an infected and dangerous state, when it was held by the magistrate of the Lambeth Police-court that the provisions of Section 22 of the Act of the 30 and 31 Vic., cap. 106, did not enable him to issue summonses against such patients. Though that Act conferred a power of detention, such power was found, in practice, to be insufficient for the safety and protection of the public. The Legislature has now given the enlarged powers referred to above in respect of patients absconding from either workhouses or asylums.

SMALL-POX JOTTINGS.

THE Guardians of Shoreditch have voted a sum of £25 to each of the six District Medical Officers for extra services during

the prevalence of the small-pox epidemic.—Small-pox has broken out in Nightingale-lane, Limehouse. Eight persons have been attacked.—The disease threatens to assume an epidemic form in Birmingham, and the Medical officers of the town are urging especial activity on the municipal authorities.—Small-pox is very prevalent in Dublin. Five persons died of the disease last week. Bedford-street is described by the Medical Registrar as “a very hot-bed of disease.”—At Bridgwater, on Monday, a baker was summoned for allowing his son to assist in the manufacture of bread while suffering from small-pox. He was fined £10, and a quantity of bread of the value of £5 was ordered to be destroyed.—At a meeting of the Shoreditch Vestry, held on Tuesday, a resolution previously passed, providing for the sale of the wooden building temporarily used as a small-pox Hospital in the Hackney-road, was rescinded, as the materials might disseminate the disease throughout the district.

PROFESSOR HUXLEY'S THIRD AND FOURTH LECTURES AT THE
LONDON INSTITUTION.

PROFESSOR HUXLEY commenced his third lecture on “Nervous Matter: its Structure and Properties,” by remarks on the disputed question of vivisection. While fully admitting it to be cruel and objectionable if performed unsuitably or unnecessarily, he maintained that, as a means of increasing human knowledge, with the view to the alleviation of human suffering, it has already yielded and continues to yield such important results as, in his opinion, quite outweigh all objections to it on account of its apparent cruelty. He stated it to be well known that scientific men who, by this mode of investigation, have discovered facts of the utmost importance in the elucidation of the phenomena of disease, have, nevertheless, been so maligned and run down, that, instead of enjoying the legitimate reward of their labours, they have passed their lives in disappointment and comparative obscurity. It was, therefore, with the object of vindicating the claims of such men to a proper estimation of their services, and, in fact, of publicly expressing his approval of and sympathy with them, as well as of impressing certain facts upon his audience, that he purposed to commence the present lecture by displaying some experiments in vivisection. In order to obviate or remove any disagreeable impressions which might arise on witnessing such experiments, he assured his hearers most positively that the results which he was about to show them no more produced the sensation of pain or even consciousness on the part of the animal submitted to them than does the striking of a repeater, on the pressure of the spring, produce any sensation in that piece of mechanism. The first and second experiments, however, were on the lower extremities and portions of the spinal cords of dead frogs. By the first preparation, in which the skin had been removed, he showed the influence of the electric current generated by a slip of platinum passed behind the nerve-tissue in the spinal canal, and a piece of zinc touching the platinum and the spinal cord in front. The muscular contractions so induced were very decided. It was thus evident that the limbs of the frog so prepared represented a piece of mechanism, in which the nerve fibres, on the passage of an electric current, underwent a change capable of producing muscular contraction. The nature of this change has not yet been ascertained, but it is evidently the determining cause of the muscular contractions. By the second preparation, in which the skin had not been removed, he demonstrated the extent of the muscular action maintained by the nervous influence of the attached spinal cord, by showing that when held up the limbs remained contracted for a few seconds, until dragged down by their own weight; but on irritation of the skin, by being touched with the point of the forceps or finger, muscular action was again induced, and the limbs were pulled up towards the trunk. The repetition of this part of the experiment appeared to take the fancy of the younger portion

of the audience so much, that Professor Huxley considered it advisable to request them to refrain from any display of their amusement, informing them that the results so observed formed an important part of the most wonderful series of phenomena which have ever been studied by men of science. That the presence of the skin is necessary for the success of this experiment is proved by the fact that no muscular contractions are produced by direct irritation of the muscles in a preparation from which the skin has been removed. He next showed the effect of the application of a still more powerful irritant to the skin by touching one of the limbs with a glass-rod steeped in strong acetic acid: not only were very active jerkings of that limb induced, but the other limb was applied, and rubbed along the part which had been touched exactly in the manner in which it would have been had the animal been alive, and desirous of removing an offending substance from the limb—this, Professor Huxley observed, being an instance of instinctive muscular action induced by irritation of the skin.

The subject of the third experiment was a living frog, from which, by a rapid operation, the cerebral lobes had been removed, thus reducing the creature to the condition of a piece of mechanism—living, indeed, but as completely unconscious of external sensations as if it were a watch or other apparatus constructed by human hands. It could breathe as usual, and swallow if food were placed in the throat, and might thus be kept in that condition for twelve months, as all the nutritive functions would proceed regularly; but it was utterly incapable of voluntary motion; by no noise or approach of external object could it be caused to move, and unless fed and attended to it would remain in the same position until actually dried up. On taking this creature into his hand, Professor Huxley showed how it remained perfectly motionless, so long as he kept the palm of his hand perfectly horizontal. On altering the position of the palm so as to cause in the frog a tendency to fall by its own weight, the animal, by a series of the most accurate climbing movements, maintained itself on the upper surface of his hand while it was being gradually turned until the palm was underneath, by which time the frog was securely perched on the back of the hand.

Taking these experiments as his text, Professor Huxley then, in a manner peculiarly lucid and simple, without the introduction of a single hard word, built up, as it were, before his hearers the whole modern theory of reflex muscular action. He illustrated by diagrams the relations of the afferent and efferent nerves to one another, to the spinal cord, to the muscles to which they are severally distributed, and to the skin. He explained that if the posterior or afferent root of a nerve, as it enters the spinal cord, be cut, irritation of the skin will not cause contraction of the muscles supplied by the efferent fibres, and that it is thus proved that the spinal cord is the seat of a certain sort of nervous power, capable of producing muscular contraction, but not attended by sensory impressions. He demonstrated the structure and appearance of a section of the spinal cord, the relative positions and functions of the white and grey nerve-tissue. He illustrated the connexion between the ultimate fibres of the efferent nerves and the ganglionic cells of the grey nervous matter, while no such connexion has yet been proved to exist between the afferent fibres and the ganglionic cells. Proceeding upwards along the cord, he explained the functions of the medulla oblongata in maintaining the movements of respiration, and of the cerebellum in regulating and co-adapting all the complex motions of the body necessary for progression and prehension. He showed that, in the frog prepared for the lecture by the removal of the cerebral lobes, all these parts of the spinal cord existed undisturbed, and thus accounted for the power which the creature still retained of performing the complex climbing movements which he had shown them. He also stated that such a frog, if placed on its back, would be able to bring itself round to the usual squatting position, in

consequence of its movements being guided by the co-adapting power of the cerebellar lobes; but this he did not show by actual experiment. He traced the climbing movements, from the cutaneous impression produced on the frog by the altering position of his hand, and conveyed through the afferent cutaneous nerves to the spinal cord, thence to be reflected through the efferent or motor nerves to the muscles, thus producing in them the contractions necessary for maintaining its position on his hand.

He concluded his lecture by seriously warning his hearers against the cruelty of injuring or destroying the lives of any of the lower animals for the mere purpose of wanton amusement; but maintained that for the purpose of extending human knowledge, or for the investigation of obscure physiological problems, a correct solution of which would be likely to exert a beneficial influence upon the health and happiness of mankind, well-devised and skilfully performed vivisections are necessary and perfectly justifiable.

Professor Huxley commenced his fourth lecture by supplying an omission in his third—namely, the notice of the controlling power of certain portions of the nervous system over others. This he illustrated by first describing the structure and rhythmical action of the heart of a frog, as may be observed for hours after the death of the animal. He showed by a diagram the position of the ganglionic nerve-centres between the auricles and ventricles of the frog's heart—how these nerve-centres are connected by nervous filaments with the pneumogastric nerve coming from the medulla oblongata; and described how irritation of that nerve retards, and if carried beyond a certain extent actually arrests, the action of the heart. Other nervous filaments, again, connect the ganglionic centres of the heart with the great sympathetic nerve, which is itself in connexion with the grey matter of the spinal cord, and irritation of which has been demonstrated to exert a powerful influence in accelerating the action of the heart; so that the heart's action is regulated on one hand by the *inhibitory* power of the pneumogastric nerve, and on the other by the *adjuvant* power of the sympathetic. On the basis of these facts, he explained how it is that severe injury—such as the crushing of a limb—reacts, through the nerves connecting the seat of injury with the spinal cord and medulla oblongata, on the ganglionic centres in the heart, producing in that organ slowness and depression of action and the general phenomena expressed by the term "*shock*," and which sometimes even proceed to complete death.

Having thus noticed the action of the nervous system so far as it can be expressed in the terms of "matter and motion" employed by Hobbes, and considering it simply as a material automaton of wonderfully perfect construction, far surpassing all the mechanism that man has ever succeeded in devising, Professor Huxley proceeded to the consideration of the totally different series of phenomena presented by states of mental consciousness. To these he applied the short term "psychoses"—derived from the Greek word $\psi\upsilon\chi\eta$ (*psyche*, signifying soul); and to the other conditions of the nervous system which he had hitherto been explaining he applied the term "neuroses," which he also mentioned may be classified as "afferent, efferent, inhibitory, and adjuvant." The *psychoses* may be briefly enumerated as sensation, thought, volition, vision, and the muscular sense. He further illustrated the term psychosis by a strikingly vivid description of the internal phantasmagoria presented to the mind of a person entirely removed from all sources of external impressions in a dark, quiet, retired place, and with his eyes shut. Under such circumstances, there passes through the mind a train of thoughts or ideas, sometimes even without effort, often quite beyond the control of the will, and apparently without any connexion. By an effort of will they may be regulated to a certain extent, but on the slightest relaxation of that effort they go on of their own accord, as it were. The influence of pleasure or

pain in bringing forward certain ideas more frequently and more powerfully has been felt by all of us—such influence having in many persons become so powerful that the same "fixed idea" is always uppermost, producing the condition known as monomania.

Psychoses may be classified as "original and reproduced." The former are regulated by no definite laws, as they have their origin entirely in external impressions. He illustrated this condition by his own sensations in looking up at the mass of strange faces before him as he spoke, each producing in him an "original psychosis." The latter he described as the re-collection of facts of consciousness or memory, the action of which is regulated by certain conditions, which may be called the laws of memory. These are as follows:—

1. The intensity of the original psychosis.
2. The repetition of the original psychosis—on which point he impressed upon his audience the value of repetition as making up for lack of original strength of memory.
3. The association of ideas by similarity—which, he observed, is also the origin of that play of words known as "punning."
4. The association of ideas by contiguity, or *association proper*. This he illustrated by the fact that sensations, such as smell, in certain cases, will invariably raise up in the mind the memory of some past event or scene. Taking himself as an instance, he observed that he never can read a book written by a person with whom he may be acquainted, without having constantly before his mind's eye every peculiarity of voice tone, and manner of the author.

Whatever may be the substratum on which the nervous system acts in the production of memory, that particular psychosis, although it may be aided, modified, or temporarily put aside, can never be prevented or obliterated by an effort of the will—it is absolutely involuntary. The relation of volition to the organ of memory is similar to that of nervous matter to muscular action. Volition may refuse attention, but the machine works uninterruptedly, and memory, on the application of the stimulus, brings up again the ideas with which it is charged. Leibnitz gave expression to similar ideas when he applied to the body the term "material automaton," and to the mind, "spiritual automaton." The reflex machine of memory always begins to work on the application of the stimulus: hence volition, by the suggestion of approximate or actually connected ideas, can aid memory in its search or effort to renew a previous psychosis.

LONDON SMOKE.

THE public are beginning to have a languid kind of idea not only that London smoke is a great nuisance, but that it does admit of some remedy. Two letters on the subject have appeared in the *Times* in the course of a week. We should be glad to see the matter taken up warmly in the public journals, as the first step towards doing something. The scientific elements are few and simple. The first point is, to diminish the formation of smoke. This is already done, by a careful method of stoking, in all furnaces used for manufacturing purposes within the metropolitan area. Something may be done towards this end in private houses by more careful stoking—by never letting a fire get too low, and never putting on more coal at a time than will get into a blaze in a few minutes. It is the slow heating of too large a mass of coal that generates black smoke. Some kinds of grate are devised to answer this purpose. But, after all, even with the greatest care in stoking, much smoke must escape; and even if no black smoke, the quantity of fine dust and ash, and of the products of sulphur-combustion, that contaminates the air is very great. We want "smoke arcades," to collect the fumes of chimneys and conduct them into underground sewers, where the smoke may be purified and utilised. The plan was made public in the *Medical Times and Gazette* of August 20, 1853, by Mr. Spencer Wells.

DR. RICHARDSON ON THE USE OF ETHER SPRAY IN DIAGNOSIS.

At the Medical Society of London, on Monday last, Dr. Richardson explained a new application of ether spray, which he had for over two years past employed—viz., for the purpose of diagnosis in some forms of nervous disorder. He had noticed from the first use of the spray that the period required for producing freezing of the surface of the body varies with the condition of the patient, the weak and the aged being much more easily influenced than the robust. He therefore had been led to the practice of using the spray as a test of vascular tonicity of parts of the body, and inferentially of the nervous control over the vessels. In the case which had led to these observations—a case of obscure paralysis, brought before the Medical Society by Dr. Alfred Carpenter, of Croydon, on which a committee, consisting of Drs. Richardson, Lockhart Clarke, Broadbent, Hughlings-Jackson, Carpenter, and Mr. Brudenell Carter had drawn up a report for the Society—this method of employing ether spray had been adopted, with the effect of finding that in certain of the paralysed parts the freezing of the tissues could be established in from two to three seconds, while in a healthy subject, and in the same subject on other parts of the body, from eight to nine seconds of time were required, the ether used and the external conditions being the same. The practice is suggestive of extensive application in estimating what, in the absence of a better term, we may still venture to call “the vital power” of different individuals or of the same individual, generally and locally, under various conditions of disease.

SURGEON-MAJOR WYATT ON GUNSHOT WOUNDS.

We last week published with pleasure a memorandum which appeared in the *Times* of the 16th inst., stating that in the opinion of the gentlemen whose signatures were attached, Mr. Stokes' treatment of the gunshot wound which resulted in the death of police-constable Talbot was judicious, and can in no way be connected with the fatal result. We have this week to notice with very different feelings a reference to that memorandum published in a subsequent number of the *Times* by Surgeon-Major Wyatt, of the Coldstream Guards. From the fact of Surgeon-Major Wyatt's name not having been attached to the original memorandum either in accord with or protest against the opinion therein expressed, we feel justified in coming to the conclusion that his opinion had not been asked by the distinguished Surgeons who framed that memorandum. Under such circumstances the good taste of Surgeon-Major Wyatt seems to us questionable when he puts himself before the public in the columns of the *Times*, in the position of an unfavourable critic (so far as regards the knowledge of the treatment of gunshot wounds) of “those who undertake the mission of Surgical instruction at our Medical schools,”—considering that most of the gentlemen whose signatures were attached to the original memorandum may be justly said to rank in the highest class of teachers in our metropolitan schools. Mr. Wyatt's experience of gunshot wounds during the sieges of Sebastopol and Paris was doubtless very extensive, but we are not aware of any important addition made by him to our knowledge of the subject, nor of any reason why he should set himself forward as the exponent of the theory and practice of the treatment of gunshot wounds by English Surgeons.

ARE “EXTRACTS OF MEAT” NUTRITIVE?

It appears from the experiments of Dr. R. Müller, referred to in the *Moniteur Scientifique*, that we have been under a delusion respecting the nutritive properties of extracts of meat. Dr. Müller contends that “meat extracts” are neither directly nor indirectly food, being, as he says, deficient in the necessary albuminous matter. If given alone, he says—and the same applies to beef-tea—these extracts only tend to retard the recovery of convalescents. Can this be true?

HOSPITAL RULES OF PRACTICE.

AN inquest was held this week in Charing-cross Hospital on the body of a girl, 10 years of age, who was burned by accident at her father's house. She was taken to King's College Hospital. The House-Surgeon having looked at the injuries, ordered the child to be taken up to bed by one of the porters. On hearing this the child became much frightened, and screamed loudly, calling out that she would not be taken from her mother. The mother then said she would take the child home if the House-Surgeon would dress the wounds. This, however, he refused to do, alleging as a reason that it was a case for admission into the Hospital; and as the mother would not leave it, the rules of the Hospital precluded him from doing anything for the child. The mother then took the child home, and sent for a Doctor, who said it had better be taken to the Hospital. The burns were then dressed by the child's father, and the following day it was again taken to King's College Hospital; but the Surgeon now said he could not take it in, as all the beds were full. The child was then taken to Charing-cross Hospital, where it remained until its death. Mr. Slack, the House-Surgeon, said the child was admitted on October 10. It went on favourably until the following Thursday, when it was attacked with inflammation of the kidneys, and died on the 18th. The inflammation had been accelerated by the burns and the shock to the system. In reply to questions by the coroner and jury, the witness said it was the custom of all Hospitals, when the cases were of a serious nature, for the House-Surgeon to refuse to attend to it if the patient declined to remain in the Hospital. The verdict eventually was one of “Accidental death.” Much, of course, must be left to the discretion of the House-Surgeon of a Hospital; but to assert that in *no* serious case assistance will be given if the patient does not remain in the Hospital, is hardly credible.

CIRCULATION OF QUACK-BOOKS BY POST.

ONE of the greatest nuisances to which respectable persons can be subjected is the receipt of some obscene quack-book by post. Complaints have been made over and over again in the columns of the press, magistrates have been applied to, and proceedings threatened under Lord Campbell's Act; but none of these endeavours have had any effect in stopping the atrocious system. The consequence has been, that dirty little obscene pamphlets have been scattered broadcast over the length and breadth of the land through the Post-office. These outrages on decency have thus frequently found their way into the hands of women and young persons. There is some chance that the nefarious practice may soon be put a stop to. We learn, from the *Birmingham News*, that the question as to whether the circulation of the books of quacks, by means of the Post-office, was not forbidden by No. 14 of the General Regulations, has been duly considered. In consequence, instructions have been issued that this class of books is to be considered as “obscene.” They have hitherto been considered as Medical works; just as some journals insert filthy advertisements under the plea that they are “Medical announcements.”

ILLEGAL POST-MORTEM EXAMINATIONS.

In consequence of the insufficiency of the evidence adduced to prove who made the post-mortem examination of a child in the Ratcliff-cross Hospital, in the case mentioned by us last week, the magistrates of the Thames Police-court have refused to grant a summons against the Hospital Surgeon. This case has broken down simply upon a technical ground. There can be no doubt that when sufficient evidence can be adduced against an offender, he will, if convicted, be severely punished. We trust that the practice of performing unauthorised or forbidden examinations will cease in our public institutions. Nothing is so injurious to the true interests of charity and the Profession.

MEMORIAL TO DR. PRIESTLEY.

It was said that in Athens "statues were as common as men." We have no such complaint to make of London, or any of the large towns of the kingdom, though it must be confessed that memorials are sufficiently plentiful. Strange it seems that no public tribute to the memory of one of the most amiable of men, the profoundest of philosophers, and the ablest of chemists should have been erected in the town in which he passed much of his life—Birmingham. Probably party-feeling, and the tenets to which Dr. Priestley subscribed, and for upholding which he suffered so grievously, may account for this. We are rejoiced to see that the men of Birmingham have at length taken steps to remove what may be regarded as negligence in a good cause. It has been decided that a memorial to Dr. Priestley should be founded: that it should embrace three objects—viz., the founding of a scholarship for the support of a student of science at some public scientific institution, the purchase of the site, and a statue. It was stated that £3000 would be required for these objects. Several handsome subscriptions have been received.

INDIAN MEDICAL SERVICE.

THE advertised announcement, that at least forty vacancies in the Indian Medical Service will be thrown open to public competition in February next, will no doubt be received with pleasure by many young Medical men, who have been looking forward to an Indian career. We have, however, lately noticed some of the changes which have latterly sprung up in the position and prospects of Medical officers in the Indian Service. These changes have certainly not been for the better; and we should not feel much surprise if the Government of India were to observe the natural result of the recent modifications which they have introduced into the conditions of their Medical Service, in not finding the supply of candidates quite equal to the demand. It certainly appears to us that the native Indian gentlemen, who had, at considerable expense and inconvenience, qualified themselves for the Indian Medical Service, by study in this country, while there were no vacancies to reward their efforts, have very just claims for reparation against the Indian Government.

CAN IT BE TRUE?

LIVERPOOL has long had an unenviable notoriety for its rate of sickness and mortality. Under the able administration of its indefatigable Health Officer, Dr. Trench, many of the causes of disease and death have been removed. But how can Liverpool, or any other town, be anything but a "hotbed of disease" when such places exist as the following, described by Dr. Trench to the Liverpool Health Committee? He said that in Rachel-street there are nineteen houses in a dilapidated state—without doors or windows—occupied by people suffering from typhus and relapsing fever. It was determined by the Committee that proceedings should be immediately taken against the house-owners, who seem to have had reason to hope that the Corporation would buy the property. It may be pertinently asked how long these houses have been so dilapidated. There must have been a want of energetic action somewhere to have allowed matters to get to such a pass.

HEALTH OF THE NAVY.

THIS Report for 1869, which has only just been issued, shows an increased (1 per 1000) death-rate in the fleet, compared with the previous year. This was attributable to the prevalence of yellow fever in North America and the West Indies and South American stations. The Report also contains reports from all the home naval and marine Hospitals and dockyard establishments, giving full information as to their sanitary condition. This latter information is quite a new feature, and is for the first time introduced in this Report.

OPHTHALMIA IN THE MITCHAM SCHOOLS OF THE HOLBORN UNION. Some discussion of an animated nature took place, last week, at the meeting of the Holborn Board of Guardians. It appears that ophthalmia prevails to a great extent amongst the children of the Holborn Union located at Mitcham. The Medical Officer suggested that an infection ward should be added to the Infirmary for the purposes of the schools. Several members of the Board denounced what they called "allopathy," and suggested that a homoeopathic Practitioner should be called in. Eventually, the report of the Medical Officer was referred to the School Committee.

MEDICAL OFFICER OF HEALTH FOR LAMBETH.

AT the meeting of the Vestry of Lambeth, last week, it was decided that an Officer of Health, at a salary of £500 a year, should be appointed. It is understood that his whole time should be devoted to the duties of the office. If the duties are properly performed his whole time must be devoted to them, for the parish is one of the most extensive in the kingdom. The salary is sufficiently moderate for the work required.

THE INDIAN MEDICAL SERVICE.

IT has always been felt a hardship that, when Indian Army Medical Officers are ordered from India for duty in England, the Indian allowances should cease on embarkation in Bombay. We are pleased, therefore, to record that it is most probable the Indian authorities will for the future grant the ordinary servant's allowance during the homeward passage.

ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.

THE anniversary session of this Association, which is announced for December 1 and 2, bids fair to be of considerable interest. On the 1st, at 8 p.m., a discussion on "Habitual Drunkenness and its Treatment, Medical and Legislative," is to be introduced by Dr. Swete; and on the 2nd, at 5 p.m., the President, Dr. Day, of Stafford, will deliver the anniversary address, "The Historical Steps of Modern Medicine."

LADY MORDAUNT.

AN influential Scotch paper—the *Dundee Advertiser*—states that it has been informed that Lady Mordaunt's friends are still doubtful as to the soundness of her mind, and that, with the view of having their doubts settled, they last week placed her under the care of experienced Physicians in England.

FROM ABROAD.—M. BERTILLON ON THE ADVANTAGES OF MARRIAGE
—EXPULSION OF GERMANS FROM FRENCH MEDICAL SOCIETIES.

AT the meeting of the Académie de Médecine, on the 14th inst., M. Bertillon read a paper on "The Influence of Marriage on the Duration of Life, and on Intellectual or Moral Diseases." Engaged for some time past in preparing an article on Marriage for the new French "Dictionnaire des Sciences Médicales," he has had occasion to consult all the documents published on the subject in the various European countries, and has come to the conclusion "that the influence of the conjugal association, whether on the health or the morality of both sexes, is far more considerable than is generally suspected." To facilitate the comprehension of the results he has arrived at, he has exhibited them in geometrical tables, which he distributed to his auditors, and which he is also willing to supply to other inquirers on their forwarding postage-stamps to his residence, 24, Rue Gay-Lussac.

These tables at once show the differences of the conditions which prevail with respect to celibates, the married, and the widowed, according to their age, sex, and nationality—France, Belgium, and Holland being, however, the only countries in which official documents allow of an appreciation of these differences. First, as to men, it is found that from 25 to 30

years the married furnish 6 deaths, celibates 10, and widowers 22 deaths per 1000; from 30 to 35 years the deaths are respectively 7, 11, and 19 per 1000; and from 35 to 40 years, $7\frac{1}{2}$, 13, and $17\frac{1}{2}$ per 1000; and so on for all other ages the married man continues to die less easily than the celibate, and this because he is less ill and suffering less in every respect. Is this to be explained by the fact that the married comprise the men who are best off in fortune, in regular habits, and in health; and therefore it is not surprising that they should live longer? But then how are we to explain the mortality which at all ages and in all countries affects the widowed? Their longevity is not due to their own superior qualities, but to the fact of marriage; and on this ceasing to exist, they die more rapidly than before marriage. *Very early marriages* do not follow this rule; for of 8000 men who marry before 20 in France, and whose mortality before marriage was hardly 7 per 1000, rises after marriage to 50 per 1000! This is the result of a careful examination of French, Belgian, and Dutch returns during ten years: young married men from 18 to 20 years dying at the same rate as aged men of from 65 to 70.

M. Bertillon finds that in women the advantage derived from marriage is somewhat less marked than among men. It does not show itself at all until after 25, and is scarcely remarked until 30. From 30 to 35, the deaths amongst spinsters are 11, and only 9 per 1000 amongst wives, the difference increasing until 55, beyond which age the advantage diminishes somewhat. From 50 to 55, wives exhibit but 15 or 16 deaths per 1000, while spinsters or widows furnish 26 or 27. Prior to 25 years for France, and 20 years for Paris, marriage is injurious to the vitality of women, the mortality of spinsters from 15 to 20 being 7.53, and of wives 11.86 per 1000; and of spinsters from 20 to 25, 8.32, of wives 9.92 per 1000. While speaking most positively as to the exactitude of the above facts, M. Bertillon is more circumspect when treating of their causes. Among these are the dangers of accouchements, especially of the first, the mortality of married women diminishing markedly after 40, when these become rare. In Holland there is, indeed, no diminution until that age. It is difficult to say whether parturition is more difficult among the Dutch than the French, but at all events it is more frequent—for while 100 French women produce twenty-one infants per annum, 100 Dutch women produce thirty-three or thirty-four. We have seen the lugubrious effects which M. Bertillon found constantly attached to the condition of widowhood in man. In women its effect is singular, and especially in Paris. From 25 to 30 it is mischievous; for while but 9 deaths per 1000 per annum were furnished by maids and wives of these ages, in widows the figures rose to 17. But in France, and especially in Paris, this mortality soon diminishes, and after 45 it is not greater than in maids of that age. At this age it is the mothers who are most spared by death.

"Thus, it is in vain that old maids have deprived themselves of the pleasures of love, and dispensed with the dangers and anxieties of maternity. Contrary to generally received ideas, they are more sickly and more fragile, and we may say that, whether as regards the animal economy or the mental condition, hymen in women retards old age and alleviates its miseries. The general conclusion of this investigation is, that marriage is a far more powerful element of health than has been supposed, exerting its salutary effects on men, especially during their period of vigour, and in women (by reason of the dangers of childbirth) at the decline of age. Finally, the calculation of probabilities shows us that the man who marries between 20 to 25 has yet a mean of forty years to live in place of thirty-five years, and that the girl who marries at the same age has forty years of life to hope for in place of thirty-six, which she would have lived unmarried—the one adding five years to his existence, and the other four years to hers."

M. Bertillon next considers the influence that marriage exerts in relation to criminality, which is very considerable. For 100 criminal celibates, there are but 49 married, as regards crimes against the person, and only 45 in crimes against

property; and not only does this enormous disparity exist, but in the gradual diminution of criminality which has taken place since 1840 the married have borne the largest part. The criminality of widowers, and especially that of widows, is generally somewhat in excess of that of the married. The number of suicides among celibates and the widowed is about double that which takes place among the married. Insanity also appears to affect the married in a still lesser proportion.

"Thus," M. Bertillon observes in conclusion, "from all these investigations I must conclude with Franklin that it is in the morning of life (not too early morning, though) that it is of importance to cement this conjugal association, this true social union—the delight of those who have known how to well choose each other. It is a fortress assailed with most difficulty by the miseries of existence, strong against criminal or foolish suggestions, strong against despair, strong against disease, and strong against death itself."

One of the Paris Medical societies—the Medico-Pratique—has, in the matter of its German members, exhibited less sense and discretion than the Société du Département de la Seine, which has resolved to institute a preliminary investigation before taking action against them. This, at least, has the semblance of something like justice, although, as we recently showed, whatever may be its result, it can never justify the step contemplated. The Medico-Pratique scorns any such dilatory procedure, and in hot haste has issued a circular to its German members, announcing to them their peremptory expulsion, in these somewhat high-flown terms:—

"This Society loudly proclaims that one of the noblest conquests of modern civilisation is, beyond all contradiction, scientific neutrality; but it hesitates not to declare that any nation which shelters espionage and pillage behind science, voluntarily places itself beyond the pale of civilisation. Consequently, this Society decrees the definitive expulsion of all German Physicians who have the honour of belonging to it; and, moreover, it expresses the wish that for the future all the Faculties and Medical Societies of France may remain closed against the subjects of Germany."

To this resolution, which can only be regarded as insulting to men who would just as strongly blame any ill-conduct on the part of members of the Medical Body as its proposers, Dr. Wolff replies in a very temperate letter. In this he states that during the war he was Director of the Military Hospitals at Worms, and that in these and the town itself hundreds of French prisoners were treated between August, 1870, and June, 1871, with a humanity and success that have been even admitted by the French Government; and that there, as in the other German Hospitals, the nationality of the patients has only been a motive for exhibiting greater tenderness towards them. He states that the news of the action of the Society towards its German members was at first received with utter incredulity in Germany, where it was not believed that the opprobrium due to the alleged calamitous acts of espionage and pillage would be allowed to fall upon the entire nation. He protests against this ignominious ostracism, as a violation of all laws of Medical confraternity, in the absence of any proof of those affected by it being in any way, in thought or deed, implicated in any of the actions stigmatised; and he feels certain that he may safely appeal against this decree of a mere fraction of it to the general body of the Profession in France, a long residence among whom has taught him to esteem.

TRANSLATION OF THE STRASBURG MEDICAL FACULTY.
—This question, which has been so warmly debated between the advocates for the transfer being made to Lyons and to Nancy, is now said to be settled in a manner which will prove satisfactory to both sides. There are to be two new faculties created, one at Lyons and the other at Nancy. That of Lyons will have the Professors of the Faculty of Strasburg, and will be the most important, in consequence of the numerous Hospitals there. That at Nancy will be especially reserved for *savants*, and will be provided with physical, chemical, and physiological laboratories, in which the scientific progress in Germany may be studied and communicated.

SPURIOUS TEA.

On Thursday last a deputation from the Sanitary Committee of the City of London waited on the Chancellor of the Exchequer, by appointment, for the purpose of explaining the inefficacy of the law as regards the importation and sale of spurious and unsound tea. The deputation was introduced by Mr. Deputy Kelday, the Chairman of the Committee, and it was attended by the solicitor and the Medical Officer of Health. Mr. Kelday described the position of the sanitary authorities of the City, and said that, although they were most anxious to put a stop to a practice which was not only notorious, but was really a public scandal—the manufacture and importation of spurious tea—yet they had hitherto failed to accomplish it on account of the imperfect and uncertain condition of the law, and they were desirous to have it amended.

Dr. Letheby directed attention to the fact that the manufacture of spurious tea in China for exportation to this country was a recognised business; and that not only were large quantities of leaves, other than tea-leaves, and notably willow-leaves, manufactured for the sole purpose of adulterating tea, but it had also become a practice to manipulate the exhausted leaves of tea already used by the Chinese, and to send them into commerce under the names of "Moning Congou," "Maloo mixture," etc. Large quantities of these spurious and exhausted teas had come under his observation, chiefly at the Commercial Sale-rooms in Mincing-lane, where they were publicly sold by auction; and, although many attempts had been made by the sanitary authorities of the City to put a legal stop to such proceedings, and to bring the offenders to justice, yet, from the peculiar nature of the transaction, and the way in which wholesale business is conducted, it was found impossible to reach the guilty parties; for not only was it difficult to ascertain who were the owners of such tea, but it was still more difficult to gain access to the bonded warehouses for the purpose of inspecting the tea, and it was actually impossible to remove it for condemnation; in addition to which all kinds of technical legal difficulties have been raised as to whether tea can be considered as an article of food or drink, or of provision, or even as a vegetable, within the meaning of the Act of Parliament. In illustration of this, Dr. Letheby referred to some of the proceedings of the sanitary authorities at various times. In the early part of 1866, it came to the knowledge of the Commissioners that the salvage tea from the fire at Beal's Wharf, in Tooley-street, was to be offered for sale in the City. Samples of the tea were obtained, and they were found to be either so charred by the fire or exhausted by the water from the engines that they were quite unfit for human consumption. Proceedings were, therefore, taken before a justice to obtain the condemnation of the 350,000 lbs. of damaged tea offered for sale; but they failed on account of technical difficulties—chiefly in the circumstance that tea was not sufficiently defined in the Act of Parliament, and could not, therefore, be called a vegetable or an article of diet. In the month of March, 1870, 201 chests of putrid tea, called Moning Congou, and fifty chests of spurious tea, called Orange Pekoe siftings, were advertised for sale at the London Commercial Sale-rooms, in Mincing-lane. Samples of these teas were obtained with great difficulty from the bonded warehouses; the former was found to be the putrid and rotten leaves of exhausted tea that had been already used by the Chinese, and re-dried, and the latter consisted in great part of spurious leaves. By way of testing our powers, six chests of the Moning Congou and nine of the Pekoe siftings were seized, under a guarantee to the Dock Company, and carried before the magistrate, who condemned the former without hesitation, but who declined to condemn the latter, as it was not proved that the spurious leaves were unwholesome. While these proceedings were afoot, the rest of the tea was taken from the warehouses beyond the jurisdiction of the City authorities, and it was found to be impossible to obtain the names of the owners of the tea. Still more recently, in the month of April of the present year, 628 chests of spurious tea were advertised for sale in the City, and, although they consisted in great part of dirt and iron filings, and realised by public auction from only three-farthings to five-farthings per pound, yet we had no power to interfere. Under these circumstances Dr. Letheby contended that the Act of Parliament required revision; and, considering that the port

of London, like every other port in the kingdom, is under the jurisdiction of many sanitary authorities, whose modes of action are not always the same, he contended that the duty of inspecting tea, and of executing the powers of the Act of Parliament in respect of the seizure of adulterated and unwholesome tea, should rest with some authority having jurisdiction over the whole port. He pointed to the Custom-house officers, and their machinery already in complete existence, as the best suited for the purpose—for, in the first place, they have power over the whole of a port; in the second place, they have the most perfect and intimate knowledge of all incomings and outgoings of every port; in the third place, they are present at the sampling of teas, and at the emptying of the chests for the purpose of taking the tare for duty; and thus they have an immediate inspection of all tea which enters the port; in the fourth place, there is a chemical laboratory, with a competent staff of experts for the analysis of tea when necessary; and, lastly, they have the power of refusing a permit for the delivery of any unsound tea from the bonded warehouses into commerce.

The Chancellor of the Exchequer, however, was afraid that the power would be too large and too delicate for such a class of officers, and in this he was supported by Sir Thomas Fremantle, who was present at the interview; and he recommended the sanitary authorities of the City to apply to the Home Secretary for an amendment of the law. In this manner the City authorities have, in their endeavour to deal with a very important public question, been passed from the Board of Trade to the Chancellor of the Exchequer, and by him to the Home Office.

ON THE PREVALENCE AND DISTRIBUTION OF FEVER IN DUBLIN.

THE following is an abstract of a paper read before the Medical Society of the College of Physicians, Ireland, on November 15, 1871, by Thos. W. Grimshaw, M.D. Dub., etc., Physician to Steevens's and Cork-street Fever Hospitals:—

In bringing forward the following remarks at the present time I am performing an unpleasant duty—unpleasant, because I have to show not only that fever is now more prevalent in Dublin than it had been during the past few years, and that it is still on the increase, but that the form of fever considered by sanitarians as the most preventible is the one which has become most prevalent. At the same time, the conditions which favour the development and extension of fever and of all forms of zymotic disease are so rife in our city that we must look for some great change in our present sanitary system.

I shall first consider the question of the prevalence of fever in Dublin. From a consideration of the admission returns relating to two of our Hospitals most largely set apart for the reception of febrile and other zymotic diseases—the Cork-street Fever Hospital and the Hardwicke Fever Hospital—we see that, commencing with the year 1857, the number of fever cases fell until 1859, when it rose for one year (1860), again declined in 1861, to rise in turn continuously up to 1866, when the number of admissions into the two Hospitals mentioned reached 3562. In these are counted 187 cases of Asiatic cholera admitted into the Hardwicke Hospital. This year (1866) had the largest amount of fever of any year of the period under discussion. Subsequently fever steadily decreased in frequency until 1869, when the admissions fell to 1821. Since that time, however, the numbers have been again rising—2264 in 1870, and 2345 in 1871. To leave out of consideration the Hardwicke Hospital returns, it appears from a comparison of the admissions to Cork-street Fever Hospital with the death-rate from fever published in the Registrar-General's Reports, that the former are a close and tolerably accurate gauge of the total prevalence of fever throughout Dublin. The general result is that fever is now pretty much as frequent as it was ten years ago, and is above the average of the last five years.

With respect to the relative prevalence of the various forms of fever of late, we may leave relapsing fever altogether out of the question, as but two cases of this disease have been admitted into Cork-street Hospital within the last two years. Of the other fevers, it appears that, while typhus and simple fever have been decreasing, enteric fever has gradually increased. Thus, in the year ending September 30, 1870, typhus was above the average during eight months, while the follow-

ing year it was so during four months only. On the other hand, enteric fever was above the average for one month only in 1870, while in the year just ended (September 30, 1871) it exceeded the average during nine months.

It is very difficult to account for this relative and actual increase of enteric fever, as the water-supply of our city is nearly perfect, and drainage operations have been making steady progress. A consideration of the meteorological conditions of the period of increase has also failed to throw any light on the subject. I am myself disposed to believe that the exciting causes of typhus and enteric fevers are more closely allied than it is generally supposed is the case.

I will now proceed to the second part of my subject—namely, the distribution of fever in Dublin.

From the Reports of the Registrar-General already alluded to, it will be seen that, of 1476 deaths caused by fever in the five years ending September 30, 1871, 922 occurred on the south side, and but 554, or little more than half that number, on the north side of the city, divided by the river Liffey. And this difference is not merely due to the larger population of the south side, for the ratios of deaths to population are far higher on the south than on the north, being annually 1 in 746.1 and 1 in 977.3 respectively. Fever would seem to bear an exact proportion to the density of the population, for the latter is 70.8 per acre on the south side and but 57.9 per acre on the north side.

Here it will be necessary to restrict the inquiry to the districts of the city which especially feed Cork-street Hospital. The fever fields of the southern half of Dublin are three in number, and may be distinguished as (1) the Coombe Valley, (2) the West River, and (3) the East River districts. The first of these furnishes by far the largest number of cases, and it presents many special features tending to make it particularly unhealthy. It consists of a hollow, bounded on the north and south by low ridges from twenty to twenty-five feet above the level of its central portions. At its lowest part, near St. Patrick's Cathedral, the elevation above datum is but forty feet, and through its centre a sluggish, polluted stream—the Poddle River—winds its way. Not only, then, is this district the worst situated of any in the city, but it also contains the greatest number of narrow courts, lanes, and densely-populated alleys; old houses, manure-yards, catgut, glue, size, and other similar manufactures; and, besides these, perhaps the most dangerous nuisance of all—numerous dairy-yards. From this Coombe Valley district, in the two years ending September 30, 1871, 1172 cases of fever were sent into the Fever Hospital. These were distributed throughout 753 houses and 156 streets. No less than twenty-six houses furnished five or more cases, and there were ninety-one bad fever-houses, or "fever-nests," in the district. The fever-streets are generally characterised by old—many of them once fashionable—houses; they are not necessarily narrow and tortuous; but even when wide and straight—as Meath-street, the very worst fever-street in the district—wanting proper drainage, without sufficient ash-pit and privy accommodation, and surrounded by narrow courts and alleys in the same plight, they breed fever unchecked, and with fearful rapidity. Meath-street, just mentioned, in the two years furnished seventy-three cases of fever, from thirty-six out of a total of ninety-five houses!

The courts are very bad; but I will describe at length a house notorious as being a prolific fever-nest. No. 58, Bridgefoot-street is entered by a passage with a filthy and rotten floor, in which are chinks communicating with the cellar below. The boards are damp and sodden with dirt. The whole upper part of the house is dilapidated, but is yet the best portion of the building. Downstairs, we reach the entrance to a small back-yard—a place ankle-deep with human filth; a privy and ash-pit totally unapproachable without wading through a sea of dirt; a water-tap running, and washing such of the dirt as is within reach into a pipe-sewer, which passes through the cellar of the house, and whose contents are poured through a hole in its side into the latter, converting it into a cesspool. This cellar—or cesspool—lies immediately beneath two rooms which were until lately inhabited by a family of fifteen persons, every one of whom suffered from enteric fever. "*Ab uno disce omnes.*"

I may mention that of the houses furnishing five or more cases, thirteen sent in cases of the three kinds of fever, nineteen gave cases of febricula and typhus, four those of febricula and enteric fever, four those of typhus and enteric, and two those of febricula only.

The remedies for this state of things are not far to seek. They are—cleansing, draining, and clearance; in the last, the abolition of closed courts being included. I would advocate

the appointment of sanitary police under the immediate direction of well-qualified Health Officers, and no better could be found than the Poor-law Dispensary Medical men; and, finally, I would appeal to my Professional brethren in general to use their influence with the public to compel the authorities to do their duty, and prevent—under Providence!—the spread of contagious disease in our midst.

THE INFLUENCE OF STARVATION ON WOMAN'S MILK.

M. DECAISNE has lately contributed to the Academy of Sciences an important paper "On the Modifications which Woman's Milk undergoes in consequence of Insufficient Food." He begins with a brief notice of the experiments of MM. Dumas Payen and Boussingault, which have shown that the amount of nutriment required for the maintenance of a cow depends upon the weight of the animal, the surplus of food going to form the milk, the quantity of which is found to be proportionate to the excess of alimentation. Under conditions such as these it was found that the cow preserved her weight; but if the same animal was kept upon an amount of food only barely sufficient for its maintenance, it was in a short time observed to lose in weight, the milk being produced at the expense of the animal's tissues—the deterioration of the cow going on with a rapidity proportional to the amount of milk that is secreted. In order to show that a nearly analogous condition of things exists in the case of women, M. Decaisne, availing himself of the circumstances of the siege of Paris, which were especially favourable for observations of the kind, instituted a series of most carefully conducted experiments on forty-three women, whom he divided into the three following groups:—

1. Twelve women, between the ages of 21 and 28 years, whose milk was tolerably good, both as to quantity and quality, and whose children were thriving, although at the expense of the mothers; the women themselves evidently growing weaker day by day.

2. Fifteen women, between the ages of 18 and 33 years, whose milk was deficient in quantity, and found on analysis to be poor in quality. The children of these women fell away, and suffered generally from enteritis.

3. Sixteen women, between the ages of 25 and 32 years, who scarcely gave any milk, and of whose children more than three-fourths were literally dying of hunger.

All the women included in these three groups were in the greatest distress, and had suffered for various periods from insufficient nourishment. M. Decaisne proposed to give *in extenso* the history of these forty-three cases, as soon as he has submitted his analysis to a further examination; but in the meanwhile he limits himself to a notice of three observations (one taken from each of the three groups above referred to), for the purpose of clearly demonstrating the influence exerted by insufficient food on the augmentation of the albumen in the milk and the corresponding diminution of the caseine.

Case 1.—Josephine D., 22 years of age, has two children, the younger of whom has been at the breast for five months. This woman, when seen for the first time on December 2, 1870, was tall and well made, but rather pale. She stated that from the beginning of the siege she had suffered great privation, and often experienced a feeling of faintness and sinking, with a gnawing, griping pain in the region of the stomach. She had not observed any diminution in the quantity of her milk, which she considered to be good in quality, as her child had not shown any derangement of health since the beginning of the siege. On examining the child, M. Decaisne found it robust, with every appearance of health. The entire nourishment taken daily by this young woman during the three weeks preceding the day on which she was first seen had been as follows:—300 grammes of bread, two or three potatoes, about 50 grammes of peas or haricot beans, and the fourth part of a litre of wine. During the five days intervening between the morning of December 4 and December 9, M. Decaisne kept Josephine D. on the following diet:—At 8 a.m., a cup of chocolate made with milk, and 50 grammes of good bread; at noon, a sardine, 30 grammes of salt butter, 200 grammes of horse-steak, 50 grammes of smoked ham, a little gooseberry jam, 200 grammes of bread, half a bottle of good claret, and a cup of coffee without milk; at 7 p.m., rice and sorrel soup,

30 grammes of salted tunny, 150 grammes of preserved beef, 100 grammes of stewed chicken, 50 grammes of apricot jam, half a bottle of wine, and 200 grammes of bread. At the beginning and at the close of these five days, analyses of the milk were made, the results of which will be subsequently given in a table. She was kept upon a sufficiently nourishing diet for two months, by which time she had recovered her health, while her child was also strong and well.

Case 2.—Hortense G., aged 21 years, had suckled her first child for six months, when she was placed under precisely similar conditions to those of Josephine D. When first seen, on December 11, 1870, she was pale, and had lost flesh. Her condition had been aggravated by domestic trouble, and her child was suffering from choleraic diarrhoea. Her daily food during the preceding fortnight had been only 200 grammes of bread, a little bean- or rice-gruel, seasoned with dripping or some other form of fat, with an extra allowance of 100 grammes of horse-flesh every third day. She drank nothing but water, and occupied a damp lodging. Her milk had a thin, bluish appearance, and was scanty in quantity, and her child was losing ground daily. On December 12, M. Decaisne put this woman on the same régime as the previous case, but was obliged to stop it on the following day, in consequence of the indigestion produced by the suddenness of the change; but on December 15, after several attempts and suitable precautions, he was able to let her resume the more generous diet, which she bore very well during the five days she was under examination. Means were taken after the experiment to provide the woman with sufficient nourishment, under which she and her child continued in good health. The analyses of her milk are given in the table.

Case 3.—Louise D., aged 29, had been nursing her first child nearly ten months. Her husband had left her for the last three months, and she had been unable to procure work at her regular employment of dressmaking. She presented all the symptoms of constitutional debility, with excessive anæmia, and was suffering from an attack of gastralgia. Her child, whose appearance was strikingly cachectic, had had diarrhoea for a month. She lodged in a damp court, where disease was rife, had no fire, and for a month had lived on a daily ration of 250 grammes of bread, a little rice or ground pease, with an extra allowance of 100 grammes of horse-flesh every two days, pease-soup flavoured with grease, and two litres of wine weekly. M. Decaisne first saw her on December 21, and finding that she, as well as the child, was suffering from diarrhoea and nausea, he began to administer the more generous diet with some caution; but on December 26 the woman was found to be able to bear the full régime, which was accordingly begun on that day, and continued for five days, as in the other cases. The analyses of her milk are recorded below.

The child died on January 2, 1871, from the effects of the diarrhoea, which had assumed a most aggravated character.

Composition of 100 Parts of Milk (1) Before and (2) After Five Days' Food.

	Case 1.		Case 2.		Case 3.	
	1.	2.	1.	2.	1.	2.
Butter . . .	3.10	4.16	2.90	5.12	2.95	4.10
Caseine . . .	0.24	1.05	0.18	1.15	0.31	1.90
Albumen . . .	2.20	1.15	1.95	0.95	2.35	1.75
Sugar . . .	6.25	7.12	6.05	7.05	5.90	5.95
Salts . . .	0.20	0.30	0.16	0.25	0.25	0.31

M. Decaisne considers that we are justified, from these three observations (which are calculated to demonstrate the influence of insufficient food on the proportion of albumen in the milk), in accepting generally the three following conclusions, for which, however, he does not claim the merit of absolute novelty:—

“1. That the effect of insufficient food on the composition of woman's milk presents great analogy with that observed in the case of animals:

“2. That these effects vary according to constitution, age, hygienic conditions, etc.

“3. That insufficient food always gives rise, within varying proportions, to a diminution in the amount of the butter, caseine, sugar, and salts, whilst it augments generally that of the albumen.

“4. That in three-fourths of the cases observed the proportion of the albumen is in an inverse ratio to that of the caseine under an insufficient diet.

“5. That the modifications in the composition of the milk due to a reparative diet always manifest themselves in a striking manner by the end of four or five days.”

ANOMALIES IN THE HUMAN SUBJECT, IN THEIR RELATION TO THE ORIGIN OF MAN.

MR. BESWICK PERRIN has contributed to *Nature* a paper “On an Additional True Rib in the Human Subject.” He cites two cases in which an incipient additional rib was discovered in recent dissections at the College of Surgeons, while in two male skeletons (one that of a negro) in the Hunterian Museum he found an eighth sternal rib on the right side.

On examining the higher quadrumana, etc., he “noticed that this additional true rib was present only in one young chimpanzee, but not in the gorillas and orangs. It was present in the gibbon and silvery gibbon, the pig-tailed monkey, macacus rhesus, galeopithecus, and indri. The aye-aye, the slender lemur, and the squirrel-monkey, have each nine true ribs. The grand galago, the awantilo, the slender loris, the douroucouli, and the potto have each ten true ribs.

“The scientific value of this additional sternal rib in a Darwinian sense is (in the author's opinion) simply great. It evinces in a clear and forcible manner a latent disposition in the human subject either to revert to an original and lower condition, or to retain traces of that previous condition. We have already seen that some of the lowest forms of primates have ten true ribs, others have nine, some eight, and others, again, seven, as in the human subject. But it is interesting, indeed, to find that the conflict between the major number (ten) and the minor (seven) takes place in the lower primates. As we pass up to the higher primates there seems to be a decided tendency towards fixity at the number of seven true ribs. But yet a few solitary examples—besides the human subject—illustrate the lower type, as in the chimpanzee already mentioned. The number of ribs in the lower forms of monkeys seems to be a repetition of that of the carnivora, and subject to the same fluctuations between seven and ten true ribs. Although the few specimens which I have examined of the higher primates show a decided tendency towards fixity at the number of seven, yet I believe that in a very large number of skeletons of each of the higher species various transitional grades would be met with closely according with those in the human subject. It is somewhat remarkable that each of the variations of the eighth rib in the human subject which I have described should all be on the right side.

“From the preceding facts,” Mr. Perrin thinks, “it may be inferred that the tenth, ninth, and eighth true ribs are gradually lost in the transition from the lower to the higher primates, except in a few isolated examples. The recurrence of the eighth true rib in the human subject cannot be looked upon as an accident, any more than the presence of a distinct peroneus quartus, and a moderately large extensor primi internodii hallucis coming from the tibialis anticus, exactly as in the chimpanzee, in the same individual whose sternum with an almost complete eighth rib has been described.”

THE LOCAL GOVERNMENT BOARD.—Mr. J. N. Radcliffe has been despatched by the Board to investigate the causes of the excessive mortality at Sunderland. Dr. Brydges attended the St. Olave's Board of Guardians on Thursday, and urged the extension of the Rotherhithe Infirmary, at a cost of £15,000.

HEALTH OF SCOTLAND FOR THE THREE MONTHS ENDING SEPTEMBER 30, 1871.—16,835 deaths were registered during the quarter ending September 30, being in the annual proportion of 200 deaths in every 10,000 persons, or 2 per cent. The mean death-rate of the quarter during the ten previous years was 195 deaths in every 10,000 persons, or 1.95 per cent.; so that the death-rate of the past quarter has been above the average. Of the eight principal towns, the mortality during the quarter was lowest in Aberdeen and highest in Glasgow. Thus, for every 1000 persons in each town, there occurred the proportion of 18.6 deaths in Aberdeen, 20.7 in Perth, 23.5 in Leith, 23.7 in Greenock, 24.2 in Edinburgh, 24.4 in Dundee, 26.2 in Paisley, and 30.0 in Glasgow. Of the deaths, 5694 were registered during July, 5774 during August, and 5367 in September, being at the rate of 184 deaths daily during July, 186 deaths daily during August, and 179 daily during September.

GENERAL CORRESPONDENCE.

THE INFLUENCE OF AGGREGATION ON THE MORTALITY OF LYING-IN WOMEN.

LETTER FROM DR. JAMES MATTHEWS DUNCAN.

[To the Editor of the Medical Times and Gazette.]

SIR,—It is very desirable that the true position of the argument on this extremely important question should be known. It is in order to state it that I now address you, and it is imperative on me to do so, not to correct misrepresentations of my views and arguments, but to correct gross misrepresentations of the present state of the great question, whether or not aggregation is a cause of increased mortality of lying-in women.

It is well known that, following up doctrines lately strongly urged as to the baneful effects of general Hospitals, Dr. Evory Kennedy attempted to prove, by statistics, that aggregation of lying-in women in the Dublin Hospital was a potent cause of much mortality in that special institution. Among others, I contested the validity of his arguments, on grounds whose value no one has attempted to dispute, although many have failed to see their force, and have ignorantly described them as if they were mere beating of the air. But such incorrect description does no harm to arguments which are incontrovertible. To advance the solution of this question a stage, it is necessary to get new arguments for or against Dr. Kennedy's opinion. His arguments have been shown to be unsound.

Such statements as the following (and there have been several), which I extract from page 625 of the number of the *Medical Times and Gazette* for November 18, are very misleading, and have stimulated me now to address you. Speaking of Miss Nightingale's recent work on lying-in institutions, the anonymous writer says—"She refers to Dr. Matthews Duncan's suggestions for the improvement of the records of obstetric practice; but without attempting to explain the enormous variance between the conclusions of that gentleman and of Dr. Evory Kennedy, on the influence of aggregation on the mortality of lying-in women—the latter from the statistics of the Rotunda Lying-in Hospital, in Dublin, having, as our readers must be aware, formed the opinion that aggregation immensely increases the mortality; and the former, from the same records, treated in a different way, having drawn exactly the opposite inference—that the mortality in the Rotunda Hospital was lowest during the periods in which the greatest number of women were delivered."

Now, in this, and similar statements in periodicals which I might quote, there are many grave errors which indicate total misapprehension of the state of this important question. I shall give them one after the other.

1. Dr. Evory Kennedy did not form an opinion about the influence of aggregation. He believed, and said he had demonstrated or proved, its terribly adverse influence in the Dublin Hospital. This differs from forming an opinion. When I pointed out that the mortality was lowest during the periods in which the greatest comparative number of women was delivered, I was not drawing an inference exactly opposite or of any kind—I was merely stating a fact, which anyone can verify for himself in a moment.

2. I did not draw the exactly opposite inference to that of Dr. Kennedy. I drew no opposing inference. I showed incontrovertibly that Dr. Kennedy's reasoning was erroneous, and that, therefore, his conclusion was not proved. He used only partial or selected data.

3. I showed that the whole data of the Dublin Hospital—not partial or selected data—if used in the way that Dr. Kennedy used the data he employed, would prove the exactly opposite inference to that of Dr. Kennedy; but I said that to hold them as proving such an opposite inference would be to commit a logical error. I therefore disclaimed the opposite inference, instead of drawing it.

4. I said that the data of the Dublin Hospital appeared to support the opposite inference—but only *appeared* to do so. I never dreamt of maintaining the opposite inference—namely, that the greater the aggregation the greater the safety to lying-in women. Nor did I ever hear of anyone doing so.

5. When critics speak of Dr. Kennedy and me as using the same data, they make a great mistake. Data selected and partial are totally different from the whole data without selection or partiality. Data are not the same, although taken from the same heap, or the same Hospital's records.

Dr. Kennedy's views as to aggregation may turn out to be

true, notwithstanding all I have said; and if they are true, all I have said will remain true also—incontrovertibly true. I could suggest many ways of explaining the fact of the mortality being diminished though the aggregation was increased, while it was held as true that aggregation increased mortality. I shall only reluctantly give one way. It is easy, for example, to imagine, and even believe, that when there were few delivered, the few included especially the urgent, bad, dangerous cases; while, when there were many delivered, the excess over the time of few was composed especially of healthy women drawn to the Hospital only by poverty. In such circumstances the injurious influence of aggregation might be overshadowed or overpowered by the badness of the cases when they were few and by their more generally prosperous character when they were many.

As I have elsewhere said, it is intensely desirable that the influence of aggregation should be determined. Possibly this statement or explanation of the present position of the argument about it may contribute to the attainment of the desirable result.

J. MATTHEWS DUNCAN.

DISTRICT MEDICAL OFFICERS AS OFFICERS OF HEALTH.

LETTER FROM DR. JOSEPH ROGERS.

[To the Editor of the Medical Times and Gazette.]

SIR,—The questions raised by Dr. Druitt, in his address at the last meeting of the Association of Medical Officers of Health, are of such present public interest that I shall be obliged, if you will permit me, briefly to refer to some of them.

Dr. Druitt's statement as to the want of harmonious co-operation between the Medical Officers of Health and the District Medical Officers under the Poor-law has been long known to be correct by all those who have watched the practical working of sanitary superintendence since the introduction of Sir Benjamin Hall's Act, and the various other enactments subsequently adopted by the Legislature for amending the state of public health; the explanation being that the District Medical Officer has, not unnaturally, objected to the imposition of any additional obligations beyond those for which he has been so badly remunerated. But if those who frame our Acts, on the one hand, or those who have to carry them into practical effect, on the other, had been at all up to their work, they would have availed themselves of the opportunity afforded by the introduction of the Poor-law Dispensary system in the metropolis to secure that harmonious action so much to be desiderated; for District Medical Officers would not have had cause for complaint if such arrangements had been made that, when relieved of the cost of providing and the labour of dispensing drugs, a *quid pro quo* had been demanded in the shape of reports as to the insanitary condition of their respective districts. Of course such a proposition would have necessitated that some diminution of the size of districts and equalisation of payment for the number of cases annually attended should have at the same time been enforced.

I refer to this point particularly, because, if success should attend our efforts to extend the Dispensary system to the provinces, the suggestion I here make could be turned to useful account.

It will be seen from this that I entirely agree with Dr. Druitt in considering that it should be the duty of the Health Officer to make himself acquainted with all and every local circumstance bearing on the maintenance of the public health. Again, I agree with him that the preventive and curative services should go together, but I should only be disposed to recommend this so far as it applies to the duty proposed by the Royal Sanitary Commission to be superadded to that of the present Parochial Surgeon (whose name, whether altered to that of Civil Surgeon as Dr. Druitt recommends, or Dispensary Medical Officer, which, I expect, would be his future title)—viz., that of reporting the existence of epidemics and all circumstances calculated to prejudice the public health, in the first instance, to the local authority, by whom it would have to be transmitted to the Health Officer of the city or division of the county, as the case might be; and who would, in case of contumacy on the part of those causing a nuisance, be enabled to direct proceedings with the view to its removal.

I have said I would limit the double duty solely to the District Medical Officer. My reasons for objecting to curative duties being superadded to those of control and prevention in the higher class of Health Officers are—that if combined with

private practice I fear their efficiency would be marred, first, by the jealousy that might be excited amongst other Practitioners, secondly, by the natural fear they would entertain lest activity in their duties should give offence to opulent or influential consultants; or, if trammelled with public occupations, such as that of an Hospital, by the encroachment on their time, which, I hold, would be sufficiently taken up if they had the supervision of a considerable area, more especially if it should hereafter become their duty to undertake the various obligations shadowed forth by Dr. Druitt.

I am aware that much might be said as regards the view entertained by Dr. Druitt as to the "responsibility of attendance on the sick being an inducement to keep pace with the day"; but I think that the difficulty may be got over by providing that no superior Health Officer should be appointed until he had given proof that he had been engaged—say fifteen years at the least—either in general, Physician's, or Hospital practice, exception being made in favour of those who had shown by competitive examination their fitness for the special requirements demanded of such superior grade of Health Officers.

In conclusion, I should like it to be understood that I am firmly of opinion that no scheme of sanitary control will ever work satisfactorily so long as the provincial District Medical Officer remains in his present anomalous and degraded position. The Dispensary system must be, therefore, first extended to the provinces; all the other changes which have been proposed will then have a firm basis on which they may be built up.

I am, &c.,

Dean-street, November 23.

JOSEPH ROGERS.

THE EDUCATION OF WOMEN IN MIDWIFERY.

LETTER FROM DR. J. BRAXTON HICKS.

[To the Editor of the Medical Times and Gazette.]

SIR,—The proposal of Miss Nightingale, that ladies should be educated as Physicians-accoucheuses, and not as Medical Practitioners, to take charge of lying-in institutions, is one which opens up an important question which requires careful consideration. Without expressing any opinion as to the adaptiveness of women to learn and practise Medicine, or as to the expediency of such a step, I do most strongly feel that the views of some of the advocates for the education of women in midwifery are very deficient in precision. And this remark applies to many members of our Profession, who, either from their inattention to the subject, or from their habitually regarding midwifery and the diseases of women as something beneath general Medicine and Surgery, have given expression to the idea that women might be educated so far as to attend labours and women's and children's complaints, but not educated up to the standard required for the treatment of general diseases.

Against this argument I most energetically protest. To stand by whilst natural labour is being accomplished, I admit, requires little more than patience; but we must reflect that the after-treatment, and often treatment before delivery, is intimately mixed with the most intricate questions, which only those accustomed to treatment of general disease can hope to combat. Need I allude to the very intimate connexion between puerperal fever and the zymotic diseases; the necessity of distinguishing cellulitis from peritonitis; and the importance of a competent knowledge of the treatment of this latter disease. How can the vomiting of pregnancy, the œdema of pregnancy, and puerperal convulsions, puerperal mania, and a long list besides, be treated by a person only partially acquainted with these conditions? Again, the diseases of women, as far as my experience goes, require a still greater knowledge of general Medicine than midwifery proper, and I am sure that any attempt to allow anyone with a partial knowledge to treat them will be attended by most serious consequences. I am horrorstruck with the thought of the employment of the sound, of powerful caustics, of the hysterotome, of tents, etc., by the half-educated. It cannot be but that if women practise at all they must be taught completely, and give proofs of competence equal in general subjects to that required from their contemporaries of the other sex.

But involved in the question there is one other, much forgotten, but of great importance to the Profession at large. If midwifery and the diseases of women are taught separately, a separation takes place, and what will then occur? A "speciality" is set up, and all the disadvantages of "specialism" in its worst form will occur. Imagine a school beginning in imperfect education, continuing in the same,

without the opportunity of studying diseases generally, unable, by reason of that want of general knowledge, from fully discussing with those of the Profession who have! Thus the very advantages gained by ourselves and the public of late years, through the practice of midwifery by fully educated Medical men, will be much lost, a branch of the healing art will be retarded, and, collaterally, the Profession also.

It follows, therefore, if the views here expressed are correct, that if women are to practise they must either be as fully educated as their contemporaries of the other sex, or not at all; and, still further, that their knowledge must be in strict unity with that of the general mass of the Profession—or how would Medicine fare if there exist two schools running side by side, with only a partial interchange of ideas?

The case, of course, is different where midwives act under Medical supervision as their *locum tenens*, for they can always call in assistance in abnormal cases. The advantage of the education of a greater number would be of great service in many parts of England in the place of the ignorant and totally uneducated. But upon this point I need not dwell.

I must apologise for thus intruding on your space, but I fear lest the influence Miss Nightingale possesses so justly, and the admiration in which all hold her, would divert many from foreseeing the natural tendency of the step suggested by her and by many others interested in the welfare of women.

I am, &c.,

A CLINICAL URINOMETER.

LETTER FROM DR. JAMES WILSON.

[To the Editor of the Medical Times and Gazette.]

SIR,—The daily use of a three-inch clinical thermometer has suggested to me how invaluable to the general Practitioner a three-inch urinometer would be. The ordinary one requires a vessel or tube to be carried along with it, and although both in one case, occupies too much space in the pocket. A wine-glass—to be had in every house—would be suitable for holding the urine, with a three-inch clinical urinometer.

I am, &c.,

JAMES WILSON.

Cromlet-bank, Old Meldrum, N.B., November 20.

TREATMENT OF GUNSHOT WOUNDS.

[To the Editor of the Medical Times and Gazette.]

SIR,—It is much to be regretted that Medical men are acquiring the habit of addressing the editor of the *Times* on matters purely Professional. The subject can rarely be of real interest to the public, and such communications are only liable to mislead. Medical men who do this are exposed to having their motives interpreted in several ways, and possibly to the disadvantage either of themselves or their brethren. It is impossible to understand what good can result from Mr. Wyatt's letter on the above subject, or what his precise motive was.

November 22.

I am, &c.,

F.R.C.S.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 10, 1871.

Dr. W. W. GULL, F.R.S., President, in the Chair.

MR. CHRISTOPHER HEATH read a paper "On a Case of Wound of the Intestine during Ovariectomy, with recovery." The patient was under his care in the Hospital for Women, in November, 1870, suffering from an ovarian tumour, which had been repeatedly tapped, and for the removal of which an attempted ovariectomy had been undertaken by another Surgeon a year before. The patient was worn out with pain and sickness, and was anxious that another attempt at ovariectomy should be made. This was undertaken by Mr. Heath on November 25, 1870, when very extensive adhesions to the surrounding structures were found. On enlarging the abdominal incision with scissors in the ordinary way, an empty coil of small intestine, which was closely adherent to the wall, was divided in three-quarters of its circumference. The removal of the cyst was accomplished with considerable difficulty, the pedicle being

tied and dropped. Mr. Heath then attached the bowel to the skin with silk sutures, forming an artificial anus, and closed the abdominal incision with wire sutures. The patient made a perfectly good recovery, fæces and flatus passing by the artificial opening on the second day, and solid motions per anum. The silk sutures were removed on the eleventh day, and the patient was moving about at the end of a month. Three applications of the actual cautery were made to the edges of the fistula to contract it, but it did not close, and the patient left the Hospital in April, 1871. She was presented to the Society in a very comfortable and healthy condition, the use of a belt and air-pad satisfactorily retaining all fæcal matter, and the patient having regular stools.

Mr. MAUNDER thought the moral of the operation to be that we should be cautious in such circumstances not to use scissors.

Dr. EDIS had been present at the operation, and alluded to the difficulties of the case. He believed that the accident was unavoidable, and that Mr. Heath deserved all credit for having shown himself equal to the occasion by taking care of the gut, and sewing the cut edges to the abdominal wall, instead of leaving the injury alone in the belief that there was no hope for the patient.

Mr. JOHN SCOTT also referred to the unusual difficulties of the operation, at which he was present. Had a director been used, the result would have been the same as had occurred in the use of the scissors. The gut could not be separated from the peritoneum.

Mr. DE MORGAN, in expressing surprise at the favourable termination of Mr. Heath's case, referred to the extraordinary differences observed in the recovery of patients from ovariectomy. Cases in which great interference with the abdominal viscera has been found necessary, the tumour being perhaps torn away, recovered; while others, presenting the most favourable conditions for operation, proved fatal. He then related several illustrative cases, and expressed his opinion that Mr. Heath showed great aptitude and skill in treating the case as he did.

Mr. LAWSON remarked that serous membranes, which had been long inflamed, might be interfered with to a very great extent—as, for instance, the tunica vaginalis, which might be dissected out without producing alarming symptoms.

The PRESIDENT, after complimenting Mr. Heath on his honesty in bringing forward the case, expressed his desire to know in what position of the small intestine the opening was, and what Mr. Heath had to say about the propriety of using the scissors.

Mr. HEATH, in reply, said that he was in the habit of using the fingers first, but was not prepared for the existing state of things. He disagreed with Mr. Maunder, however, about the use of the scissors in the case. He could not give any definite answer regarding the position of the wound in the intestine. The contents hardly possessed a fæcal odour.

Dr. JOHN MURRAY read a paper "On Thoracentesis in a Case of Simple Pleuritic Effusion." The patient, a healthy-looking and muscular man, aged 38, was the subject of very extensive serous effusion into the left pleura, the heart being pushed completely over to the right side of the chest, and the left lung completely compressed. His respiration was generally about 30 per minute, his pulse 120, and the temperature 101°. Although the acute symptoms had subsided a month after the commencement of the attack, and a fortnight after the pleura had become completely filled, still there were no evidences of diminution of the fluid, notwithstanding many of the usual remedies having been tried. The ultimate and complete recovery of the left lung was being endangered, and the healthy one and the heart and large vessels interfered with, while the man's general health was suffering. Dr. Murray decided to employ thoracentesis. Accordingly, Mr. Hulke performed the operation, and drew off thirty-five ounces of clear serous fluid by means of Nyrup's modification of Bowditch's aspirator, the trocar being passed into the chest between the fifth and sixth ribs, where the digitations of the serratus magnus meet those of the obliquus externus muscles. The effect of the operation was to diminish in six hours the respirations, pulse, and temperature in a remarkable manner. Ten days after the operation, all evidences of fluid were gone, and vesicular breathing had returned to a considerable extent over the upper two-thirds of the lung. He was discharged five weeks after the operation with evidences of a good recovery. The breathing and percussion resonance were still deficient over the left side, and friction was everywhere heard; but he suffered no inconvenience from the last symptom, and appeared in excellent general health. Dr. Murray thought that paracentesis thoracis was the proper treatment in this patient's case; and expressed his opinion, after quoting the experience of Dr.

Bowditch, of Boston, and others, that in all cases of extensive and uncomplicated serous effusions, the operation should be performed at least immediately after the subsidence of the acute symptoms.

Dr. MOXON related a case in which the patient rapidly recovered during treatment by the dry method—by diminishing the amount of fluid in the diet; and asked Dr. Murray if this plan had been adopted in his case.

Dr. ANSTIE referred to the dry method of treatment as painful and doubtfully effective. He asked why we should continue to give, in such cases as that brought forward, iodide of potassium, diuretics, and the like, when we had the means of withdrawing the fluid at once in a safe manner. If properly performed by Bowditch's aspirator, air need not enter the pleura, and the operation produced little or no pain. The trocar furnished, also, the means of completing the diagnosis without harm.

Dr. PLAYFAIR testified from considerable experience to the good results obtained by the operation. When the fluid was serous, as much should be removed as would allow the remainder to become absorbed; but the aspirator was costly, and the fluid might be readily withdrawn by a tube under water. In empyema, when it was desirable to effect a continuous drainage, to reduce absorption to a minimum, he was in the habit of employing, at the Evelina Hospital for Sick Children, with much benefit and comfort to the patients, a plan whereby this constant drain was kept up by passing into the chest a drainage-tube, which was conducted below the bed and kept under water. By this means he had found a rapid diminution of pus in a very short space of time.

Dr. THOROWGOOD thought that the operation was now much more successful; but this was due, not to the complicated instruments in use, but to a more careful selection of cases. In empyema he thought it a matter of little importance whether air were admitted into the pleura or not.

Dr. WILKS asked what advantage the instrument employed in the present case possessed, and whether it assisted the lung to expand.

Dr. DOUGLAS POWELL remarked that the principle of the instrument was that, by means of a fine trocar, a large quantity of fluid which might not come out was withdrawn by suction. He thought the object should be to withdraw a certain amount, to allow the rest to be absorbed. He believed it to be of importance in empyema to withdraw the fluid without admitting the air.

Mr. DE MORGAN referred to his having, he believed, been the first Surgeon to adopt the plan of putting a tube through the chest in empyema. He doubted whether Dr. Playfair's plan would be of much advantage in purifying the pus in those cases in which it becomes putrid.

Dr. EDIS alluded to the stress which Dr. Bowditch laid on the early performance of the operation, the value of which had been borne out in his own experience.

Dr. ALTHAUS said that the application of electricity was known to cause the absorption of fluid from some serous sacs, as in hydrocele, and referred to a case of ovarian dropsy abroad in which a similar result had ensued, and suggested this mode of treatment in pleuritic serous effusions.

Dr. BARCLAY had always found simple pleuritic effusion very amenable to treatment, and would like to know what were the advantages of the operation.

Dr. DUFFIN spoke in favour of thoracentesis, and pointed out that, by allowing the functions of the organs to be interfered with, and the organs dislocated, absorption of the effusion became thereby diminished.

Dr. JOHN OGLE referred to the experience at St. George's Hospital, which was favourable to the operation. He alluded to a case in which the patient had died during the operation.

Dr. DUCKWORTH, in advocating the great advantages of thoracentesis, observed that, if the chest refilled, it might with safety be tapped again and again.

Dr. LANGDON DOWN related his experience of this method of treatment, which was favourable. He had recourse to the operation in five cases—in one to relieve dyspnoea, and in the others to save time.

The PRESIDENT pointed out that several things were being discussed by the members. The case in point was one of simple catarrh of the pleura, and the question was, whether such cases should be left to dry up or not. The issue was, Did the operation hasten the recovery? He alluded to the remarks which had been made on the supposed value of diuretics in pleuritic effusion; and said that he had thought all such opinions had been now given up. His own practice in simple pleuritic

effusions had always been to get the patient hungry and keep him hungry.

Dr. MURRAY, in reply, said that the question discussed in his paper was limited to thoracentesis in simple and extensive pleuritic effusion—a plan of treating such cases which he strongly advocated immediately the acute stage had passed off. By this means the chest is at once relieved, and practically without danger, if done carefully with the aspirator. The sufferings of the patient are in every way diminished, the danger to the compressed lung is reduced as far as possible, and much time is saved in getting rid of the fluid, as compared with the old plan of treatment by diuretics and the like. Moreover, the operation may be repeated again and again, if need be. Why, then, not withdraw the fluid by this means? He had found no difficulty on one occasion in drawing off under water fluid from the pleura by means of a common trocar and piece of tubing. The advantages of the aspirator over such a plan lay chiefly in this—that a fine trocar could be employed, and more fluid could frequently be withdrawn, aided as it was by suction. The instrument, he thought, had, however, no influence in expanding the lung.

MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 23.

Mr. WEEDEN COOKE, Vice-President, in the Chair.

MR. SPENCER WATSON showed a case of Traumatic Dislocation of the Crystalline Lens into the Anterior Chamber. Glaucomatous symptoms were set up, with very severe pain and intra-ocular tension. The lens was extracted through an incision made in the ciliary region of the sclerotic at the lower and outer side. The result was good; useful vision was retained four months after the operation. The operation was performed in consequence of the generally unfavourable results following the scoop and flap extractions in similar cases, and partly from the occasionally good results following rupture of the eyeball and escape of the lens through a rent in the margin of the sclerotic. The choroid had been injured by the accident. Case 2, S. A., aged 14, Congenital Displacement of both Lenses. When the pupils are natural in size the irides are tremulous, and when the eyeball is moved inwards the pupil becomes oval, and the plane of the iris near the pupil is obliquely inclined on the inner side, as if from the lens pushing it forwards at that part; there is a slight divergent squint, and the child's aspect is peculiar. The child's father has defective sight, but the sight of the mother and of a younger child is good.

Mr. HENRY SMITH then related an interesting case of Lithotrity followed by Lithotomy. The crushed stone was shown. The patient was a healthy country gentleman, aged 70, who was determined to have lithotrity performed. The bladder was healthy, and tolerant of the sound, the urethra capacious, and the stone of a size convenient for crushing. The stone was seized without trouble, and crushed in a few seconds. In forty-eight hours violent inflammation came on, and his life was placed in peril. In ten days he was free from danger, and then consented to have lithotomy performed. The lateral operation was done, and he made a speedy recovery. Mr. Smith thought that a second operation of lithotrity would have proved fatal. Sir B. Brodie has pointed out that sometimes a second crushing operation removed the symptoms of inflammation.

Mr. BRYANT called attention to the extreme importance of a course of sounding. In stricture and stone in the bladder, especially in the latter, the passage of a sound may set up urethral fever. In a case of stone, for which lithotrity was proposed, he sounded several times; on the third occasion the lithotrite failed to detect the stone, and the operation was postponed. Rigors and much constitutional fever set in, and the patient died on the fifth day. Disease of the kidneys was present.

Mr. SMITH admired Mr. Bryant's courage in bringing the case forward. Two years ago he had, in King's College Hospital, a strong, healthy agricultural labourer with a small stone in his bladder. The stone was taken up with a lithotrite, measured, and let fall again, no violence having been done. Severe inflammation ensued, followed by death in ten days.

Mr. JOHN GAY read the abstract of his paper "On Hypo-venosity of the Lower Limbs." The disorder was due to inefficiency in the saphenous system of veins, followed by deep vein-dilatation and embarrassment. The outlines of bone, muscle, and tendon become gradually effaced, the skin becomes

of a dusky colour, the whole limb dense or brawny, and muscular action difficult and painful. There is scarcely a vein to be seen, except it may be here and there, and then as a thin blue line, which exercise or heat fails equally in filling. Degeneration and consequent incompetence of the saphenous veins and their branches is its direct or exciting cause; whilst its remote cause is phlebitis, especially in its gouty or rheumatic forms. The treatment is the reverse of that ordinarily employed—viz., an entire freedom of the limb from all compression; enforced walking, begun in moderation and periodically increased; hot application, especially hot seawater, to the limb; and, it may be, the internal administration of the liq. potassæ—in short, by the use of all those measures, hygienic and therapeutical, which can, on the one hand, restore the circulation of the limb, upon the principle that its use is its stimulus to health and perfection, and, on the other, relieve it of its superabundant fat.

Mr. De Méric, Dr. Routh, Mr. Bryant, and Mr. Weedon Cooke took part in the discussion.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, NOVEMBER 18.

Dr. DRUITT, President, in the Chair.

THE PRESIDENT read a paper "On the Position and Duties of Medical Officers of Health." After some introductory observations, he said:—I wish to bring before your consideration the general sanitary organisation of the country, and the means by which the greatest work may be done with the greatest economy. This subject is more peculiarly appropriate just now, when a most important reform has been effected in the central administrative offices, which would be well extended, according to the recommendation of the Royal Sanitary Commission, to the smallest areas of authority.

The reform I speak of is that effected by the Act 34 and 35 Vic., c. 70, "For constituting a Local Government Board, and vesting therein certain functions of the Secretary of State and Privy Council concerning the Public Health and Local Government, together with the powers and duties of the Poor-law Board." This Act, in fact, consolidates into one body the various authorities which heretofore looked after the Public Health, the Relief of the Poor, and Local Government. The Poor-law Board, *eo nomine*, is abolished, so is the Medical Department of the Privy Council. All the powers and duties of the Secretary of State relating to Registration, Public Health, Local Government, Drainage, Sanitary Matters, Baths and Washhouses, Public Improvements, Towns' Improvements, Artisans' and Labourers' Dwellings, and Local Taxation; and all the powers and duties of the Privy Council relating to Vaccination and the Prevention of Disease are made over to this new Local Government Board, and thus the first step is taken, in the words of the Report of the Royal Sanitary Commission, to "consolidate the present fragmentary and confused Sanitary Legislation."

How fragmentary and confused that legislation was and is, must have been felt with great bitterness and vexation by every Officer of Health originally appointed in 1856. The very functionaries under whose authority we acted were liable to shift with varying conditions. The "local authority" in most Metropolitan parishes was elected to carry out the "Nuisances Removal Act"; and if it were desirable to use the apparently larger powers given by the "Metropolis Local Management Act," that could only be done by the vestry itself; and if the Nuisances Removal Committee attempted to use the powers of both Acts (as happened in a notable instance in one parish), it was defeated at law with costs. On the appearance of the last epidemic of cholera, it was found in some places that the Medical Officer of Health, together with the authority which appointed him and under whom he acted, was superseded through some flaw in the Diseases Prevention Act put in force by the Privy Council. This was, if I mistake not, the case in the City. Our ordinary functions had to be carried on under a variety of authorities, all jealous of each other. The vestry, as a whole, was jealous of the Nuisances Removal Committee of its own appointment, and seemed to delight in thwarting and crippling them. Our knowledge of the existence of sickness amongst the poor was obtained from the books kept by the Parochial Medical Officers, the permission to consult which was rather grudgingly given by the guardians of the poor. Our knowledge of mortality was got from the Registrar-General, whom

we may name as an example to all functionaries from his liberality. With regard to the Medical officers who undertake the curative treatment of the poor, there was often felt to be a want of harmonious action. Questions of a very innocent and natural character, asked by the Medical Officer of Health in visiting premises where there had been sickness, are said to have been resented by the Parochial Medical Officer, as if a Medical Officer of Health had no business to inquire into the sufficiency of diet or any matter which especially belonged to the other functionary. Information as to the existence of sickness was not given as it might have been by men who were, as it were, fellow-servants of the same master; but for that I blame not the Parochial Medical Officers, because I blame no man for resisting the imposition of fresh tasks without payment. But the harmony and co-operation such as existed was friendly, and personal, and voluntary, rather than official and necessary. On more than one occasion I have known of a sort of conflict between a Medical Officer of Health who wished premises to be emptied and purified after fever, and a Parochial Medical Officer who interfered to certify that the patients were not in a fit state to be removed; and so the premises remained unpurified an unconscionable time.

Not only was the work of the Medical functionaries not harmoniously blended, but in the Sanitary Department, properly so called, there was a want of organisation. The Inspector of Nuisances held an independent appointment under the Metropolis Local Management Act, with certain duties and powers; and there might be, with a half-educated, presumptuous man, a tendency to set up his own dignity, and act independently as far as possible.

I hold it to be the bounden duty of every Medical Officer of Health to make himself acquainted, by personal inspection and measurement, with the nature of the house accommodation of all classes, the quantity of cubic space, the degree of ventilation, the rents, the water-supply, the drainage, and what the class of occupants, the density of the population, the proportion of the sexes—particulars which my learned colleague and myself did not neglect, as our published reports and the evidence given before the Royal Sanitary Commissioners may testify. Thus armed, the Medical Officer of Health is able, from an inspection of the sickness returns in those houses, to see if the prevalent diseases are connected with the periodically recurring impurity which must affect the latrines, the drains, the water-butts, etc., of closely crowded houses. But, having this knowledge, which may enable him to check, as it were, any information brought him, he surely need not be subjected to the fatigue and loss of time requisite for personal inspection in every case of illness; but the curative Medical officer ought to inspect the general state of the house and report to him at once, so that remedies might be adopted without delay.

What I mean will be more clear by an example. There is no disease respecting which prevention and cure ought to go hand-in-hand more than diarrhoea. There are three things which may be affirmed about it. One is, that simple diarrhoea, *per se*—like the other diseases with discharge from mucous membrane—is, under certain conditions, infectious. I have known diarrhoea spread in a nursery to the nurse and elder children, when set going by the very offensive pale motions of an infant cutting its teeth. Secondly, diarrhoea may be a symptom of typhoid fever, or, thirdly, of cholera; and patients not laid up with all the specific symptoms of these two last-named maladies may yet be subjects of diarrhoea, which shall convey the whole disease to other persons—just as one scab of modified small-pox may be the germ of thousands of cases of the worst forms. As these dangerous forms are not always recognisable at sight, every case of diarrhoea ought to be suspected, and the evacuations be disinfected. The preventive remedy and the curative ought to go together. With the medicine for the diarrhoea ought, in epidemic seasons, to go the packet of disinfectant. Moreover, in every zymotic disease, the fæces may be the vehicles for diffusing germs of contagion. As things are managed at present, the evacuations of a person ill with scarlet fever may be deposited in the imperfectly cleansed latrine visited by a score of children, besides being allowed to diffuse their odours through the house on their way thither. The moral is, that some disinfectant should be distributed to every house where any one of these contagious maladies prevails, and that it should be the duty of the curative officer who visits the sick to see that the disinfectant is properly applied, and that instant notice be given to the preventive Medical officer.

Whereas, as things are, a poor patient may be treated for diarrhoea at some Hospital out-patient room, where no notice is taken of his name or address; or he may be treated at a Dispensary, where, although the name and address are entered,

six, seven, or eight days may elapse between the outburst of the disease and the giving of information to the Medical Officer of Health. As things now are, it is no part of the duty of any voluntary charity, nor yet of the curative officers, to give the early information that is requisite for prevention, or to take other means to the same end.

The gist of my observations will be seen to be the recommendation of a fusion of the preventive and curative functions—the *non bene junctarum discordia semina rerum*—which at present exists; and the organisation of sanitary districts in such a way as to save labour and time, and to hinder two people from going over the same ground.

As you are aware, amongst the recommendations of the Royal Sanitary Commissioners is one to the effect that there shall be one Local Health Authority in every district, and not more than one; and that every Local Health Authority shall have a Medical Officer of Health—and it is suggested that the Poor-law Medical Officer shall be that Medical Officer of Health in rural districts; and that every such officer should have the power of an Inspector of Nuisances—that is, power to enter upon premises, and inspect and order what is necessary to be done without special authorisation in each case from the "Local Authority." We may rejoice in the hope that preventive Medicine will thus be put on a level, if the recommendations of the Commissioners become law, with curative Medicine, and that the powers necessary for abolishing the causes of disease will be conferred on the indefatigable and humane and intelligent Practitioners who now attend the poor. Don't let me be supposed guilty of the wish to impose new and unpaid duties upon the present holders of Poor-law offices. I should wish their status and emoluments raised, and that they should be regarded as "Civil Surgeons," or have some other attractive title. As the Poor-law Board has been abolished, so should Poor-law Surgeons. The same reform, it may be hoped, will be carried out in London; one law for the whole kingdom, and that the Civil Curative Officer will everywhere work with and under the Medical Officer of Health. I do not hesitate to use the word "under," not in any invidious or derogatory sense, but simply because higher qualifications ought to be exacted from the Medical Officer of Health—his duties ought to be more of an inspectorial order, and less compatible with general practice; and amongst gentlemen there can be no bickering arising out of supposed difference of status. The Curative Civil Surgeon, by having preventive and sanitary duties attached to his present ones, ought to have increase of status and pay, and no honest man need be ashamed to give proof that his work is genuine.

And this leads me to another branch of this subject. We, as Medical Officers of Health appointed under the Metropolitan Local Management Act, must have felt that we were isolated; responsible only to those who appointed us, but with no definite relation to each other, or to any central inspectorial body. Every parish has its own standard of duty, and its rate of salary, and the reports of no two parishes agree in size, style, and period. For my own part, I always regretted the want of inspectorial visitation by a superior authority, who should harmonise the work of various parishes, and combine the results of all in one metropolitan sanitary report. In all that I say, gentlemen, you will agree, I hope, in seeing that I have no wish to promulgate opinions which if put into practice would disturb the present holders of offices; but, looking at the thing in a practical light, I affirm that there would be immense benefit if the actual Civil Surgeons were subject to visitation and inspection by Medical Officers of Health, and if Medical Officers of Health were themselves subject to the same control from a central office, and if for this purpose every institution—be it Hospital or Dispensary—supported by voluntary contributions which undertakes the treatment of the poor were placed in the same category.

Thus, I urge that a portion of preventive treatment should be required at the hands of the curative officers, both in town and country, and that the whole of their work, preventive and curative, should be subject to the inspection and criticism of the Medical Officer of Health of the district, or Superior Civil Practitioner (the term Medical Officers of Health is imperfect, because liable to be confounded by foreigners with the *Officiers de Santé*, an inferior class of Practitioners), just as the Superior Civil Practitioner ought to be subject to the same control from the Local Government Board. The only defect I see in the recommendations of the Royal Sanitary Commissioners is the want of some consulting and inspectorial referee nearer than the Local Government Board in London. Let us take the case of a wide district, rural or partly manufacturing. The duty of reporting on local and scattered insanitary conditions, and

the recommendation of remedies, ought to belong to the Civil Surgeon, or, as we now call him, the Poor-law Medical Officer, who visits the sick, and whose duty it should be to act as Sanitary or Preventive or Health Officer in the first instance. But he must make it his duty, when he sends in his sickness report, detailing his cases of fever or cholera, to account for them, if possible—to say whether any insanitary conditions exist, and whether proper notices have been served, and if not, why not. These Superior Civil Practitioners would relieve the ordinary Civil Surgeon of the trouble of initiating law proceedings, and of the embarrassment of offending his friends and patients. These latter might be told by the local Practitioner, "I do not want to annoy you, but when my superior sees cases of fever entered as occurring in your cottages, he will come down upon you if I do not."

The possible duties and qualifications that may be required of the real Medical Officer of Health or Civil Inspecting Practitioner—or whatever other name you may please to designate him by—are multifarious. It is to him that the public would look for statistical information as to sickness and death, and their causes, over the area of his jurisdiction; for initiating and carrying out legal proceedings against nuisances; for inquiring into cases of uncertified deaths. Moreover, he should conduct post-mortems, make analyses, test adulterated food, determine the purity of water, act as coadjutor or substitute for the coroner, report on epidemics affecting animals; and, in fact, Dr. Rumsey suggests that he should be ready to perform more functions than, I fear, come within the competency of most even of the best qualified Practitioners, and that he should be debarred from private practice. Now, all will agree that the best men possible should be obtained. But there are in Medicine many lines which a highly educated man may follow, and it is impossible that any one man should embrace them all. The two most widely divergent lines are physical science and pathology; but excellence in either is an admirable qualification for a Superior Sanitary Officer. You see what chemical and physical studies can produce, in the example of the present Medical Officer of Health for the City of London; but if you look at his eminent predecessor, or at your late colleagues, Sanderson and Buchanan, their *forte* was pathology—in fact, the qualification seems to be *brains* in general rather than any specialised routine of study. But the Sanitary Officer, if he is not to fall behind the age, must have some kind of study which shall connect him with the progress of biological science in some branch. You may remember that Mr. Simon pleaded most justly that the Medical Officer of Health should be connected with a Hospital; but if he may give up a certain measured portion of his time to Hospital attendance, his duties to his patients and his pupils and the regulations of the treasurer and governors might quite as much interfere with urgent sanitary business as might the much more elastic attendance on private patients. I think it must be conceded that the greatest possible inducement to keep pace with the day is, responsibility of attendance on the sick; and it would be limiting the choice of officers unduly if all degrees of private practice were disqualifications. One of the best and most practical sanitarians that ever I knew was the late Sir James Clark, Bart.; and many a time I used to receive practical hints from him when I held office. Now, perhaps it may not be very well known that the ideal combined curative and sanitary Medical organisation which I advocate was foreshadowed by the arrangements in some rich and liberal London parishes thirty years ago. For instance, the parish of St. George, Hanover-square, used to employ a Physician and Surgeon with handsome salaries, besides the general Practitioners. The last holders of those offices were Sir James Clark (then Dr. Clark), who resigned on being appointed Physician to the Queen; and Mr. Howship, who was Surgeon. The parochial Infirmary had a status equal to that of any Hospital. It is this kind of organisation which should be restored, provision being made that sanitary and preventive Medicine shall be duly included. Let me add, how much better such an arrangement than that of the Hampstead Infirmary and kindred institutions, with isolated Resident Medical Officers, and no visiting Physicians! Whoever desires the public to have the services of the best men will not be too ready to elect a Practitioner to an Infirmary or Dispensary, require him to give his whole time, and debar him from private practice.

Truly, gentlemen, the present aspect of things promises no repose to Medical Officers of Health. The air seems thick with epidemics. Of the small-pox, we hear that, after having ravaged Europe, it is raging in Syria, with a mortality of 88 per cent. amongst the unvaccinated at Smyrna. It appears, also, to be making its way in Ireland, despite the good repute

of the Irish vaccination; and it thus seems to show that there is an epidemic wave, such as Inspector-General Lawson describes—a set of conditions which slowly spreads from country to country, and overcomes at times the protection which the best vaccination can give. Perhaps it is well for the human race that this is so. Vaccination enables certain individuals to avoid a disease, but society needs something more: we want the lurking-places hunted out, where not only small-pox, but other diseases of the same class have their strongholds. Let us hear what our microscopical pathologist Beale says. Describing the matter of contagion to be certain infinitely minute particles of germinal matter, allied to pus, he shows how pus will preserve its vitality in urine, may pass through the air, adhere to sponges, clothes, towels, and the like. "A warm moist atmosphere, small close rooms, with curtains, carpets, and plenty of clothes and rugs, so arranged as to cause air to be pent up in confined spaces, with very slow interchange"—such are the circumstances which favour the vitality of contagious matter, and keep it pent up ready to spread; whilst a dread of currents of air is a mental characteristic of those who are usually the sufferers from, and propagators of, contagion. So long as the population is dirty and frowsy, so long will zymotic diseases destroy the cleanest.

The cholera is hanging about Constantinople. In August we learned that it prevailed at Broussa and the neighbourhood on the Asiatic side of the Bosphorus. At the end of the month we hear of it at Kherson and the Sea of Azof. It is curious to note the kind of opinions held about it. On September 8 we find a leading Constantinople newspaper denying positively the existence of the disease in Constantinople, and affirming that the two persons who were said to have had it had been made ill by eating haricots cooked and kept in a copper vessel. No surer harbinger of cholera than fictions of this sort, which resemble what is said about plums in England. On September 18 the same paper protested in the most solemn manner against the idea of cholera in Constantinople, and said that the only persons who died had been proved by "investigations particulières et enquêtes officielles" to have died of indigestion. On September 21 the Conseil de Santé, with a suspicious absence of numbers, declared the existence of "quelques cas de cholera, dont quelques uns mortels"; yet on September 23 *La Turquie* attacks a Physician whom it refuses to name, and who asserted that a patient in the suburbs had cholera, though it was only fever. Under date of September 24 we learn that cholera had abated at Tauris, in Asia Minor, after having destroyed 8000 victims. On the 28th the same paper complains of want of official information, and that no one knows whether there be cholera or not. On October 5 two cases in the Artillery; one fatal. On October 11 we have at last an official report detailing the existence of the cholera for five weeks in the suburbs—viz., at Arnaout Keuy on the Bosphorus, and afterwards at Kassim Pasha on the Golden Horn.

With no attempt at figures, this report states that, first of all, about September 3 two porters died at Arnaout Keuy, a suburb inhabited by Armenians and fisherman; during the next fortnight half a dozen other fatal cases, and many more not fatal. Towards the middle of September several cases at Top-hané and other suburbs, with six deaths. Physicians were employed, disinfectants and medicines distributed. On September 24 there were forty-seven attacks and twenty-one deaths at Kassim Pasha, where is the naval arsenal, and on the 29th fifty attacks with thirty deaths. On September 29 the Sanitary Commission took the energetic measure of turning out the garrison from the arsenal, and all the inhabitants of the affected quarter, and putting them under canvas on high ground. There were but six attacks in the next twenty-four hours. Meanwhile, spite of the decrease of the disease in its original focus, cases were constantly appearing in the adjoining low quarters, which were believed to be imported from Kassim Pasha. Therefore, in addition to measures of disinfection and cleansing, a *cordon sanitaire* of military was drawn round the infected quarter, in which the inhabitants were confined, and none allowed to go in and out save mollahs, priests, Physicians, and sisters of charity. This was done on the evening of October 1. Rations were provided for the enclosed population, pure water was brought to them in barges, and measures taken to disinfect their open sewer with coal-tar from the gas-works. The effect of this measure seemed beneficial, for on the 7th were reported twelve attacks only, and ten deaths. On October 24 we learn that Dr. Zitterer, one of the Physicians appointed to attend the cholera patients, had a narrow escape with his life from an attack.

About October 15 a serious outbreak occurred at Hasskeui amongst a colony of English workmen and Jews quartered

there. Eight deaths soon occurred amongst the English, and thirty amongst the Jews. It is said that the injection of ammonia into the veins was practised with success. A cordon was at once drawn round the infected place, but the English residents broke through it, and went in a body to Sir Philip Francis, at the Consulate, to represent the difficulty of obtaining bread, meat, and medicine, and to complain of the enormous nuisance of an open sewer. On October 25 we learn that three or four more deaths had occurred amongst the English colony at Hasskeui, and that there were in the whole city and suburbs forty cholera deaths on Sunday (22nd), and twenty-two on Monday, and that several deaths had occurred from exhaustion and cold amongst the population of native labourers encamped in tents. On November 1 we learn that the encampment was broken up. The total number of English who have fallen victims from the commencement at Hasskeui is thirty-three; and the deaths over all Constantinople amounted to ten on Saturday, the 28th, and to forty on the Monday, October 30. We learn, further, that the disease is creeping along the Bosphorus; but as one crumb of comfort, we hear it surmised that the disease may not be the true cholera after all, but some choleric disease engendered by a locally poisoned atmosphere. If this be the case, the propriety of shutting up persons by a *cordon sanitaire* within the poisoned district is very questionable.

The main facts are, an occasional death-rate of from ten to forty daily, in a population of about 1,200,000 souls, living in bad sanitary condition on the north side of the Bosphorus.

I have thought these details might be interesting, as they show the real nature of the plague that overhangs us. The fear is lest we should hear of it at Vienna, Trieste, Brindisi, Malta, or Marseilles; if so, we shall not long be spared.

I had intended to have brought some other subjects under your notice, and especially the sanitary relations of public education, the evils of the forcing or cram system, the subjects of intemperance, the Contagious Diseases Act, and other topics which clamour for a settlement; but the length to which I have gone prevents me from doing so this evening. Let me say, in conclusion, that if the working-men of England are in earnest in that sevenfold demand of which we hear in political circles—of healthy homes, unadulterated food, pure air, education, and the like—such of them as are attainable are most likely to be attained through the medium of sanitary science and practice.

OBITUARY.

GEORGE BULLEN, F.R.C.S. ENG. (HON.), L.S.A., ETC.,

DIED at Carr-street, Ipswich, on the 11th inst. He was born at West Downham, Isle of Ely, 1791. His father (who subsequently was Head-master of Oundle Grammar School) was at that time the curate of the parish. The deceased was educated by his father, and became a pupil of the late Mr. Stebbing, a Medical Practitioner of Ipswich. In 1813, at the age of 22 (the earliest age then allowed), he passed the Royal College of Surgeons, and for a short time was an assistant to a Medical Practitioner at Birmingham. He afterwards returned to Ipswich, and was assistant to Mr. Stebbing, and at the latter's death succeeded to his practice. He was elected, on the establishment of the East Suffolk Hospital, one of its Surgeons, and held the appointment until two years ago. He was remarkable (although a nervous man) for his skilful operations. He had a very fine and interesting collection of calculi, which are now in the Museum of the Royal College of Surgeons. He was a most vigilant man; no new important Medical work, instrument, or medicine would escape his examining and ascertaining their value. He was conversant with general literature and the fine arts. His conversational powers were of no mean order. In politics he never took any leading part, but would at Conservative meetings make some well-timed and pointed remarks. He was once elected an alderman of the borough, but only held the office for about six months. He was elected, on the resignation of Mr. William Rodwell, President of the Public Library, and continued so till his death. He was also a member of the Museum Committee and of the Dock Commission. He held the office of Deputy Provincial Grand Master of Suffolk for several years. He was married twice, but survived both his wives. He leaves several daughters by his first wife; but his only son (a successful Medical Practitioner in Ipswich) died a few years since. His funeral was attended by upwards of thirty of the principal Medical Practitioners of the town and neighbourhood, as a last tribute of respect to one whose death is deeply lamented, and

who will be long remembered. He was F.R.C.S. Eng. (Hon.), 1844; M., 1813; L.S.A., 1816 (St. Barthol.); Senior Surgeon East Suffolk Hospital.

FREDERICK BOND EATON, M.R.C.S. AND
L.R.C.P. EDIN., ETC.,

DIED at Nuneaton, North Warwickshire, on Saturday, under most melancholy circumstances. He had visited a patient on Friday, at a distance of about six miles from the town, and drove home about ten o'clock at night. Nothing more was seen of the deceased until eight o'clock the next morning, when a labourer who was passing along the road—some distance from the patient's house—observed the deceased in a sitting posture on the side of the road. He asked him what was the matter, but, getting no reply, he did not trouble himself further, and went on about his business. On returning, however, about an hour afterwards, he found him still sitting upon the ground, his head resting upon one of the wheels of his chaise, and one of his arms being between the spokes. He then ran home and told his master, who went immediately, and after asking the deceased several times for his name and address, the latter with some difficulty told him who he was. Brandy was at once procured, but the deceased was unable to swallow it. He was then taken home, but died very soon after his arrival. On examination of the deceased, his apparel showed that he must have got into some water during the night, his clothes being saturated, and some of them frozen and stiff. Mr. Nason, Surgeon, who was called in, said he found the deceased quite cold and unconscious. He breathed at long intervals five or six times, and then died. An inquest has been held upon the body, and the jury returned a verdict, "That deceased died from congestion of the brain consequent upon exposure." He was M.R.C.S. Eng.; L.R.C.P. Edin., and L.M., 1866; L.F.P.S. Glasgow, 1864; Medical Officer, Nuneaton District; Certifying Factory Surgeon, Nuneaton and Bedworth. He had resided for the past five years in Nuneaton, and was much respected.

JOHN DEMPSTER, M.D., INSPECTOR-GENERAL OF
HOSPITALS,

DIED on the 10th inst., at 47, Great King-street. He entered the Service in October, 1813; became Surgeon, March, 1836; Surgeon-Major, October, 1848; Deputy Inspector-General, 1852; and retired on half-pay, with the rank of Inspector-General, January, 1859. He served with the 38th Regiment throughout the first Burmese war, including the capture of Rangoon, storm and capture of the Stockades, Kincardine, and Kamaroot, and the battles of Rangoon, Kokein, etc.—medal and clasp.

NEW INVENTIONS.

CHAPMAN'S ENTIRE WHEATEN FLOUR.

(Orlando Jones and Co., 18, Billiter-street, E.C.)

OF late years, since Liebig demonstrated the necessity of providing in the food all the chemical constituents of the living body, Physicians have written much on the pernicious custom of using too fine a flour for ordinary food. The loss of all the bran involves the loss of much nutritive matter, of an ingredient which stimulates the alimentary canal to discharge its contents, and of much phosphate of lime, which is required at all ages for the growth and repair of the bones, teeth, and, in fact, of muscle and all tissues. To make up for this, it is customary to recommend brown bread or brown biscuits, in which a portion or the whole of the bran is retained. But then young infants cannot bear so coarse a diet, and some adults find the bran irritating. To obviate these objections, the "entire wheaten flour" contains the bran in a very minute state of division, so that it shall not irritate by its mechanical qualities, and so that it may be readily consumed by young children. We have tried it in the form of a cake made according to a recipe on the cover, and found it very palatable—the bran is just enough to cause an agreeable crispness to be felt by the teeth. This is an expensive method, but the flour may be used economically in biscuits and in some kinds of puddings. It does not make what is called a good nursery pudding, with eggs and milk; and it seems to us that, in the case of a backward child with weak bones, the best plan would be to make it into palatable biscuits, so that every day's diet may contain its dose of bran.

MILLER'S NEW BUNION SPRING.

The object of this little apparatus is to take off pressure from the joint affected with the bunion. It consists of two little pads, to each of which is attached a short wire spring, and a ribbon which fastens the spring like a sandal on the foot. The pads are placed between the great and second toes. The effect is that the great-toe is drawn into its proper place, and the pressure relieved. It is a simple and apparently a most effective invention.

MEDICAL NEWS.

KING AND QUEEN'S COLLEGE OF PHYSICIANS, IRELAND.

—At the examinations held on November 1, 14, 15, and 16, the following candidates were successful:—

For the Licence to Practise Medicine.

Coppinger, Charles Philip.	Galgey, Otho.
Crookshank, Harry Maule.	May, Walter.
Doyle, Jeremiah.	Ward, Michael Francis.

For the Licence to Practise Midwifery.

Beamish, James Maybury.	Galgey, Otho.
Crookshank, Harry Maule.	May, Walter.
Doyle, Jeremiah.	Smith, James Edward.
Elliott, Christopher.	

ROYAL COLLEGE OF SURGEONS.—The following Members of the College, having passed the primary or Anatomical and Physiological Examinations for the Fellowship, at a meeting of the Court of Examiners on the 21st inst., will be admitted to the final examination when eligible, viz. :—

Evans, George Harrison, M.B. Edin., Hagley-road, Birmingham, diploma of Membership dated April 22, 1868, student of St. Bartholomew's, Birmingham, and Edinburgh Schools.
 Harvey, William, L.S.A., Royal Navy, January 29, 1862, of the Charing-cross Hospital.
 Higgins, Charles, L.R.C.P. and L.S.A. Lond., Hambledon, April 21, 1868, of Guy's Hospital.
 Joubert, Charles Henry, M.B. Lond., Newton Lodge, Hungerford, May 5, 1868, of St. Mary's Hospital.
 Page, Herbert William, M.B. and B.A. Cantab., Carlisle, November 16, 1869, of the London Hospital.
 Partridge, Samuel Bowen, L.S.A., H.M. Indian Army, August 5, 1851, of King's College.
 Roe, Thomas Alexander, M.D. St. Andrews, Royal Navy, April 22, 1862, of the Cork School.
 Wells, John Soelberg, M.D. Edin., Savile-row, December 21, 1860, of King's College.

The following gentlemen, *not* members of the College, also passed the examination, viz. :—

Dundas, George Albert, student of Guy's Hospital.
 Donkin, Horatio Bryan, of St. Thomas's Hospital.
 Moss, Herbert Campbell, of King's College.
 Massiah, Benjamin Jones, of the Bristol School.

Nine candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their Professional studies for six months.

The following gentlemen, having undergone the necessary examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 16th inst., viz. :—

Boon, Alfred Pearl, Delamere-erescent, student of St. Mary's Hospital.
 Cable, George Hughes, L.S.A., Royal-hill, Greenwich, of Guy's Hospital.
 Cowley, John Selwyn, Upton-on-Severn, of St. Bartholomew's Hospital.
 De Méric, Henry Eugene, Brook-street, Grosvenor-square, of King's College.
 Ewart, William, Montpellier-square, S.W., of St. George's Hospital.
 Gill, Stanley Augustine, L.R.C.P. Edin. and L.F.P. & S. Glasg., Torquay, Devon, of the London Hospital.
 Harrison, Thomas, Stafford, of the Liverpool School.
 Head, William Cave, L.S.A., Lewes, Sussex, of St. Bartholomew's Hospital.
 Hendry, James Alexander, Liverpool, of the Liverpool School.
 Jago, Thomas, Saltash, Cornwall, of St. Bartholomew's Hospital.
 James, David Philip, Narberth, South Wales, of St. Bartholomew's Hospital.
 Johnsou, Frederick Philippo, Taunton, Somerset, of University College.
 Julius, Stanley Alexander, Mortlake, of King's College.
 Lee, Alfred Robert, L.R.C.P. Edin. and L.S.A., Tollington-park, of University College.
 Sergeant, Edward, Preston, Lancashire, of St. Thomas's Hospital.
 Smith, Joseph Priestley, Edgbaston, Birmingham, of the Birmingham School.
 Thomas, John Howell, L.R.C.P. Lond., and L.S.A., Carmarthen, of the London Hospital.
 Yate, Edward, Godalming, of St. Bartholomew's Hospital.

The following gentlemen were admitted Members of the College on the 17th inst., viz. :—

Harbinson, Alexander, M.D. Queen's Univ., Ireland, Newry, co. Down, student of the Belfast School.
 Lees, Frederic Arnold, Meanwood, near Leeds, of the Leeds School.

Magill, James, B.A., M.D. & M.C. Queen's Univ., Ireland, Cork, of the Cork School.
 Masterman, George Frederick, L.S.A., Croydon, of Guy's Hospital.
 Ramsay, Ebenezer John, Queen Anne-street, of University College.
 Rogers, William Richard, M.R.C.P. Lond., Berners-street, of University College.
 Scale, George John, L.S.A., Merthyr Tydfil, of the Middlesex Hospital.
 Slater, John Samuel, L.S.A., Bath, of St. Thomas's Hospital.
 Sloane, Ebenezer Erskine, M.D. Queen's Univ., Ireland, Lisburn, co. Antrim, of the Belfast School.
 Walsham, William Johnson, M.B. & C.M. Aberd. and L.S.A., Tyndal-place, Islington, of St. Bartholomew's Hospital.
 Wright, John Rowland, The Bank, Leicester, of St. Mary's Hospital.

We find that 100 candidates for the Membership of the College appeared before the Court of Examiners during the past week: of this number seventy obtained their diplomas, thirteen were approved in Surgery, and, when qualified in Medicine, will be admitted Members of the College, and the remainder were referred to their Hospital studies for six months.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, November 16, 1871:—

Hosking, Ethelbert, Woburn-square, W.C.
 Parkhouse, Henry, Braintree, Essex.
 Whittington, Charles Edward, Tuxford, Notts.

As an Assistant in compounding and dispensing medicines—
 Kimber, Benjamin Tindall, Southampton.

The following gentlemen also on the same day passed their first Professional examination:—

Lewis, Frederick William, Middlesex Hospital.
 Paradise, Thomas Decimus, Guy's Hospital.
 Warren, Alfred, Charing-cross Hospital.
 Whitaker, James Sealy, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALLEN, THOMAS, L.R.C.P.L., L.S.A.—House-Surgeon to the Great Northern Hospital, *vice* Mr. J. Willis, resigned.
 COVEY, GEORGE, M.R.C.S. and L.S.A.—Medical Officer for the Branghur District of the Bishop Stortford Union.
 ELDER, GEORGE, M.B.—Resident Surgeon to the General Hospital, Nottingham, *vice* A. G. Mickley, M.B. Lond.
 GILMOOR, R., M.R.C.S.E. and L.M. Univ. Glasgow—Medical Officer for the Landport District of the Portsea Island Union.
 HAMILTON, ALEXANDER, L.R.C.P. and L.R.C.S. Edin.—Medical Officer for the Tenth District of the Ashton-under-Lyne Union, *vice* F. Cooke, M.R.C.S.E., L.S.A., deceased.
 LAWRENCE, H. CRIPPS, L.R.C.P. Lond.—Pathologist to the Sophia Nursery for Infants, Fulham.
 SUTTON, WILLIAM, M.R.C.S.E., L.S.A., and L.M.—Officer of Health to the Smethwick Local Board of Health.

MILITARY APPOINTMENTS.

2ND DRAGOONS.—Staff Assistant-Surgeon George Ballingall Stuart, M.B., to be Assistant-Surgeon, *vice* Thomas Rudd, M.D., promoted.
 7TH FOOT.—Staff Surgeon Thomas Rudd, M.D., to be Surgeon, *vice* John Hendley, appointed to the Staff.
 22ND FOOT.—Staff Assistant-Surgeon Edward O'Connell, to be Assistant-Surgeon, *vice* Francis Henry Welch, appointed to the Staff.
 40TH FOOT.—Surgeon-Major Archibald Henry Fraser, from 88th Foot, to be Surgeon, *vice* Surgeon-Major William, M.D., who exchanges.
 52ND FOOT.—Staff Surgeon Thomas Norton Hoysted, to be Surgeon, *vice* Henry Alexander Gogarty, M.B., appointed to the Staff.
 88TH FOOT.—Surgeon-Major George William Peake, M.D., from the 40th Foot, to be Surgeon, *vice* Surgeon-Major Archibald Henry Fraser, who exchanges.
 MEDICAL DEPARTMENT.—Deputy Inspector-General of Hospitals Francis William Innes, M.D., C.B., to be Inspector-General of Hospitals; Surgeon-Major John Hendley, from 7th Foot, to be Staff Surgeon-Major, *vice* Thomas Rudd, M.D., appointed to the 7th Foot; Surgeon Henry Alexander Gogarty, M.B., from 52nd Foot, to be Staff Surgeon, *vice* Thomas Norton Hoysted, appointed to 52nd Foot; Assistant-Surgeon Thomas Rudd, M.D., from 2nd Dragoons, to be Staff Surgeon, *vice* Staff Surgeon-Major Brinsley Nicholson, M.D., who retires upon half-pay; Staff Assistant-Surgeon Henry Cole Peppin, from half-pay, to be Staff Assistant-Surgeon, *vice* George Ballingall Stuart, M.B., appointed to 2nd Dragoons; Assistant-Surgeon Francis Henry Welch, from 22nd Foot, to be Staff Assistant-Surgeon, *vice* Edward O'Connell, appointed to 22nd Foot.
 BREVET.—Staff Surgeon-Major Brinsley Nicholson, M.D., who retires upon half-pay, to have the honorary rank of Deputy Inspector-General of Hospitals; Thomas Benjamin Briscoe, gentleman of the Bengal Subordinate Medical Establishment, who holds the local rank of Honorary Assistant-Surgeon, to have the honorary rank of Assistant-Surgeon.

BIRTHS.

BALLARD.—On November 20, at 7, Compton-terrace, N., the wife of Edward Ballard, M.D., of a daughter.

- DEAN.—On November 20, at The Cottage, Church-road, Upper Norwood, the wife of Dr. P. T. Dean, of a son.
- HILLS.—On November 16, at Thorne, near Norwich, the wife of W. Charles Hills, M.D., of a daughter.
- LITTLEJOHN.—On November 13, at 24, Royal-circus, Edinburgh, the wife of Dr. Littlejohn, of a daughter.
- LOMAS.—On November 20, at 35, Finsbury-square, the wife of William Lomas, M.D., of a son.
- LYNCH.—On November 15, at 41, Chepstow-villas, Kensington-park, the wife of J. Roche Lynch, L.R.C.P. Lond., of a daughter.
- SPACKMAN.—On November 18, at Bowers House, Harpenden, the wife of Frederic R. Spackman, M.D. Lond., of a son.
- WORKMAN.—On November 16, at 1, Clarendon-terrace, Teignmouth, the wife of Charles J. Workman, M.D., of a son.
- WRIGHT.—On November 17, at Aldershot, Hants, the wife of Dr. J. Hornsby Wright, 2nd Battalion 17th Regiment, of a daughter, stillborn.

MARRIAGES.

- BARWELL—SHUTTLEWORTH.—On November 15, at Christ Church, Preston, Richard Barwell, F.R.C.S., George-street, Hanover-square, to Mary Diana, second daughter of Thomas Starkie Shuttleworth, Esq., Preston.
- HEFFERNAN—HEATH.—On November 16, by special licence, at the parish church of Wolstanton, James Joseph Heffernan, Surgeon Madras Army, to Mary, eldest daughter of Robert Heath, Esq., The Bramptons, Staffordshire.
- JOTHAM—WARWICK.—On November 16, at Southend, Essex, George William Jotham, M.B., of Kidderminster, to Edith, third daughter of W. R. Warwick, M.D., of Southend.
- WOODCOCK—NOAD.—On November 16, at St. Stephen's Church, Westbourne-park, William Hugh Woodcock, of 25, Auckland-hill, Lower Norwood, second son of William Woodcock, Esq., Tor Villa, St. John's-road, Brixton, to Helen Margaret, only daughter of Dr. Henry M. Noad, F.R.S., of 72, Hereford-road, Bayswater.

DEATHS.

- ANDERSON, WILLIAM JOHN, F.R.C.S., son of William Anderson, Esq., 71, Seymour-street, Hyde-park, on the voyage from Sydney, New South Wales, in the 51st year of his age.
- BIGSBY, CAROLINE, wife of John J. Bigsby, M.D., F.R.S., at 89, Gloucester-place, Portman-square, on November 19, aged 82.
- DELAGARDE, PHILIP CHILWELL, F.R.C.S., at 23, Southernhay, Exeter, on November 17, aged 74.
- DEMPSTER, JOHN, M.D., Inspector-General of Army Hospitals, at 47, Great King-street, Edinburgh, on October 10.
- HAWKINS, VINCENT SAMUEL BENT, the eldest beloved son of the late Dr. Vincent Hawkins, of King's Lynn, Norfolk, at Redhill, Surrey, on November 20, aged 40.
- METCALFE, FENWICK, Bengal Medical Staff (Civil Surgeon, Kurnaul), son of the late Charles Metcalfe, Esq., of Inglethorpe Hall, Emneth, Norfolk, at Mussoorie, Himalayas, on October 13, aged 31.
- SMITH, ALEXANDER, M.D., late of the Bengal Military and Civil Service, at Gothic House, Herne Bay, on November 16, aged 67.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

AMERSHAM UNION.—Medical Officers required for the First and Second Districts of this Union. Gentlemen applying for this appointment are required to possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. H. Bedford, Clerk, Amersham, on or before November 28. Election the same day.

- BIRMINGHAM GENERAL HOSPITAL.—House-Governor and Secretary. Applications and testimonials to Mr. Francis Fowke, on or before November 30.
- BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House-Surgeon. The gentleman appointed must be a Member of one of the Colleges of Surgeons of the United Kingdom. Applications and testimonials to the Secretary, on or before December 4. Election on the 12th.
- BRADFORD FEVER HOSPITAL.—Honorary Medical Officer. Must be duly qualified under the "Medical Act" of 1858. Applications and testimonials to Mr. C. Woodcock, on or before November 27. Election on December 12.
- CENTRAL LONDON OPHTHALMIC HOSPITAL, GRAY'S-INN-ROAD, W.C.—Assistant-Surgeon. Must be F. or M.R.C.S.E., not engaged in the practice of Midwifery or Pharmacy. Applications and testimonials to the Secretary, on or before December 2.
- CHARING-CROSS HOSPITAL, WEST STRAND.—Surgeon-Dentist, who must be a Fellow or Member of the Royal College of Surgeons of England. Applications and testimonials to the Secretary, on or before November 29.
- DERBY COUNTY LUNATIC ASYLUM.—Superintendent Physician. Applications and testimonials to Mr. John Barber, on or before November 28.
- EDINBURGH ROYAL INFIRMARY.—General Superintendent. Applications and testimonials to Mr. Bell, Clerk to the Corporation, on or before December 1.
- FARRINGDON DISPENSARY, BARTLETT'S-BUILDINGS, HOLBORN, E.C.—Resident Surgeon. Medical and Surgical qualifications required. Applications and testimonials to Mr. S. Green, on or before December 4.
- GREAT NORTHERN HOSPITAL.—Surgeon. Must be a Fellow of one of the Colleges of Surgeons. Applications and testimonials to the Secretary, on or before December 7.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, S.W.—Resident Clinical Assistants. Candidates must have some Medical qualification. Applications and testimonials to the Hon. Sec., on or before December 2.
- INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST.—Visiting Physician. Applications and testimonials to Mr. F. Baily, 27, Margaret-street, Cavendish-square, W.

LIVERPOOL ROYAL INFIRMARY.—Physician. Must be F. or M.R.C.P.L., or a Graduate in Medicine of one of the following Universities—namely, Oxford, Cambridge, Dublin, Edinburgh, Glasgow, or London. Applications and testimonials to Mr. E. Gibbon, on or before December 1.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—The Chair of Ophthalmology is vacant. Applications to the Registrar, on or before December 3.

PARISH OF ST. MARY ABBOTTS, KENSINGTON.—Medical Officer for the Notting-hill and Kensal-green District. For further particulars, apply to the Clerk to the Guardians, 1, Devonshire-terrace, Wright's-lane, Kensington, W.

REETH UNION.—Medical Officer for the Muker District. Candidates are required to possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. James R. Tomlin, Richmond, Yorkshire, on or before December 1.

ST. MARY'S HOSPITAL AND DISPENSARY FOR WOMEN AND CHILDREN, QUAY-STREET, MANCHESTER.—Medical Officer for Out-patients. Must have Medical and Surgical qualifications. Applications and testimonials to Mr. J. Barber, on or before December 2.

SOUTH STAFFORDSHIRE GENERAL HOSPITAL, WOLVERHAMPTON.—Physician's Assistant. Candidates must be graduates in Medicine of a British University. Applications and testimonials to the Chairman of the Medical Committee, on or before November 27.

STOCKPORT INFIRMARY.—Assistant-Surgeon. Qualifications in Medicine and Surgery required. Applications and testimonials to the Honorary Secretary, on or before November 30.

SUSSEX COUNTY HOSPITAL, BRIGHTON.—Surgeon. Must be M.R.C.S.E. Edin. or Dub. The office of Assistant-Surgeon is also vacant; the qualifications required are the same as for the appointment of Surgeon. Applications and testimonials to Mr. A. Vesey, on or before December 6.

TORMSHAM, DISTRICT OF.—Medical Officer of Health. Applications to Mr. B. Hooper, Local Board Offices, Town Hall, Torquay, on or before November 25.

VICTORIA HOSPITAL FOR SICK CHILDREN, GOUGH HOUSE, QUEEN'S-ROAD WEST, CHELSEA.—House-Surgeon. Must possess at least one qualification to practise. Applications and testimonials to Mr. St. John H. Young, on or before November 27.

WANDSWORTH AND CLAPHAM UNION.—Medical Officer to the Workhouse and Infirmary. Candidates must be duly qualified and registered. Applications and testimonials to Mr. John Sanders, on or before November 27. Election on the 28th.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Bosmere and Claydon Union.—The Claydon District is vacant; area 8589; population 3462; salary £42 per annum.

North Bierley Union.—Mr. Joseph W. Hodgson has resigned the Sixth District; area 2630; population 6268; salary £15 per annum.

Wem Union.—The Prees District is vacant; area 14,754; population 3504; salary £40 per annum.

Woodbridge Union.—Mr. Charles E. Covey has resigned the Fifth District; area 10,850; population 3439; salary £62 per annum.

APPOINTMENTS.

Bramley Union.—James Hall Evans, L.R.C.P. Edin., L.F.P.S. Glasg. to the Wortley District.

King's Lynn Union.—Edwin Woodward, L.R.C.P. Edin., M.R.C.S. Eng., to the Workhouse.

Marlborough Union.—Francis J. Ryder, M.R.C.S. Eng., L.S.A., to the Second District.

Plymouth Incorporation.—John N. Stevens, M.R.C.S., L.S.A., to the Southern District. George Jackson, M.R.C.S., L.S.A., to the Western District. Robert J. Shepherd, M.R.C.S., L.S.A., to the Northern District. Frederick A. Thomas, M.R.C.S., L.R.C.P. Edin., L.R.C.S. Edin., to the Workhouse.

South Shields Union.—James Dalziel, L.R.C.P. Edin., L.F.P.S. Glasg., to the Westoe District.

Ware Union.—George Covey, M.R.C.S., L.S.A., to the First District.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Council held on the 16th inst., Dr. W. Handsel Griffiths, Ph.D., L.R.C.P., and L.R.C.S.E., was elected Assistant-Librarian of the College.

NOTICES have been given of an intended application to Parliament for an Act to supply London with sea-water from Brighton.

MR. S. GODDARD, Medical Officer of Health at Burslem, in his report to the Local Board, drew the attention of the Board to the death of Mary Ann Robinson, who had died, aged 100 years and 10 months.

A MEDICAL MAYOR.—Dr. James Coombs has been unanimously elected Mayor of Bedford for the ensuing year. He is M.D. Erlangen, and Member of the Royal College of Surgeons of England. He was educated at St. Bartholomew's Hospital.

CHOLERA IN CONSTANTINOPLE.—It is officially announced that there were 379 deaths from cholera in Constantinople during the week ending November 12; but we are glad to see by the latest intelligence that the disease is on the decrease.

PARISH DISPENSARY SYSTEM.—This system appears to be a failure to some extent, at least, in the large parish of Bethnal-green. At the last meeting of the guardians, in a discussion respecting the arrangements for administering Medical relief in the parish, they passed a resolution to abolish the Quilter-street Dispensary.

MR. ALFRED COOPER, F.R.C.S., has been elected Surgeon to the Royal Hospital for Diseases of the Chest. There were seven candidates in the field.

It is proposed to extend the Infirmary at Manchester, and to amalgamate St. Mary's Hospital with it.

WE regret to hear that Dr. Metcalfe, in civil Medical charge of Karmal, India, has been thrown from his horse and killed.

PACHMARHI, as a station for European troops and for invalids, has been very favourably reported on to the Indian Government for its healthiness.

FEVER has attacked the troops in the Colombo Fort, Ceylon.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—Mr. Geo. Hanbury, of Portman-square, has accepted the office of Treasurer to this old-established and excellent charity in the vacancy occasioned by the decease of Mr. John Savory. The Hospital, formerly called "The Queen's," has been in existence nearly 120 years.

THE ROYAL SOCIETY.—The annual meeting of the Fellows of this Society will be held as usual on St. Andrew's-day, the 30th inst., at Burlington House, when the following members of our Profession will be nominated as Councillors, viz.:—William Sharpey, M.D., LL.D., as one of the Secretaries; *George James Allman, M.D.*; George Burrows, M.D.; *George Busk, President of the Royal College of Surgeons*; Professor Peter Martin Duncan, M.D.; and *Sir James Paget, Bart., D.C.L., F.R.C.S.* Those gentlemen whose names are printed in *italics* were not members of the last Council. At this meeting the annual award of the gold medals of the Society will be made in favour of Mr. George Busk, F.R.S., President of the Royal College of Surgeons; and Dr. John Stenhouse, F.R.S. The Capley Medal will be presented to Dr. Julius Robert Mayer, of Heilbronn.

DR. WALLACE, of Greenock, has been presented with a silver salver, on which were sovereigns to the amount of between £300 and £400, by a few of his patients, as a token of regard and acknowledgment of Professional skill, on the occasion of his going to the Mediterranean for the benefit of his health.

MR. THOMAS COE, F.R.C.S. ENG.—The thirtieth anniversary of the St. Edmund Lodge of the Manchester Unity Independent Order of Odd Fellows was celebrated by a dinner at the Town-hall, Lord A. H. C. Hervey, M.P., in the chair, at which Mr. Coe was presented with a handsome silver epergne, on which was inscribed, "Presented to Thomas Coe, Esq., F.R.C.S., as a small token of respect, after thirty years' services as Surgeon, by the Officers and Brothers of the Loyal St. Edmund Lodge, No. 2988, M.U.I.O.O.F., at the celebration of their thirtieth anniversary, Nov. 13, 1871."

MR. ROBERT ROBERTS, M.R.C.S. Eng., Surgeon to Mrs. Oakeley's Hospital and to the Festiniog Slate Quarries, has been presented with a long and very complimentary address (written in English and Welsh), a purse containing £218 18s. 3d., and an elegantly-bound book containing the names of the subscribers, from half-a-crown upwards, by the quarrymen and inhabitants of Festiniog and the surrounding districts, "as a token of esteem on account of the skill and faithfulness which he has displayed in the discharge of his duties as a Medical Practitioner whilst attending upon the numerous accidents which have occurred, and the severe epidemics and diseases with which that neighbourhood has been visited during the course of his Medical career among them."

MEDICAL STUDIES AT CAMBRIDGE.—The Board of Medical Studies at Cambridge, finding that time is lost by students of Medicine in the University not adopting some defined plan in their attendance on the various courses of lectures, certificates of which are required previous to the several Medical examinations, recommend them to adopt, so far as practicable, the following plan. To pass the Previous Examination, with additional subjects, in their second term of residence (*vide* Reg. 17, Prev. Ex.), and then to attend lectures and pursue their studies in the following order:—Easter Term: Botany, mechanics and hydrostatics, heat and electricity. Long Vacation: Botany, chemistry, human osteology. Michaelmas and Lent Terms: Human anatomy and physiology, anatomical demonstrations and dissections, physics and chemistry. Easter Term: Anatomy and physiology, chemistry and practical chemistry, hospital practice. Also, to pass in this Easter Term the First M.B. Examination, unless intending to take honours in the Natural Science Tripos. Long Vacation: Practical physiology, practical pharmacy, hospital practice.

Michaelmas Term: Human anatomy and physiology, comparative anatomy, materia medica, anatomical demonstrations and dissections, hospital practice. Lent Term: Pathology, materia medica, human anatomy and physiology, comparative anatomy, anatomical demonstrations and dissections, hospital practice. Easter Term: Pathology, materia medica, hospital practice, practical physiology. The Board consider it very desirable that students should, as far as possible, complete their general education before commencing Medical study. They also consider it advisable that students of Medicine should be encouraged to remain in the University and pursue their studies during part, at least, of the Christmas and long vacations. The same Board have issued an amended report. The only alteration concerning the additional requirements for the Third M.B. Degree is, that the time of the regulation being enforced is changed from Easter Term, 1872, to Michaelmas Term, 1872. The recommendation respecting experimental physics is amended as follows:—"That 'experimental physics' be added to the list of courses of lectures in Section 10 of Regulations for Degrees in Medicine, provided that no certificate of attendance on a course of lectures on any branch of experimental physics which is not recognised in the First M.B. Examination shall be accepted as evidence of Medical study in the University, unless the student shall produce, also, a certificate of attendance during the same term on the practice of Addenbrooke's Hospital, or on a course of lectures on human anatomy, physiology, materia medica, and pharmacy or pathology."

EXAMINATION QUESTIONS.—The following is a copy of the questions submitted to the twenty-one candidates at the primary examination on Saturday last for the Fellowship of the Royal College of Surgeons, viz.:—1. Describe, in the order in which they occur, the anastomoses of the arteries on the walls of the alimentary canal from the cardiac orifice of the stomach to the anus. 2. Describe the white corpuscles of the blood, and state the evidence which exists concerning their origin and destination. 3. Give the origin, course, relations, and distribution of the glosso-pharyngeal nerve; and describe the dissection required to expose it in its course below the base of the skull. 4. Describe the cochlea—(1) Its osseous structure; (2) Its membranous portion and the structures connected with it, including the mode of distribution of the cochlear division of the auditory nerve. N.B. *All* four questions *must* be answered. At this examination there were nine senior members of the College, four junior, five who had passed the primary examination for Membership, and three who had not passed any examination. The following questions were submitted to the candidates at the Pass Examination on Wednesday last, viz.:—1. Describe precisely the different modes of performing amputation of the thigh, and include amputation at the knee-joint. State the advantages of each mode of operation, and the reasons for selecting it. 2. A knee-joint becomes acutely inflamed, and the result is a complete ossific union of the bones. Explain the process by which this is accomplished; point out the symptoms pathognomonic of the structural changes. State the duties of the Surgeon in the treatment of such a case, and the time probably required for its natural course. 3. Give the signs which indicate the impaction of a foreign body in the œsophagus, indicating the points at which it is most likely to be arrested. Mention the various instruments that may be useful for its removal, and the circumstances under which œsophagotomy may be necessary. Then describe that operation, and give the Surgical anatomy of the parts concerned. 4. Describe wounds of the abdomen—contused, punctured, and incised; mention the parts most liable to be injured; the chief dangers attending these wounds; and give the treatment, general and local, according to the seat, nature, and extent of the wound. N.B. *All* four questions *must* be answered. At this examination there were twelve candidates—viz., five seniors and seven juniors. The names of successful candidates cannot be published until after the next meeting of the Council.

DUBLIN OBSTETRICAL SOCIETY.—The opening meeting of the thirty-fourth annual session was held on the evening of Saturday, the 18th inst., in the Hall of the College of Physicians. The chair was occupied by the President of the Society, Dr. George H. Kidd. The visitors included the Presidents of the College of Physicians and Royal College of Surgeons, and the Governor of the Apothecaries' Hall. The following officers were elected to serve during the session:—*President*: George H. Kidd. *Vice-Presidents*: J. A. Byrne and H. Sibthorpe. *Treasurer*: H. H. O'Halahan. *Honorary Secretary*: Lombe Athill. *Council*: J. Denham, Thomas E. Beatty, Alfred

McClintock, and F. Churchill. The President's address was an able review of the more modern improvements in obstetric science. The first among these of which he treated was the use of the forceps in cases of tedious and difficult labour. From the statistics of the Rotunda Lying-in Hospital, it appeared that this instrument had, during the past three years, been used by the present Master, Dr. George Johnston, on an average, once in 14.74 cases, and with the most favourable results as regarded the mortality of mothers and children. He (Dr. Kidd) defended the instrument from the charge brought against it of causing vesico-vaginal fistula. The diminished frequency of embryotomy was next taken up, and the different improvements recently made in the instruments employed in this *dernier ressource* of Obstetric Physicians were described at length. Among others, Professor Pajot's method of decapitation was mentioned. The subject of post-partum hæmorrhage was next dwelt upon, and the treatment by injection into the uterus of a solution of perchloride of iron (Barnes), and in some instances by transfusion (as in Dr. Robert McDonnell's process), were detailed. Laceration of the perineum was in many cases to be relieved by sutures, and putrid or fetid discharges from the uterus (as recommended by Dr. Hicks) by uterine injections of permanganate of potash.

MEDICAL WOMEN IN NEW YORK.—The progress of the Medical women question on the other side of the Atlantic is shown by the fact that the Medical Society of the County of New York has amended its by-law (55 to 19 votes) in regard to admission of members, by the addition of the words "or her" after "they shall grant him" a certificate of membership.

FRENCH MEDICAL DÉCORATIONS.—M. Algave, the editor of the *Révue Scientifique*, remarks that it is difficult not to believe that France must have been the victor in the late struggles, seeing the avalanches of *décorations* that have been distributed on every side; and to all sorts and manners of men they have been given in excessive profusion. It is calculated that at Paris at least one *décoration* must have been given for every ten wounded—counting all the losses of the six months' siege. Some of the awards are said to have been the result of the most scandalous nepotism. The thirst for *décorations* which so rages in the French Medical world not only shows a want of dignity, but manifests an effect of pecuniary speculation, since patients have the simplicity to give their preference to, and pay higher fees to, decorated Doctors.

THE CHICAGO FIRE.—The *New York Medical Record* states that an active organisation has been formed by the Profession in that city for the relief of their brethren who have lost their all in the destructive conflagrations of Chicago and in the North-west. Five thousand dollars were speedily raised, and the Profession is being widely canvassed. Two-thirds of the Practitioners are for the time ruined, their houses, books, instruments, and the resources of their patients having been destroyed. "We are well aware that of all the money so liberally sent to Chicago from every quarter of the globe, and which finds its way into the General Relief Fund, but a very small proportion will be drifted into the emptied coffers of the desolate Physician. He does not, as a rule, belong to the whining class, and not being by nature importunate for help from outsiders, he is very likely to be overlooked in the general clamour after the necessaries." Dr. Hubbard, 27, West Ninth-street, is acting as treasurer.

CANCER.—More cases of cancer have been seen than during any former year. The cancerous diathesis is, generally, very strongly marked in the Chinese suffering from this affection. From their lack of vitality and reparative power, both constitutionally and arising from diet, coupled with the still further lowering of the tone of the system by opium, to which they generally have recourse to allay pain, the cases present great difficulties. The improvement in most cases has been short-lived. The man with cancer of the right lower jaw—mentioned in last Report—refused time after time to submit to an operation, when it appeared admissible, but latterly presented himself desiring interference when all hope was gone. Another man with the right cheek perforated, and three men with the lateral half of the tongue affected, presented themselves, also to no purpose. One man with the tip of the tongue in an incipient state, holds out some hope; but the case is not yet severe enough to induce the patient to submit. A beggar left the Hospital made an eunuch by this disease, apparently cured, but returned not long after with the groin affected. Advanced cancerum oris in a few children has been seen with no good results.—*Report of the Peking Hospital for 1870, by Dr. John Dudgeon.*

NOTES, QUERIES, AND REPLIES.

It is that questioneth much shall learn much.—Bacon.

We regret to announce the deaths of Dr. Steggall, of Southampton-street, Bloomsbury, and of Mr. Delagarde, of Exeter. Obituary notices of these gentlemen shall appear next week.

J. H., jun.—There will be an examination for the midwifery licence of the College of Surgeons early in the ensuing month. Write to the Secretary.

T. E., Adlington.—Yes, certainly; and sometimes a donkey.

A Reader.—It would be too much to guarantee the good sense of everybody who writes to a Medical journal. We would not undertake, for instance, to guarantee even that of our correspondent.

A Dublin Surgeon, not engaged in Kelly's case, is very wroth with the London Surgeons who lately testified to their opinion that, in the case of Talbot, Mr. Stokes had done all that Surgical skill could do, and that he acted most properly. "The Dublin Surgeon" thinks the document is an "assumption of superiority on the part of the London Profession," and so on. He publishes his protest in the *Irish Times*, and it is to be hoped by this proceeding he has "had his revenge."

Bow, E.—The celebrated Manchester chemist, Dr. Henry, F.R.S., invented the disinfecting apparatus by heat. He has been long dead. His papers, with a figure of the apparatus, are in the *Philosophical Magazine* about the year 1831. Messrs. Geo. Fraser Bros. make a well-known apparatus.

THE ORTHOGRAPHY AND PRONUNCIATION OF GREEK—ANGELS OR AGGELS?
TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I was glad to see your remarks last week on the barbarity of transcribing Greek, without regard to its old Latin equivalents in sound. The Latin mode of spelling Greek words is intensely valuable, because it preserves to us in many instances an authentic record of how the Greeks used to pronounce it. I will give as an example the word "angel." This is a Greek word—ἄγγελος—spelt with two gammas. But it is clear that the Latins wrote it "angel," softening one *gamma* into the corresponding nasal "n," because the Greeks so pronounced it themselves, else surely they would have written "aggelus," and not "angelus." Now I should like to ask some of those purists, who write "apodermic," "ekthuma" for "ecthuma," and the like, why don't they go further, and talk of the "aggels" instead of angels? Unless the old pronunciation had been "angel" the Latins would never have written it so; and St. Gregory would never have made his famous pun, "*Non Angli, sed angeli*;" and St. Augustine might never have been sent to convert the descendants of Hengist and Horsa; and we might have been eating raw horse-flesh, beating our wives, drinking mead out of skulls, boiling prisoners of war alive, and doing other good old-fashioned Anglo-Saxon deeds up to the present time. THE ACTION OF CONDY'S FLUID ON METALS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the notice of Mr. Gardner Brown's patent self-acting disinfecter, which appeared in your issue of the 11th inst., you state that chloralum, chlorinated lime, and Burnett's fluid cannot be used with that apparatus, on account of their energetic action on metals, but that there is no objection to Condy's fluid on that score. I would ask you whether you are quite sure of the accuracy of the above statement as to the behaviour of Condy's fluid with metals, because I find that Dr. Angus Smith, in his evidence before the Army Sanitary Commission, has asserted that the latter preparation acts energetically on metals. My own impression is that it does not. I am, &c.,
JOSH. OAKMAN,
Medical Officer of Health for Battersea.

The Square, Battersea, S.W., November 21.

PHYSIC versus PHYSICS.

A man, whose leg a train had lopp'd, Leaving a shapeless lump, Came to the Hospital—and there They lopp'd away the stump.	He lingered on in wretched plight, No medicine but the Bible, With ecchymosis of the eye, Chemosis of the eyeball.
When asking, under chloroform, Why <i>two</i> must be endured, They said that men of Med'cine held That like by like was cured.	Morbid his thoughts and tissues now, His lachrymation plenty— Proving a <i>sympathetic</i> nerve— Repenting, though <i>repentè</i> .
He groan'd in silence, and with grief, For such a wasted leg; To go on such extremities, Would henceforth seem to beg.	To broken leg a broken heart, And mental agitation; While sighs, denoted puerile, Disturbed his respiration.
"Alas! like maids in wedlock, woes Come rarely single," said he; "Their theatre of operations, Is large and ever ready."	But when the right leg passed away, The wrong leg sympathised; For, while the one was dyeing sheets, The other nearly died.
Stump must supply what Nature gave, To every expectation— A limb which well might illustrate "Chance upon Malformation."	Great by example as by toe, This leg behaved ridiculous; And, just as men go into mourning, Went into erysipelas.
The Surgeon, saying few believed In bleeding and in blue pills, Unsheath'd his weapon, to the joy Of his dilated pupils.	But now the art that saves came in, To that which cuts and mangles; And Medicine saved the life which hung, Like fishes hang, on <i>angles</i> .
The limb now fell beneath the stroke A butcher's knife inflicted, And, gathered to its fathers, soon Was ruthlessly dissected.	The <i>left</i> leg triumph'd o'er the <i>right</i> , By few prescriptions pithy; That cured by Abercrombie's art, And this by Abernethy.
Oh, Hospital-ity! thy sons Co-operate so readily, And this is why their students 'tend The theatres so <i>steadily</i> .

A NEWLY-FLAYED SHEEP'S SKIN APPLIED TO SIR WALTER SCOTT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I was interested at seeing by your last number that Mr. Le Sage, of Stratford-on-Avon, had used the old remedy of animal warmth, by applying a recently flayed sheep's skin to a poor child whose legs had been torn off. It is a practice with a venerable parentage, and it may interest your readers to compare the following description of it in Sir Walter Scott's Autobiography. (a) It is well known that Scott, when an infant cutting his teeth, suffered an attack of what is stupidly called "essential paralysis," affecting his right leg. After the regular faculty had given up the case, he became the subject of every form of treatment recommended by friends of the family. "Amongst the odd remedies," he said, "recurred to, to aid my lameness, someone had recommended that so often as a sheep was killed for the use of the family, I should be stripped, and swathed up in the skin, warm as it was, flayed from the carcase of the animal. In this Tartar-like habitment I well remember lying upon the floor of the little parlour in the farm-house, while my grandfather, a venerable old man with white hair, used every excitement to make me crawl."—(P. 15.) Formerly the Bath waters (or Waters of the Bath, as they were called) were recommended for paralysis, because they were not merely hot, but impregnate with the "essential heat" contained in the bowels of mother earth; so the sheepskin was considered not merely hot, but hot with "vital heat." I am afraid that in these materialistic days most of us look upon heat as a "mode of motion," and vital heat as a result of oxidation. But the reeking sheepskin may not be a bad remedy for a poor devil bruised and battered, for all that.

APPOINTMENTS FOR THE WEEK.

November 25. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

27. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. Alfred Freer (of Stourbridge), "A Case of Impalement." Mr. Wm. Adams, "A Case of Webbed Fingers treated by Mr. Tamplin's Instrument." Mr. Brudenell Carter, "Ophthalmic Demonstrations."

28. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. Fairlie Clarke, "On Unilateral Atrophy of the Tongue." Dr. Priestley, "On Inter-menstrual or Intermediate Dysmenorrhœa."

29. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

SOCIETY OF ARTS, 8 p.m. Mr. W. Bridges Adams, "On Tramways and their Structure, Vehicles, Haulage, and Uses."

30. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

December 1. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.91 in. The highest was 30.19 in. on both Monday and Saturday evenings, and the lowest 29.60 in. on Wednesday morning.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

By R. LIEBREICH,

Ophthalmic Surgeon and Lecturer to the Hospital.

LECTURE V.

ON A NEW METHOD OF EXTRACTION OF
CATARACT.

GENTLEMEN,—Until now we could perform but small operations at our Thursday meetings. The Ophthalmic Ward having been opened last week, we shall be able to receive patients for operations of greater importance. We shall begin with cases of iridectomy and cataract; and as for this latter, I shall have to explain to you my new method of extraction, the more detailed description of which will appear in our next Hospital Reports.

The frequent occurrence of total suppuration after flap-extraction induced the celebrated operators of Moorfields Hospital to return to, and to improve, the linear extraction, which at that time had been almost abandoned. Graefe, struck with the results which Messrs. Bowman and Critchett had obtained, submitted the question to further studies, and so formed the method which is now generally adopted in England as well as on the Continent.

There are numerous statistics which prove that in Graefe's method there is a much smaller percentage of total suppuration than in flap-extraction; also that, even in cases of very bad general constitution, weak and marastic individuals with thin and flabby cornea, the prognosis is not so unfavourable as in flap-extraction; and that the precautions we have to take after the operation, and the restrictions we have to impose upon the patient, are not so great.

On account of these advantages of Graefe's method, it was natural that the flap extraction was soon abandoned. To me, however, it appeared that the mechanism of Graefe's operation was still too complicated and too violent; that prolapse of the vitreous body and hæmorrhage into the anterior chamber were too frequent during, and iritis and strangulation of the iris in the corners of the wound too frequent after the operation; and that the most favourable results, compared with the most favourable results in flap-extraction, were not yet perfect enough.

If these inconveniences are carefully inquired into, it is found that they can all be brought back to one and the same principal cause—namely, the peripheric position of the incision. This peripheric position is—

1. The reason why it is impossible to remove the lens without iridectomy.
2. That the excision of the iris is to be large and extensive, else it causes too great an inclination to prolapse of the iris.
