3. That it is necessary to perform the operation above, so as to cover a part of this large pupil by the upper eyelid. The removal of the lens upwards is by far more difficult, on account of the tendency of the eye to escape upwards; and, consequently,
4. During the whole operation the eye has to be kept open by the speculum, and to be drawn downwards by the forceps. This is not only painful and injurious to the eye itself, but causes—
5. Not unfrequently prolapse of the vitreous body, to which a peripheral incision itself already tends. Prolapse of the vitreous body and hæmorrhage into the anterior chamber are the chief impediments to a careful removal of all the *débris* of the cortex, and cause—
6. Those grave forms of iritis which are sustained by the permanent irritation caused by the tumefied remainders of the lens behind the iris.

Of those disadvantages I was perfectly aware after I had followed for a short time Graefe's original plan; and I proposed, therefore, in 1867, in an article on Cataract which I wrote for the *Nouveau Dictionnaire de Médecin et de Chirurgie* (Paris: Baillière), some modifications. They are, however, but the first step I made; and in the last four years I have come, by a large series of systematic experiments, to a method which

Vol. II. 1871. No. 1118.

I now—after more than 300 operations performed in this manner—consider definitely settled.

The incision of the cornea is to be made with the smallest possible Graefe's knife in the following manner:—

Puncture and contrapuncture to be situated in the sclerotic about one millimetre beyond the cornea, the whole remaining incision to pass with a very slight curve through the cornea, so that the centre of it is about one millimetre and a half distant from the margin of the cornea. This incision can be made upwards or downwards with or without iridectomy, and the lens can be removed through it with or without the capsule.

If, as I now practise, the extraction is made downwards without iridectomy, the whole operation is reduced to the greatest simplicity, and does not require narcosis, assistance, elevator, or fixation; but only calls into requisition two instruments—namely, Graefe's knife, and one cystotome, with Daviel's spoon.

What are the advantages of this method of operating?

1. It is undoubtedly of all methods the simplest and the least painful.

2. It is unconditionally the easiest to perform, and requires the least practice. It may, therefore, be performed by those operators who from time to time only have an opportunity of doing so; and those patients benefit by it who are unable to reach a central point in order to place themselves in more practised hands. On account of the greater facility of operating, the last pretext for reclamation of cataract is removed, which, though almost universally and justly condemned, is still here and there performed.

3. It is preferable to the flap extraction, on account of the safer and constantly regular incision. The flap incision scarcely ever acquires the regularity which may theoretically be demanded—even if made by the most practised operator, with the best assistance, the most enduring patient, or under chloroform—by the use of elevator and fixation instruments. Now its height or breadth is not what it is intended to be; now its position is incorrect, or the wound irregular—indeed, part of it is due to the difficult form of the incision; but by far the greater part, according to my conviction, is due to the mechanism by which the cuneiform cataract-knife is to make the incision. A small Graefe's knife would make a flap safer and more regular than the various other cataract-knives. The incision I designed can easily be made, in giving it in every case exactly the desired form and position—even if the patient is very restless—without assistance, without elevator or fixation. It mainly depends on the facility with which the place of the contrapuncture can be chosen, the knife drawn back and made to pierce at another point if a mistake is made in the selection of the place for contrapuncture, and in the freedom with which, in terminating the incision, the inclination of the knife can be changed, if necessary.

A little practice will enable every operator to avoid these corrections, and to make the contrapuncture, as well as the whole incision, correctly to his original plan, without subsequent alterations.

4. Against Graefe's method it has the advantage of a more favourable position of the field for the operation, and avoids through it all the inconveniences to which I have referred, as arising out of the peripheral position of the wound.

5. In regard to the mode of healing, it favourably contrasts, like Graefe's method, with the flap extraction, on account of the diminished influences which age, constitution, general state of health, season, and other causes exert; also on account of the less demand made upon the patient to remain quiet after the operation; and, above all, on account of the lesser tendency to suppuration of the cornea.

6. The advantages of my method over that of Graefe are shown by the ultimate results obtained—by not showing a greater percentage of total suppuration than in Graefe's method, my best results are, in regard to optical and (if I may use the term) anatomical perfection, identical with the best results obtained in flap-extraction.

ORIGINAL COMMUNICATIONS.

TWO CASES OF A
HÆMORRHAGIC DIATHESIS IN WOMEN.By J. WICKHAM LEGG, M.D.,
Casualty Physician to St. Bartholomew's Hospital.

MARY ANN B., aged 37, applied at St. Bartholomew's Hospital on August 7, 1871, for the relief of bleedings from the nose, and pains in the shoulder. She says that she enjoyed good health until she was about 15 years old; she then began to grow thin and pale; for a few minutes she would lose all recollection; going on an errand, for example, she would forget, while on her way, for what she was sent. She was treated for this complaint by a Physician for three months. Menstruation had begun at 13 years of age, but continued during this illness; but from the very first the discharge was always excessive and irregular, appearing about every fortnight or three weeks, menstruation often lasting a week.

When 18 years old she was married, and eleven months after marriage she was delivered; the flooding was excessive, and there was also much flooding while suckling the baby. She has been pregnant twelve times; several children were still-born, and seven are now alive. There was always great flooding after delivery.

She cannot exactly say when she first became subject to bleedings other than the floodings. She is positive, however, that before marriage she was not subject to hæmorrhage. Twelve years ago she made a cut on the thenar eminence of the thumb; the bleeding was excessive, lasted several days, and was only stopped by compressing the wrist. Now she bleeds very much from slight wounds; pricks and cuts, which another person would not notice, bleed in her for ten or fifteen minutes. She cannot remember exactly when the ecchymoses and petechiæ first began; she thinks it is not more than two or three years. During her pregnancies she used to bring up blood with a cough. The day before she applied at the Hospital she passed some blood with her motions, and the same thing had happened a few months before. The bleedings from the nose first began about ten months ago; the bleeding is very frequent. She says, also, that the nose bleeds every morning when first she wakes, and that if the blood did not come she would feel uncomfortable. Two months ago the flooding became so great that she had to keep her bed for four days; great clots were passed, but she cannot guess how much came away.

Last autumn the right knee became swollen and stiff, and this lasted till the May of the present year. Five weeks ago she found her left arm growing weaker, and a pain in her left shoulder to increase. The pain in the left shoulder began when she was 11 years old, after falling upon her hand and jarring her shoulder. During the last few months she has lost flesh.

Her father died, when 50 years old, of "consumption following an accident." Patient does not know of any ill-health until this accident. Her mother died, over 54 years old, of "a diseased liver." She was subject to severe and frequent bleedings at the nose. She bore eight children; only two, a daughter, aged 47, and present patient, are now alive. This daughter is in good health, and not subject to bleedings. The first child and the last two were stillborn; the other three died young, of acute diseases. Her father had only one brother, about whom she knows nothing. Her mother's brothers all died before patient can remember; two, she believes, died of consumption.

The patient has borne twelve children; seven were boys, of whom five are now alive, but none subject to bleedings. She has a daughter, the third child, now about 15 years old, who has frequent bleedings from the nose; but her mother and daughter are the only relations, of whom she knows, that are in any way subject to bleedings.

Present State.—The woman is highly anæmic; the face is pale and flabby; blood from the finger shows no increase in number of white corpuscles, nor is the spleen enlarged. Nothing unnatural can be detected with the shoulder or knee. Twenty minims of the tincture of the perchloride of iron were given in water three times a day.

October 25.—The woman has been very irregular in her attendance at the Hospital, but the bleedings from the nose have almost disappeared. The pain in the shoulder is still

severe. Her anæmia has greatly diminished; the mucous membranes and face are now quite ruddy.

November 9.—The day after the last visit she had a severe bleeding from the nose, which lasted quite an hour. It came on again the next day, and continued nearly the whole of the day. She complains to-day of a cough, which has lasted three or four days. She was directed to take two fluid drachms of cod-liver oil, in addition to the steel.

The following are the notes of a case which occurred at St. Bartholomew's Hospital among the out-patients under Dr. Gee's care. I wish to express my thanks to him for his kindness in drawing my attention to the case, and also for allowing me to publish an account of it.

Louisa C., aged 30, applied at St. Bartholomew's Hospital, on August 5, 1871, for the relief of bleedings from the nose and of floodings. She says that she was not subject to bleedings, nor to blue marks when bruised, before puberty; she is quite sure of this. Menstruation began when 16 years old, and it was always irregular and excessive. She enjoyed good health up to the time of her marriage at 19, but since that time she has never been quite well. Soon after marriage the discharge at the catamenial periods became a flooding, lasting for eight days; sometimes she would have floodings lasting six weeks. She did not become pregnant till two years and three months after marriage. During the pregnancy there were no floodings. The child (a girl) was born at the end of the third year of marriage. The labour was hard, and instruments were used. A flooding took place at the birth of the child, and also a fortnight later. The baby was suckled fifteen or eighteen months, and during lactation no floodings took place. The next pregnancy ended in a miscarriage at the fourth month—fifteen months after the birth of the first child. There were no floodings. A year and nine months after this miscarriage she was delivered of a boy, with no floodings. She was next delivered of a girl, one year and eleven months after the birth of the boy. In the seventh month of this pregnancy the first bleeding from the nose came on. At first it lasted twenty-four hours. The nose was then plugged, and thus the bleeding was stopped for a time; but it soon came on again, and lasted off and on till the end of the pregnancy. After delivery she noticed that, whenever she bruised herself ever so slightly, the place became black; she also noticed that several black and blue spots came of themselves, without any known cause. At the same time she observed that when she wounded herself the bleeding was very great, and lasted for a very long time. All these symptoms have continued up to the present time. A few weeks ago she cut her thumb; the place bled continuously for twenty-four hours. There are now on the shins and forehead black patches, which, she says, were caused by very slight blows. The fourth confinement was two years and a month after the third. During this pregnancy bleedings from the nose were common; the bleedings would sometimes last so long as four days together, and very commonly all day; they came on every three or four weeks. There was no flooding during the pregnancy, but great flooding at the labour. She was delivered of a girl. The next confinement was in two years. The boy died when 8 months old, of diarrhoea. Soon after this confinement she had a white swelling of the right knee, which lasted for about two months. On examining the knee, the bursa patellæ is found distended with fluid, and she says this was the part which was most inflamed; that it was probed, and stuff like the white of an egg came out.

Her father is alive, aged 60, "well and hearty." He is not subject to bleedings. Her mother is also alive, aged 58; she has pretty good health. She tells patient that she was much surprised to hear of her disposition to bleed, for none of her family were at all subject to such a complaint. Her mother did not have great floodings at her confinements, nor at the "change of life." She bore ten children—two sons and eight daughters. Both the sons are alive; the elder, aged 25, is not strong; he is pale and weakly, and has been subject to bleedings from the nose since he was 22; any exertion or worry will cause his nose to bleed; since he was 17 he has bled more than natural when wounded; he has never had any swellings of his joints. The second son is 19; he is not subject to bleedings. Two daughters are dead—one of "enlargement of the heart," the other of "typhus fever"; the menstruation of the latter was always defective. None of the other daughters have excessive menstruation. None of the patient's own children are liable to bleedings.

Present State.—Dr. Gee informs me that he was unable to detect any enlargement of the spleen, or any increase in the number of the white corpuscles in blood drawn from the finger.

The woman is highly anæmic; she has very light brown hair, and grey eyes, and is of moderate stature.

Under Dr. Gee's direction, the ergot of rye was given, but without any success in stopping the hæmorrhages; on the contrary, they became so urgent that the oil of turpentine was given, in ten-drop doses, every two hours; this checked the hæmorrhages, especially the flooding, for a week or ten days. At the end of that time they returned with great severity. During the last month (October), the tincture of the perchloride of iron has been given in half-drachm doses three times a day, with marked benefit, the hæmorrhages having very much abated.

These two cases so closely resemble each other in their history and symptoms that they may be most conveniently studied together. It will be seen that both are cases in which a hæmorrhagic diathesis showed itself after puberty; in which there was only slight hereditary tendency to hæmorrhage, and none to a hæmorrhagic diathesis. The diathesis showed itself by traumatic and spontaneous hæmorrhages, and ecchymoses and petechiæ under the skin. In both there was also said to be some affection of the knee-joint, but this proved in one case to be only an inflammation of the bursa patellæ.

The diagnosis, therefore, was a matter of some difficulty. At first sight the resemblance to hæmophilia seemed complete; there were present traumatic and spontaneous hæmorrhages, ecchymoses, and in one case a swelling of the knee-joint. But on further inquiry there appear good grounds for rejecting the diagnosis of hæmophilia. Hæmophilia is essentially a congenital disease, and in these cases there were no symptoms till after puberty. Again, there was no history of hæmophilia in the relations; and, what is of great importance, the women had not transmitted hæmophilia to their sons. Had the mothers been suffering from hæmophilia, hæmophilia would, following its law of hereditary transmission, beyond a doubt have reappeared in its most intense form in the sons of these women. It has been seen that the sons are quite free even from any tendency to bleed. On these grounds the diagnosis of hæmophilia appeared to me to be insufficiently established, and the cases were referred to a class of hæmorrhagic diathesis, the natural history of which has not yet been worked out.

To this class of hæmorrhagic diathesis belong the case, supposed to be acquired hæmophilia, of Magnus Huss (*Arch. Gén. de Méd.*, 1857, vol. ii., p. 165); the case of Higginbotham (*St. Petersb. Med. Ztschrft.*, 1869, Bd. xvi., p. 111); and the old cases of Patrick Murray (*Edinb. Med. Essays and Obs.*, vol. ii., art. xx.) and Boivin (*Dict. des Sciences Méd.*, t. iv., p. 188).

No post-mortem examination of these cases has, so far as I know, been made. The blood appears to be natural in its naked-eye and microscopic appearances. In the four cases quoted above, the disease made its appearance after some great mental emotion. It is possible that it may be connected with a lesion of the vaso-motor nerves. The disease does not appear to shorten life.

As to treatment, large doses of the tincture of the perchloride of iron seem to be of most use. A nourishing diet is, of course, of considerable importance.

8, Old Cavendish-street.

CEREBRAL AND GANGLIONIC DISORDERS OF MENTATION.

By METCALFE JOHNSON, M.R.C.S.E., L.S.A.

PART II.

MR. LECKY says, (a) "He who raises moral pathology to a science will probably take a place among the master intellects of mankind." But past history tells us that the pioneers of advanced truth must look for briars and thorns in their path in life, and that the laurel crown must be worn only after the cold brow has been encircled by the wreath of "immortelles"; for "In the kingdom of the blind," says Helvetius, "who is most odious?—He that can see clearly." In the empire of ignorance the same fate attends the enlightened inhabitant. Between those who realise phenomena (spiritualists) and those who phenomenise realities (Berkleyans) the number is small who are content with objective experience. The preconception of metaphysics is so mixed up with pietistic creed that there is a reluctance on the part even of thinking men to accept literally the psychology of the scalp. Nevertheless, "mind and body

are so closely connected that even those who most earnestly protest against materialism readily admit that each acts continually upon the other." (b)

I have elsewhere (c) called attention to the relation of the ganglionic system to mentation, and endeavoured to show that the sympathetic nerve presides over the instincts, controls the vascular supply to the grey matter of convolutions, and influences the organs concerned in the vital process—nutrition and reproduction,—while the cerebro-spina is the storehouse of sensation and reflex action. Condorcet says (d)—"L'homme naît avec la faculté de recevoir des sensations, d'apercevoir et de distinguer dans celles qu'il recoit les sensations simples dont elles sont composées, de les retenir de les reconnaître, de les combiner, de conserver ou de rappeler dans sa mémoire, de comparer entre elles ces combinaisons, de saisir ce qu'elles ont de commun et ce qui les distingue, d'attacher des signes à tous ces objets pour les reconnaître mieux, et s'en faciliter de nouvelles combinaisons. Cette faculté se développe en lui par l'action des choses extérieures." (e)

The distinction between cerebration and ganglionism in the development of the function of mentation is here the more insisted on because post-mortem investigation is too often abandoned in consequence of the failure to find morbid lesion of cerebrum to account for the phenomena of insane mentation. (e) Under this view of the case, elucidated by a paper on "Hedonism" (in *Medical Times and Gazette*, April 8, 1871), the brain is considered not so much as the organ of mind, but as one of the "force-centres" of which mentation is the nervous or spiritual "sum."

The present ignorance as to the function of each particular lobe or gyrus of the brain may be materially lessened by continued pathological and physiological investigations of the separate parts of the organ. And here I may be allowed to say that a perusal of Dr. Turner's (Edinburgh) pamphlet on the convolutions has added much of interest to post-mortem examinations of the brain. The example of M. Pridéaux in his investigation of the functions of the cerebellum (see *Medical Times and Gazette*, November 20, 1869) is worthy of more frequent imitation. A more critical attention to the comparative anatomy of the brain of the vertebrata, side by side with the foetal changes of development in intra-uterine life, would add much accuracy to our notions respecting that most interesting question of "arrest of development." The cases herewith recorded present for consideration numerous points of interest, some of which I will now attempt to indicate.

The Cases 1 and 2 (A. B. and B. B.) are instances of microcephaly in which is demonstrated a larger amount of intelligence than might have been expected. In these two people there was an absence of power to combine facts to form an inference. The power seemed limited to a reproduction by memory of single past experiences. Possibly Mr. Maudsley might consider this an evidence of Thieroid degeneracy, as it would seem that one of the apparent points of difference in the mentation of the brutes and man consists in the power of the former to receive simple sensations, and of the latter to combine the results of the five channels of sense, and to apply them by reproduction to compound or constructed ideas. The mental development in both is characterised by a power of language sufficient to receive and convey their daily wants. The first deficiency of power is in muscular sense, evidenced by ungainly gait and want of power to execute delicate muscularity. A second deficiency is indicated by an absence of moral sense. A. B. once told me, without consciousness of anything wrong, that B. B. had struck the person who took care of them so severely that it "deaded" her. Another deficiency was that of memory. Again, she was deficient in the power of adaptation. She would, if employed in washing clothes, continue the operation on one article all day, if not ordered to give over. B. B. has rather more power of adaptation. As a coal-carrier, he is neat about his work, and clears up as he goes on, picking the places in the heap with his shovel in which the coals fall easiest.

H. C. (No. 3) is an idiot of a more common form, although presenting larger measurements.

It is worthy of remark that the angle formed between a horizontal line (proceeding from the tragus across the nose) and the eyebrow or temporal-measurement is very constant, and corresponds with the base of the skull containing corpus striatum and thalamus opticus, in which limit, it would seem from Fleurens' experiments, are contained the sources of

(a) Lecky, "European Morals," vol. i., p. 167.

automatic actions. A consideration of the experiments of Fleurens, together with the other anatomical facts of the case, seem to point out that the seat of conscious feeling or sensation resides in some part of the brain which is removed in the pigeon (convolutions of grey matter), but that automatic action may be carried on as a reflex act, without the assistance of conscious volition. In these two cases the seat of automasis, then, is perfect, but the surface which performs the perceptive sense, evolves the reproduced or restored sensation (memory), and produces compound sensations or ideas, is deficient—hence the deficient power of mentation. No doubt the similitude of the pigeon recently deprived of convolutions, which have educated the powers of automasis from the central ganglia, is not true to the man congenitally deficient in convolutions.

A. D. (No. 4) presents a small brain, with deficient power, which under temporary disturbance becomes necessarily the subject of control. The intelligence, however, is on the whole sufficient to render her "worth her salt" as a servant.

As we rise in the scale we have B. E. (No. 5) possessing sufficient intelligence to earn an independent living as a factory operative, but who, on the accession of some disturbance, probably genital (catamenia had ceased three years), loses her power of self-control, and requires the supervision of an asylum.

In A. F. (No. 6) we have increased measurements, a higher development of cerebrum; but under ganglionic derangement the power of self-control is lost. I have generally found the delusion about creatures devouring the food in the bowels very permanent, and associated with apparent brain-disease.

In C. G. (No. 7) we have larger development of cerebrum over the crown of the head; but with a defective intelligence which is congenital in this case, the deficiency is in quality of cerebrum. Her being Irish may account for some strangeness of manner.

We now come to A. H. (No. 8), and are presented with what is ordinarily termed a sane man, who is admitted to serve in the army for some years. There is, however, a manifest deficiency in the occipital measurement. Here was a radical defect, which may have assisted an unruly ganglionic nerve to produce a disordered hedonism, such as his assuredly was. This was a most difficult man to manage. He was too cunning for ordinary legislation.

J. K. (No. 9) is chiefly remarkable for having a good head, heavy brain, but one that, like many others, became subject to the "*chose extérieure*" alcohol. As such, the early interference of a parental state might have made him a tax-payer, not a tax-consumer—a productive, instead of a non-productive article. (See "Sane or Insane," *Lancet*, March 19, 1870.)

The interest attaching to No. 10 (C. L.) is due to the enlarged condition of the left lateral ventricle, which was, in all probability, due to infantile hydrocephalus. The result of the full-grown physique of this man—the "sum" of his "force centres"—was a strong bony man, of very powerful build; a very coarse, and almost ferocious, aspect of face; a rather ungainly gait, slightly stooping, and flat-footed; his hair very coarse and rough. He would live for weeks without soap and water, and was only shaved about once a week. His manner was shy, and at the same time rough and bearish; his voice harsh. He was very cunning, and fond of drink. His great strength made him useful in carrying sacks of corn, for which he would always get paid by both buyer and seller if possible. If sent with a message, he would always be paid by the sender, and would ask for pay from the receiver as well. He spent his money in drink. His manner was so reserved that it was impossible to form an accurate gauge of his intelligence, so as to estimate the defect of his mind caused by the abnormality. On broad principles, it might be said that he exhibited signs of deficiency in the moral sense—in the power of acquiring facts, and of retaining or reproducing them; but the perverted hedonism of his nature led to such erroneous ideas of right and wrong that it was impossible to analyse his mind with any prospect of a successful result.

No. 11, A. O., is remarkable for the symmetrical shape and large size of his head, while the amount of his intelligence is so small. He is "a merry little grey fat man," who always laughs at everything said to him, and shows other marks of deficient shrewdness. Of his early history I have no means of obtaining the particulars.

No. 12, B. J., was an intelligent lad to the age of 9 years, when he had several fits, and from that time his intelligence seems to have disappeared. He is now simply a man with a pleasing countenance, an ungainly gait, a limited power of comprehension when spoken to, and a versatile disposition. If he takes a liking, he will be guided by a person to work or employment; but if he dislikes, he is very violent, so much so

that he has been obliged to be dismissed from the home of a relative to the workhouse in consequence of his ferocity. His relatives are remarkable for cleverness, and possibly (as was most likely the case in No. 10, C. L., and No. 11, A. O.) he has narrowly escaped being a man of considerable talent. The measurements of Nos. 13 and 14 are inserted for comparison, as being those of men much above the average of intellect and culture.

The case of No. 15, H. M., is chiefly remarkable for a disordered hedonism, probably due to hereditary—or, at any rate, inborn—abnormality, whether of structure or quality we have no means of judging.

The two following cases (16, E. N., and 17, O. P.) have a special bearing on the influence of the ganglionic system on mentation and on life. As will hereafter be shown, although at present the least attractive, they are the most important in a socially moral and in a political-economy point of view.

One remarkable feature in Case 17, O. P., was the eating of onions. The quantity she consumed was very large; she vomited most of them back, but some passed per alveum. This is a striking feature of cases of ganglionism, that they frequently exhibit not only taste, but all the senses in a depraved state, as is shown by the distaste for sugar, the readiness to take assafoetida and the fetid preparations in hysteria. There is also an inclination to say very dirty things—to use words which fill our minds with astonishment—to commit actions of the most offensive kind with apparent pleasure and satisfaction. Cases of this kind are too common in every Medical man's experience to need the record of more of them. The most refined and modest woman, under ganglionic disorder, will betray a knowledge of the dirty or night side of nature which her friends could never suppose she had even heard of, much less have revolved in her mind.

(To be continued.)

CLINICAL REMARKS ON THE SEVERAL FORMS OF PULMONARY PHTHISIS.

By R. DOUGLAS POWELL, M.D., M.R.C.P.,
Senior Assistant-Physician to the Hospital for Consumption and
Diseases of the Chest, Brompton;
Assistant-Physician to the Charing-cross Hospital.

(Continued from page 124.)

On Hæmorrhagic Phthisis—Subject divided into Hæmorrhagic Phthisis proper and Recurrent Hæmoptysis: Distinction between the two—True Hæmorrhagic Phthisis very rare; difficult to ascertain the true relation of the Hæmoptysis to the Primary Disease: Views of Niemeyer—Illustrative Case of Hæmorrhagic Phthisis—Remarks: (1) Why considered a Case of Phthisis; (2) Why Hæmorrhage not Bronchial, and affecting Lung secondarily; (3) Why probably coincident with and caused by Active Pulmonary Congestion; General Conclusion, with Definition of Hæmorrhagic Phthisis; further Points for and against Hæmorrhage in such Cases being Bronchial—Disease has no relation to Hæmorrhagic Diathesis—Remarks on Treatment: Value of Thermometer as a Guide.

THE term "hæmorrhagic phthisis" (a) has crept into use to distinguish those cases of phthisis which have a distinctly hæmorrhagic origin, and also those in which, however they may have arisen, hæmoptysis is a marked and oft-recurring symptom. For clearness sake it will, I think, be better to restrict the term to the first set of cases to which it was originally applied—those of hæmorrhagic origin; and to refer to the second class later as cases of phthisis with recurrent hæmoptysis.

The question as to the frequency with which phthisis arises as the direct result of hæmoptysis is one of great difficulty to determine, and must, I think, ever remain one of opinion. Of the possibility of blood having obtained entry to the air-cells and coagulating there, giving rise to broncho-pneumonia, and subsequently to phthisis, the observations of Professor

(a) "Phthisis after Bronchial Hæmorrhage" (Niemeyer, Bürger, 1864), "Phthisis Hæmoptoïque" (Herard and Cornil, 1867), "Hæmorrhagic Phthisis" (Dr. Williams, 1868), "Tuberculose nach Hæmoptoë" (Waldenburg, 1869), "Hæmoptysical Variety" (Dr. Peacock, 1870). These several authors, though doubtless they would agree in acknowledging certain typical cases as representative of this hæmorrhagic form of consumption, would differ widely in the liberality with which they would group more doubtful cases among such representative ones, nor would they more closely agree as to the pathology of the affection. The observation of this difference of opinion among observers so eminent, is alone, I hope, sufficient to make me fully aware of the difficulties of the subject.

Niemeyer, and Drs. Hermann Weber, Baumler, and others have furnished us with clear evidence. I have myself seen on several occasions post-mortem examples of inhaled blood forming the nucleus of fresh lobular pneumonia in the grey stage in cases—it is true, of tolerably advanced phthisis—in which death ensued after recent hæmoptysis. The difficulty, of course, lies in determining whether the hæmorrhage is the cause of the disease or is itself the result and evidence of pre-existing or coincident disease. It is an undisputed fact that in a certain number of cases, more or less copious hæmoptysis is the very first symptom of the pulmonary disease, preceding, even for a considerable time, all reliable physical signs. Professor Niemeyer asserts that the hæmorrhage in these cases—as in the majority of cases of phthisis in all its stages—proceeds from the bronchial mucous membrane; that a portion of the blood becomes inhaled into the air-cells of the previously healthy lung, coagulates there, giving rise to irritative lobular pneumonia, the consolidations of which may subsequently decay and soften, leading to destruction of the lung, or may become cheesy, and give rise at some subsequent period to tuberculosis of the lung of a secondary or infective kind. (b) I must confess that I have never met with a case which I could distinctly refer to this category, nor are the cases which Niemeyer quotes in support of his view to my mind conclusive. (c)

I think the phenomena exemplified in the following case may be fairly regarded as illustrative of the hæmorrhagic variety of consumption, while they also point to the hæmorrhage being of pulmonary, not bronchial origin.

J. P., aged 20, a servant residing at Faringdon, came to see me at the Brompton Hospital on September 21 last. She was a fine, well-developed woman, with a decided tendency to *embonpoint*, a clear complexion, a high colour, in which, however, a slight degree of lividity was noticeable. She was complaining of shortness of breath and bad cough with expectoration, and had the following history:—Of healthy parentage, and with no hereditary tendency to consumption; (d) she had enjoyed good health—with the exception of the formation of an abscess at the top of the sternum, which discharged eight years ago, leaving a depressed scar—until twelve months ago, when she began to suffer from palpitation on exertion; she did not consider that she had been ill, however, for more than six months, with increasing breathlessness and palpitation and slight dry cough. Three months ago she had an attack of tolerably copious hæmoptysis, which lasted nine days, and kept her in bed three weeks; five weeks ago she had a repetition of the hæmoptysis to a less degree. She had not menstruated for four months, having previously done so with regularity; but though the catamenia ceased about a month previous to the first attack of hæmoptysis, she did not herself connect the two facts together; they had again appeared a day or two ago. She had never suffered from epistaxis. She now complained of shortness of breath, troublesome cough with expectoration, which, however, was not tinged with blood. She had got thinner of late, and the pulse was rather accelerated and small. There was at this date no alteration in the shape of the chest, which was remarkably good, nor any decided dulness; but on the right side there was diffused crepitation throughout, mingled with vesicular harsh breath-sound. On the left side the respiratory murmur was exaggerated. The case was regarded as one of irritative catarrhal pneumonia of the right lung, secondary to copious hæmorrhage (probably vicarious) from the apex of that lung. At this time there was no evidence of positive destruction of lung, and I strongly advised her to seek the shelter of the Hospital as an in-patient, with the hope that she might make a complete recovery. She has only been able to do so quite recently, however, after having had a slight return of the hæmoptysis at the end of October.

November 17.—Having been in the Hospital for a few days, under the care of Dr. C. T. Williams, I again examined her. There was slight but decided dulness on percussion at the right supra- and infra-clavicular region, fading both downwards and laterally towards the median line into good resonance; above the clavicle the resistance to percussion was greater than on the opposite side; at the extreme posterior base there was almost complete dulness for three fingers' breadth, not so

anteriorly or in the axillary region. Heart's apex-beat in normal situation. The respiratory murmur at the apex was entirely masked by coarse moist crepitation accompanying both inspiration and expiration; vocal resonance increased, however, in supra-spinous fossa. Below the apex respiratory murmur feeble; crepitation to base, but less abundant than above; at posterior base absence of respiration over the dull portion, with some incomplete ægophony. On the right side respiration loudly puerile, well audible to mid-sternal line. The complexion was still fresh and highly coloured, without, however, any lividity. Cough now only slight; expectoration a tenacious mucus, clear and slightly pigmented. Temperature normal; pulse 104 to 112; weight of patient, nine stone.

I quote this case because I think it is as good an example of hæmorrhagic phthisis, in the sense of phthisis secondary to hæmoptysis, as is ever met with. There are three queries which must, however, be answered respecting it: 1st, Is it a case of phthisis at all? 2nd, Is it a case of phthisis caused by the inhalation of blood effused from the bronchial mucous membrane—phthisis *ab hæmoptoë*, in the sense of Niemeyer and others? or, 3rd, Is it a case of pulmonary hæmorrhage coincident with the occurrence of that active pulmonary congestion which is the very first stage of a certain number of cases of phthisis?

1. Though at present there is no evidence of *wasting* of the lung, yet there is sufficient evidence of irreparable damage to its texture—*i.e.*, there has been slowly diminishing breath-sound, with abundant crepitation, since she first came under observation in September, until, at present, the signs at the right apex seem only compatible with the air-cells there having become completely blocked with their epithelial products, now in the process of degeneration (caseous pneumonia). The significance of such gradually developing apex-signs after hæmoptysis cannot, I think, be mistaken; softening and removal of lung tissue, to a greater or less degree, with inductive shrinking of the lung, are the almost necessary consequences. In all probability, the disease in the lower part of the lung is the direct result of the irritation of the inhaled blood, and much of it may no doubt yet clear up—indeed, had the patient obtained proper shelter and care from the first, it might have done so entirely; but, though all fever is now absent, the physical signs show that much of the lung yet remains clogged with inflammatory products.

2. I think the facts (a) of the opposite lung having wholly escaped, and (b) of the apex of the right lung being so decidedly affected, are very strong evidence against the possibility of the hæmorrhage having been from the bronchial mucous membrane.

3. The same two facts, and more particularly the gradual increase in the apex-signs, and the concurrence of the *copious* hæmoptysis with the severe lung-symptoms, are equally strongly in favour of the hæmorrhage being truly pulmonary—*i.e.*, of an acute pulmonary congestion—the true first stage of this (pneumonic) form of consumption having been attended with hæmoptysis to an unusual extent, the blood having also gravitated to other parts of the lung, and set up irritative changes there.

No doubt, at first—*i.e.*, soon after the hæmoptysis—the basic were in excess of the apex signs; this is the case in many instances of copious hæmoptysis in the first stage of phthisis. The explanation which appears to me most plausible is, that the natural effect of gravitation, aided by the expansive movements of the lung, is to remove the blood from the air-cells at the apex of the lung, (e) which, therefore, often escape blocking, while they are the very physical conditions which most aid its entry into the lower portions. On the other hand, had the blood welled up from the base of the lung, it is unlikely, for the same reasons, that the opposite lung would have escaped.

It may be said—and here lies the uncertainty of all cases of this kind—that there was some disease existing at the right apex prior to the hæmoptysis. It is true that the patient had some cough, but it was only very slight, unattended with constitutional symptoms of any special kind, and not

(b) Waldenburg, fully admitting this view, seems inclined further to think that the inhaled blood, by the re-entry of its shrivelled elements into the circulation, may give rise directly to true tuberculosis ("Die Tuberculose," p. 496.)

(c) This point is very fully discussed by my colleague, Dr. C. T. Williams, in his chapter on Hæmoptysis in the recent work on "Pulmonary Consumption," by himself and Dr. C. J. B. Williams.

(d) There is some doubt about one sister who died of bronchitis, after about six weeks' illness, at the age of 4 years.

(e) The blood sometimes coagulates too quickly for this, and then the physical signs vary greatly from day to day, as in an interesting case of Dr. Gee's, of which he has kindly shown me the notes. In this case the signs were *nil* after the first hæmoptysis; immediately after a second attack, however, there were signs at the right apex, which were modified from day to day. The hæmorrhages were frequently repeated here, and the blood expectorated was commonly dark, clotted, having apparently been retained some little time. Some temperature observations are much wanted immediately after the first copious hæmoptysis in cases presumed to be of hæmorrhagic character. Dr. Gee considers it to be elevated from the first.

apparently differing from the short cough so commonly associated with palpitation, of which she also complained.

We may say, at least, that the *onset* of the disease was with *copious hæmoptysis in a person previously with no apparent chest disease*, and, with the exception of some menstrual irregularity and palpitation, so commonly associated with this condition, in fair health; we are further certain that a *considerable amount of the disease present is the result of the hæmoptysis*; and these two facts are sufficient to mark the disease clinically as one of *Hæmorrhagic Phthisis*.

It is obvious that it is impossible to draw the line between those cases in which the acute congestion—whether of vicarious or mechanical(f) source, or originating from a chill or other cause—results in hæmorrhage in a lung previously sound, or determines what is often the first sign of consumption—hæmoptysis—from a lung whose vessels are frail from previous error of nutrition or disease at one portion. The distinction is mainly drawn from the clinical history of the case; and there is perhaps no true pathological difference, since we cannot on present evidence admit the hæmorrhage to be bronchial. The chief facts upon which those who attribute early hæmoptysis to hæmorrhage from the bronchial tubes rely, is the extreme difficulty often experienced by the ablest auscultators in detecting any physical signs (but those, perhaps, of bronchial irritation) a short time after even very copious hæmoptysis. A man comes for examination a day or two after bringing up a large quantity of blood, and absolutely no signs which one could definitely pronounce as indicative of the origin of the hæmoptysis are discoverable. This very commonly happens. There may be the slightest comparative harshness and feebleness of respiration at the summit of one lung, from which long experience of the subsequent phenomena leads one to judge that the hæmorrhage has arisen there, but which without such experience would be considered wholly inadequate to account for the astonishing hæmorrhage. I have already pointed out above that the readiness of escape permitted to the blood from the apex by the aid of gravitation and expansile motion of the air-cells appears to me to be the explanation of this difficulty. It is the too common experience of the subsequent development of physical signs indicative of decided disease, at the point which we could only guess to be the source of hæmorrhage before, which enables us in such cases to speak decidedly upon what would otherwise be insufficient evidence.

It will be observed that the *hæmorrhagic diathesis* has not been spoken of in connexion with hæmorrhagic phthisis. I believe, indeed, that the two diseases have no causative relation to one another. Cases are common enough in which there is a tendency to slight hæmorrhage from the gums, slight hæmoptysis apparently from the mucous membrane of the large bronchi or the throat, often associated with menorrhagia. I have watched many such cases for a long time, but none of them have ever become phthisical, or suffered from very copious hæmoptysis. Cases of true hæmorrhagic diathesis are of course rare, and I am therefore glad to have the opinion of my friend Dr. Legg, who has paid much attention to *hæmophilia* and its literature, and who finds the subjects of this disease are rarely themselves affected with phthisis, and that copious hæmorrhage from the lungs is almost unknown among them.

Perhaps the chief advantage in retaining the term "hæmorrhagic phthisis" lies in its directing attention forcibly to the fact that hæmoptysis must not be looked upon only as the symptom or sign of disease, but as being also the *potential cause* of fresh disease. This consideration has a very important bearing upon the treatment of hæmoptysis.

We know that this early hæmoptysis is rarely, if ever, fatal, and therefore, after calming the patient and securing for him perfect repose, we may anticipate spontaneous arrest of the hæmorrhage, or may endeavour to stop it by appropriate drugs and other means. Our whole anxiety is, however, in the immediate future, to watch for, and, if possible, to avert, the secondary consequences of the bleeding. Any detailed physical examination of the chest is, while the hæmorrhage continues, to be carefully avoided. The thermometer, happily without danger to the patient, gives us the information we most require, and, together with the pulse and general aspect of the patient, is the best guide in the management of the case. If the temperature is raised at the time, or within a few hours of the hæmoptysis (it is often depressed for a few hours by

(f) The term mechanical source is meant to include those cases in which the excited action of the heart and pulmonary engorgement connected with violent muscular exertion—excessive dancing, rowing, etc.—lead to hæmoptysis. I do not know of any well-authenticated case of the kind. In Dr. Weber's first case (*Clin. Trans.*, vol. ii., p. 143), dancing evidently caused a recurrence of the hæmoptysis.

hæmorrhage from the lungs), we may conclude hæmoptysis to be of congestive or inflammatory origin, and we anxiously watch for a few days to see whether the fever subsides with the hæmoptysis, or whether a fresh accession takes place significant of those secondary inflammatory changes we have reason to dread.

The patient is usually seen after the first burst of hæmorrhage; and if the bleeding continue after quiet is secured, astringents may be found useful. I believe gallic acid to be the best of them, but it must be given in large doses of gr. xx. or ʒss. Unless, however, active bleeding is going on, I am content in cases of hæmoptysis to give nitro-muriatic acid and ipecacuanha, the acid serving, I fancy, to give tone to the relaxed vessels which have yielded the blood. The subsequent treatment of these cases requires the greatest care, and may be rewarded with brilliant results; for they are cases in which the disease is often in the smallest sense constitutional, and therefore in which recovery is always to be hoped for, while in no kind of condition is neglect attended with more unfortunate results than in hæmoptysis. I shall have a few more special remarks to make on the treatment of hæmoptysis in connexion with the subject of Recurrent Hæmoptysis.(g)

The prophylactic treatment is of much importance when we have any suspicion of a tendency to pulmonary hyperæmia, especially in young girls before menstruation is thoroughly established, or if it be irregular. Violent exercise of any kind should be strictly forbidden, the underclothing should be of flannel throughout, and the air of the bedroom should be warmed.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

CASES UNDER THE CARE OF PROFESSOR WOOD.

IN operating for the excision of the wrist-joint, Mr. Wood now generally adopts the method employed in this instance. The lines of incision are the same as those advocated in what is known as Lister's operation, the advantages of which are, that the extensor tendons of the thumb and fingers—so liable to be injured by the other modes of excising the wrist—are not at all implicated. The only tendons which run the risk of being divided are the extensors of the carpus, and the division of these is of less importance, owing to the firm fibrous ankylosis of the wrist which results from a successful operation.

The method adopted by Mr. Wood does not, however, correspond in detail to Mr. Lister's. Mr. Wood does not think it necessary so far to detach the soft parts as to allow the ends of the bones to be turned out through the wound. By feeling for the diseased structures with the forefinger of the left hand passed through one of the incisions, the cutting pliers and gouge can be substituted for the saw, and the sense of touch for that of sight; and by these means all the diseased parts can be removed without causing that extreme interference with surrounding parts which is otherwise necessary. The last four or five cases of wrist-excision operated on by Mr. Wood have been done in this way, and with good results.

Mr. Wood did not remove the trapezium, nor interfere with the radio-ulnar joint, as these were not involved in the disease. He pointed out the advantages, so far as the movements of the thumb are concerned, of leaving the trapezium.

(For notes of these cases we are indebted to Mr. Cross, House-Surgeon to the Hospital.)

Case 1.—Caries of Wrist-joint, commencing probably in Disease of the Synovial Membrane—Partial Excision of Joint.

Henry P., aged 40, admitted September 25. Mother and brother died of phthisis. Patient (a hatter) has not suffered from any symptoms of this disease. Eighteen months ago he struck the back of the knuckle of the third finger of his right hand. Some swelling, which soon subsided, occurred at the back of his hand. Two months afterwards the front of the wrist-joint on the ulnar side swelled considerably. Rest, iodine

(g) Drs. Bäumler's and Weber's cases, recorded in the *Clinical Transactions*, vol. ii., in which, however, they take a different view as to the source of the hæmorrhage, are most instructive in pointing out the value of the thermometer as a guide in the management of cases of hæmoptysis.

paint, and bandaging reduced this. He returned to his work, though he still suffered pain, and he could not grasp his iron, as the three inner fingers were weak and flexed, and the whole region supplied by the ulnar nerve painful. Six months since the swelling occurred on the back of the wrist as well as on the front, and pain increased, especially at night. For a fortnight before he came into Hospital he had done no work. When admitted his right wrist was about half an inch larger in circumference than the left; it was puffy and elastic to the touch, but not fluctuating. Three fingers were semi-flexed. There was great pain along the course of the ulnar nerve. He had no cough, but stated that he had been losing flesh. A splint was applied to the front of the wrist and arm. The swelling subsided on the front of the joint, but increased at the back.

One month ago Mr. Wood made an incision into the wrist on the posterior surface, letting out some thick pus. The probe led down to a gelatinous kind of tissue, but no bare bone could be felt. The wound was syringed out, and lint soaked in carbolic oil used to keep it open.

On November 18 Mr. Wood excised the joint, gouging away the diseased structures through an opening on the ulnar side. The original incision at the radial side of extensor digitorum was lengthened, so as to allow one finger to be retained in the joint during the operation and to act as a counter-opening for dressings afterwards. A quantity of brownish-yellow gelatinous material and several pieces of carious bone were removed. A piece of lint, soaked in carbolic oil, was passed through the double opening into the joint. The forearm and hand were then placed upon a padded straight splint, covered with oil-silk, and a somewhat wedge-shaped small pad was placed beneath the palm of the hand, so as to keep the fingers in a position between flexion and extension. The whole was then retained in position by strips of adhesive plaster and a bandage, and directions given that the joint was to be "flushed" out every day with carbolic acid lotion.

Case 2.—Epithelioma of Tongue—Removal with the Scissors.

Thomas M., aged 54, admitted into King's College Hospital, under the care of Mr. Wood, October 20. An old soldier. Has been married. No history of syphilis, nor any sign of it on the patient. No history of cancer in his family. Five weeks before admission he noticed that his tongue was sore, and that there was "a kind of blister" on its left edge towards the under-surface. It merely caused a little uneasiness when he took food; but for a fortnight before admission into the Hospital it had pained him, especially at night. He is a smoker, but holds his pipe on the opposite side to that attacked by the swelling. When admitted he was noticed to have a cachectic, sallow look. There had been profuse salivation of late. There were to the under side of tongue, opposite the front molar tooth, two small ulcers of a quarter of an inch in diameter, with very hard bases, and covered with a dirty secretion. There was no enlargement or induration of any of the glands. The local application of caustic chloride of zinc and the anti-syphilitic treatment were continued till November 18, when, as the affected part increased in size, and no marked benefit ensued, Mr. Wood took out a block of the tongue by the scissors, douching it well with a solution of xl. grs. ad ʒj. of chloride of zinc and perchloride of iron.

Remarks.—At the time of the operation, this affection of the tongue had not the common appearances either of epithelioma or of syphilis. There was a small raised hard swelling, the size of a pea, with a whitish surface superficially ulcerated in one spot, and a hard base; behind the swelling were two small irregularly shaped surface-ulcerations. The man had been treated for syphilis, but without checking the increase of the disease, and Mr. Wood decided on removing it, because, as he said, if it were not epitheliomatous at the time, it would have a great tendency to become so in a man of his age. We were allowed to take a portion of the removed tissue for microscopic examination, and found in it well-marked evidences of epithelioma—viz., groups or nests of epithelial cells, as well as cells spreading into the muscular tissue.

Case 3.—Third Operation for the Radical Cure of Hernia in the same Patient.

Frederick H., aged 27. In January, 1869, Mr. Wood operated on this patient (apparently successfully) for the radical cure of a large scrotal hernia of the left side. At the end of February, 1870, he had jungle fever in India, followed by a sunstroke and severe vomiting, which brought down a rupture on the same (left) side as large as a plum. He continued to wear a truss until November 17, 1870, when another operation was performed by Mr. Wood, the patient having returned to

England for that purpose. At this operation there was great difficulty in pushing the needle through the thickened cicatricial tissue. Wires were removed on December 9, and when discharged convalescent he was ordered to wear a truss for a while.

On returning to India he left off his truss earlier than he should have done, but no ill-consequence resulted till he had a severe fall from a horse, which brought down the rupture again.

On admission, on November 16, the intestine was seen to come chiefly through an opening opposite the internal ring, apparently the upper part of the external ring, the lower part being very thick and strong. Only a small quantity of intestine then protruded.

On November 18, 1871, another (the third) operation was performed, when the inner and outer portions of the ring through which the hernia descended were brought together, and the sac invaginated in the usual way.

GUY'S HOSPITAL.

REMOVAL OF RIGHT BREAST FOR CANCER— RETRACTION OF NIPPLE OF LEFT BREAST.

(Under the care of Mr. POLAND.)

ELIZABETH B., aged 46, had suffered at different times from strumous ulceration about the right arm, the cicatrices resulting being distinctly marked. There is no history of tumours of any kind in members of her family. About Christmas last the patient noticed a small hard swelling in her right breast, which gave her no great amount of pain, but became tender about three months ago, and has been gradually increasing, especially during the last month. The gland tissue of each breast is wasted, and each nipple is drawn in in a transverse linear manner. The tumour is of stony hardness, and after removal measured two inches by one inch in diameter. It was situated beneath the nipple; was movable upon subjacent tissues, but adherent to the skin and nipple. The glands in the axilla were not enlarged, and there was no thickening about the clavicle. Mr. Poland removed the whole breast, and drew attention to the fact that though retraction of the nipple was regarded as a pretty constant sign of malignant tumours of the breast, it must not be regarded as infallible, as here was a case in which the nipple of each breast was retracted, and in much the same manner, although in the left breast there was no disease existing.

PERIOSTEAL NECROSIS EXTENDING ALONG THE SHAFT OF THE TIBIA TO THE KNEE-JOINT— AMPUTATION THROUGH THE LOWER THIRD OF THE THIGH.

(Under the care of Mr. BRYANT.)

This patient, a child of 7 years of age, was admitted under Mr. Bryant on September 29 last, having received a blow on the leg from a stone one week previously. On admission, there was swelling and redness of the leg, with tenderness, as high as the middle of the thigh; acute suppuration soon followed, and the leg was evidently doomed. Owing to the refusal of the parents to permit an operation, the life of the child had been jeopardised. The whole of the shaft was diseased, and there were several sinuses around the knee-joint, leading to the conclusion that the disease had extended into the joint. The general state of the child was most precarious, and numerous large bedsores existed over the sacrum and trochanters.

Mr. Bryant, believing in the immense reparative power of children after any source of wasting discharge is removed, had fair hopes of the recovery of the child in spite of her unsatisfactory general condition; and he strongly impressed upon the students the importance, where there is no visceral disease present, of always giving a patient the chance of recovery by amputation, even in such or even more extreme cases than the one before him. He referred to a case he had seen under Mr. Key, in an otherwise healthy man, the subject of a compound comminuted fracture, who was rapidly sinking from profuse acute suppuration. The propriety of the operation having been discussed, amputation was performed on this patient, but without moving him from the bed, and the tibial arteries were tied before the amputation was completed, in order to save every drop of blood.

On examining the limb of this child after its removal, it was found that the periosteum was stripped off the bone in nearly its whole length; it was very soft and pulpy, and the surface of the tibia was necrosed. On opening the knee-joint

the fibro-cartilages were seen to be softened, and in the articular cartilage, on the head of the tibia, was a small circular punched-out-looking opening, through which red carious bone could be felt. On a vertical section through the thickness of the bone the medullary substance was also found diseased, and this extended upwards through the epiphysial cartilage to the knee-joint, so as to present the appearance described. No ligature was used at the operation, as the femoral artery was twisted by the torsion-forceps.

The following case—which is at the present time under Mr. Bryant—though similar in some respects, presented a contrast to the other. For notes of it we are indebted to Mr. R. S. Mutch:—

PERIOSTEAL ABSCESS OF FEMUR.

(Under the care of Mr. BRYANT.)

Ann W., aged 38, married, admitted October 25, 1871; no family; regular. Three weeks ago felt pain in inner side of right thigh, followed in a week by swelling, so as to render her unable to walk. No cause could be assigned—no injury or cold. Had no advice, but of her own accord applied poultices and took opening medicine.

On admission the whole of the middle two-thirds of right thigh is uniformly swollen and very tender; skin red; fluctuation doubtful. Ordered quinine, and poultice applied.

October 28.—Chloroform. Mr. Bryant considered deep-seated suppuration evident. An incision about three inches long was made on the antero-external aspect of the thigh, at the junction of the upper and middle third. About a pint and a half of pus and blood escaped. On inserting the finger, the upper half of femur was found exposed. A sponge was placed in the wound, and the thigh was bandaged.

30th.—Leg much easier, only smarting pain. Sponge removed. Discharge slight, but offensive. Oiled lint inserted between edges of wound, and thigh bandaged.

31st.—Temperature 99.2°.

November 9.—Has been doing well. Wound dressed the same. Discharge profuse, and still offensive.

10th.—Wound thoroughly washed out with water by means of an elastic catheter inserted.

16th.—The same treatment, and the patient is now considered convalescent. Temperature 99°.

THE LONDON HOSPITAL.

GANGRENE OF TIP OF NOSE AND PART OF EAR—IRIDOPLEGIA, ETC.

(Under the care of Mr. HUTCHINSON.)

THERE was in the London Hospital a few months ago a curious case (sent by Dr. Lomas to Mr. Hutchinson) of circumscribed gangrene of skin, associated with peculiar symptoms. The patient was an Irishwoman, aged 30. She stated that throughout last winter she had frequently suffered from fits of shivering. These attacks always came on after some exposure to cold, and from her account it seemed that they were often accompanied or followed by sufficient general *malaise* to prevent her from doing her work for periods of two or three days. She asserted, but only when the question was put directly, that her urine had often been very dark, and that it had varied considerably in colour at different times.

One cold day, when she had been out of doors (in February), she found, on returning home, that her nose and left ear were quite dark ("black," she said), and very cold. Soon afterwards a black spot appeared on the tip of the nose and the most exposed part of the helix of the affected ear. These two black spots remained, and on admission they were found to consist of small patches of dry gangrenous skin, about the size of horsebeans. The surrounding duskiness went off a few days after its first appearance, but it had since many times returned, and always in connexion with a rigor from exposure to cold. Whilst in the Hospital she had often slight shiverings, with intense icy coldness and purple congestion of the parts immediately around the gangrenous spots. She always referred these cold fits to some exposure. Thus, she very often had them in the morning, when the ward window had been open, and the congestion and coldness of the skin of the nose and ear disappeared when she again felt warm. Her urine was often looked at, but was never seen to contain blood or blood-colouring matter. Her temperature was usually below normal at the time she felt cold—her morning temperature being frequently 96° or 97° F.; in the evening, on one or two occasions, it rose to 101° and 103° F. Her pupils were noticed

to be rather large. On examination, they were found unequal (the left being the larger), and quite motionless. Neither exposure to light nor the efforts of accommodation produced any movement. Her vision for near and far objects was good. Calabar bean quickly produced marked contraction of the pupils.

Mr. Hutchinson remarked on the predisposition to gangrene of the most exposed parts, brought about in this patient by her want of power to resist a low temperature, a slight degree of cold producing an effect in her which would have required a more prolonged exposure to greater cold in persons less susceptible to changes of temperature. Although positive evidence of the passage of blood-colouring matter by the kidneys was wanting, yet Mr. Hutchinson inclined to regard the morbid state as allied in its nature to intermittent hæmatinuria, a disease in which, as is well known, exposure to trifling cold often suffices to induce a rigor and the passage of dark urine. There did not appear to be any reason for supposing her under the influence of malaria, and her attacks were not periodic. The partial dilatation and absolute fixedness of the pupils was a very singular point in the case. Attention was drawn by Mr. Hutchinson to the importance of testing the movement of the pupil in association with accommodation; he pointed out that in some cases the iris will act in conjunction with the ciliary muscle, although the stimulus of light alone is quite unable to produce any alteration in the size of the pupil. In this instance, however, neither light nor the act of accommodation had the slightest effect. Probably this condition of iridoplegia was in some connexion with disease of the vasomotor system, and thus due to the same cause as the remarkable tendency to shiver when exposed to slight cold. The phenomena of a rigor are, no doubt, due to arterial (or vaso-motor) spasm.

The subject of our case remained in the Hospital some weeks, and, under tonic treatment and liberal diet, her health, which had been very feeble, much improved; the little sloughs separated, and the sores healed. At the date of her discharge she had, however, by no means lost her peculiar susceptibility to slight changes of temperature.

SATURDAY, DECEMBER 2, 1871.

H.R.H. THE PRINCE OF WALES.

THE Prince's illness seems to date from the visit which he paid to Lord Londesborough at his villa, near Scarborough. He went there on October 30, and remained till November 4. Lord Londesborough's house is not large enough to receive all the guests who were invited to meet his Royal Highness; many of these, therefore, were "put up" in rooms secured for the purpose in the neighbourhood. Of the party who slept at Lord Londesborough's house, it is said that five have been more or less ill, with symptoms indicating some form of blood-poisoning; and that not one of the guests who slept out was so affected. Of these five patients, one noble personage is said to have suffered severely from intestinal irritation, but soon got well. Four others were affected with symptoms of typhoid. Lord

Londesborough himself is said to have been one of the first, and to have been just able to accompany the Prince to the station on the 4th, then to have gone home to bed. Lord Chesterfield and Colonel Tyrwhit, two others of the guests, are said to be still extremely ill. The Prince returned to Marlborough House on the 4th; celebrated his birthday at Sandringham on the 9th; then visited Lord Carrington. On his return to Sandringham, he is known to have expressed himself as feeling extremely out of spirits, as though he had a severe chill, which he could not shake off; yet he went out shooting as usual, and attempted to throw off his illness by means of hot baths. One source of uncertainty in typhoid fever is, that it is extremely difficult to fix the exact time of its commencement, for it may creep on insidiously, under the guise of "feverish cold," for many days before its real character is recognised. Equally uncertain is the time when it ceases—it may be seven, fourteen, twenty-one, twenty-eight, thirty-five, or forty-two days. The symptoms that have been reported to us, from the observation of those about the illustrious patient, are not unfavourable—the pulse never over 92, and some refreshing sleep—yet it is useless to deny the peril of the uncertain period that is yet to be gone through. Lord Londesborough, in to-day's *Times*, gives reasons for disbelieving that the Prince's visit to Scarborough had any connexion with his illness; but, unfortunately, we know that the floods of contaminated water which escape from house-drains are apt often to find their way where they are least expected. We should like to hear of such an examination as Dr. Ballard instituted at Islington, in the case of the fever caused by milk watered with contaminated water.

* * * Since writing the above, we have received the following from a Special Correspondent:—The etiology of the typhoid fever in the Prince's case is yet obscure. It was imagined that his Royal Highness might have contracted the disease when visiting near Scarborough; but this is doubtful. Since his Royal Highness fell ill, one of the grooms at the Sandringham stables, who did not attend his Royal Highness to Scarborough, has sickened with the same fever; and it is notorious that at this particular time typhoid is prevailing in many parts of England. Of course, there will be no delay in instituting the fullest investigation as to every possible source of the contagium. The early symptoms of indisposition were, in his Royal Highness's case, accompanied with slight suppurative inflammation at the base of the finger-nail (whitlow). The connexion of this with the incubation of typhoid may be only accidental, but should be noted. It was early suspected by Mr. Clayton and Dr. Lowe that there was more in the feverish symptoms than could be accounted for by the whitlow. On Monday, November 13, his Royal Highness was chilly after a day's shooting; he had not, indeed, felt well on leaving home in the morning, but there was nothing noticeable to create the suspicion of typhoid fever for four days subsequently. Then it was that headache became a prominent symptom, with the other attendant prodromata of typhoid. Up to the present time we believe the course of the illness has been characteristic of a rather severe attack of typhoid fever. When the public journals write about there being this or that symptom present or absent, the Profession know, of course, that such statements are worthless, and, further, that it is absurd to talk about critical days, since the malady must run a definite course, which, we are glad to learn, up to this time it does favourably, and without complication.

THE MEDICAL SUPERVISION OF ASYLUMS.

ON Saturday last the fortnightly meeting of the Metropolitan Asylums' Managers was held, and, among other subjects of importance, the very important one of the Medical Supervision of Asylums was discussed at some length, or, more correctly speaking, an opportunity was given to Mr. Wyatt and some other

members of the Board to state very positively their opinions on the Medical supervision of asylums. Mr. Shaw Stewart brought forward the adjourned portion of the Report of the Stockwell Asylum's Committee—the portion, namely, relating to the subject of appointing a Medical Superintendent in the place of Dr. Barbour, who had resigned in consequence of ill-health. They had reconsidered, "by the light of the experience they had gained in the working of the present system, the question of placing the Medical supervision and responsibility of the Hospitals in the hands of Visiting Physicians, rather than in the hands of Resident Medical Superintendents"; and after full consideration of the subject, "were not prepared to recommend any alteration in the present system." Mr. Shaw Stewart having moved that the Managers concur in the Report of the Committee, Dr. Stallard moved, as an amendment—"That it is desirable that the staffs of the small-pox and fever Hospitals shall consist of one or more Visiting Physicians, who shall be Members of the Royal College of Physicians of London, and of a Resident Medical Officer"; and that a Committee should report on the respective duties and salaries of these officers. He showed how well this system worked in the general Hospitals, and pointed out the many and great advantages which would follow the application of similar principles of management to the Board Hospitals; and he enforced his arguments by a reference to what is generally known as the "Hampstead Hospital scandal."

The Board, however, seemed so perfectly satisfied with all that has occurred, that Dr. Stallard's amendment would have fallen to the ground, from want of a seconder, had not Mr. Galsworthy said that, "though he did not altogether like the amendment," he would second it, "in order to have the discussion raised, and to take the opinions of Mr. Wyatt and Mr. Charrington, the Chairmen of the Hampstead and Homerton Committees"; and observed that if the motion were carried as it stood, the Managers would be committed never to try Visiting Physicians, which he really seemed to think objectionable.

Mr. Wyatt was altogether opposed to Dr. Stallard's views. He held that the Hospitals under the Board stood in a far different position to general Hospitals, and observed that "the Board could not expect eminent Physicians would, at the loss of their practice, undertake the visiting of Hospitals containing so many dangerous contagious diseases." The Medical Superintendents could, as matters stood, call in other advice if they found any occasion for it. And, moreover, "the proposed plan would lead to the payment of unnecessary and extravagant salaries." And Mr. Wyatt "regarded the remarks on Hampstead as exceedingly ill-timed." Mr. Charrington also was opposed to Dr. Stallard's amendment, and said that "the Committee of Homerton were inclined to leave well alone; for, after their experience of the present system, they did not wish to introduce any other."

Now, after Mr. Wyatt's evidence in the Hampstead Hospital inquiry, one cannot be surprised, we suppose, that he is quite satisfied with the working of the present system; but we greatly doubt whether outside the Asylums Board he will find many, who know anything at all about Hospital management, to agree with him. The Board Hospitals are large Hospitals for the treatment of acute disease, and it is difficult to imagine why they should not be managed on something the same principles as have for so long been found to work well in our general Hospitals—that is, there should be two, three, or, if necessary, more, Resident Medical Officers, like the House-Physicians of a general Hospital, with fair salaries, and a staff of Visiting Physicians, one at least of whom should visit the patients daily, and be responsible for their treatment. "Eminent Physicians" would not be required, nor would it be necessary to pay "extravagant salaries." We do not believe for a moment that it would be at all difficult to find, among the young Physicians waiting for Hospital appointments, perfectly fit and

efficient men to undertake the work, and to do it thoroughly well; and it would not require large salaries to tempt them. We have never heard that it has ever been difficult to fill up vacancies on the staff of the Islington Fever Hospital; and we are certain that, as Dr. Stallard stated, this plan "would be advantageous to patients, Medical officers, and the Managers alike,"—and, we would add, infinitely more satisfactory to the public. The visiting Physicians under this system would not, and need not, be "eminent Physicians"; they would be men of the same high and large Medical education as the Assistant-Physicians to our general Hospitals, and, as at those Hospitals, they would command the confidence of the public and the Profession. Moreover, under such a system of Medical management, it might be confidently expected that the experience and practice of the Board Hospitals would be made to add largely, and on most important subjects, to the science and art of Medicine—a secondary consideration, perhaps, yet nevertheless one the importance of which cannot easily be exaggerated, though it has been too little thought of, notwithstanding it was, we believe, plainly contemplated by the promoters of the Act by which these Hospitals are established. We need not point out how the knowledge and experience gained at the old fever and small-pox Hospitals have been made, by the able Physicians who have been on their staffs, to benefit mankind at large; and the public and the Profession have a right to look for similar gains from these new Hospitals. But this result would, we venture to assert, be infinitely more likely to be gained under the system we advocate than under the present one.

As to the observation that Dr. Stallard's remarks on the Hampstead Hospital were "exceedingly ill-timed," it seems almost an impertinence. We do not understand that Dr. Stallard in any way anticipated the judgment of the Local Government Board on the matters which were the subject of inquiry, but that he pointed to the evident want of discipline and efficient Medical supervision there as a strong proof of the need of such a change of system as he proposed; and as the question before the Board was whether the same system exactly should be adopted at Stockwell, it is difficult to conceive how it could be "ill-timed" to make use of the experience already gained of the working of that system—unless, indeed, its advocates felt that that experience was strongly against them.

Mr. Wyatt seems keenly alive to the £ s. d. side of the question. We should like to know how he and other Managers would look at requests by their Medical Superintendents for "other advice." We suspect that, to take such a step, unusually great moral courage would be needed, especially if the Medical Superintendent were mindful of the fate of Oliver Twist when he "asked for more."

The result of the discussion was, that Dr. Stallard, finding himself without support, withdrew his amendment, and the original motion was agreed to.

We hold that this is greatly to be regretted, and the more so because small-pox is again becoming much more prevalent. The Committee of the Hampstead Hospital "drew attention to the fact that the numbers during the last two periods of a fortnight showed a great increase over any other like period since August." At the Homerton Small-pox Hospital also, the number of admissions had increased during the last fortnight, and "the number of deaths had likewise unfortunately been greater." The class of cases admitted had been worse than any that had been received since the opening of the Hospital. Any serious increase of small-pox or fever will be a serious strain on the present system of Medical arrangements at these Hospitals, and it will be fortunate if there is no recurrence of complaints like those made against the Hampstead Hospital. We are quite ready to "leave well alone," but, *pace* Mr. Charrington, the question is, Is it well? and our answer is in the negative.

CHOLERA IN SOUTHERN INDIA IN 1870.

MR. CORNISH, Sanitary Commissioner for Madras, in his recently published "Record of the Progress of Cholera in Southern India in 1870," before considering the phenomena of later epidemics, critically re-examines some of the older data available in regard to the prevalence of the disease in earlier times. This he considers it necessary to do, in consequence of Dr. Bryden having lately given in his adhesion to the doctrine that cholera-movement is due in the main to meteorological influences, and that human intercourse plays but a very secondary part in the distribution of the pestilence. While such views are declared to be formed on the basis of statistical data by one of the most painstaking and intelligent investigators of modern times, and while directly contrary theories, the result of experience and induction, are held by the great bulk of the Profession, both in and out of India, he feels called upon to proceed with caution, and to weigh carefully every real or assumed fact before drawing inferences therefrom. He therefore reproduces in full the report of the epidemic of cholera in the Madras Presidency in 1818, compiled by Mr. W. Scott, Secretary to the Medical Board—first published in 1822, but now long out of print. This report he considers to be all the more valuable at the present time, because it was compiled, not to illustrate any "theory" of invasion, but to record in a connected form the testimony of the officers of the Medical Department who had personally witnessed the outbreak of this, the first epidemic invasion of modern times. The history of the epidemic advance of cholera in 1818, as detailed in Scott's narrative, is, he states, in point of fact the history for all time of the mode in which the Peninsula and Southern India are invaded. There are, of course, minor differences as to the rapidity of movement of, and the extent of country covered by, cholera, but the main facts are unalterable.

The great body of cholera which invades Southern India, leaves its natural home in Lower Bengal by what Bryden calls "the southern epidemic highway," across the central provinces, and southward through the Deccan and Bombay towards the Madras Presidency. In all true epidemic invasions, from 1818 to 1870, it has been carried on to Ceylon. In this southern progress two years may elapse, as in the latest invasion, or the whole journey from Bengal to Ceylon may be completed in six or seven months, as in 1818. It is certainly a remarkable fact that, notwithstanding the facilities of communication introduced during the last half-century, the cholera of 1868 should not have reached Ceylon till 1870. By this, Mr. Cornish thinks, it is indicated that in the movement of cholera from its endemic home there are other agents than human intercourse at work, and that cholera moves in accordance with laws similar to those of small-pox, and possibly of some other epidemic diseases. It finds the fittest conditions for its growth among populations which have not recently been subjected to its ravages; it is affected more or less by peculiar meteorological or climatic conditions. Like small-pox, also, after a season of wide-spread and unusual devastation it dies away completely, and is not renewed until the occurrence of a further invasion from without. The contagious particles of small-pox at the acme of an epidemic must be infinitely more numerous than at the beginning; and why should that disease ever decline, if capable of unlimited propagation? To this Mr. Cornish replies that, as in cholera diffusion, there is a limit to epidemic distribution, and that this limit is reached just as the contagium exists in the greatest abundance, and that, by a law peculiar to each, the contagium of probably all diseases of the infectious type ceases to multiply beyond a certain number of years. Judging from its fatality, the maximum power of cholera is not attained in the first year of invasion, either in India or Europe. Thus, in Great Britain the mortality was greater in 1833, 1849, 1854, and 1866 than in 1832, 1848, 1853, and 1865, the actual years of invasion. In some of the Madras districts the mortality goes on increasing up to the third year, while in

others the virulence of the epidemic is not prolonged beyond the second year. Curiously enough, in Madras the cycles of increase and decline of cholera and small-pox alternate, as has also been observed by Inspector-General R. Lawson, with reference to cholera and paroxysmal fevers; so that the years 1867 and 1868, which marked the decline of cholera all over Southern India, were noticeable for a great and general augmentation of small-pox. It would be very remarkable if in this country the impending epidemic of cholera—of which we have had such long notice, and the nearer approach of which has within the last week been heralded by the arrival at Newcastle-on-Tyne of a vessel from Russian Finland, having one of its crew actually suffering from Asiatic cholera—should be preceded by the still further decline or complete disappearance of small-pox from amongst us.

Mr. Cornish states very distinctly that, in his opinion, the theory supported by Dr. Bryden, of cholera being an "air-borne" miasm, does not rest on such a basis of fact as to commend itself to the credence of men practically acquainted with the phenomena of Asiatic cholera. It is only necessary, he says, to refer to Scott's narrative to prove, beyond the possibility of a doubt, that cholera did in that period traverse the Peninsula from east to west, and for many hundreds of miles from north to south, during the season of prevalence of the south-west monsoon, or, in other words, that an invading cholera advanced in opposition to a prevailing wind; and, moreover, that the change of monsoon from south-west to north-east did not hurry the advance of the disease over the southern districts. Nor, he says, does the theory of cholera-distribution by monsoon winds in any way account for the circumstance that, simultaneously with the movement of a new epidemic out of Bengal in a north-west or south-west direction, a corresponding movement is going on towards the south and south-east. During the season of their prevalence, atmospheric movements are in one direction, while cholera may be moving in several directions. It follows, therefore, that there is a movement of cholera independent of strength or direction of winds, and that aerial influences cannot be so all-powerful as indicated by Bryden. He does not, however, wish to deny that the *matériel* for cholera-propagation may be conveyed to a distance by the atmosphere; but there has been as yet no relation shown between the velocity of movement of cholera and of monsoon winds. These winds at certain periods of the year travel at the rate of from 200 to 300 miles in twenty-four hours; but he is not aware of a single fact which shows that cholera can advance epidemically at the same rate.

Mr. Cornish frequently makes use of the now familiar expression "cholera-wave"; but to this he attaches a meaning differing considerably from that assigned to it by Dr. Bryden or Inspector-General Lawson. He illustrates his idea of its nature, as a "radiation from a centre," by the commotion produced in water by a stone flung into it. As troubled water is first seen in the neighbourhood of the disturbing cause, so in a cholera epidemic it is the tract immediately outside of the endemic area that is first troubled, whether that tract lie to the south-east, south-west, or north-west. The fact that the sea lies to the south of the endemic area, and a mountain barrier to the north-east, is a sufficient reason for there being no extension of the widening circle in those directions; but wherever there may be population, and an absence of hilly barriers to prevent the circular extension of the cholera-wave, it will continue to spread out until it be lost, in the extreme East of China on one hand, and Africa, Europe, and America to the west. While mountain tracts, either uninhabited or occupied by people holding but little intercourse with the low country, also deserts and seas, interfere with the regular expansion of the circle, the points of protuberance of the advancing wave will be indicated by the valleys of great rivers or tracts of country but little elevated above the sea-level.

While Mr. Cornish admits that—seasonal and other conditions being favourable to the preservation of the vitality of the contagium of cholera—an epidemic wave from Bengal will spread over unoccupied country, he by no means agrees with Dr. Bryden in the cheerless—and, we may add, dangerous—doctrine he has laid down as to the inutility of sanitary precautions in limiting the destructive powers of cholera. This conclusion Mr. Cornish considers to follow logically from the theory of cholera being an "air-borne" miasm. But, he says, when it can be shown that cholera does *not* move against a wind, and that there *is* a direct relation between the movement of wind and the movement of cholera, it will be time enough for sanitarians to fold their hands and admit the inutility of their efforts to mitigate the horrors of a cholera-invasion. Meanwhile, it seems to him that much may be done to abate the evil; and he believes that there is sufficient evidence already accumulated to show that sanitation has diminished mortality from cholera, as from many other diseases. He trusts that the day may not be far distant when a systematic effort to attack and defeat cholera in its endemic home shall be made with every prospect of modifying those periodical invasions of epidemics which now carry terror and dismay and destruction of life over nine-tenths of the habitable globe.

Mr. Cornish is a firm believer in the influence of water-contamination as one of the factors in the extension of cholera, but does not consider it by any means the sole agent.

In our notice of Mr. Cornish's extremely able and valuable Report, we have necessarily left untouched many points of great interest. We have freely used the author's own words, as thereby we give our readers a better opportunity of correctly estimating his views. As a contribution to the history of cholera in India, and as an example of clear inductive reasoning on a question presenting so many difficulties, and beclouded by so many theories, as has been that of the mode of extension of cholera, we can honestly recommend Mr. Cornish's Report to the careful study of all interested in this most important subject.

THE WEEK.

TOPICS OF THE DAY.

THE prophecy of a particular day on which the Prince of Wales's fever might be expected to take a favourable turn, oracularly pronounced last week by a Medical contemporary, and reproduced in the public journals, strikes us as (to say the least) somewhat injudicious, as it is calculated to raise hopes which have little actual foundation. That a certain number of cases of typhoid fever are found to recover from the twenty-first day of the disease, is true, but undoubtedly a large proportion have a longer duration. In a young subject, without any serious complication, improvement may be hoped for at even an earlier period; but it is dangerous to pledge the weight of Medical science, as expounded by one of the reputed organs of the Profession, in favour of a prognosis as to time, which is not supported by the statistics of the disease, and is very likely to prove mistaken.

The opening address, by Dr. William Farr, to the Statistical Society, will be read with interest by many who regard statistics with a natural and just abhorrence. In felicitous terms he described statistics as being the essence of politics without party colouring, and likened the present race of politicians, sagacious though they be, in their neglect and ignorance of statistics, to the skilful Physicians before the discovery of the circulation, owing any success they may have achieved to a gifted empiricism. Dr. Farr is evidently not anxious to hide the failings of either politicians or Physicians—

"As we know that the introduction of philosophy into Medicine has at every step forward been strenuously resisted by leading Practitioners, so we must not expect the acquiescence of all conspicuous politicians in the doctrine that to be a states-

man a man must be a statist and study politics as a profession. At present it is notorious that men without experience, without special knowledge, with interests opposed to the public good, with their time entirely engrossed by business, not only not fit, but unfit in every way, are candidates for places in the Legislature at every election wherever representative government exists. Other things being equal, the success of such men should diminish year by year, and qualification in the legislator should be as rigidly insisted upon as it is now in the lowest office in the public service. In order that such qualification may be gained, politics must be studied and taught as a science by duly appointed professors. The next step would be to institute examinations, and ultimately to grant distinctive degrees, to which every statist, every young politician, would naturally aspire, as they would weigh with enlightened constituencies. Statisticians should, therefore, unite in asking the Universities to accord to the science all the importance it deserves."

It is possible, though not probable, that the development of the Chinese system in this country may culminate in the House of Commons instituting an examination for candidates for the degree of M.P. But Dr. Farr's reform is as yet a long way off.

We learn that the Council of the Royal College of Surgeons are discussing the question of improving the examination for the Dental diploma. It is proposed that the examination shall be made more practical, and shall be carried on partly in writing. Without expressing any opinion on the abstract question of the policy of granting Dental diplomas, we may say that, if the Royal College of Surgeons does institute an examination of the kind, it should be at least a good one. Neither for this diploma nor for the Midwifery licence are the candidates numerous.

The Corporation of London hope to secure Epping Forest for the people, and next session a Bill is to be introduced into Parliament with this end. We trust that the object of the Corporation will be attained, though not by means of an impost upon corn, which has been proposed.

Mr. Thoms, the disbeliever in longevity, has attacked Dr. Massy's account of the centenarian Geeran, which we published last week. Mr. Thoms disbelieves that Geeran was the old man he represented himself to be, and wrote to this effect to the *Times* newspaper. Dr. Massy has answered Mr. Thoms's letter. Neither controversialist, however, adduces much proof of his position. For ourselves, we are convinced that centenarians are not very uncommon, and that there is enough evidence to this effect to satisfy ordinary people. The amount of old disease which Geeran carried about him is undoubtedly a very interesting feature in his case.

Many of our readers are already aware that a committee has been formed for the purpose of placing a window to the memory of Dr. Jenner, the discoverer of vaccination, in the parish church of Berkeley, Gloucestershire, where Jenner lived and died. The church has been lately restored, and it is proposed to fill the east window with painted glass representing Our Lord in various acts of healing. The estimated cost is £500. Mr. Henry Kingscote, of 96, Eaton-place, is the honorary secretary to the committee, which includes Earls Bathurst and Ducie, Lord Fitzhardinge, etc.

A COTTAGE HOSPITAL FOR EALING.

CONSIDERING the short time that has elapsed since the first cottage Hospital was established as an experiment, it is wonderful how many similar institutions have been erected. Their great usefulness and small cost recommend them strongly. A large and influential meeting of gentlemen residing at Ealing was held on Friday last, under the presidency of the Right Hon. Spencer Walpole, M.P. A resolution was passed unanimously to erect, at once, a cottage Hospital for that portion of Middlesex.

THE LIBRARY OF THE ROYAL COLLEGE OF PHYSICIANS.

WE are glad to announce that the College has now extended to its Licentiates a privilege which was, until very lately, limited to its Fellows and Members—namely, the use of the library and reading-room. With a view to the general comfort of readers, the reading-room has been redecorated, and, for the most part, newly furnished. The daily papers are provided, as also the quarterly, monthly, and other periodicals; besides which, a large number of carefully selected recent works in Medicine, Surgery, Midwifery, and the collateral sciences will be found on the tables for perusal. These volumes are replaced by others every three months, or oftener, as the Library Committee considers desirable. The reading-room is open under the following regulations:—"The reading-room at the College, for the convenience of Fellows, Members, and Licentiates using the library, shall be open daily—Sundays and such other times as the Library Committee shall direct excepted—from one o'clock until four o'clock from October 1 to March 1, and from one o'clock until six o'clock from March 1 to September 1."

MILITARY ETIOLOGY.

WE hear from Dublin that the Board of Field Officers, assembled to investigate and report upon the cause of the prevalence of enteric fever among the soldiers confined in the Military Prison at Dublin, has concluded its labours, and sent in its report. So far as we can judge from our correspondent's communication, it is highly probable that, as we anticipated, the gallant officers have completely failed to discover any cause for the appearance of the disease. It could hardly have been expected that they should have done otherwise. An exhaustive inquiry into such a question is an undertaking for which a special and technical education is required. The investigation should embrace not only the personal antecedents for a considerable period of the sufferers from the disease, and all the local conditions to which they had been subjected for some time before its appearance, but also every channel by which the contagium of the disease may have been introduced from without. The water-supply and the state of drainage are, of course, the first and most obvious points to which attention should be directed. But in these, simple as they may seem, a perfunctory and superficial inspection by either military or Medical officers can afford no information whatever. It is now pretty generally known that enteric fever, as demonstrated by Dr. Ballard in our own pages, may be introduced into households in milk. We should like to know whether, in the assembled wisdom of the field officers at Dublin, there was any knowledge of this possibility. We should also like to be informed whether there was any special examination made of the cell or room in which each sufferer from enteric fever had been confined before his discharge from prison to his regiment as fit for duty. Two of the men who, we understand, were so discharged—one of them having been a prisoner for at least five months, and the other about three months—were on the next day admitted into their regimental Hospitals with incipient symptoms of enteric fever: one of them at least, died. Now, we maintain that such an event having once occurred, its repetition under similar circumstances is not only highly probable, but almost inevitable. The contagium of the disease was either of local origin or was introduced from without; and until this question be decided, and the cause, if local, removed, and, if extraneous, obviated for the future, we are of opinion that the military authorities at Dublin can hardly justify themselves to the public in submitting military prisoners to such risks. The military etiologists having failed in their mission, it appears to us that the matter should not be allowed to rest without further and complete investigation, even if it should be necessary to detail a specially trained Medical officer from Netley for the purpose.

THE PLYMPTON BOARD OF GUARDIANS AGAIN.

THE Guardians of the Plympton Union do not appear to be more liberal to those they praise than to those they blame. We lately had to find fault with them for passing a vote of censure on a Medical gentleman, which we considered impertinent and uncalled for. At their last meeting they were discussing the services rendered to the Union by Dr. Ellerley, the Surgeon to the workhouse, in stamping out the attack of small-pox which had lately visited the house. What amount of remuneration were they to make him for attending nine cases of small-pox for nine weeks, at a distance of two miles from the workhouse? Everyone admitted that Dr. Ellerley had been put to much trouble and expense in attending these cases. The Guardians were anything, however, but unanimous as to what amount the honorarium should be. Mr. Pearse thought five guineas as much as the Board would be justified in awarding. The resolution was seconded. Mr. Dewdney thought this would not be sufficient; and if the Board did not show a more liberal spirit, they must expect their Surgeons to get a little lukewarm. Mr. Croaker moved as an amendment that £20 be presented; he thought the sum not extravagant. Mr. Cecil Bewes seconded the amendment. The original resolution was put to the vote, and lost by an overwhelming majority. Mr. Cork proposed, and Mr. Dewdney seconded, that the amount be £10. This was carried. Now, this is really a shabby sum, under the circumstances of the case. The extra work was thrust upon Dr. Ellerley. He had much labour and expense thrust upon him, and moreover, as stated by several of the Guardians, had lost much private practice in consequence. The Guardians of Plympton, as of elsewhere, may rest assured that the kind of "economy" they have exercised in this case, in the long run is "the penny wise and pound foolish" system.

SMALL-POX JOTTINGS.

THE waves of the epidemic ebb and flow. In some districts the disease is on the increase, in others stationary, in others, again, decreasing. Dr. Stevenson's monthly report to the St. Pancras Guardians states that the mortality from small-pox in the parish was identical with that of the preceding month, whilst the average number of cases reported to the sanitary department fell from sixteen to ten per week. During the last week of the month, however, the number of new cases rose to twenty-two. Small-pox appeared to be increasing not only in the parish, but also throughout the metropolis at that time. During the week ending November 4, the number of new cases fell to nineteen, and during the following week thirteen cases were reported. Nearly all of these were of the pauper class.—Small-pox in Sheffield is very prevalent; two Hospitals are about to be erected for the accommodation of the patients. Upwards of 400 cases are reported by the relieving officer alone.—The disease is still on the decrease in Marylebone, and Dr. Whitmore has no apprehension of a renewed attack.—The returns presented on Saturday to the Metropolitan Asylum Managers showed that fever was greatly increasing, no less than fifty admissions having been made to Homerton during the fortnight, and there were now eighty-nine against forty-seven a fortnight since. Small-pox maintained the same high number of fresh cases as a fortnight since, but there was no apparent increase.—In his last monthly report for St. George's, Hanover-square, Dr. Aldis said only one person had died in the district from small-pox since his last report.—A small-pox Hospital having been opened at Taunton, a general exodus has taken place from the neighbourhood, and an action against the Local Board is threatened by the owners of property in the locality.—Small-pox is spreading rapidly in Philadelphia, New York, and other American cities.—On Monday night, at Wakefield, two military Hospital tents used as a small-pox Hospital were destroyed by fire, and two of the three patients who occupied one of the tents, and one of the two nurses who occupied the other, were burnt to death.

A LEGAL CORONER ON UNQUALIFIED MEDICAL PRACTITIONERS.

ANOTHER of those cases which are constantly cropping up to show the dangers of unqualified Practitioners occurred last week. At an inquest held by Mr. Humphreys on the body of a child, aged 9 years, it appeared in evidence that the deceased was the daughter of a cabinet-maker. For the last three weeks she had been ill, and had been taking medicine supplied to her by a druggist. The mother believed him to be a "regular Doctor," and he had "never told her different." The deceased getting worse, she sent for Mr. Richards, who promptly attended, but the child died soon after. Mr. Richards said, when he saw the child she was too far gone for him to render any assistance, and she died from water on the chest. In his summing-up, the Coroner emphatically remarked, "There can be no question that the life of this child would have been saved if proper Medical assistance had been rendered, and there is no reason on earth why such assistance was not forthcoming, except the fact that the first witness—the mother—believed a druggist to be a Doctor, and he did not undeceive her. It was lamentable to think of the number of lives that are sacrificed for the want of Professional assistance, poor people blindly believing that every druggist is a Medical Practitioner." Legislation cannot do everything, but it can effectually prevent a mere drug-seller from holding himself out as a legally qualified Practitioner of Medicine.

PATHOLOGICAL SOCIETY OF DUBLIN.

THE inaugural meeting of the thirty-fourth annual session of the Society took place on Saturday, November 25, in the Anatomical Theatre of the School of Physic, Trinity College. The chair was occupied by the President, Dr. James Stannus Hughes. Dr. William Moore exhibited several interesting specimens of Amyloid Degeneration removed from the body of a soldier, 28 years of age. Mr. John Hamilton presented an example of Extensive Chronic Disease of the Knee-joint, in which the various stages of synovitis, ulceration, and finally erosion of cartilage were all well characterised. Dr. Hayden showed a case of Aneurism of the Heart, in which death suddenly supervened in consequence of rupture into the pericardium. The case was remarkable, as having presented absolutely neither signs nor symptoms during life. The muscular structures of the heart had undergone extensive fatty degeneration. The Chairman notified that the subject selected by the Council for competition for the Society's gold medal, to be awarded at the close of the session in April next, was "The Diagnosis and Pathology of Injuries of the Thorax and its Contents." The Society subsequently adjourned for the transaction of private business. On the motion being put that the election of officers for the forthcoming session be proceeded with, an amendment was moved by Dr. Athill, seconded by Dr. Bennett, and carried, that the meeting be adjourned until December 9 next.

THE MEDICAL STUDENTS OF PARIS AND ROSSEL.

IT is creditable to the Medical students of Paris that they have been foremost in appealing to the President for a commutation of the sentence on Rossel. The first signature to the appeal is that of a Medical student, and he was supported heartily by his *confrères* throughout the capital and the country. It would appear that the appeal was unsuccessful. Rossel was shot on Tuesday morning last. Whatever his crimes, he was heroic, able, and single-minded, and was well worthy of the efforts to save him made by the students of Paris.

A LUCRATIVE APPOINTMENT.

WHO shall say that the Medical officers of unions are overpaid? Wherever they may be treated liberally, the Surgeon of No. 8 District of the Honiton Union is not amongst them. The Guardians advertise for a Medical officer at a salary of £9 per annum! Who can resist such a tempting offer?

THE MURPHY ANNUITY FUND.

THE funds subscribed and promised by the Profession towards the purchase of this annuity have already amounted to a sum sufficient to secure for Dr. Murphy a life annuity of fifty pounds. Some inevitable delay in obtaining the necessary age certificates, etc., has prevented the treasurer (Dr. Arthur Farre) from purchasing the annuity. The papers, however, will be ready, and the amount purchased, on January 5, 1872. In the meantime, the amount subscribed being in excess of that which is necessary to purchase an annuity on the sole life of Dr. Murphy, and many of the friends of Dr. Murphy being desirous to include in the provision his wife, who would otherwise be left destitute at his death, it is intended that an effort shall be made to increase the existing surplus to a sum sufficient to extend the proposal over the two lives. For this purpose £130 will be wanted, and it must be collected before the close of the year. Mr. Campbell De Morgan, 51, Upper Seymour-street, will act as treasurer of the supplementary fund, and Dr. Wiltshire, 57, Wimpole-street, W., as honorary secretary. When the full amount is collected, it will be handed over to Dr. Farre, the treasurer of the original fund, who will invest the whole sum in the names of the trustees originally announced.

THE CATERHAM ASYLUM.

It appears that there is some little foundation for the statement made by Dr. Stallard, at a late meeting of the Holborn Board of Guardians, to the effect that cases not fit for the Asylum at Caterham had been removed from the workhouse to that place. The Committee of Caterham, in their report, do not admit that any sane person was there admitted as insane, or that any sane person whatever was in the Asylum. The Committee, with reference to some aged persons, "thought that they ought never to have been brought to the Asylum, for it was obviously wrong to remove these people so far, and the Committee had remonstrated with the parish authorities against this being repeated." The result is that the Metropolitan Asylums Board have addressed a memorial to the Local Government Board, asking that further checks should be imposed on the admission of patients to the metropolitan asylums.

PRESENTATION TO A SURGEON.

A FEW of the friends of Mr. Leach, Surgeon, of Shaw, near Oldham, have presented him with a very handsome brougham, built by Cowburn, of Manchester, along with a testimonial, of which the following is a copy:—

"Dear Mr. Leach,—To mark the esteem in which you are held after following the Profession of a Surgeon in this place since (if we recollect aright) the year 1824, a few of your friends beg to offer a brougham for your acceptance; and they would gladly persuade themselves that it may be one means the more by which they may the longer have the benefit of your services.

"Dear Mr. Leach,

"Yours very truly, on behalf of the subscribers,

"JOHN CROMPTON."

"High Crompton, November, 1871."

MIDWIVES FOR THE KENSINGTON UNION.

IN many of the unions of the metropolis and the country, midwives have the sole charge of the patients, subject, of course, to an application, in cases of necessity, for assistance from the Medical officer. As a rule, we believe the plan works well, and, where the guardians are liberal in their views of what are called "extras" in midwifery, no just ground of complaint can be urged against the system. The subject of appointing midwives to the Kensington Union was before the Board last week, and the discussion, which excited much interest, will be resumed at an early date.

CHOLERA IN CONSTANTINOPLE.

By the latest advices, we learn that cholera is increasing at Stamboul and the neighbourhood near the Sultan's palace.

FROM ABROAD.—M. PÉAN'S CASES OF GASTROTOMY—CAMPHOR WITH BROMINE AS A SEDATIVE—THE FRENCH SCIENTIFIC SOCIETIES AND THEIR GERMAN MEMBERS—PROGRAMME OF THE PARIS FACULTY OF MEDICINE.

IN an oral communication recently addressed to the Academy of Medicine, M. Péan stated that, notwithstanding the troublous times of these last two years, he had performed gastrotomy thirty-two times in Paris, upon subjects aged from 16 to 68 years, during this period. In at least two-thirds of these cases, the patients at the time of the operation seemed as if they had but some months, or even some weeks, to live. In twenty-six instances the operation was well borne, and gave rise to no accidents that could be attributed to it. Four of the patients, however, died afterwards—two from epidemic dysentery, then ravaging Paris; one (a patient aged 16) from convulsions, which were probably tetanic, and came on six weeks after the operation, when the patient's health seemed quite re-established; and one from senile exhaustion, the subject being 68 years old. All the others are now in good health, and eighteen of their number recovered without having, even during convalescence, experienced any complication. Of the six patients who succumbed in consequence of the operation, two died some days after it from pelvic peritonitis, brought on by the entrance into the cavity of the peritoneum of some of the fetid pus contained in the tumour; another died some days after the operation, from the fright caused by the cannonade of Fort Bicêtre; one died from senile cachexia, she being 61 years of age, and deprived of proper nutriment during the blockade; and another also died from scorbutic hæmophilia, due to physical privations and moral suffering of all kinds during the siege. All these operations were performed at Paris, either within the fortifications or at a *maison de santé* at Levallois-Perret, and the results prove that the air of Paris cannot be so deleterious as it has been represented to be. But, if the place of operation does not go for much in the cure of these patients, this is not to be said with regard to the attentions paid to the cases consecutive to the operations. These are of capital importance, and it is to the extent to which they were carried out at this *maison de santé* that M. Péan attributes in great part the unexpected result he there attained of fourteen cures in sixteen operations.

Professor Deneffe, of Ghent, states (*Presse Méd. Belge*, November 19) that for more than two years he has employed a combination of camphor and bromine, which he thinks is entitled to general attention. The celebrated chemist Laurent showed that bromine will easily unite with camphor at the ordinary temperature, but that the product is slowly decomposed by exposure to the air. M. Swartz, Professor of Chemistry at Ghent, has shown that this body heated in a closed vessel is resolved into hydrobromic acid and a crystallised compound which is monobromised camphor (*camphor monobromé*), a body differing only from ordinary camphor by the substitution of an atom of bromine for an atom of hydrogen. It is a perfectly crystallised substance, fusible at 76° C. and boiling at 274°. At Professor Swartz's request, M. Deneffe has investigated the therapeutical properties of this body, and has found it to be an excellent sedative for the nervous system. He intends shortly to publish his cases in proof of this, and, in the present communication, furnishes one of these, in which excitement of the nervous system passing into true delirium tremens was effectually relieved. He prescribed it in the form of pills, seventy grains being made into thirty pills, of which one was given every hour until twenty had been taken. For three days longer from forty-five to sixty grains were given in the twenty-four hours, the quantity being diminished from forty-five to thirty grains daily for a week longer. The recovery was progressive and stable.

In relation to our note of last week upon the expulsion of its German members by the Société Médico-Pratique, we may

mention that we have seen a letter from M. Giraaldès, in which he states that no importance should be attached to the action of these minor societies in this matter. Neither the Institut, the Académie de Médecine, nor the Societies of Surgery, Anthropology, or Biology have erased the names of the German members from their lists—"placing the scientific question above all," and endeavouring to forget that German *savants* have performed or sanctioned unworthy actions. This is as it should be. Whether such actions have or have not been committed, and whether, as M. Giraaldès asserts, the Geneva Convention was intentionally violated before Paris by order of the German staff, time will prove, and European opinion will pronounce; but it is a great point gained that heated passion has not been allowed to involve the votaries of science in a line of conduct that would afterwards have led to inextricable embarrassments. The letter in question contains, also, a reproof, the justice of which will be admitted:—"If Professor Virchow and other *savants* regard us at the present time as occupying the lowest place in the ranks of science, it may be as well to remind them that their revelation is somewhat late in making its appearance; for they have hitherto highly prized the distinctions and prizes at the disposal of those thus characterised as the lowest among *savants*." We are not aware that Professor Virchow himself has employed expressions justifying this rejoinder; but some of his colleagues, writing for the press, have spoken of the state of affairs in France with a coarse brutality and heedless vanity which are very reprehensible. All who are acquainted with the history of what science in all its branches has heretofore done in France, and who are aware of the elastic energy inherent in its cultivators, confidently anticipate that when the oppressive agency of past subjection and the disturbing influences of present turmoil have yielded to the genial encouragement springing from free institutions, she will again take her place amongst the foremost teachers of the age—rendered also, it is hoped, less unmindful than heretofore of the labours of investigators working elsewhere.

The following is the programme of the courses of lectures to be delivered at the Paris Faculty of Medicine during the winter session of 1871-72. It will be remarked that there is no provision in it for teaching Physiology:—1. Medical Physics, M. Gavarret; General Physics—Electricity and Light—twice a week; and Biological Physics—Vision and Audition—once a week. 2. Surgical Pathology, M. Verneuil—Traumatic Lesions—thrice a week. 3. Anatomy, M. Sappey, thrice a week. 4. General Pathology and Therapeutics, M. Chauffard; Disease in general—Classification of Diseases and Morbid Etiology—thrice a week. 5. Comparative and Experimental Pathology, M. Brown-Séguard, thrice a week. 6. Medical Chemistry, M. Wurtz—General Chemistry—twice a week; and Biological Chemistry—the Chemical Phenomena of Digestion, and the Chemistry of the Blood—once a week. 7. Medical Pathology, M. Axenfeld—Diseases of the Nervous System—thrice a week. 8. Operations and Apparatus, M. Denonvilliers—Treatment of Gunshot Wounds; Ligatures and Amputations—thrice a week. 9. Histology, M. Robin, thrice a week. 10. History of Medicine and Surgery, M. Daremberg—History of Medicine—once a week; and History of Diseases, principally in relation to Diagnosis, twice a week. 11. Clinical Medicine, M. Isambert for M. Bouillaud, and M. Sée at La Charité, M. Béhier at L'Hôtel-Dieu, and M. Lasègue at La Pitié, daily from eight to ten. 12. Clinical Surgery, M. Laugier at L'Hôtel-Dieu, M. Broca at La Pitié, M. Gosselin at La Charité, and M. Richet at L'Hôpital des Cliniques, daily from eight to ten; M. Broca will also give lectures in the theatre thrice a week. 13. Clinical Obstetrics, M. Depaul. 14. Clinical Lectures on Diseases of Children, M. Roger, once a week.

MR. A. H. HACKNEY has been elected Medical Officer of St. Mary's District, Marylebone.

AUTOBIOGRAPHICAL RECOLLECTIONS OF THE PROFESSION.

No. XVIII.

By J. F. CLARKE, M.R.C.S.,

For nearly forty years on the Editorial Staff of the "Lancet."

A MEDICO-LEGAL TRIAL.

Oxford, the assumed attempted Assassin of the Queen: Did he Fire with Loaded Pistols?—The Plea of Insanity successful; Righteousness of that Plea in this Case—Medical and Legal Insanity—Oxford not Legally Convicted—Erskine, and Trial by Jury.

IN the afternoon of June 10, 1840, a fine bright day, the town was startled with the announcement that an attempt had been made to assassinate the Queen. The news soon spread over the entire kingdom. Intense indignation was expressed and felt against the would-be assassin, and intense joy at the "marvellous escape" of her Majesty. The evening newspapers published late editions giving an account of the proceedings, which occupied the thoughts and tongues of everyone. It appeared that the Queen and Prince Albert were proceeding from Buckingham Palace up Constitution-hill in an open carriage, and that when they had reached about half-way up the hill two discharges of firearms in quick succession were heard. These sounds proceeded from the railings of the Green-park. A young man was seen by several persons near him to fire off two pistols. He was immediately arrested, and given into the custody of the police. He proved to be a bar-boy—or, more properly speaking, pot-boy—of the name of Edward Oxford. It is said that on arriving at the police-station he inquired whether the Queen had been hurt. He was taken before a magistrate, and eventually committed for trial for "shooting at the Queen with pistols loaded with ball."

I knew the prisoner and his family well, and I immediately exclaimed, on hearing of his arrest, "The boy is mad. I am not surprised."

Immediately after his committal his mother, a widow—herself most eccentric, if not insane—came to me respecting her son. She had retained for his defence Mr. Pelham, a most respectable solicitor at the East-end of London; and at an interview with that gentleman I gave my opinion as to the state of mind of young Oxford, and advised that the plea of insanity, or rather of "unsoundness of mind," should be urged in his defence. At this time the Society for "Abolishing Capital Punishment" were making great efforts to carry out their object, and the late Mr. Sidney Taylor was the barrister who represented them, not only in courts of law but also in the newspapers—more particularly in the *Morning Herald* of the time, in which leading articles in favour of the objects of the Society were constantly appearing from the pen of Mr. Taylor. Sidney Taylor was a man of good ability, an able writer, and a sound lawyer; but he was not a good speaker, was in wretched health, and unable to bear prolonged fatigue. He was a man of most humane sentiments, and of the highest honour. Mrs. Oxford was in very straitened circumstances, and made application to the Society which Mr. Taylor represented for pecuniary assistance to enable her to defend her son. This was promised, and granted on condition that Mr. Taylor should "lead" in the case. The conditions were agreed to, and I had several interviews with him at his house in Chancery-lane respecting the defence and the Medical witnesses whom we should engage in the matter. I suggested Dr. Conolly (then the Resident Physician of Hanwell), Dr. Hodgkin, and Dr. Chowne; to these were added Dr. Birt Davies and Mr. Partridge, of Birmingham, as they had known the father of the prisoner, and could testify to the fact of his being of unsound mind. It was arranged by Mr. Taylor and myself that it was desirable the Medical witnesses should avoid all definition as to what insanity really was—that the evidence should be as simple as possible, and conveyed in language that the jury could understand and appreciate. In truth, we were to speak only to facts, and leave the lawyers to fight the legal questions that might arise. The wisdom of this arrangement was fully borne out by the proceedings at the trial, which was not only one of the most remarkable that ever took place, from the nature of the offence, but for its results, and the course the

law officers of the Crown and their associates thought proper to pursue. The Government seemed determined to convict the prisoner of the highest crime known to the country—that of high treason. So satisfied were they that he would be convicted of this, that, singularly enough, the prisoner was indicted on a single count, which indicated a “foregone conclusion” in the mind of the prosecution. That count was as follows:—That he, on June 10, 1840, “discharged a certain pistol, the same being loaded with gunpowder and a certain bullet, at the Queen.” It has always appeared to me most extraordinary that the prosecution relied upon this single count, because there was no evidence whatever, and merely a surmise, that the pistols contained a bullet. The Crown lawyers were well convinced of this, and, as the result showed, they made a grave mistake in not indicting the prisoner on other counts. I can only attribute this oversight—for such it was—to the impression that the popular indignation against the prisoner—and justly so—was sufficient in itself to prevent any jury from arriving at a verdict which would release the prisoner. Happily, though the evidence entirely broke down as to the ball in the pistol, the verdict had the effect of imprisoning the foolish boy, who had, as he called it, “popped at the Queen.” But the prosecutors had to thank the witnesses for the defence that this result was arrived at. Had the plea of insanity not been urged in his defence, and the verdict given in accordance with that plea, the prisoner, according to all principles of law and justice, must have been discharged. I shall show, in the course of this narrative, that no other conclusion could have been arrived at by the jury. This is the more striking because the prosecution, represented in the summing-up by Sir Thomas Wilde (then Solicitor-General, and afterwards Lord Truro) ridiculed the plea altogether; and the cross-examination of the witnesses for the defence went mainly to show that they were philanthropists, and entirely mistaken with respect to what “legal insanity” really meant. When I give a short account of the trial I shall show what grounds I have for this statement. When it was determined that the defence should be based on the “unsound state” of the prisoner’s mind, I immediately took steps to secure the attendance of the witnesses I have named above. The most important of these was Dr. Conolly, and I arranged with Mr. Pelham, one afternoon shortly before the trial, to go with him to Dr. Conolly at Hanwell, to seek his advice and opinion on the matter. We went accordingly to Hanwell, and found the Doctor at home. On stating the object of our visit, he immediately said, “I cannot believe that the prisoner is responsible for his actions. There is an entire want of motive, and, from what I have heard of his conduct since his committal, I feel convinced that a plea of insanity can be maintained; but, of course, I can only satisfy myself on this point by seeing and carefully examining him.” We stated that our resources were limited, and we could not remunerate him for his attendance in the way we desired. He at once emphatically refused to accept of any kind of remuneration, would give all the time and attention to the case he could, and, with the benevolence and high-mindedness which distinguished him through life, said, “If he were a rich instead of a poor man, I would not accept a farthing; it is a duty I ought to perform, not less for the sake of humanity than of science.” It is something to say in favour of our Profession that not a single farthing was paid to any of the Medical witnesses who appeared at the Criminal Court of the Old Bailey in defence of Oxford. Some of these witnesses attended at considerable expense, all at great inconvenience, and none of them without considerable sacrifice of time and money. It was decided on July 8 that the Medical witnesses should visit Newgate to see and examine the prisoner. Accordingly, by an order of the Home Secretary, permission was granted to us for that purpose. We arrived at Newgate about one o’clock—Dr. Conolly, Dr. Hodgkin, Dr. Chowne, and myself; and Mr. Pelham, the solicitor. On presenting ourselves we were received most courteously by Mr. Cope, the late governor of the prison. On Mr. Pelham handing to him the order for our admission, he expressed himself as extremely sorry to keep us waiting, but his instructions were imperative that no Medical gentleman should have an interview with Oxford except in the presence of Mr. Aston Key. It is difficult to understand why such instructions should have been given; but given they were, and we were kept waiting until a messenger was sent to Great St. Helen’s for Mr. Key. The messenger returned. Mr. Key was out, and it was quite uncertain when he would return home. Mr. Maule, the then Solicitor of the Treasury, was present, but declined to take the responsibility of admitting us to the prisoner. After waiting for, I think, nearly two hours, I appealed to Mr. Cope to take

upon himself the onus of admitting us; and particularly urged upon him the fact that, as the trial would take place on the next day or the day following, the refusal to admit us would be, in fact, a denial of justice to the prisoner. “Well, gentlemen,” he said, “I will be no party to such denial of justice; be good enough to follow me, and you shall see and examine Oxford.” We followed Mr. Cope accordingly, and were ushered into a superior kind of cell in which the culprit was placed. Mr. Maule accompanied us. The prisoner was well acquainted with me. I shook hands with him, and introduced him to the gentlemen who were with me. Those who had not seen him before were at once struck with his youthful appearance and his manners. A short thin youth, with an expression mild and respectful, but still not abashed, stood before them. He answered all questions readily and without the least reserve, and made a favourable impression on all. Dr. Conolly very carefully examined his head, and took me aside for a moment to remark that there was a peculiarity in his forehead which he had never observed except in persons who were either idiotic or otherwise unsound. This peculiarity consisted in a depression at the upper part of the forehead, as if some absorption of the brain at that point had taken place, and the frontal bone had adapted itself to the deficiency. “This youth,” said Dr. Conolly, “cannot with such a configuration be entirely right.” We all were convinced that, in spite of his manners being in the main rational, the prisoner was not of sound mind; and, taking our examination of him in connexion with the fact that his father was a lunatic, and his mother little (if any) better, that we might go into court the next day confident that, with corroborative testimony as to his antecedents and the hereditary taint from which he suffered, we could convince the jury, if not the lawyers, that he was not responsible for his actions. I should state that the prisoner’s perfect *nonchalance* with respect to his position, perilous as it was, impressed us strongly with his mental condition. We held a consultation after the interview, and we all felt convinced that we could justly uphold the plea of insanity, notwithstanding the opposition we contemplated from the Government—an anticipation which we had sufficient grounds for entertaining.

On Thursday, the 10th of July, the prisoner was put upon his trial. Great interest was excited by it, and the court was crowded. Owing to the good arrangements made by the under-sheriffs, the witnesses and persons interested in the proceedings were well accommodated. The Medical witnesses, consisting of the gentlemen I have previously named, were placed in an excellent position in the middle of the court, and to the left of the judges. For seeing and hearing we could not have been better placed. The presiding judges were Lord Denman (Lord Chief Justice), Mr. Baron Alderson, and Mr. Justice Patterson. On the first day the Crown was represented by the Attorney-General (Sir John Campbell), the Solicitor-General (Sir Thomas Wilde), and Mr. Wightman, to whom were added on the following day Sir F. Pollock, Mr. Adolphus, and Mr. Russell Gurney, the present Recorder of London. On behalf of the prisoner were Mr. Sidney Taylor (then suffering from a painful disease, which shortly afterwards ended his life), and Mr. Bodkin (the present Assistant-Judge of the Middlesex Sessions). On being placed at the bar, the prisoner was the object of everyone’s attention. A small, slim youth, aged 18 or 19, but looking younger, with a somewhat pleasing expression of countenance, stood forward, and, during the whole time the trial occupied, appeared less concerned than any one of the numerous auditory that thronged the court. This *nonchalance* and carelessness was manifested even up to the retirement of the jury and to their return with the verdict, inasmuch that Lord Denman, in his summing-up, made particular allusion to it, and said such conduct seemed scarcely compatible with a right condition of mind. The evidence of the act of firing at the Queen was that of some bystanders, who deposed to having seen him level the pistols at the Queen, and fire them off. The evidence that there were bullets in them totally failed—in fact, there was no colourable pretence for saying so, except that, when at the station-house, he was asked if they were loaded with bullets, and he acknowledged that they were. This was no doubt suggested by his insane vanity and wish to deceive; but I have every reason to believe that the charges consisted simply of a little powder. It is all but impossible, if bullets had been in them, they should not be found—*there were, in fact, no bullets in them.* The prosecution, it was evident to all present, had broken down, and the prisoner, on the solitary count on which he was indicted, must be acquitted. Whether this had any influence on the manner in which the Medical witnesses were cross-

examined, or not, I cannot say; but it seems on reflection to be a second illustration of blundering on the part of the Crown lawyers. However this may be, the cross-examination was more than severe; and the attack on us by the Solicitor-General in his answer was so unmeasured in its terms, that the Lord Chief Justice told the jury some of the remarks were uncalled for, and that the witnesses had given their evidence with remarkable propriety and discretion. The defence was "Not guilty" on the ground that the pistols did not contain bullets, and "Not guilty" on the ground of insanity. The axiom laid down by the lawyers was in the following words, or words to the precise effect:—"The first question would be, whether, supposing the prisoner to be accountable for his actions, he was guilty of the offence laid to his charge; and the second question would be, whether, at the time he committed the act, he was accountable to the law for his actions." Now, the prosecution assumed an affirmative to both questions. The defence assumed that the prisoner was not guilty on the ground of insanity, as evidenced by the hereditary taint, the manners and appearance under peculiar circumstances, cerebral configuration, and absence of adequate motives for the offence with which he was charged, and that he was inflamed by a morbid and uncontrollable impulse. Evidence on all these points was given. With a solitary exception there was nothing technical or over-learned in the evidence; but I have said that it was treated with an amount of severity and rigour on the part of the Crown which was scarcely justifiable. The Solicitor-General contended that, as the prisoner knew what he was doing—that he was doing wrong, and would be punished for so doing—he must be in a sound state of mind; so far as the legal definition of that term, *quoad* the criminal law, he was sane. He ridiculed the idea of *moral insanity*, and would not admit the existence of morbid impulses, even if dependent on disease, as any excuse for crime.

In the course of the trial it came out that the prisoner, shortly before the commission of the offence, had written a letter to the barmaid of a tavern where he was pot-boy, and thus addressed it—

"Fly! postman, with this letter bound,
To a place they call the 'Pig in the Pound';
To Miss Chittenden there convey it—
And with 'spedility' obey it.
Remember, my blade,
The postage is paid."

Now, this letter was certainly not relied on as evidence either way. The worst lunatic may write doggerel verse, and even good poetry, as witness "The Morningside Star"; but the Solicitor-General ridiculed the idea that the "doggerel" could have been written by a person of unsound mind, and instanced a case in which a celebrated literary character of the day thus addressed a letter to Mr. Pollock—

"This is for David Pollock, squire;
For him in Elm-court inquire,
On the first-floor—look no higher;
There you'll catch him.
He'll pay you twopence for this letter
(He never paid it for a better);
If he doesn't, like a scetter
Watch him."

The summing-up of the Judge was impartial and able, and evidently pointed out to the jury that the verdict of acquittal on the ground of insanity was the only one they could possibly arrive at. The jury, having retired, returned into court after some time, with the following special verdict:—"We find the prisoner, Edward Oxford, guilty of discharging the contents of two pistols, but whether or not they were loaded with ball has not been satisfactorily proved to us, he being of unsound state of mind at the time."

This, in fact, was a verdict of acquittal; he was not found guilty of the crime with which he was charged, and was not therefore a criminal lunatic. The scene in court was indescribable, the excitement intense. The Attorney-General referred their Lordships to the 40th George III., which provides that persons acquitted on the ground of insanity shall be imprisoned during his Majesty's pleasure. He presumed the jury intended to acquit the prisoner on the ground of insanity by the verdict they gave, and, therefore, he applied to their Lordships under the Act of Parliament. Mr. Sidney Taylor submitted that the Act of Parliament in question did not apply to the present case, inasmuch as the jury had acquitted the prisoner of the offence with which he was charged, by negating the fact that the pistols were loaded with bullets.

Lord Denman said that the jury were in a mistake. It was necessary that they should form an opinion as to whether the

pistols were loaded with bullets or not; but it appeared that they had not applied their minds to that point, and, therefore, it would be necessary that they should again retire, and say, "Aye" or "No." Did the prisoner fire a pistol loaded with ball at the Queen?—that, in truth, was the question at issue. The foreman said they could not decide that point, because there was no satisfactory evidence produced before them to show that the pistols were loaded with bullets. After a great deal of discussion of a very animated kind, the jury retired, and, after the absence of an hour, returned, and found the prisoner "*Guilty, he being insane at the time.*" Then, said the Judge, the verdict stands thus:—"Not guilty, on the ground of insanity." The Attorney-General said, that being the case, he moved their Lordships, on behalf of the Crown, that the prisoner at the bar, Edward Oxford, be confined in strict custody during her Majesty's pleasure. Lord Denman replied, "That is a matter of course."

Thus ended this memorable trial. It appears to me to have considerable interest in its Medical aspects; of course I allude to the success of the defence set up, which was in opposition to what lawyers define to be insanity in a criminal case. The Crown went directly for the highest crime known to the law; they totally ignored the plea of insanity, and though they called no witnesses, Mr. Aston Key was present during the whole trial, and prompted the counsel for the Crown with the questions they should put in cross-examination. This case showed the importance of Medical witnesses using the plainest language and the commonest terms, so as to bring their evidence within the compass of the understanding of the jury. In this trial, as in all others in which Medical testimony is given, as a rule, the witnesses were soundly rated by the Crown lawyers. The summing-up of the judge was admirable; and as he evidently saw no jury could possibly bring in a verdict of "Guilty" on the entire count with the evidence before them, he summed up in favour of the plea of insanity. In this case, again, the evidence of insanity could not be considered strong merely from the acts of the prisoner, leaving out the firing at the Queen, which, however, was advanced as a proof of his unsoundness. This was admitted by the judge; and, coupled with the configuration of the skull and the *nonchalance* of the prisoner, the plea, I think, was fairly established. The boy was known to be vain and conceited, and had been long in the habit of reading sensational stories, and forming plans for regenerating society; and it was contended he fired the loaded pistols with the intention of having his name paraded, and his act made the subject of conversation everywhere. This may be true to some extent; but I contend that the overt act itself for which he was tried was sufficient to show that he acted under a morbid impulse—under a condition, in fact, of moral insanity. Doctors and lawyers will probably always be at issue as to what constitutes "unsoundness of mind." The legal definition as laid down by the twelve judges is certainly too limited to meet all cases, and cannot be accepted in its fullest sense by the Medical jurist. I know the danger of carrying the doctrine too far; but we must all have seen the evil of too strictly limiting it. The plea of insanity may no doubt be abused, but it is sometimes ignored most unwisely in the cause of justice and humanity.

There is one point in the case which involves important interests, and notably the value of trial by jury. No one would have desired to see the prisoner released, to "fire again upon the Queen," as the Attorney-General said; but was not justice to some extent perverted by the judge not recording the special verdict of the jury? The prisoner was tried for a specific offence, and acquitted. He should have been released upon that ground; if he had not committed the crime it was not necessary in the cause of justice to find him insane. Whatever had been the result, however unpopular at the moment, if I had been in Mr. Sidney Taylor's place, I should have insisted on the judge recording the special verdict of the jury. The prisoner was entitled to it by law and justice, and it should certainly have been done. In a time when the liberty of the subject and the press were under a cloud, Mr. Erskine defended a client against a charge of libel brought against him by the Crown. At that time the jury were assumed by some lawyers to have nothing to do with determining whether the subject-matter was libellous or not; they had only to find as to the fact of the defendant having or having not published it. In the case I refer to, the jury brought in a special verdict—"Guilty of publishing, but the matter is not libellous."

Judge Buller, an able but an arbitrary lawyer, refused to record the verdict, and requested the jury to retire and modify it. This Erskine requested them not to do, and a fierce contention arose between the court and the advocate, in which, more

than once, Buller threatened to commit the recalcitrant Erskine for contempt of court. But Erskine eventually triumphed; and it was this accident that gave rise to his famous speeches on "Trial by Jury"—that "Palladium," as it is called, "of English liberty." Had Taylor at the trial of Oxford insisted upon the special verdict being recorded, I think he would have been successful. But much may be said in excuse for his not entering into antagonism with the bench. The case was one of great peculiarity, the public mind was bent on punishing the culprit, and Taylor was in the last stage of a painful and mortal disease. The jumble which took place at the close of the trial may be clearly understood by the legal mind; to mine, I confess it still remains a jumble. How "guilty" and "not guilty" can have the same meaning I am at a loss to discover; but such is made to appear.

Oxford remained many years in Bethlehem Hospital, where at first he amused himself with knitting gloves, which he sold to visitors. He afterwards occupied himself in the study of ancient and modern languages, and was a proficient in some of them. He was afterwards removed to Broadmoor, and a short time since released, on condition that he left England, and never returned to it. I am always satisfied that the Medical evidence in his case was just and right. Many people thought that, as in after-life he gave no overt proofs of unsoundness of mind, he could not have been mad at the time of committing the act for which he was tried. But this is no real argument; it is based on the assumption that insanity is not curable, or to be kept in check, by the employment of proper and judicious means.

ENTERIC FEVER IN MASSACHUSETTS

At a time when the serious illness of the Prince of Wales from enteric fever excites such a degree of public anxiety as now exists among all classes, and renders that disease, its probable causes, and usual course a subject of conversation in almost every household, it may not be inopportune to devote a small portion of our time and attention to this subject. In the Second Annual Report of the State Board of Health of Massachusetts (published in January of the present year), among other very valuable papers, we have lately read with great interest an inquiry into the causes of typhoid fever as it occurs in Massachusetts. It is well known that the disease is most rife in the months of autumn and early winter, but that no season is exempt. It is especially a disease of adolescence and early maturity, the greatest number of deaths from it occurring between the ages of 20 and 30. It is a disease of scattered communities, rather than of crowded towns—of rural, rather than of urban districts. In Massachusetts it is more destructive in farming towns than in the manufacturing towns and large cities. The same, we may say, is our experience of the disease in this country. The general result of the study as to its causes, on the opinions of the Medical world, has been to encourage the belief that in some way typhoid fever and filth stand in certain relations. The disease is supposed to be propagated by a poison as definite as that which causes vaccine disease. The vehicles through which this poison has been supposed to be conveyed into the system are various:—1st. Drinking-water made foul by the decomposition of any organic matter, whether animal or vegetable, but specially by excrementitious matters discharged from the bodies of those already suffering from the disease. 2nd. Air contaminated by any form of filth, but specially by privies, cesspools, pigstyes, manure heaps, rotten vegetables in cellars, leaky or obstructed drains. 3rd. Emanations from the earth, occurring especially in the autumn months and in seasons of drought.

The first of these causes the compilers of the Massachusetts report consider to be essentially English. They state that, in reading the reports of typhoid epidemics occurring in England of late years, it so far predominates over all other imaginable causes, that they are led to believe either that the English drinking-water must be exceptionally dirty, or that Medical advisers are unconsciously influenced by preconceived opinions, based upon the ingenious speculations of men of ability who have directed their attention to this form of danger. The American experience on this point seems to be, that while in some instances the evidence collected from various sources was so definite as to leave no doubt that the fever poison was received through drinking-water, in others, in which towns have lately been supplied with perfectly pure water, the consequent diminution of typhoid was not to such an extent as might have been expected, supposing impure water to have been the prin-

cipal source through which the disease was spread. The diminution was only such as might have been looked for if the purification of air rather than of water were in question. The sewerage was improved by the drains being enabled to carry away impurities which would otherwise have lodged. The sewers are more thoroughly washed—and the people too. Cases are reported in which it is impossible to doubt that the disease was received by absorption through the alimentary canal; but in the great majority of cases occurring in Massachusetts in which the causes could be traced, *air*, and not water, must be regarded as the vehicle.

We now come to the second class of probable causes of typhoid—viz., propagation by air contaminated by filth. There is reason to suspect that the fever-producing poison is odourless, and that, under certain circumstances, it may be set free from decomposing substances before the foul-smelling compounds of hydrogen come to give us warning. Hence the danger may be greatest when decomposition is going on under difficulties—when it is impeded, suppressed, or imperfect. When the rotting material is *under cover*, whether in a cellar or in a drain, with a far less noticeable odour accompanying it than is often met with in the open air, or with no perceptible odour, the most disastrous consequences have been observed. As yet we ask in vain from organic chemistry what is that certain something which putrefying material gives forth under such circumstances.

The third class of causes of typhoid may be considered under the head of emanations from the soil. Soil seems at certain seasons to afford the conditions requisite for the concoction of this subtle poison, and air to be the vehicle by which it enters the body. The exposure of the bottoms of ponds and reservoirs during the season of heat and the season of decay is, of all others, the most frequent single cause assigned for the production of epidemics of typhoid fever in Massachusetts. A rich surface-soil with a sub-soil of clay has been remarked as seeming to co-exist with typhoid. Rock under a rich clay, preventing the subsidence of decaying matters beyond a certain point, where they would meet the constantly-moving current of sub-soil water, also seems likely to exert an influence in favour of the production of typhoid.

The views of Pettenkofer, that epidemics of typhoid fever stand in a fixed relation to certain obscure and as yet inexplicable changes in the soil, which changes are signalled by fluctuations in the height of the ground-water, have been interpreted in England to mean that in seasons of drought foul matters are retained in the loose soil, and that the area of drainage for each well is greatly increased by the subsidence of the ground-water level. In certain English towns the water-level was permanently reduced by artificial drainage, while pure water was brought in from springs and streams for the use of the inhabitants with a marked reduction in the mortality from typhoid. Pettenkofer, however, believes that the soil must be "typhoid ripe" before the disease will appear. While admitting the general importance of having drinking-water free from taint, he thinks that the artificial drainage of English towns signifies no more as regards typhoid fever than the movement of the face of a clock by human hands would influence the rotation of the earth. Setting the soil-clock at typhoid will not cause the disease. Filth will foster and increase its virulence, but will not produce it.

It may thus be seen that all the causes assigned, with the single exception of such changes as may occur in soil through natural processes, are under human control. They are, indeed, instances of human neglect, and, standing in the relation they do to one of our most destructive diseases, they but enforce the truth of the general statement, that clean air and clean water are among our greatest blessings.

Such are some of the conclusions of the compilers of the Report of the Massachusetts Board of Health, and they are true in England as in America;—it would be well that the general public of this country were more thoroughly acquainted with them. And we would here observe that the Report in which they are contained is addressed by the Massachusetts Board of Health, not only to the Medical Profession, but to the general public, and that the paper from which we have so freely quoted, as also all the others contained in the Report, are written in simple, non-technical language, perfectly intelligible to anyone of ordinary mental capacity. The example is worthy of imitation in our own country.

The illness of his Royal Highness the Prince of Wales has been assigned by the daily press to a wetting received during a drive in an open wagonette after shooting. Such a cause might produce pneumonia, pleurisy, congestion of the liver, or

a host of other inflammatory diseases, but not typhoid fever. The specific cause must have been at work, and encountered during some of the numerous visits the Prince has been making at various country houses of the nobility.

ASSOCIATION OF CERTIFYING MEDICAL OFFICERS OF GREAT BRITAIN AND IRELAND.

THE fourth annual general meeting of the Association was held at the Adelphi Hotel, Liverpool, on October 20 last, Dr. Arlidge, the President, in the chair.

In the report of the Committee, reference was made to the new regulations respecting the reporting of accidents, which were generally approved of. But the Committee considered that the fee of sixpence for examining each "factory hand" presented at the residence of the Surgeon—fixed by the Factory Inspectors with the sanction of the Home Office—was most unprecedented, and beyond the scope and meaning of the Acts now in force, and quite as discreditable for the Government to offer as for the Surgeons to accept.

By sanctioning the examination of children and young persons at the residence of the Factory Medical Officer, the memorandum revives a proceeding which experience had proved to be both useless and a cause of irregularities, and one that had been repealed in recent Acts.

The Committee recommended that a short memorial to the Home Secretary be prepared, and sent to every Certifying Medical Officer for his signature, praying for a modification of this order, on the ground that so small a fee was never before offered for any public service whatever; for even in the case of the registrars of births, etc., the minimum fee for a mere copy of a birth register, when given on the formal requisition issued by the authority of the Inspectors, under a special clause of the Factory Act, is one shilling, whilst in ordinary cases it is three shillings and sixpence.

The following gentlemen were elected as officers and members of the Committee for the year 1871-72:—*President*: J. T. Arlidge, M.A., A.B., F.R.C.P. Lond., Physician to the North Staffordshire Infirmary. *Vice-Presidents*: F. Jordan, Esq., F.R.C.S., Surgeon to the Queen's Hospital, and Professor of Surgery, Queen's College, Birmingham; W. Roden, M.D., M.A., F.R.C.S., Kidderminster. *Treasurer*: E. Waters, L.R.C.P. Edin., Coventry. *Secretary*: G. M. Stansfeld, Esq., Redland, Bristol. *Members of Committee*: C. D. Purdon, A.M., M.B., T.C.D., Belfast; J. T. Mitchell, Esq., F.R.C.S., Stockwell, London; Thomas Bott, Esq., Bury, Lancashire; W. Lees Underhill, Esq., Tipton-green, Staffordshire; H. Collins, M.D., Wolverhampton; G. W. Hardy, Esq., Warrington; Robert Beales, M.D., Congleton; C. R. Crossley, Esq., Leicester; W. J. Clap, Esq., Nantyglo, Monmouthshire; A. H. Balfour, Esq., Portobello, Edinburgh; C. Johnson, Esq., Lancaster; R. G. Horton, Esq., Leeds.

A very able and instructive address was delivered by the President-elect, and was ordered to be printed with the other proceedings of the Association.

The desirability of all Factory Surgeons joining the Association was strongly insisted upon at the meeting; and in order that the general purposes of the Association should be more fully understood, as also the reasons for joining it, it was resolved that the report be sent to all the Medical Officers under the Factory Acts, whose names and addresses could be obtained.

The next annual meeting of the Association was decided to be held at Bristol not later than the second week of September, 1872.

The names of new Members should be sent to the Honorary Secretary, to whom, also, all communications should be addressed.

A "MEDICAL OFFICER," in a letter to the *Punjab Times*, affirms, as the result of long experience in the treatment of snake-bites, that the offering of rewards for dead cobras and keraitis is the only effectual way of reducing the rate of mortality from this cause. The writer, who has recently tried the new "cures" without any success, recommends that this plan of extirpation should be sanctioned by Government and carried out by all civil Surgeons.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

NOVEMBER 28.

ON Thursday last, the 23rd inst., an interesting discussion took place at the Medical Institution, arising out of a contemplated alteration in the law which regulates the election of Physicians to the Northern Hospital. Not long since, on the occasion of the election of Dr. A. T. H. Waters as Physician to the Royal Infirmary, on the resignation of Dr. Inman, no candidate presented himself in answer to the advertisement issued by the Committee of the Northern Hospital, for the purpose of filling up the former gentleman's place. This led to a consideration of the rules, and the proposal was seriously entertained to throw open the office of Physician to general Practitioners. It is hoped, however, that the unanimous expression of opinion by an unusually large meeting of the members of the above-mentioned institution, that such a course would be prejudicial to the interests of the Profession in Liverpool, will lead the Committee to reconsider their contemplated change of rule, and to adopt such a modification of it as will permit any gentleman who (being properly qualified) is willing to relinquish general practice, to become a candidate. As the rule stands at present, the candidates are required, not merely not to practice midwifery, pharmacy, or Surgery, but not to have done so for six months previously to the date of election. They are required, also, to have been in the independent practice of the Profession of Medicine for at least three years. It is more than probable—it is, I believe, quite certain—that if these retrospective clauses alone are done away with, there will at once be several most eligible candidates ready to present themselves; and that if, therefore, the institution shall before long require the services of two Physicians, instead of one, as is not improbable, these services will be readily obtainable. This contingency will arise if Dr. Glynn, the second Physician to the Hospital, should be elected to fill the post at the Royal Infirmary rendered vacant by the recent retirement of Dr. Vose. There are two candidates—Dr. Glynn and Dr. Edward H. Dickinson.

For many weeks past the health of the town has been greatly improved. During the week ending October 28 the death-rate reached what for it is the exceptionally low limit of 23.5 per 1000 per year, and, although the weather has been extremely inclement, it still continues below the average. Besides the chest-affections so common at this season, the returns seem to indicate an increase in scarlatina and other forms of fever.

GENERAL CORRESPONDENCE.

ON THE RELATIVE MERITS OF THYROTOMY (OR DIVISION OF THE THYROID CARTILAGE) AND LARYNGOSCOPIC TREATMENT FOR THE REMOVAL OF GROWTHS FROM THE LARYNX.

LETTER FROM DR. MORELL-MACKENZIE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having been unfortunately absent from the meeting of the Medico-Chirurgical Society when Mr. Durham's interesting paper was read, I trust that you will kindly allow me space to vindicate my position.

In replying to Mr. Durham's strictures, I labour under great difficulty, inasmuch as I understand that many statements were made by him which do not appear in the abstract; but in my present communication I must necessarily confine myself to the matter as placed before the Profession in the published reports of the meeting.

It might be supposed from Mr. Durham's article that I objected to the operation of thyrotomy *in toto*; but quite the reverse is the case. At page 84 of my "Essay on Growths in the Larynx," I have remarked that "the introduction of the laryngoscope . . . has given an increased prospect of success to the various operations by which the cavity of the larynx may be laid bare"; and again, at page 86, that "in the case of young children, who cannot be taught to submit to laryngoscopic treatment, extra-laryngeal treatment may be required." Furthermore, pages 89, 90, and 91 are occupied in describing the steps of the operation. On the other hand, I

have endeavoured impartially to point out the contra-indications and dangers of extra-laryngeal methods.

Mr. Durham states "that if, in any case, removal of the growth by the aid of the laryngoscope should appear practicable, the idea of resorting to section of the cartilages could not be entertained until fair trial had been made of the minor operation." It will be seen, therefore, that the difference between us is not so great as would at first appear; but whilst, so far as I can gather from the abstract, Mr. Durham seems to think that external operations on the larynx are indicated where it is not practicable to remove the growths through the mouth, I, on the other hand, consider it "a cardinal law that an extra-laryngeal method ought never to be adopted (even where laryngoscopic treatment cannot be pursued) unless there be danger to life from suffocation or dysphagia."

To enter into more detail, in considering the relative merits of thyrotomy and laryngoscopic treatment, I have dwelt upon three features—1st, Danger to Life; 2ndly, Recovery of Voice; 3rdly, Chances of Recurrence; and Mr. Durham has now added a fourth element for discussion—namely, the Comparative Difficulty of the Two Methods.

1. *Danger to Life.*—Of the twenty-eight cases tabulated by me, nine terminated fatally within two years. Mr. Durham takes exception to six of these, because they were cases of cancer; and those who have not read my book might suppose that I had suppressed this fact, whereas I have taken the greatest pains to give prominence to it. At pages 94 and 97 I have stated that "in six of the nine fatal cases the disease was cancerous (or semi-malignant)," and I have drawn attention to the same fact both at the head and foot of my thyrotomy table. And here I may remark that there is often great difficulty in estimating whether a case is malignant or not—for if a growth is completely removed and does not recur, it is considered benign; but if, on the other hand, it reappears, it is often reported malignant, though there may be no evidence of its pathological nature. Subtracting these six cases, however, and giving Mr. Durham the benefit of one other case which is in dispute between us, there remain two deaths as the result of twenty-two operations tabulated by me, or, in other words, there is a mortality of 9 per cent. Mr. Durham has now related five cases that have survived the operation, thus reducing the mortality to about 7 per cent. On the other hand, I am not aware that there exists a single case on record in which death has resulted from the removal of a growth *per vias naturales*.

2. *Recovery of Voice.*—According to Mr. Durham's own statement, of thirty-seven cases which he has collected, only nineteen were successful as regards voice, or, in other words, the natural voice was regained in only about half the cases; whilst of ninety-three published cases which I have treated laryngoscopically, the voice was completely restored in 75 per cent.—*i.e.*, in three-fourths of the cases.

3. *Chances of Recurrence.*—On this subject Mr. Durham has given no statistical information whatever, but has simply begged the question in the following words:—"With regard to the chances of recurrence, there could be no doubt that the more completely the original growth was removed, the less would be the probability of its reappearance. Neither could there be any doubt that such complete extirpation could be more easily effected in most cases after section of the cartilages than by any method practised through the mouth." The truth of the first proposition is self-evident, but that of the second is not borne out by facts. Of twenty-seven non-malignant cases (including Mr. Durham's five cases) the growth could not be extirpated at all in one, and in two the neoplasm was incompletely removed; death took place in four instances before there was time for recurrence. There remain, therefore, twenty cases, and of these recurrence took place in three, or in 15 per cent. In my ninety-three cases treated through the fauces, recurrence took place in six cases in which the growth had been previously completely extirpated—that is, in about 6½ per cent. In addition there were three other cases in which I was unable to effect complete evulsion, and a subsequent further development took place; but the cases of incomplete removal, having been excluded from the statistics of thyrotomy, may also be fairly excluded from mine.

It is true, as Mr. Durham remarks, that in my statistics of thyrotomy I have included cases of cancer; but he has entirely omitted to state that, in estimating the chances of recurrence, I have at the outset (page 97) eliminated the six malignant or semi-malignant, and only drawn my conclusions from the eighteen cases of benign character which survived the operation.

4. *Comparative Difficulty of the Operation.*—I quite admit that it is easier for a novice, who has never tried either method

to remove a growth by section of the laryngeal cartilages than to do so with the aid of the laryngoscope; but I have yet to learn that an operation is to be recommended in proportion to the facility with which it can be executed. Lithotomy can, I believe, be more easily performed than lithotomy—amputation than resection—ligature of an artery (for aneurism) than compression; but, *ceteris paribus*, the more recent and difficult methods are universally preferred, because they are less dangerous. There is, however, at least one case on record in which thyrotomy, having been unsuccessfully attempted, the growth was subsequently removed *per vias naturales*.

Mr. Durham remarks that "in very few, if any, of the cases in which the larynx was opened, would it have been practicable to remove the growths through the mouth." I venture, however, to express my belief that, in many of the cases of thyrotomy, the growths might have been removed through the mouth had the operators shown greater perseverance, or, possibly, have been more experienced. It would obviously be invidious to particularise cases in reference to this point.

In conclusion, I must express my extreme regret that I quite inadvertently omitted to include in the thyrotomy table of my essay Mr. Durham's case, contained in Guy's Hospital Reports, 3rd series, vol. xii. This omission certainly would not have occurred, but that Mr. Durham's valuable contribution to "Holmes's System of Surgery" only reached me after the first proof-sheets of my work had appeared. I subsequently made some alterations in my text, in order to acknowledge Mr. Durham's important labours; and I am only sorry that at that period I did not do complete justice to his admirable article.

November 28. I am, &c., MORELL-MACKENZIE.

EXTENSION OF THE CONTAGIOUS DISEASES ACTS.

LETTER FROM DR. WASHBOURN.

[To the Editor of the Medical Times and Gazette.]

SIR,—The meeting of the Gloucestershire Medical and Surgical Association, specially convened at the Cheltenham Hospital, was, as the report of the Secretary contained in your number of the 18th inst. shows, so scantily attended, that I thought it desirable, especially upon a subject of such importance to the community, to ascertain, either *viva voce* or by letter, the individual opinions of those members who were absent from the meeting, as to whether the provisions of the existing Contagious Diseases Acts should be extended to the sea and inland ports of the United Kingdom.

My inquiries elicited replies from twenty-seven members; of whom twenty are in favour of, and four are opposed, to such extension, the remaining three declining to express an opinion. If to these members be added the names of those who were present at the meeting and voted, the result shows that out of forty-two members, twenty-eight, or two-thirds, are in favour of extension.

I am, &c.,
Gloucester, November 29. BUCHANAN WASHBOURN.

SUBSCRIPTIONS TO THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

LETTER FROM MR. JAMES MILWARD.

[To the Editor of the Medical Times and Gazette.]

SIR,—Allow me, through the medium of your journal, to beg the members of the Poor-law Medical Officers' Association to review the position of their Society. For several years they have been united in an endeavour to procure from the Legislature certain objects. Their pecuniary outlay has been 5s. a year—not an extravagant sum for anything that is worth having. Their objects are now embodied in a Bill which Mr. Corrance has kindly undertaken to introduce next session, and which has the support of many influential Members of Parliament. But Parliamentary business costs money, and all that is wanted would be in the hands of the Treasurer if the members of the Association would but pay the subscriptions which are due, and which their membership implies a promise to pay. Yet, in spite of several appeals which have been made in the Medical papers, the Society's purse has only received 10s. The members are not asked to spend time over the work. Other men have laboured, and the members will enter into their labours, and it does seem hard that Dr. Rogers, Mr. Corrance, and their co-workers, should spend so much time and trouble over the affairs of the Association, the members of which have everything to gain by the work in which they are engaged, and that they should, moreover, have the anxiety of an empty

purse, when the sinews of war would be amply supplied by the paltry sum of 5s. each, which, I cannot too often repeat, is already actually due.

Mr. Corrance has generously offered to bear a considerable share of the cost; but I say, Sir, it would be a burning disgrace if an association of honourable gentlemen, through neglecting to fulfil their engagements, should throw on the shoulders of an outsider the onus of paying for what they want.

Now that we have almost reached the goal for which we have been straining, it would be ignominious indeed to give up the race.

I am, &c.,

Cardiff, November 28.

JAMES MILWARD.

A HAT INSTRUMENT-CASE.

LETTER FROM MR. ARTHUR STEDMAN.

[To the Editor of the Medical Times and Gazette.]

SIR,—It may interest your correspondent, Mr. James Wilson, to know that Mr. Hawksley has in hand to perfect for me a small case sufficiently light to be carried, with a stethoscope in the centre, in one's hat without discomfort. I have arranged it to contain a clinical thermometer, a small urinometer, a test-tube, and a tiny spirit-lamp; the test-tube to hold a few capillary tubes containing nitric acid. The stethoscope projects fairly beyond the case at either end.

I am, &c.,

Great Bookham, Leatherhead.

ARTHUR STEDMAN.

SMOKE NUISANCE.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your last week's impression, referring to the letters which have appeared in the *Times* on "Smoke Drainage," you say, "We should be glad to see the matter taken up warmly in the public journals."

I am satisfied that a careful inquiry into the system of furnace ventilation would go far to solve the problem of how to get rid of the London smoke and, as a corollary, the London fogs.

It seems an Irishism to say that the coldest part of the room is in front of the fire; but we have only to place our hands on a level with the hearth-rug to satisfy ourselves on this point.

It is a common expression with people who crowd round the fire at this time of the year to say, "How impossible it is to get warm!" The fact is, they are scorching the front of the body while the back is being chilled by a draught of cold air coming in from the outside. Those, again, who crowd round the fire, not only shut out the heat from others, and hinder its dispersion, but they impede the current of air going to the fire, and thus diminish the intensity of the glow; so that, in consequence of the faulty construction of our stoves, these people are a nuisance to themselves, and also to their neighbours. A large proportion of the coryzas and influenzas so prevalent at this season of the year are, no doubt, induced by such a faulty system of ventilation. Parents are fond of placing their infants on the hearth-rug, little knowing the danger they incur by the excess of heat on the one side and the blast of cold air on the other.

To avoid this draught, some houses have been constructed, of late years, with a tube passing from a brick ventilator fitted into the outside wall under the floor to the fire-place. This plan has been known to succeed very well and answer admirably in supplying sufficient air for fuel consumption, obviating the alternative of a draught of cold air drawn across the room from under the doorway.

I have long desired to bring before the notice of scientific men a plan of ventilation somewhat after this principle, but combining therewith a means of carrying away the ash and dust of the coal to a receptacle fitted in a convenient situation. The clouds of dust caused by the domestics when sweeping-up the hearth are seen by few at early morning; the nuisance is therefore not recognised. I am confident that our furniture, and especially our books, would suffer less if the necessity of sweeping-up the hearth were abolished.

The plan I have to suggest is, that a tube of a certain diameter be fitted into the brickwork and carried through the house, either parallel with or within the chimney, a communication being established below each grate. This tube could be conducted to a dust-bin either fitted into the front wall of the basement, or in the area, or possibly into an underground sewer.

By this arrangement a perfect system of ventilation is

obtained, the draught required for fuel consumption is drawn from the outside, and does not enter the room. All cinders and dust carried down the tube may be removed periodically by scavengers, according to the system now being introduced in the City, and which has been found to work so well in Edinburgh and other large towns. By such an arrangement the coal would be better consumed, and the unconsumed smoke might be diverted into these tubes and thus carried away. I am convinced we should hear less of influenza and sorethroat if some such plan was generally adopted. I am, &c.,

19A, Gt. George-street, S.W., Nov. 29.

F. C.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 14.

DR. H. A. PITMAN, Vice-President, in the Chair.

MR. ARTHUR E. DURHAM read a paper on

THE OPERATION OF OPENING THE LARYNX BY SECTION OF THE CARTILAGES, ETC., IN ORDER TO FACILITATE THE REMOVAL OF MORBID GROWTHS.

The author related in detail five cases, in each of which this operation had been performed in Guy's Hospital; in three cases by himself, in one by Mr. Bryant, and in one by Mr. Colley. The results in four of these cases had been eminently satisfactory, free respiration and good voice having been regained. The remaining case was still under treatment. Appended to this communication were more or less complete reports of all the cases the author had been able to find on record. These cases were thirty-two in number, and with the five detailed in his communication gave a total of thirty-seven. In nineteen of these the operation might be regarded as having been completely successful, natural respiration and voice (though in some instances not normal in tone) having been restored. In seven partial success was obtained, respiration having been restored, but the voice lost or very seriously impaired. In four cases some temporary relief was obtained. In three the result might be considered negative, neither good nor harm having been done. The reports of at least two were incomplete. In two cases—and two cases only—death resulted. In each of these, however, the immediate cause was blood-poisoning. Metastatic abscesses were found in the lungs in the one case; in the other, erysipelas and gangrene occurred, and broncho-pneumonia and exhaustive fever ensued, and led to the fatal issue. Comparing the results thus stated with those given by Dr. Mackenzie in his "Treatise on Growths in the Larynx," the author pointed out that death could properly be attributed to the operation in two only out of the nine cases enumerated by Mackenzie as having terminated fatally, these two being the same as those already alluded to. With regard to the other seven cases, the author specified each, and showed that in each the result of the operation was favourable, or, at any rate, in no degree mischievous, and certainly not fatal. Some of the difficulties liable to be encountered in the operation were then briefly discussed, and the opinion expressed that such difficulties were really fewer and more easily overcome than appears to be generally supposed. In conclusion, the author pointed out that it was not necessary to institute any comparison between the dangers and difficulties of this operation and those met with in the removal of growths through the mouth by aid of the laryngoscope; nor, indeed, was it at all fair to estimate the comparative merits of the two methods of proceeding by bare numerical statements of the results obtained. If, in any case, removal of the growth by aid of the laryngoscope should appear practicable, the idea of resorting to section of the cartilages could not be entertained until fair trial had been made of the minor operation. In very few, if any, of the cases on record, in which the larynx was opened, would it have been practicable to have removed the growths through the mouth. Indeed, in many instances, numerous abortive attempts through the mouth were made before resort was had to section of the cartilages. With regard to the chances of recurrence, there could be no doubt that the more completely the original growth was removed, the less would be the probability of its reappearance. Neither could there be any doubt that such complete extirpation could be more certainly effected in most cases after section of the

cartilages than by any method practised through the mouth. Dr. Mackenzie's conclusions as to the comparative chances of recurrence, as affected by the method adopted, appeared to the author unfair and likely to mislead. Cases of cancer (a malady very likely to recur) were included in one and excluded from the other of the sets of cases between the results of which a numerical comparison was made.

Mr. BRYANT said that he rose to support the operation as the only possible curative means in the class of cases described. When the morbid growths were multiple, tracheotomy could be only a temporary measure, and evulsion through the mouth must be impossible. He enlarged upon the alleged erroneous character of Dr. Morell-Mackenzie's statistics with regard to the fatality of the operation.

Mr. CROFT moved that the debate should be adjourned, in order to give Dr. Morell-Mackenzie an opportunity of being present.

Dr. PITMAN said it was not the custom of the Society to adjourn a debate on account of the absence of a Fellow who might be interested in it.

Mr. HOLTHOUSE related the particulars of a case in which he had performed the operation described.

Mr. THOMAS SMITH inquired whether the laryngeal cartilages had been united by sutures in the cases described by Mr. Durham. He also called attention to the early age of the patients, and asked whether the disease was more common during childhood than in after-life.

Mr. DURHAM replied that sutures were used to unite the cartilages, and that early age might be a reason for performing the operation, as it was more difficult to reach laryngeal growths through the mouth in children than in adults. He expressed much regret at Dr. Morell-Mackenzie's absence, and said that, had he been present, he should have joined issue with him on one or two other questions also.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, NOVEMBER 1.

Dr. BRAXTON HICKS, F.R.S., President, in the Chair.

THE following gentlemen were elected Fellows of the Society:—Eugene Goddard, L.R.C.P., Charles James Harris, M.R.C.S., John Faure Miller (Paris), F. T. Tayler, M.B., and W. Bezly Thorne, L.R.C.P.

Dr. SNOW BECK exhibited an Imperfectly Involted Uterus, and gave a minute account of its microscopical characters, from which he concluded—1. That the essential condition of the organ consisted in the elements of the different tissues retaining a portion of the natural enlargement consequent upon impregnation; but that this enlargement was due more to the increased size and amount of the soft tissue present in the walls of the uterus, as well as at the internal surface, than to the increased size of the contractile fibre cells. 2. That, although the bloodvessels were large and loaded with fluid blood, yet there was not any evidence to show that any morbid process similar to inflammation had at any time been present. 3. That the whole of the bloodvessels, to the minute capillary network at the inner surface, formed one continuous system, though the character of the distribution changed towards the inner surface; and, considering there is no division in the uterine walls to justify the description of an internal mucous membrane, this distribution appears to offer a strong argument against the idea that the internal surface can be the seat of inflammation independent of the other portions. 4. That the pulpy condition of the tissue at the inner surface, with the loaded state of the bloodvessels throughout, appear to afford a probable explanation of the frequent hæmorrhages which attend similar enlargements. 5. That, with regard to any treatment for the removal of this condition, it would appear that this should include topical applications to the whole of the uterine cavities.

Dr. F. R. HOGG exhibited a Malformed Fœtus. (Referred to a committee.)

Dr. BARNES read an abstract of a "Memoir on Osteomalacia," by Dr. Casati, of Milan. This disease is remarkably frequent in some of the rural districts surrounding Milan. During the eight years that the author had acted as assistant to the late Professor Lazzati, sixty-two cases of clearly marked osteomalacia were admitted into the Lying-in Hospital. Almost all the sixty-two women came from that part of Milan known as the Valley of Olona, the same district which also supplies the greatest proportion of cases of pellagra and of petechial

typhus (typhoid) to the Milan Hospitals. They all came from wretched villages, where food was scarce, consisting for the most part of maize or rice, often musty. Their houses were ill-ventilated, damp, and built upon clay. The drinking-water was found wanting in saline matter. Twenty-seven of the women were delivered normally after easy labour, four had difficult labour, while thirty-one were delivered artificially, but only two required the Cæsarian section. For the Medical treatment Dr. Casati recommends the use of the biphosphate of lime or of "bone powder" and cod-liver oil, and the substitution of Liebig's bread for bread made of rice and maize.

Dr. SQUIRE did not agree with the author that the pulmonary and bronchial congestions afforded any argument against the use of chloroform, since these depended on the mode of death, and in severe labours the use of chloroform tends to diminish the stress upon both respiration and circulation.

Dr. RASCH read a paper "On a Novel Method of using the Uterine Sound for Redressing a Flexed Uterus." The point upon which he particularly laid stress was, that the part of the instrument inside the uterus should be kept steady in its place, and thus avoid the irritation which resulted from making a large semicircle of motion in the uterine cavity, according to the usual method. The sound introduced into the retroflexed womb, with the point downward and backward, should be first used in that position as a lever to lift up the organ as far as possible. Then, instead of twisting the handle round and making the intra-uterine part swing round the ideal prolongation of the stem, the movement should be reversed, so that the part in the uterus and its ideal prolongation are made the centre of motion, round which the handle and stem sweep.

Dr. PHILLIPS fully appreciated the value of the method described by Dr. Rasch. He would, however, be glad to know the comparative frequency with which it was found necessary to use the sound for redressing the flexed uterus. Doubtless it could not be dispensed with in some cases, but he always attempted to restore a retroflexed uterus without the introduction of any instrument, and he believed that in a large proportion of cases this could be effected.

Dr. GUSTAVUS MURRAY could hardly admit that the method described by Dr. Rasch was new in principle. He had employed it for some years. In severe cases of flexion he was in the habit of introducing the sound in an easy manner by passing it first in the opposite direction to the displacement, until it reached the flexed point, and then, secondly, by twisting the curve of the instrument in the course the fallen body of the uterus had taken.

Dr. AVELING and Dr. EDIS also said that they had practised the method. Dr. Edis said that Spiegelberg had recently called special attention to the danger resulting from injudicious use of the sound, and any method which lessened the risk from its use was worth considering.

Dr. CONRAD, of Pesth, read a paper "On Prolapse of the Female Genitalia," in which he maintained that prolapse of the uterus is for the most part a secondary affection, a primary prolapse being very rare. Prolapse of the vagina is the most important part in any descent of the female genitals, and uterine prolapse is but a sequel of this, the prolapsed vaginal walls pulling down the uterus. Of the different forms of vaginal prolapse, that of the anterior wall is the most common, though frequently associated with prolapse of the posterior wall. A descent of the latter by itself is, however, rare. Should there be a considerable elongation of the cervix, we can certainly conclude that the vaginal prolapse was primary. The elongation of the vaginal portion of the cervix is of no diagnostic value, and is simply the result of mechanical irritation. Dr. Conrad believes it may be justly maintained that elongation of the supra-vaginal portion of the cervix and hypertrophy of the infra-vaginal portions are but secondary affections. The vagina alone is sometimes prolapsed without any descent of the uterus. The author then discussed the most important predisposing causes of prolapse—gestation, parturition, senile atrophy, etc. Prolapse in young girls occurs suddenly from a violent shock through *contre-coup*. The replacement of a complete prolapsus of long standing should always be preceded by an emptying of the bladder and rectum. The palliative treatment is best conducted by pessaries, of which the best is Meyer's ring, or Hodge's modification of it. For the radical cure, Dr. Conrad prefers Professor Spiegelberg's operation to any other: it consists of a combination of three operations. The vaginal portion of the cervix uteri, if greatly hypertrophied, is first removed by the galvanic wire. If the posterior wall of the vagina has become prolapsed with the uterus, he performs Dieffenbach's operation, by removing a

triangular piece of the mucous membrane of the posterior wall, having its apex to the os uteri, and for its base either the pared surfaces of the rent perineum (where this has been ruptured) to form a new perineum, or (where this has not happened) the labia minora, so as to contract the orifice of the vagina, and aid in supporting the posterior vaginal wall. Spiegelberg then proceeds to unite the upper portion of the posterior vaginal wall with the inferior anterior, according to Simon's operation.

Dr. EDIS thought the affection, on account of its great frequency, was too little studied. He had seen several cases where a pessary had been introduced with the intention of keeping up an elongated cervix.

Dr. PHILLIPS agreed with the author of the paper that certain cases of prolapsus uteri were doubtless secondary to vaginal prolapse—cases in which the uterus was small, and which had been called instances of passive prolapse—but he believed that this class was a much smaller one than that which included those cases where an increased weight of the uterus itself was the primary cause of its descent. This was associated with relaxation of the surrounding areolar tissue, and the heavy uterus was then sufficient to overcome the support which the vagina in the healthy state gave it, by means of the strong bands of so-called areolar tissue inserted into its walls. The arguments brought forward by M. Huguier seemed to him conclusive against the view advocated by Dr. Conrad, that elongation of the supra-vaginal portion was a secondary affection, dependent on the traction made by the prolapsed vaginal walls. He doubted whether any shock would produce a displacement of the uterus in young women, if the organ was not increased in weight, and there existed no impairment of the surrounding structures.

Dr. HEYWOOD SMITH said he agreed with what had just been said, that the chief cause of prolapsus uteri was an increased weight of the organ, producing relaxation of its supports. Another cause, however, was not generally recognised—viz., that, as age advanced, the lumbo-sacral curve becoming more or less obliterated—the plane of the pelvis thereby becoming more horizontal—the natural support that the normal position of the pelvis, together with the abdominal walls, gave to the pelvic viscera, was removed, and they tended to prolapse from gravitation. He suggested that the word "procidencia" should be held to signify the falling or tendency to fall, and that "prolapsus," being the past participle, and signifying the complete act, should be used only to indicate cases where the uterus was extruded from the vulva.

Dr. ROUTH believed that prolapsus uteri without elongation of the cervix was very rare. His own experience led him to agree with the conclusions arrived at by Dr. Conrad. Looking back at the operative measures which had been adopted for the relief of prolapsus, there were three chief methods which had been practised. First, the perineal operation, by means of which some cases were radically cured; in others, however, after some months, the uterus dilated the external opening, and appeared external to the vulva. Secondly came Emmet's operation, or a modification of it, as first practised by Dr. Rogers. This consisted in removing a very large triangular piece of mucous membrane (the apex being towards the cervix uteri) from the anterior wall, sometimes also from the posterior wall of the vagina, and bringing the edges together by sutures. This operation also succeeded in some cases, though not in all. Thirdly came the plan of removing a portion of the cervix by the *écraseur*, or actual cautery. This set up absorptive action in the uterus, and the elongation in many cases gradually but entirely disappeared. Dr. Routh thought that a cure, to be certain and radical, should comprise the three operations conjointly—or, at any rate, the last and one of the other two. He believed that any cause which produced a friction of the vagina on the cervix would produce enlargement of the cervix.

Dr. BARNES said that for some years we had all been pursuing a tentative course to find out the best mode of treating these affections. As to the mode of production of hypertrophy, he was scarcely prepared to agree with Spiegelberg and Dr. Conrad. The traction of the vagina might come in as a factor in the course of the disease; but the initiatory stage was, he believed, congestion and increased weight of the uterus. These cases were rare in women who had not borne children. They almost all began after childbearing. The passage of the child through the cervix uteri was a violent process—the cervix was forcibly stretched open; the mucous membrane was carried down before the head; the tissues of the cervix were bruised; small vessels were torn. Then, from getting about too soon, and other causes, imperfect involution resulted; the lower part of the uterus especially was increased in weight and bulk; whilst the

surrounding cellular tissue, having been gradually stretched and weakened, was less able to support the uterus—hence continued congestion and a perverted nutrition of the cervix. Small polypi on the edge of the os frequently complicated hypertrophy. Their structure was identical with that of the cervix from which they sprang. Dr. Barnes could not help thinking that simple prolapsus was far more frequent than Dr. Routh's observations would indicate. He would, in conclusion, like to know how far the experience of others agreed with his own as to the usual extent of elongation being exactly five inches. He had found the cases in which this length was exceeded very rare.

Mr. SPENCER WELLS differed from Dr. Barnes in the opinion that restoration of the perineum was "beginning at the wrong end" in the treatment of prolapsus of the uterus and vagina. It was quite true that prolapse of the anterior wall of the vagina was the first step in the progress downwards; but a sound perineum was the chief opponent to this prolapse. It would be absurd to expect the perineal operation to cure an elongated cervix; but in cases of ordinary prolapse he could say that the perineal operation often effected permanent cure. He had never seen an elongated cervix grow again after the original portion had been removed.

The PRESIDENT said that when the uterus, from whatever cause, descended, it, by its pressure on the vagina, acted like a foreign body, and set up reflex irritation and tenesmus, which, acting constantly, coupled with defæcation and the pressure of the bladder, would tend to extrude and elongate the cervix. It would clearly be better, before attempting any plastic operations, to endeavour to gain shortening of the uterine supports, either by pessaries or recumbency.

EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, NOVEMBER 8.

ROBERT LAWSON, Inspector-General of Hospitals, President,
in the Chair.

THE session was opened with an address from the President, "On the Chief Epidemics of the last Three Years." He indicated the necessity of a close observation, not of one, but of every epidemic, over the greatest possible surface, and for a series of years, to afford trustworthy data for the determination of the general laws which govern the progress of this class of diseases in their diffusion over the earth, and illustrated the value of such inquiries by the ascertained facts with regard to small-pox, scarlatina, diphtheria, fever, and cholera, not only in this country, but on the Continent and in America. An example from the last two diseases may be given. In 1868 there was much fever in Asia Minor, and along the shores of the Mediterranean as far as Spain; and in 1869 the disease, in various forms, was very prevalent through Europe, from Madrid to St. Petersburg, while it remained very active at several points along the north coast of the Mediterranean. Fever increased at Berlin in 1870, and at Vienna a pretty severe epidemic of typhus commenced at the end of that year, and continued during the first half of 1871. It will be remembered that malignant cholera made its appearance at Kiev, in Russia, in the summer of 1869, and towards the end of the year spread to some extent through the basin of the Dneiper, but acquired no great force until 1870, when it involved the whole country, from the Black Sea to St. Petersburg, but was not met with in Europe, as an epidemic, west of Russia. In 1871 cholera continued at St. Petersburg, and extended to Archangel, to Helsingfors, north of the Gulf of Finland, and along the country to the south of that and the Baltic, as far as Hamburg and Altona. There had been a severe outbreak in Persia, to the south and east of the Caspian, in the autumn of 1868, which continued into 1869; and in the course of that year this was to have been expected in Southern Russia or the corresponding latitude in Asia. It actually appeared at Kiev, some 300 miles from the nearest sea, and 1500 from the nearest point where the disease was known to exist at the time, while every attempt to trace its origin to importation failed. It has been found, from an extensive examination of facts, that cholera as an epidemic will not penetrate a district occupied by an epidemic of fever (enteric excepted) until that subside, when its place may be taken by the other. The fever in Asia Minor in 1868, and in Europe in 1869-70-71 seems to have limited the progress of cholera westward in these years, until it crept along the south shore of the Baltic a few months ago.

It is worthy of observation that the relative distribution of cholera and fever during the first approach of the former to Western Europe in 1828-29-30-31 presents year by year an almost exact parallel to that in the corresponding period 1868-69-70-71. In 1831 a fresh wave came from the south, which affected Smyrna and Constantinople, and extended into Hungary, and was experienced in this country in 1832; in 1871 a similar wave appeared in Southern Russia, and has been felt at Smyrna and Constantinople, and has given slight indications at Vienna. It remains to be seen whether the parallel will be completed by its becoming epidemic in this country in 1872.

NEW INVENTIONS.

BLACKBEE'S RESILIENT SKELETON SPECULUM.

(*Maw, Son, and Thompson, Aldersgate-street.*)

THE threefold name of this instrument correctly indicates its origin and peculiarities. It is the invention of Mr. Blackbee, a member of our Profession. It is like a skeleton, inasmuch as it is as much divested of needless incumbrances as a skeleton is of flesh; and it is resilient, inasmuch as the elasticity of a simple skeleton-wire structure takes the place of more complicated devices. The subjoined cuts show it to be composed of

a loop of wire twice folded. The uterine end can be compressed, so as to secure easy introduction, and by pressure on the lateral loops at the opposite end the uterine end can be expanded. The material is german-silver strongly gilt. There is no need of valves, for every part of the vagina is freely exposed, so that examination and the application of remedies are alike easy.

OBITUARY.

JOHN STEGGALL, M.D.

THERE are many metropolitan and provincial members of the Profession who will regret to hear of the death of Dr. Steggall, who expired on the 21st ult., at his residence, in Southampton-street, Bloomsbury-square. Dr. Steggall, who was the third son of the Rev. W. Steggall, M.A., rector of Hessel, Suffolk, at which place he was born, received his early education at Bury St. Edmunds, under the Rev. Dr. Malkin, having as one of his schoolfellows young Blomfield, afterwards Bishop of London. On the completion of his preliminary studies, he entered the London Hospital, and soon became the especial favourite of

Sir William Blizard and that veteran in Medicine (happily still surviving) Dr. Billing. Having completed his Professional studies, he offered himself for examination, and was admitted a Member of the Royal College of Surgeons on August 5, 1825, soon after which he went abroad, and, visiting Bologna and Pisa, he graduated there the following year. Returning to England, he became a Licentiate of the Society of Apothecaries in 1827, and entered on the practice of his Profession. In 1836 he was admitted a Member of the Royal College of Physicians, and was elected Physician to the Metropolitan Free Hospital. But the practice of Medicine had few attractions for him; he preferred that of teaching, both orally and by such works as "Manuals for the College of Surgeons and Apothecaries' Hall," "Elements of Botany," "Celsus, with Translation," "Gregory's Conspectus, with Translation," "Essay on Poisons," etc.; and, on the establishment of the Pharmaceutical Society, with the subsequent examinations at that institution, he published "First Lines for Chemists and Druggists." In his hours of relaxation—and they were few and far between—he amused himself with his pencil, being an excellent artist, and took some first-rate portraits of some of his favourite pupils, as the late Albert Smith, who often spoke affectionately of "dear old Steggall" as having saved him so much Professional drudgery. Another portrait, in oil, of a pupil who became notorious as an atrocious murderer—William Palmer—was a most life-like portrait of the criminal; and it deserves to be mentioned that, after the trial and execution, when sorely tempted to dispose of it for public exhibition to Madame Tussaud, he strenuously refused, although tempting terms were offered. Dr. Steggall, who was an excellent scholar, learned in the living and dead languages, was twice married. On the first occasion, being then a remarkably handsome man, it is not surprising that he won the affections of a lady of brilliant beauty—a Donna Gethruda Elbina Giuseppina (Bonetti). It was a most happy marriage, and nine children were the fruit of this union, seven of whom survive—viz., four sons and three daughters. The eldest, Mr. John Steggall, M.R.C.S. and L.S.A., obtained the gold medal of the Apothecaries' Society. The remains of Dr. Steggall were interred in the Woking Necropolis.

DE LA GARDE, OF EXETER.

CONSPICUOUS among the losses which the Profession has to deplore during the past month must stand the name of "De la Garde, of Exeter," who died at his residence, Southernhay, on the 17th ult., in his 74th year. He was the son of a clergyman at Jersey, and, no doubt, not very remotely, of French extraction. He studied Medicine and Surgery at St. Bartholomew's Hospital between 1817-18 to 1819 (when he obtained the College of Surgeons' diploma) with such success that his name is preserved at that School with the utmost respect, the present Treasurer observing very recently to the writer of these lines—"There is no name which we cherish with greater pride than that of De la Garde." With St. Bartholomew's he was always pleased to identify himself, and with it he kept up to the last friendly and unbroken relations. To it he was appointed House-Surgeon under Mr. Vincent, at a House Committee dated September 25, 1818, the other Surgeons being Abernethy and Sir L. Harvey. He became soon after connected with the Devon and Exeter Hospital—so long the scene of his labours, and of which he died Senior Surgeon—as well as of the West of England Eye Infirmary. Though an excellent Surgeon, original and thoughtful (as a reference to a list of his published works will testify), he seemed to have a special preference for Ophthalmic Surgery, and after the retirement of Barnes, he became the most popular and successful operator in the West of England. He married a daughter of Dr. Lemprière, the well-known author, by whom he had three daughters and one son, who, unhappily, as well as one of the daughters, deceased before Mr. De la Garde, to his infinite grief. Two points are especially to be noted in his character—the absorbing interest he always manifested in the Profession he followed, and his peculiar single-heartedness in respect to the treatment of those under his care. Equally remarkable were the quaintness and force which tinged his conversation and writings, which, without approaching eccentricity, invested them with a raciness peculiarly their own, and preserved them from everything trivial or commonplace. It would be invidious to say that with him ends a school of Surgeons which, comprising such men as Barnes and James, rendered Exeter famous, as did in olden times the name of William Hey the town of Leeds—no doubt men equally able and equally

zealous are to be found there and elsewhere, upon whose shoulders the mantle of De la Garde has fallen; but if some points of his character be considered, it will be admitted that we shall not easily "look upon his like again." It is to such men as he that a profession is indebted for position and dignity, while the interests of the community receive such distinct benefit; and when this is said, it must not be forgotten that the late Philip Chilwell De la Garde was a man of the most unblemished honour, the most spotless integrity—truly "De la Garde sans peur et sans reproche"—and that he, and such as he, are for ever to be found in the van of humanity and civilisation.

DR. HENRY GREENWOOD

Was born on August 6, 1793, at Calne, in Wiltshire, of which place his father was vicar. Having been educated at Calne, and afterwards at Salisbury, he was apprenticed, at the proper age, to Mr. Corfe, a gentleman at that time in extensive practice in the town of Southampton. In due time he came to London as student at the united Hospitals of Guy's and St. Thomas's. He became a Member of the Royal College of Surgeons, England, in 1814, and soon afterwards entered into partnership with Dr. Brickenden, who was then doing a large business as a general Practitioner in Horselydown and the neighbourhood. On Dr. Brickenden's retirement he succeeded to the practice, and was for many years one of the best known Medical men along the south side of the river. In the year 1842 he took the degree of M.D. at the University of St. Andrews; in 1852 he was made a Fellow of the Royal College of Surgeons, and in 1859 a Member of the Royal College of Physicians, London. But by this time incessant labour had worn out a constitution originally feeble, and he was incapacitated for practising as a Physician by increasing bodily infirmity. After some years of weakness and suffering, he expired at Blackheath on November 22, 1871. Dr. Greenwood was one of the original members of the Hunterian Society, in the discussions of which he for many years took an active part, and of which he was elected President for the year 1851. It resulted from the position of his practice, along the water's-edge on the south side of the river, that he had attended more cases of cholera than perhaps any other man living. This circumstance led him to embody the results of his experience in a short treatise on the nature and treatment of that disease, for distribution among his private friends, and this was his only written Medical work.

MEDICAL NEWS.

UNIVERSITY OF LONDON.—The following is a list of the candidates who have passed the recent Honours Examinations:—

SECOND M.B. EXAMINATION.—EXAMINATION FOR HONOURS.

MEDICINE.

First Class.

Allchin, William Henry (Scholarship and Gold Medal), University College.
 Southee, Henry Edward (Gold Medal), Guy's Hospital.

Second Class.

Lyell, Robert Wishart, King's College.
 Elkington, Ernest Alfred, General Hospital, Birmingham.

Third Class.

Carr, William Ward, University College.
 Carter, Alfred Henry, University College. } Equal.
 Lucas, Richard Clement, Guy's Hospital.

OBSTETRIC MEDICINE.

First Class.

Lucas, Richard Clement (Gold Medal), Guy's Hospital.
 Southee, Henry Edward, Guy's Hospital.

Second Class.

Humphreys, John Henry, General Hospital, Birmingham, and University.
 Lyell, Robert Wishart, King's College.

Third Class.

Carter, Alfred Henry, University College.
 Elkington, Ernest Alfred, General Hospital, Birmingham.
 Allchin, William Henry, University College.

FORENSIC MEDICINE.

First Class.

Elkington, Ernest Alfred (Gold Medal), General Hospital, Birmingham.

Third Class.

Lyell, Robert Wishart, King's College.
 Southee, Henry Edward, Guy's Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, November 23, 1871:—

Elkinton, Ernest Alfred, Birmingham.
 Maybury, William Augustus, Frimley, Surrey.

As an Assistant in compounding and dispensing medicines—
 Hyne, Harry, South Bank, St. John's-wood.

The following gentlemen also on the same day passed their first Professional examination:—

Donaldson, Henry, Charing-cross Hospital.
 Evans, Thomas, Guy's Hospital.
 Prothero, David George, Middlesex Hospital.
 Utting, James, Guy's Hospital.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- BENTLEY, ARTHUR J. M., M.B., C.M. Edin., M.R.C.S.E.—Resident Physician, Clinical Wards, University of Edinburgh.
 BISHOP, JOHN, M.B., L.R.C.P.E., etc.—Resident Physician at the Royal Infirmary, Edinburgh, under Dr. T. Grainger Stewart.
 HAVARD, DAVID, L.R.C.P. of London, M.R.C.S., L.M., and L.S.A.—Medical Officer for District No. 3 of the Cardigan Union.
 LAW, W. T., M.R.C.S.E., L.S.A.—Resident Physician at the Royal Infirmary, Edinburgh, under Dr. George William Balfour.
 LINESAY, WILLIAM, M.B., C.M.—Resident Physician at the Royal Infirmary, Edinburgh, under Dr. Rutherford Haldane.
 LOVE, A.E.B., M.R.C.S.E.—Medical Registrar to the Evelina Hospital for Sick Children, Southwark-bridge-road, *vice* David Duke, resigned.
 MACKELLAR, JOHN, M.D., L.F.P.S.—Medical Officer for the Parish of North Uist, Inverness-shire.
 MARTIN, HENRY C., M.B., etc.—Resident-Surgeon, Royal Infirmary, Edinburgh, under Mr. Thomas Annandale.
 PERKINS, HENRY ALLANE, M.B., C.M.—Resident Physician, Clinical Wards, University of Edinburgh.
 RUTHERFORD, THOMAS, M.B., C.M.—Resident-Surgeon, Royal Infirmary, Edinburgh, under Dr. Patrick H. Watson.
 SMITH, JAMES, M.D.—Medical Officer for the Western District of the Parish of Cadder, Lanarkshire.
 SUTHERLAND, JAS., M.B., M.C.—Junior Surgeon to the Ardwick and Ancoats Dispensary.
 TAYLOR, DAVID THORBURN, M.B., C.M., M.A.—Resident Medical Officer in the small-pox and fever wards, Royal Infirmary, Edinburgh, under Dr. Claud Muirhead. Also in the Lock Ward, under Dr. Duncan.
 THORNTON, JOHN KNOWSLEY, M.B., C.M.—Resident Surgeon at the Royal Infirmary, Edinburgh, under Professor Lister.
 THORNGOOD, JOHN C., M.D. Lond.—Lecturer on Materia Medica at the Middlesex Hospital, *vice* Dr. Brunton, resigned.
 WACHER, FRANK, M.R.C.S.E. and L.S.A.—House-Surgeon to the Kent and Canterbury Hospital.
 WALSH, DENIS, L.C.P.I., L.M., L.R.C.P.E., L.R.C.S.E.—Assistant Medical Officer for the Withington Workhouse of the Chorlton Union, *vice* Mr. Henry Webster.

MILITARY APPOINTMENTS.

- ROYAL ARTILLERY.—Assistant-Surgeon John Langdon, from the 10th Foot, to be Assistant-Surgeon, *vice* Edward Joseph Crane, promoted; Staff Assistant-Surgeon Edward Chandler, to be Assistant-Surgeon, *vice* Frederick Ffolliott, placed on half-pay.
 37TH FOOT.—Staff Assistant-Surgeon John Alexander McCracken, M.D., to be Assistant-Surgeon, *vice* William Samuel Chapman, promoted.
 105TH FOOT.—Staff Assistant-Surgeon John Fitzmaurice, to be Assistant-Surgeon, *vice* John Langdon, appointed to the Royal Artillery.
 MEDICAL DEPARTMENT.—Staff Surgeon-Major Vere Webb, to be Deputy Inspector-General of Hospitals, *vice* George Cuninghame Meikleham, M.D., who retires upon half-pay; Staff Surgeon-Major David Reid Mackinnon, to be Deputy Inspector-General of Hospitals, *vice* John Summers, M.D., who retires upon half-pay; Assistant-Surgeon Edward Joseph Crane, from Royal Artillery, to be Staff Surgeon, *vice* Staff Surgeon-Major Vere Webb, promoted; Assistant-Surgeon William Samuel Chapman, from 37th Foot, to be Staff Surgeon, *vice* Staff Surgeon-Major David Reid Mackinnon, promoted; Staff Assistant-Surgeon George Herbert Clifton, M.D., from half-pay, to be Staff Assistant-Surgeon, *vice* John Fitzmaurice, appointed to 105th Foot. The under-mentioned officers, who retire upon half-pay, to have the honorary rank of Inspector-General of Hospitals:—Deputy Inspector-General of Hospitals John Summers, M.D.; and George Cuninghame Meikleham, M.D.

BIRTHS.

- BATT.—On November 27, at 215, Camden-road, N.W., the wife of Edward Batt, M.D., of a daughter.
 DEBENHAM.—On November 28, at Heath House, Stepney, the wife of Robert Debenham, M.R.C.S., of a son.
 DUKES.—On November 23, at Horton-crescent, Rugby, the wife of Clement Dukes, M.B., B.S. Lond., of a daughter.
 EDDOWES.—On November 22, at Castle-street, Shrewsbury, the wife of William Eddowes, Surgeon, of a daughter.
 KAVANAGH.—On November 22, at Ierne House, Wickham-road, the wife of P. Kavanagh, M.D., of a son.
 MILLER.—On November 15, at Brafield, Church-road, Upper Norwood, the wife of R. M. Miller, M.D., of a son.
 NASH.—On November 24, at Royston Lodge, Ladbroke-grove, the wife of Edmund Nash, M.D., of a daughter.
 ROCHE.—On November 21, at 32, Rectory-place, Woolwich, the wife of Wm. S. Roche, M.B., B.A., of a daughter.
 SPENCER.—On November 23, at 47, High-street, Oxford, the wife of Henry B. Spencer, M.D., of a daughter.
 STILLWELL.—On November 25, at Springcroft, Beckenham, Kent, the wife of R. R. Stillwell, M.D., of a daughter.

MARRIAGES.

- CAVAGNARI—GRAVES.—On November 23, at Derryloran Church, Cookstown, Pierre Louis Napoleon Cavagnari, Captain Bengal Staff Corps, to Emma, second daughter of Henry Graves, M.D., of Cookstown, County Tyrone.
- CAMPBELL—RIGBY.—On the 28th inst., at St. Paul's Presbyterian Church, Westbourne-grove, London, Peter Campbell, M.D., Bridge of Allan, Scotland, to Phoebe, daughter of the late P. Rainford Rigby, Liverpool.
- CUMMING—COBBAN.—On November 21, at Abercorn Villa, Joppa, Portobello, Captain G. P. Cumming, Bengal Staff Corps (retired), to Jeannie Marshall, youngest surviving daughter of the late George Cobban, M.D., of Garmouth, Morayshire.
- MILLS—MERRYWEATHER.—On November 23, at St. Stephen's Church, Clapham-park, Samuel Mills, M.R.C.S., of Southampton-street, Covent-garden, to Mary Compton, eldest daughter of M. Merryweather, Esq., Clapham House, Clapham-common.
- STEAD—READ.—On November 7, at Savannah, Georgia, U.S., Walter Collins Stead, of Surrey, England, to Lizzie, daughter of Dr. James B. Read, of Savannah.
- TEMPLE—THOMSON.—On September 12, at the British Consulate, Santos, Brazil, Thomas Cameron Temple, M.R.C.S., etc., to Helen Jane, eldest daughter of the late William Thomson, Esq., of Kennington, and step-daughter of the Rev. R. W. Dixon, M.A., Minor Canon of Carlisle Cathedral.
- YORKE—NEWINGTON.—On November 24, at Charlton, Kent, Frederick Augustus Yorke, eldest son of Major-General Yorke, Royal Engineers, to Lucy Elisabeth Haynes Newington, eldest daughter of the late Charles Edward Haynes Newington, M.D., of The Vineyard, Ticehurst, Sussex.

DEATHS.

- BARRY, THOMAS STOWELL, late Staff Surgeon in her Majesty's Army, and eldest son of St. George Ryder Barry, Esq., late of the 12th Royal Lancers, at Charles-street, Cavendish-square, on November 21, aged 36.
- COLSON, PLEASANCE, relict of the late P. H. S. Colson, M.D., of Hackney at 19, Cavendish-street, Ramsgate, on November 20, in her 73rd year.
- DAVIS, CRESSWELL, M.R.C.S., at 9, Onslow-gardens, South Kensington, after a short illness, on November 26.
- DICKEN, PUREFOY HUDDLESTON, M.R.C.S., Scholar of St. Bartholomew's Hospital, at Norton, Suffolk, on November 24, aged 21.
- FREEMAN, MATILDA ANNE, the wife of Thomas Anthony Freeman, M.R.C.S.E., at Bracknell Lodge, Winchfield, Hants, on November 22.
- GREENWOOD, HENRY, M.D., at his residence, Talbot-place, Blackheath, on November 22, in the 79th year of his age.
- HALLEY, KATRINE HAY, the dearly-loved second daughter of Alexander Halley, M.D., F.G.S., 16, Harley-street, Cavendish-square, at Seaton, South Devon, on November 28, aged 20.
- KIERLANDER.—At Asseerghur, India, the wife of William Coleridge, Kierlander, Garrison Surgeon, on October 30, aged 27.
- NAPPER, T., Surgeon, at Ockley, Dorking, on November 24, aged 61.
- STEGGALL, JOHN, M.D., at 2, Southampton-street, Bloomsbury, on November 21.

VACANCIES.

- In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.
- BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House-Surgeon. The gentleman appointed must be a Member of one of the Colleges of Surgeons of the United Kingdom. Applications and testimonials to the Secretary, on or before December 4. Election on the 12th.
- BLYTHING UNION.—Medical Officer for the Wrentham District. Candidates are required to possess the qualifications prescribed by the General Orders of the Local Government Board, and to be registered. Applications and testimonials to Mr. C. White, Clerk, on or before December 9. Election on the 11th.
- BRADFORD FEVER HOSPITAL.—Resident Medical Superintendent. Gentlemen applying for this appointment must be duly qualified Medical Practitioners. Applications and testimonials to Mr. C. Woodcock, on or before December 11.
- CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House-Surgeon. Must be a registered Medical Practitioner. Applications and testimonials to the Secretary, Infirmary, Bangor, on or before January 2, 1872.
- CENTRAL LONDON OPHTHALMIC HOSPITAL, GRAY'S-INN-ROAD, W.C.—Assistant-Surgeon. Must be F. or M.R.C.S.E., not engaged in the practice of Midwifery or Pharmacy. Applications and testimonials to the Secretary, on or before December 2.
- DENTAL HOSPITAL, 32, SOHO-SQUARE.—Lecturer on Dental Surgery and Pathology. Applications and testimonials to the Honorary Secretary, on or before December 12.
- EARLSWOOD ASYLUM.—Assistant Medical Officer. Must be duly qualified and registered. Applications and testimonials to the Secretary, on or before December 18.
- FARRINGTON DISPENSARY, BARTLETT'S-BUILDINGS, HOLBORN, E.C.—Resident Surgeon. Medical and Surgical qualifications required. Applications and testimonials to Mr. S. Green, on or before December 4.
- GREAT NORTHERN HOSPITAL.—Surgeon. Must be a Fellow of one of the Colleges of Surgeons. Applications and testimonials to the Secretary, on or before December 7.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, S.W.—Resident Clinical Assistants. Candidates must have some Medical qualification. Applications and testimonials to the Hon. Sec., on or before December 2.
- HOSPITAL FOR SICK CHILDREN, 29, GREAT ORMOND-STREET, W.C.—House-Surgeon. The gentleman appointed must possess some legal qualification to practise. Applications and testimonials to the Secretary, on or before December 12. Election on the 13th; the duties to commence on the 18th.
- INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST.—Visiting Physician. Applications and testimonials to Mr. F. Baily, 27, Margaret-street, Cavendish-square, W.

- KILBURN, MAIDA-VALE, AND ST. JOHN'S-WOOD GENERAL DISPENSARY, 13, KILBURN-PARK-ROAD.—Resident Medical Officer. A qualification to practice is required. Applications and testimonials to the Secretary, on or before December 13.
- LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—The Chair of Ophthalmology is vacant. Applications to the Registrar, on or before December 3.
- LIVERPOOL SOUTHERN HOSPITAL.—Senior House-Surgeon. Must have Medical and Surgical qualifications. Applications and testimonials to Mr. James Houghton, Treasurer, on or before December 13.
- METROPOLITAN FREE HOSPITAL, DEVONSHIRE-SQUARE, CITY, E.C.—Honorary Surgeon. Must be F.R.C.S., or pledged to become such within twelve months. Applications and testimonials to Mr. G. Croxton, Secretary, on or before December 23.
- NORTH STAFFORDSHIRE INFIRMARY, HARTSHILL, STOKE-ON-TRENT.—House-Physician. Election on December 28. Further particulars in our next.
- ST. MARY'S HOSPITAL AND DISPENSARY FOR WOMEN AND CHILDREN, QUAY-STREET, MANCHESTER.—Medical Officer for Out-patients. Must have Medical and Surgical qualifications. Applications and testimonials to Mr. J. Barber, on or before December 2.
- SEAMEN'S HOSPITAL (LATE DREADNOUGHT, GREENWICH).—House-Physician. Candidates must possess at least one qualification. Applications and testimonials to Mr. Kembell Cook, House-Governor and Secretary, on or before December 12.
- SUSSEX COUNTY HOSPITAL, BRIGHTON.—Surgeon. Must be M.R.C.S.E. Edin. or Dub. The office of Assistant-Surgeon is also vacant; the qualifications required are the same as for the appointment of Surgeon. Applications and testimonials to Mr. A. Vesey, on or before December 6.
- UNIVERSITY COLLEGE HOSPITAL.—Assistant Obstetric Physician. Applications to Mr. John Robson, B.A., on or before December 18.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

- Blything Union.—Mr. A. H. Robinson has resigned the First District; area 12,181; population 2850; salary £54 per annum.
- Nuneaton Union.—The Nuneaton District is vacant; area 7520; population 7845; salary £55 per annum.
- Toxteth-park Township.—Mr. T. F. Morrish has resigned the Second District; salary £250 per annum.

APPOINTMENTS.

- Ashton-under-Lyne Union.—Alex. Hamilton, L.R.C.P. Edin., L.R.C.S. Edin., to the Tenth District.
- Bishops Stortford Union.—George Covey, M.R.C.S., L.S.A., to the Braughing District.
- Bodmin Union.—Bartholomew G. Derry, M.R.C.S.E., L.S.A., to the Third District and the Workhouse.
- Dorchester Union.—Alfred Emson, M.R.C.S.E., L.S.A., to the First District and the Workhouse.
- Dudley Union.—Matthew Septimus Allen, M.R.C.S.E., L.S.A., to the Dudley North District.
- Hackney Union.—Charles H. Welch, F.R.C.S. Edin., L.F.P. & S. Glasg., L.M., L.S.A., to the Sixth District. Robert H. Smith, M.R.C.S.E., L.S.A., B.A., to the Eighth District.
- Monmouth Union.—George Allen Norman, M.B. Oxon., L.R.C.P. Edin., L.R.C.S. Edin., to the Rockfield District.
- Portsea Island Union.—Robert Gilmour, M.R.C.S.E., L.M. Glasg., to the Landport District.
- Weymouth Union.—Henry Nathan, M.R.C.S.E., L.S.A., to the Melcombe Regis District.

DR. THOMAS NELSON has been appointed Deputy Inspector-General of Haslar Hospital.

THE WORKS OF SIR J. Y. SIMPSON, BART.—Messrs. Black expect to have volume iii. of "Diseases of Women" ready early in January, 1872.

ALEXANDER SMITH, M.D., late of the Bengal Military and Civil Service, died on the 16th of November, at Gothic House, Herne Bay, aged 67.

THE new wing of the Stockport Infirmary, expressly built for infectious and contagious diseases, has just been opened.

THE office-bearers of the Medico-Chirurgical Society, Aberdeen, elected last week are—*President*: J. Corbet, Surgeon. *Secretary*: Dr. Beveridge. *Librarian*: W. Fraser, Surgeon. *Curator of Museum*: R. Smith, Surgeon. *Council*: Dr. Jamieson, Dr. Will, Dr. J. W. F. Smith, Dr. A. Fraser, Dr. G. G. Brown.

THE SECRETARY OF STATE FOR INDIA IN COUNCIL has ordered twenty-five copies of Dr. Porter Smith's work on "Chinese Materia Medica and Natural History" for distribution amongst the libraries of the Medical colleges and public institutions of India.

WE remind our readers that the anniversary session of the St. Andrews Medical Graduates' Association will be held at the Freemasons' Tavern, Great Queen-street, Lincoln's-inn-fields, on December 1 and 2. On Friday, the 1st, at 8 p.m., Dr. Swete will introduce a discussion "On Habitual Drunkenness and its Treatment, Medical and Legislative." On Saturday, the 2nd, at 5 p.m., the President, Dr. Day, of Stafford, will deliver the anniversary address, "The Historical Steps of Modern Medicine."

QUEEN'S UNIVERSITY IN IRELAND.—On November 22 the following were elected by the Senate as Examiners for the year 1872-73:—*Medicine*—Professor Colahan, M.D.; *Surgery*—John K. Barton, M.D.; *Midwifery*—T. More Madden, M.D.; *Materia Medica*—Thomas Wrigley Grimshaw, M.D.; *Medical Jurisprudence*—Edmund W. Davy, M.D.

ROYAL MEDICAL SOCIETY OF EDINBURGH.—The following gentlemen have been elected Presidents of this Society for the current year:—E. Willis Way, M.B., etc.; Lewis Shapter, B.A. Cantab.; Henry C. Martin, M.B., etc.; Arthur J. M. Bentley, M.B., etc.

EDINBURGH OBSTETRICAL SOCIETY.—The following office-bearers were elected on November 22:—*President*: Dr. L. Ramsay Thomson, of Dalkeith. *Vice-Presidents*: Professor Simpson, Dr. J. Matthews Duncan. *Treasurer*: Dr. James Young. *Secretaries*: Dr. R. Peel Ritchie, Dr. J. Andrew. *Council*: Dr. A. Keiller, G. Stevenson Smith, Dr. T. H. Pattison.

THE CHARITY ORGANISATION SOCIETY.—Mr. W. H. Smith, M.P., has consented to take the chair at the conference on the Dispensary and Hospital out-patient relief which is to be held on December 12.

THE Hackney District Board have voted to their Medical Officer the necessary authority to commence proceedings against Mr. Ayrton, the Chief Commissioner of Works, on account of the "filthy and unwholesome state of the water in the bathing-lakes, Victoria-park."

THE French Government has conferred on Dr. A. Vintras the Cross of Chevalier of the Legion of Honour, in recognition of the services he has rendered to his countrymen for the last ten years at the French Hospital and Dispensary, London.

HOSPITAL SUNDAY IN RICHMOND.—On Sunday, November 19, the sum of £222 12s. 7d. was collected in the churches and chapels of Richmond and the vicinity. It is contemplated, at the beginning of the new year, to increase the accommodation by the addition of six new beds, in consequence of a legacy of £6800 which has been left to the Hospital by a wealthy tradesman of the town, of which £2000 has already been paid.

THE ROYAL SOCIETY.—At the annual meeting of the Fellows of this institution, held on Thursday last (St. Andrews-day) at Burlington House, the gentlemen whose names as candidates have already been published in the *Medical Times and Gazette* were elected Members of the Council. On this occasion the gold medals were presented to Mr. George Busk, President of the Royal College of Surgeons, for his valuable researches in Comparative Anatomy, Physiology, and Zoology; to Dr. Stenhouse, for his researches in Chemistry; and to Mr. Mayer, for his researches on Heat. Professor Airey, the Astronomer Royal, was elected President of the Royal Society in the vacancy occasioned by the retirement of General Sabine, who has filled the chair for ten years, having succeeded the late Sir Benjamin Collins Brodie, Bart., in 1861. It is not generally known that the Royal Medals of the value of twenty guineas each, which are presented annually, are a gift from the privy purse of her Majesty. In the evening upwards of 100 Fellows with several distinguished visitors dined together, as usual on this occasion.

BABY-FARMING IN ST. PANCRAS.—Dr. Lankester, on Saturday, held an inquest on a child, aged eight months. A fortnight after its birth the father died, and her mother, to obtain a living, went out to service, and put deceased out to nurse at 4s. a week for its support. Deceased gradually fell away to a skeleton. Medical advice was obtained, but the child never rallied. A post-mortem examination disclosed marks of a bruise on the head, that the stomach was devoid of food, and that the cause of death was wasting of the body from continued neglect, accelerated by want of breast-milk. The Coroner severely reprimanded the nurse for her inhuman conduct, and warned her to be careful with children for the future, for only last week a woman had been sent to prison for eighteen months, because she had neglected a nurse-child. A verdict in accordance with the Medical testimony was returned.

A PARISH DOCTOR CENSURED.—Mr. John Humphreys held an inquest on Monday, touching the death of a boy, aged one year and eight months. The mother, the wife of a painter, living in Bethnal-green, said that on Thursday, finding her child was ill, she took him to the parish Dispensary, in Morpeth-street, and she there saw Mr. Massingham. When he saw the child, he said, "What is the matter?" but he did not examine the child. (Mr. Massingham: "You are a liar!")

The witness continued, and said that the Doctor prescribed for the child, and she took it home. On the following day, she lifted the child out of bed, and found him dead. Another witness proved that the parents were kind to the child, and that the father was out of employment. Mr. Massingham deposed that the child had died from whooping-cough and convulsions consequent thereupon. The child had been brought to him under a parish order, but he did not know where the parents lived at the time. The order was referred to, and it was found to contain the address of the parents. After a long inquiry, the jury returned a verdict of "Death from whooping-cough," and they censured the Doctor for using the words, "You are a liar!" They also subscribed 10s. 6d. for the mother of the child. The Coroner informed the Doctor that he must respect the verdict.

WITHIN WHAT PERIOD, UNDER PECULIAR CIRCUMSTANCES, DEATH MAY BE PRESUMED.—A somewhat curious case, which may possibly lead to some complications involving a not altogether dissimilar question of identity and survivorship to that set up in the Tichborne trial, though arising out of totally different circumstances, came before the Master of the Rolls on Saturday last. The name of the case was *Greetham v. Miles*. The question raised was, within what period the death of a member of Dr. Leichardt's exploring party was to be presumed to have occurred. The party left Sydney for the interior of Australia in February, 1848, with the intention of traversing the continent, and have not since been heard of. The testator died in February, 1850, having devised his real estate in trust for his nephews and nieces, as tenants in common, with a discretionary trust for sale, which was exercised by the trustees in June, 1850. Arthur Milnes Hentig, a member of the exploring party, was one of the testator's nephews, and the share he would have been entitled to, if living at the testator's death, had been carried to a separate account, in consequence of it being uncertain whether he had survived the testator. It was contended that the probability was that Hentig, who was a strong healthy young man, survived the testator. In support of this view, reference was made to *Chambers's Encyclopædia*, where the results of subsequent experience are collected, showing that the interior of Australia is by no means so inhospitable a place as is generally supposed, and that travellers need not die of thirst, which was supposed to have been the fate of Leichardt's party. The learned counsel read an affidavit of Hentig's brother of a rumour which had recently reached Sydney, that a white man, who is supposed to be one of the survivors of the expedition, has been seen somewhere in the interior with a party of natives after the death of the testator. The Master of the Rolls said that the inference he must draw from the established facts was that Hentig died within a year of the exploring party leaving Sydney, and that the heir-at-law of the testator, and not the heir-at-law of Hentig, was therefore entitled.

THE LARVAL ASCIDIAN.—Since the publication of Mr. Charles Darwin's "Descent of Man," the larval ascidian has become almost a household word amongst us. The observations of Kowalevsky and Kupffer on the nature of the *chorda dorsalis* in the larvæ of these molluscoids, and the presumed relationship which it indicates between the invertebrates and the vertebrates, led M. Donitz, a Berlin naturalist, to study the development, from the egg, of *Clavellina lepadiformis* during a recent visit to Naples. The conclusions at which he arrived are totally antagonistic to those of the above-named zoologists, and he regards the development of the ascidian as telling *against* the assumed relationship. The formation of the intestine, the body cavity, the nervous axis, and the axial rod are, according to him, quite different in the tail of the ascidian larva from the development of the same organs in the vertebrate embryo. A Russian observer, E. Menschnokoff, holds similar views, and maintains that there is no analogy between the development of the ascidians and the vertebrates. In spite of these antagonistic criticisms Kowalevsky maintains his former ground, and, in *Schultze's Archiv*, 1871, contributes additional observations on the "Development of the Simple Ascidians." He describes and figures the development of the free-swimming larva of *A. mammillata*, and thinks that he has now conclusively proved that the *chorda* of the ascidian is both analogous and homologous with the *chorda* of the vertebrates. A reviewer of Donitz's memoir, in the July number of the *Quarterly Journal of Microscopical Science*, suggests that the discrepancies in the conclusions of these observers are due to the fact that Donitz gives a very different definition of the *chorda* from that which is generally accepted.

CENTENARIANS.—No less than twelve of the deaths from all causes registered in London last week were of persons aged 90 years and upwards, including two centenarians—a carpenter, who died in the Shoreditch Workhouse, aged 102; and a widow, who died in Clapham, aged 101 years 11 months and 18 days.

PAPER AS A PRESERVATIVE FROM COLD.—It should be generally known that paper is a good non-conductor of caloric, and that during the Polish campaign of 1831 the soldiers preserved themselves from cold by covering their hands, feet, chest, and back with dry paper.—*Rev. Méd.*, September 30.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

* * * In reference to Professor Fayrer's case of Penetrating Wound of the Abdomen, published last week, we have received the following note:—

"Dr. Chevers ascribed this sense of inability to relieve a full bladder to outward compression of the bladder, caused by the presence of extravasated blood in the pelvic cavity. The same distress was experienced by a European patient of his who died from rupture of the spleen in intermittent fever. In that case the quantity of blood which had fallen into the pelvis did not exceed a pound."

Student.—The McGill Medical College, Montreal, beginning at the same time as do the English schools.

A Successful Candidate.—The names of those gentlemen who passed for the Fellowship of the College of Surgeons cannot be published until confirmed by the Council.

A Magistrate, Rotherham.—The "L.K. & Q.C.P. Ireland" does not entitle the holder to place "M.D." after his name. Counsel's opinion has been taken more than once on this subject.

Dr. Harding, Waikouati.—Your letter with enclosure, has come safely to hand.

Dr. D. Campbell, Lyttelton, New Zealand.—Your communication has arrived; the enclosure was correct. The last date was February 4, 1871.

Etiquette.—The rule of conduct is clearly defined. Sir Astley Cooper, in the very zenith of his practice, was never known to be five minutes beyond his time at a consultation. This was not more out of respect for the time of a Professional brother than for his own sake. He would say—"If I lost five or ten minutes at any time in an appointment, I should be running after it the whole day, and, like a man running after his shadow, I should not overtake it." If a Medical Practitioner took a patient to Sir Astley's house, whether by appointment or otherwise, he was admitted as soon as possible to the presence of Sir Astley. He would walk out into his waiting-room and select his Medical friend. "Ladies and gentlemen," he would say in his fine way, "my friend is a Surgeon (or Physician, as the case might be), and I am sure you would regret that I should keep him waiting. He may be wanted elsewhere." This was the rule observed by the leading Practitioners of the last generation. Any departure from it now, by any person, however high his position or extensive his practice, must be regarded as offensive and impertinent. Cases like that mentioned by our correspondent have come under our notice before, but it is to be hoped they are very rare indeed.

ON THE INTRINSIC CAUSES OF TYPHOID FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—At a time when the hope of England lies stricken with fever of a typhoid character, I trust that the experience of a working Medical man, with a Professional career of more than half a century, may not be considered presumptuous. A short time since, coming from a case of the kind with an M.D., I asked him how he considered the disease was engendered. He replied, by the escape of soil into the water used; and he told me the case of a young man, the son of a banker, a short distance from town, and that it was satisfactorily proved, by the leak having been discovered. I asked of what number the establishment consisted, and whether that was the only case. I think he said thirty-five in family and servants, and that no other case occurred. I replied, that I attributed the disease to a totally different cause; I considered the predisposing cause to be blood-poisoning, arising from the absorption into the blood of feculent matter, which had been constricted in the cells of the large intestines and had become putrid, and been carried into the blood. My impression is, that this occurs more especially in the upper portion of the descending colon. The blood being thus poisoned, too much fatigue, getting wet, depression of the mind, or any other general lowering of the system, produces the fever of a typhoid character.

I am, &c.,

F. C.

EKZEMA v. ECZEMA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As you have touched on the question of ekzema versus eczema, I cannot help wishing that Mr. Erasmus Wilson, who is, I believe, the only person who spells it with a "k"—and he has only lately taken to doing so—would kindly consent to spell it with a "c." If he objects to doing that, I think he almost ought to explain why he will spell it in such a curious way. No doubt he will say, The Greeks spelt it with a kappa, and so why should not he spell it with a "k"? but that is scarcely enough. In the first place,

a Greek who spelt it with a kappa had, at least, the excuse that all the other Greeks did the same; whereas of the Englishmen who spell it with a "k" Mr. Wilson is in himself the alpha and the omega. The universal custom of educated persons should at least go for something.

Then, again, if we are to follow Mr. Wilson—and it is to be presumed he desires that his example should be followed—we must, for consistency's sake, go further. We cannot stop at "ekzema and ekzematous affections," and leave out all the other words that come to us originally from the Greek. Cosmetics should by the same rule be kosmetics; eccentricity should be ekcentricity; a cataract should be a katarshakt—and so we go on to such funny spellings as would in our school-days have entailed on us a traumatic urticaria of both palms.

Mr. Wilson, in the ardour of an original research, has overlooked the fact that many, indeed most, of the words in our language that are of Greek origin do not come to us by any means directly from the Greek language—we derive them, in fact, as I fancy most persons are aware, not from the Greek but from the Latin tongue. We use them not so much because the Greeks used them as because the Romans adopted them. It would even be more correct to say that we learnt them from the Norman-French, who in their turn acquired them from the Romans. In either case we get them intermediately through the Latin language.

"How, then," (might Mr. Wilson ask) "came the Romans to commit so grave a mistake as to put a 'c' for a 'k'?—where were their 'k's' I should like to know?" The answer to this is simple; they hadn't got any. But let me anticipate any disparagement of them by adding that the Greeks were just as bad, only in another way. They were totally and absolutely without "c's"—indeed, quite as much so as some of our Londoners are destitute of *aitches*.

Any Greek who wanted to spell in his own language a Latin word spelt with a "c" would have to put a "k" as the nearest patch he could make, or else go without it altogether; and, conversely, any Roman who desired to spell in his own language a Greek word spelt with a "k" was obliged, for want of better, to write a "c"—so that we must not blame him if he did so. Now, as we are immediately indebted to the Latins (not intermediately to the Greeks, let me assure Mr. Wilson) for so very many of the words of Greek extraction that enrich our language, I think it is almost ungrateful to shelve the Latins at last after they have helped us so much for so many centuries. Mr. Wilson's skill has often slaughtered ekzema, but he ought to respect the memory of so stout a foe, and spare its name.

Nov. 25.

I am, &c.,

BALMANNO SQUIRE.

RELAXATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—On the invitation of a kind patient we ran down to Brighton, to find her little boy flourishing on the prison diet of milk-and-water and Scotch oatmeal, although a year old and his teeth coming.

Resembling the old soldier who never misses a review, our first visit, of course, was to the clean, cheerful, wholesome, and well-regulated Sussex County Hospital. Next we criticised the ladies' riding—some bumping along on screws, unsightly objects, hair down, bad get-up, loose ribbons floating about, and the groom in old clothes and dirty tops; whilst other girls in blue, plain, tight-fitting, well-padded habits, were perfect pictures, managing their thorough-bred nags admirably. Strolling along the parade, we met ladies' schools (artful-looking witches), cavalry officers (very quiet), retired captains (terribly ferocious), also invalids in bath-chairs, including unpromoted venerable Assistant-Surgeons. "Hope deferred maketh the heart sick." A certain young lady has a photograph of a martial Medical officer in a black belt, the hateful cocked hat, and the dismal green feathers, who, ten years ago, promised to marry her when able. She, alas! grown thin and angular, has an ugly cough; and he, qualifying for delirium tremens, cannot be trusted with a razor. On the pier more pretty girls in Chinchilla furs and red silk skirts—a hundred a year, allowed by the parents on marriage, would soon be expended. What with the bracing air, the clear atmosphere, the tiny waves dancing in the sunbeams, and the band playing the "Beautiful Danube," the wearied Practitioner feels a new man. Until in the promenade, the world is very small—a pale, careworn face recalls dreadful hours of strained mental torture, when his young wife (with a history of uræmic convulsions in a previous labour) succumbed to malignant scarlet fever. Can we never shake off work and consequent brain-softening anxiety? Apparently not.

In the afternoon, in a well appointed red-wheeled carriage, with supercilious powdered cockaded lackeys, we pass the worshipful M—r in an exquisite brougham, reading "Phthisis as a Neurosis," an interesting paper in the *Medical Times and Gazette*, and, catching the attention of Poole and other tradesmen, we feel assured that certain little accounts can stand over. But in a showy equipage, with jingling plated harness, the servants in blue coats and red plush breeches, our jaw drops to observe Jewish ladies accompanied by Chutnee Currie, the quack money-lender, in a Scotch cap, a velvet coat, and his legs wrapped in the skin of the tiger we shot in India. Somehow, at the goldsmiths' ball, his daughters were neglected; now they return grovelling obeisance with stony contempt, whilst he, smoking a cigarette, rolls his dark sleepy eye, and, smiling maliciously, clearly intends to lock someone up ere long.

Victorias, mail phaetons, carriages of every description passing by. Can that be Dr. — (oblivious of drains and ventilation) flirting on a drag with the rich widow who graciously received opera-boxes, expensive dinners at Greenwich, tickets for balls and flower shows, gratuitous Medical attendance, vaccination gratis—in short, accepted everything but ourselves? A hint to beginners: Never have crests and monograms engraved on presents, which, returned, will go the round again. We had a second-hand emerald ring doing duty for several years until this cunning widow kept it.

Vanity Fair becoming monotonous, we read at the club Parkes and Sanderson's report on the degraded condition of Liverpool. Poverty, dirt, and intemperance are all bad enough, but for a working-man not even to have heard of the *British Medical Journal* is simply astounding; whereas at the North Pole, in the Mexican forest, or the unexplored African wilds, the inhabitants are weekly punctual subscribers! Also, there is a curious account of a Dispensary, where the patients not merely receive Medicine and Medical attendance free gratis and for nothing, but expect a hamper containing a goose and Christmas gin (Gilbey Castle G.). At the hair-dresser's information is received that a quiet Indian cavalry regiment occupies the barracks; all the officers have been cadets—that is to say, risen from the ranks. Rather tickled, we inquire about a former crack corps who spent everything and went to almighty smash. "Oh! sir, they did nothing; absolutely nothing." So much for entertaining at Brighton. The great unknown, the respected Editor, doubtless of sporting turn, here, in P. R. language, impatiently calls—

TIME.

COMMUNICATIONS have been received from—

Dr. ARCOLEO; Rev. G. GREENWOOD; STUDENT; Mr. F. W. STONE; Mr. S. B. MIRD; Mr. W. B. WILSON; Dr. PLAYFAIR; Messrs. A. and C. BLACK; Mr. C. WOODCOCK; Mr. W. W. REEVES; Mr. J. MILWARD; Mr. A. STEDMAN; Mr. HORDLEY; Mr. AXON; Mr. STANSFELD; F. C.; Dr. THOROWGOOD; Professor LIEBREICH; Dr. DAY; Dr. J. WICKHAM LEGG; Dr. PHILLIPS; Mr. J. CHATTO; Dr. R. DOUGLAS POWELL; Dr. J. HUGHLINGS JACKSON; Dr. SEDGWICK; Mr. R. H. LEACH; Dr. CORFIELD; Mr. TOBIN; Mr. H. C. MAULEY; Dr. B. SQUIRE; Mr. H. C. LAWRENCE; Dr. FAYRER; Professor HUMPHRY; Mr. MACDONALD; Dr. PORTER SMITH; Mr. P. BELL; Mr. WILLIAM THOMSON, Victoria; Dr. RITCHEL; Mr. H. KINGSCOTE; Dr. G. LAWSON; Dr. WARWICK; Mr. J. B. WALKER; Dr. WASHBOURN; Dr. E. SYMES THOMPSON; Dr. PITMAN.

BOOKS RECEIVED—

Report of the Medical Committee of the Charity Organisation Society—Beasley's Pocket Formulary, ninth edition—Higginson's Report on Thirteen Cases of Transfusion of Blood—Fleming's Notes on the Carbolic Treatment of Leprosy—Report on the Sanitary Condition of the Whitechapel District—Berkart's Preliminary Notice on the Treatment of Emphysema of the Lungs.

PERIODICALS AND NEWSPAPERS RECEIVED—

Detroit Review of Medicine and Pharmacy, November—Nature—Pharmaceutical Journal—Chloralum Review, November—The Journal of Psychological Medicine, October.

APPOINTMENTS FOR THE WEEK.

December 2. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

4. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

ANTHROPOLOGICAL INSTITUTE, 8 p.m. Meeting.

MEDICAL SOCIETY OF LONDON, 8 p.m. Mr. Walter Coulson, "Two Cases of Successful Transplantation of Skin on extensive Tertiary Ulceration." Dr. Hughlings-Jackson, "A Case of Tumour and Cyst of the Right Lobe of the Cerebellum."

ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

5. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited:—Dr. C. T. Williams (for Dr. Quain), "Disease of Aorta," etc. Dr. C. T. Williams, "Disease of Supra-renal Capsules in a Phthisical Subject." Mr. A. Norton, "Cancer of Larynx." Mr. F. Churchill, "Fatty Tumour simulating Ranula." Dr. Green, "Interstitial Pneumonia." Dr. Crisp, "Cirrhosis of Liver and Baggy Stomach; Disease of Hip-joint and Kidneys."

6. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICO-PSYCHOLOGICAL ASSOCIATION (Rooms of the Medical Society of London, 32A, George-street, Hanover-square), 8 p.m. 1. Clinical Reports, Morbid Specimens, etc. 2. Paper by Dr. Maudsley (President), "Is Insanity on the Increase?"

OBSTETRICAL SOCIETY, 8 p.m. Mr. Eugene Goddard, "On a Successful Case of Ovariectomy during Pregnancy." Dr. Brunton, "On Fibroid Enlargement of the Uterus." Dr. Edis, "On the Systematic Examination of the Uterus, with the view of rectifying Malpositions of the Fœtus." Dr. Meadows, "On a Case of Extra-uterine Fœtation, with Remarks on Treatment."

ROYAL MICROSCOPICAL SOCIETY, 8 p.m. Mr. J. Bell, "Fermentation and its Results." Dr. L. Beale, F.R.S., "The Nerves of the Capillary Vessels, and their probable Action in Health and Disease."

SOCIETY OF ARTS, 8 p.m. Mr. J. Bailey Denton, "On Sewage as a Fertiliser of Land, and Land as a Purifier of Sewage."

7. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

HARVEIAN SOCIETY (Special Council Meeting, 7½ p.m.), 8 p.m. Mr. G. G. Gascocoy, "On Spermatorrhœa and its Treatment."

8. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

CLINICAL SOCIETY, 8½ p.m. Dr. Ogle, "On the Temperature in certain Affections of the Nervous System, and especially in Tetanus." Dr. Habershon, "On Cases of Heart Disease." Dr. Broadbent, "Tumour in Left Half of Floor of Fourth Ventricle, with Small Tumour in Cerebellum."

QUERKETT MICROSCOPICAL CLUB, 7 p.m. Extra Meeting, for Conversation and Exhibition of Specimens only.

VITAL STATISTICS OF LONDON.

Week ending Saturday, November 25, 1871.

BIRTHS.

Births of Boys, 1083; Girls, 1036; Total, 2119.
Average of 10 corresponding weeks, 1861-70, 2034.9.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	917	946	1863
Average of the ten years 1861-70	773.3	757.9	1531.2

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.98 in. The highest was 30.28 in. on Sunday morning, and the lowest 29.74 in. on Saturday afternoon.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

PORTABLE HOT-AIR AND VAPOUR LAMP.

Temperature attained, as a vapour bath, in ten minutes: With thick flannel cloak, 120°; with mackintosh ditto, 130°. Temperature attained, as a hot-air bath, in ten minutes: With flannel cloak, 150°; with mackintosh ditto, 170° to 180°. The above temperatures may be sustained for forty-five minutes. The lamp is very portable, burns methylated spirits, and is without trouble or difficulty in preparation; it may be used with an ordinary bed-room chair. Each bath costs about 3d. Three kinds of cloaks are provided—1st, a mackintosh cloak, lined with flannel, with sleeves in front; 2nd, a mackintosh cloak alone; 3rd, a double flannel cloak; 4th, a single flannel cloak. The 1st and 4th are most usually used. Special covers are adapted to the lamp for hot air when calomel, iodine, or sulphur is to be used. Chairs and bed-cradles provided especially for the use of the lamp by invalids. Price-list forwarded.

IMPROVED TONSIL GUILLOTINE,

By Mr. JOHN EWENS, of Cerne Abbas.

This instrument has metal guards passing from the two finger-rings to near the circular blade. Their use is to prevent the patient closing his mouth while the tonsil is being transected by the barbed spear, or during the excision of the

tonsil, thus obviating the necessity of a separate gag, and rendering the operation less difficult.

Inventor, Patentee, and Sole Maker, HAWKSLEY, 4, Blenheim-street, Bond-street, London, W.

NEW PATENT.

MESSRS. BLAISE and CO. (late SAVIGNY and CO.) beg to inform the Medical Profession that they are manufacturing URINOMETERS, &c., of Vulcanite, which far surpass those made of glass or metal, being proof against acids, and not liable to break; and they invite inspection at 67, ST. JAMES'S-STREET, and 276, WESTMINSTER-BRIDGE-ROAD. (*Vide* "British Medical Journal" and "Lancet" of October 28th, 1871.)

Second-hand and New Surgical Instruments at greatly Reduced

PRICES.—A great variety of SECOND-HAND MICROSCOPES, TELESCOPES, and OPERA GLASSES, MAGIC and DISSOLVING VIEW LANTERNS, PHOTOGRAPHIC APPARATUS, CAMERAS, LENSES, &c., by the best makers.

Address, WM. LAWLEY, 78, Farringdon-street, City, London.—Enlarged and Revised ILLUSTRATED SURGICAL CATALOGUE forwarded for 6 Stamps.

SECOND-HAND SURGICAL INSTRUMENTS.

The LARGEST ASSORTMENT IN LONDON is at C. BAKER'S Old-Established INSTRUMENT WAREHOUSE, 244 & 245, HIGH HOLBORN. Every description of NEW supplied at the Wholesale prices. Second-hand Instruments of all kinds Purchased or taken in Exchange.—Observe, 244 & 245, HIGH HOLBORN (Opposite Day and Martin's).

29, LEICESTER-SQUARE, LONDON, W.C.

W. MILLER,

Anatomical, Surgical, and Orthopædic Mechanician.
ARTIFICIAL LIMBS, TRUSSES, BANDAGES, &c. | INSTRUMENTS FOR DEFORMITY, CRUTCHES, &c.

MR. GROSSMITH'S ARTIFICIAL EYES, LEGS, AND HANDS

Were awarded the Prize Medals at all the Great International Exhibitions of London, Paris, and Dublin, and pronounced by the Surgical Juries "perfectly life-like," "excellent in manufacture," and on a "system superior to all others." The Legs enable the Patient to walk, sit, and ride with ease and comfort, wherever amputated; are lighter and less expensive than the old style; will last a lifetime; and can be worn by Ladies and Children with perfect safety. The Eyes are fitted in a few minutes, without pain or operation, in any case where sight has been lost, and have a perfect movement.

MANUFACTORY, 175, FLEET-STREET, LONDON.—Established in London and Paris, 1760.

Fox's "palatable" Castor Oil

MELBOURNE MEAT-PRESERVING COMPANY (LIMITED).

COOKED BEEF AND MUTTON, IN TINS,

With full Instructions for use.

PRIME QUALITIES AND FREE FROM BONE.

Sold Retail by Grocers and Provision Dealers throughout the Kingdom. Wholesale by

JOHN McCALL & CO., 137, HOUNDSDITCH, London.

WESTERTON'S PATENT ZYMOTIC DISINFECTING FLUID

Prevents the spread of infection; protects the nurse and those about the sick-room. Sponging over the body with the Fluid disinfects the emanations from the skin and (being volatile) exhalations from the lungs of the sufferer. Destroys the noxious properties of the excretions, and purifies the atmosphere.

PREPARED BY

W. C. WESTERTON, 85, Abingdon-villas, Kensington, London;

and may be had of all Chemists, in bottles, 1s., 1s. 9d., and 3s. 6d.; 10s. per gall.

ORIGINAL LECTURES.

LECTURES ON EXPERIMENTAL AND PRACTICAL MEDICINE.

By BENJAMIN W. RICHARDSON, M.D., F.R.S.

ON THE SCIENCE AND ART OF EMBALMING THE DEAD.

LECTURE I.

GENTLEMEN,—I have been led to the study of the subject of embalming the dead by an almost unconscious and unintentional progression. When I first entered on the field of experimental research, the very first inquiry followed out had reference to the antiseptic properties of gases. At that time (1849-50) the action of chemical substances inhaled in a state of gaseous or vaporious diffusion was the leading topic in the Medical world. Speculations were rife as to the mode in which narcotic vapours produce their narcotic effects after their inhalation; and Snow, taking the lead, perhaps, in this controversy, advanced the theory that all narcotic vapours act by arresting the process of oxidation in the living tissues—in other words, that they subdue the animal fire. He was wont to illustrate his views on this point by this his well-known experiment of dipping a lighted candle into an atmosphere containing vapour of chloroform, and showing that the burning of the candle is reduced and extinguished.

As time has rolled on I have been led to think that the theory founded by Snow, on the experiment I have just shown, wide as the basis of the experimental fact may be, is perhaps, after all, not a correct unfolding of the question it would solve, but is rather a step towards the solution. Nevertheless, to me and to many more, it carried with it originally a truly useful fascination; it led me specially to direct attention to the inquiry into the antiseptic properties of gases, of which mention has been made. If, I reasoned, these gases arrest the process of oxidation of living tissue by their presence, they ought, in like manner, to prevent the oxidation—that is to say, the decomposition—of dead matter; and so I set industriously to work to try what would be the effect of exposing dead structures to the influence of various gases and vapours. It was a study full of rich results, and was the more delightful because the responses got by knocking at the great door of nature were almost uniformly in one tone, and that in favour of the theory on which the research was based. The experiments were conducted with an almost childish simplicity. A piece of dead structure, usually a specimen showing some pathological change, was set up in a bottle; then, if a gas had to be introduced, the bottle was filled with water, the water was displaced by the gas, and the gas, well dried and warmed in its transit, was driven on until the inner surface of the bottle was dry; afterwards, the bottle was stopped under the water, and was carefully sealed up. If a vapour yielded by a volatile liquid—chloroform, for instance—were employed, the specimen was fitted up as before; then the volatile liquid was poured in sufficient quantity beneath the specimen, and the bottle was immersed in a water-bath and heated gently until the fluid had boiled nearly all away. At this point, the bottle, filled with the vapour only, was carefully closed.

By this process, step by step, I learned that a great number of vapours and gases arrested, by their presence, the process of putrefactive change. Chloroform, ether, arsenuretted hydrogen, hydrogen, and many more gases, were found to possess singular antiseptic power. On these researches and their results a paper on the antiseptic properties of gases was founded. The paper was read before the Medical Society of London, and had a fortunate reception. At the reading there was a gentleman

present, then a stranger to me, but now an old friend—Mr. John Fernandez Clarke—and a kindly line or two from him in one of his reports to the *Lancet* did more for the subject than I can tell. It had previously been supposed that, in order to keep a dead tissue in preservation, immersion in spirit, or in some saline solution, or injection of it, was requisite; now, the action of gases and of vapours was proved to be effective, and, the notice of the fact having been made very prominent, a new advance was promised, the end of which is not yet seen. Continuing the same line of research, I discovered the antiseptic property of vapour of ammonia, and communicated that also to the Medical Society of London.

There are some specimens at this moment on the table which show how well the process of preservation of dead structure may be maintained by the contact of gases and vapours. Here are two kidneys, showing the extreme congestion of these organs that is found in fatal cases of congestive fever—that sudden nervous lesion of the vessels of visceral organs, during which the heart pours its blood into them until, from engorgement, they cease their function. These parts have been in vapour of ammonia for the period of twelve years, and here they remain nearly as at the moment they were removed. There is a specimen of portions of intestinal tract studded with minute and large hæmorrhagic spots, in which the lesions are equally perfect, and in this instance the preservation has extended over twelve years.

I found this method of preserving animal substances of great use to me in teaching. Dissections of various organs, as of the heart, I have kept from week to week, and have demonstrated readily from them, without the trouble of new dissection.

Pursuing this subject of preservation still further, but in a slightly different course, I attempted to bring back animal tissue that had undergone actual putrefaction to something like a recognisable pattern of natural condition; and once, in the interests of justice, I manipulated on an unrecognisable putrid body, and so far succeeded as to enable important evidence of identity, which could not before be obtained, to be secured. The process was confessedly imperfect, as all such first efforts, made without any previous light to guide the inquirer, necessarily are; but it answered the purpose, and, repeated in California by Dr. Henry, of Alta, it succeeded so well that a miserable murderer, who thought his victim hidden conclusively in the putridity of death, was so paralysed by the result that he confessed his crime and all its terrible details.

Still pursuing the same research, I constructed a fluid for treating organs of the body that had become absolutely offensive from putridity, so that they could be examined for marks of injury or other lesions. This fluid, some of which I send round, is made as follows:—Iodine, ʒj.; methylated ether, of sp. gr. 720 (by measure), ʒx.; absolute alcohol (by measure), ʒj.; strong sulphuric acid (by measure), ʒiv. Dissolve the iodine in the ether and alcohol mixed together, then slowly drop in the sulphuric acid.

The fluid, when it is poured upon the putrid tissue, is almost instantly absorbed; the soft mass is deodorised effectually, and is rendered sufficiently firm to admit of being dissected with ease. In the open bottle I hand to you is a piece of once putrid lung that was thus treated three years ago; and you can see how perfect it remains. The action of this solution is that the iodine deodorises, while the sulphuric acid engages the water and the alkaline products of decomposition, and produces the necessary firmness of structure. The ether escapes; it is simply the fluid menstruum for the other agents.

The labours thus glanced at becoming known, I was asked some years since if I would embalm a body that was to be sent abroad. Accepting the office, I began to study the history and practice of embalment. Finding the study of the art (the history of it especially) instructive, I have sedulously pursued it, with many unusual advantages; and, as I have also striven, with some success, to improve the art, I venture to recall it to your minds. I say I recall the study; for in our time it has hardly been thought worthy even a place in our text-books. I know not why it is so; but the fact exists, and it implies a misconception. The process of embalming is a scientific process, equal certainly with that of conducting a post-mortem examination, and it is sometimes a useful process. I have known its successful performance make living lovers of the dead happier in their distress. It is often so imperatively demanded that, on the refusal of men of science to do it, the ignorant are paid large sums to attempt it. Lastly, it is an art which essentially belongs to the professors of Medicine, who can never let anything that pertains to the physics of the body, living or dead, pass out of their hands without proclaiming that part of their legitimate occupation has gone.

DISPOSALS OF THE DEAD.

On the three methods of disposal of the dead most commonly practised in the different stages of the human history of this planet—viz., burial, or concealment of the body in the earth; cremation, or destruction by fire; and preservation, by preparing the body with a balm, that it may be long kept, "embalming"—on these three methods of disposal, many learned books have been written and much controversy has been waged. Which of the three modes was first instituted? What particular nations favoured one mode in preference to the other? What was the ideal that prompted preference for either method?

As it seems to me, the natural course of history on this subject is exceedingly plain and simple. The custom of savage life, to leave the human dead to the carnivorous birds and beasts, passed readily enough, and with little development of refinement, into the more human practice of hiding the bodies from these animals in the earth, and led to the second primitive stage of disposal, which, on the whole, has outlived all other methods—viz., burial in earth. We trace the remnant of this custom in countries of wonderful civilisation, even after other, and, as it was assumed, more refined, practices had generally replaced it. Thus, in Greece, where cremation was the established custom, and interment, except under special circumstances, was interdicted, the traveller who should find a dead body was enjoined to bury it, or, if he could not do so much, to cast dust of earth upon it three times—

"Quamquam festinas, non est mora, licebit
Injecto ter pulvere curras."

Indeed, such was the anxiety of the early Greek in respect to decent burial, that Pluto, who taught first the rites of burial, was raised, like Æsculapius, into the number of the immortal gods. No deeper curse could be passed from one person to another than that which conveyed the wish that the cursed should have no burial; and when the sailor died at sea, he was consigned to the deep with horror, bearing on his body the most costly gift he could bear, with the request that, if on some friendly shore he were cast, and found, the finder would accept the reward for the pains of burial.

Later on, in the course of civilisation, new ideas sprang up respecting the continuance of man as a veritable existence, destructible or indestructible, or, as the poets would have it, mortal or immortal. As the intelligent part of the human nature became developed, the value of the intelligent part rose in estimation, while, in respect to matchless intelligences manifested as man, it was accepted as impossible that with the dissolution of the grosser or material parts of the organism the whole could resolve. At the same time, the mind, unable to isolate its idealisation of spirit and matter, could hardly receive the conception of a great intellectual unembodied force. Thus great men were crystallised into imaginary figures of gods, and in time the notion was conceived of retaining the matter for the re-reception of the spirit. Thereupon sprang forth two methods of disposal of the dead—one, the subjection of the body to fire; the other, the subjection of it to a process that should save it from decay. Strange it may seem, that two plans so different in effect should have the same origin. Yet the fact is so. The institution of the process of burning the body, by the ancient Greeks, from whatever source or suggestion they may have derived it, had no touch of materialistic feeling. The men who transformed their greatest men into gods, and who carried out their young dead to the funeral pile before sunrise, that the sun should not be the witness of so terrible a calamity as the cessation of life while yet it had not neared its perfected glory, were not men tainted with the doctrine of negation after death. Not at all! The burning to which they subjected the dead body was to them a process of purification for the soul, which, left unclean in its earthly state, required to be made perfect by the absolute purification of the easement in which it had been enshrined on the earth: so they subjected it to the *pur*, in later times the *ignis*, in our times the great purifier—the fire. Further, they thought in this purification they the sooner set free the indestructible principle of life, that it might enter the more speedily into the domains of the blessed. This was the Greek ideal of cremation; and it colours still the many thoughts of man. It is the root of a faith to the present hour, though differently symbolised.

The second process had its origin in the same but in a slower current of development. The noblest human representation was by the Greek subjected to the most consummate purification, that it might be freed of dross of earth; by the other intellectual process the effort was attempted to preserve the animal body so that it might, in course of the suns, and at some strange and eventful moment, be united with the principle that had left

it, and revivify. Again, in this ideal projection, we see the origin of a thought that remains still in the many thoughts of mankind, the root of a faith symbolised differently, but a faith of millions of our race.

On this last named ideal rose the art of embalming the dead, and as it developed it gained a new strength—a second limb, I might say—from the lower or instinctive interests of humanity. It led to the retainment of those who on earth had been loved and admired, nearer and longer, as it seemed, with those who lived to love, to remember, to admire. For this reason the practice of embalming great personages has retained its unabated power, while recently, in a country amongst the most civilised and the most advancing—America—the practice has received advancement, not merely in its application to the great dead, but to the dead generally, by those in whom the tie of attachment is closest and most abiding. Moreover, from America as a new centre, the practice extends; so that in brief course it will, if my experience be not at fault, largely prevail again in all civilised communities.

ORIGINAL COMMUNICATIONS.

CLINICAL REMARKS
ON THE SEVERAL FORMS OF PULMONARY
PHTHISIS.

By R. DOUGLAS POWELL, M.D., M.R.C.P.,

Senior Assistant-Physician to the Hospital for Consumption and
Diseases of the Chest, Brompton;
Assistant-Physician to the Charing-cross Hospital.

(Continued from page 676.)

Recurrent Hæmoptysis: Illustrative Case—Main Features of the Disease; Repeated Copious Hæmoptysis; Chronicity of Pulmonary Disease—Pathology: Slowly forming or Old Excavation, not necessarily Tubercular; frequent absence of Secondary Fever; Modes of Arrest of Hæmorrhage—Treatment, Prophylaxis—Both the forms of Hæmoptysis described rare; Significance of true Hæmoptysis but little weakened by modern research.

THE following very typical example of recurrent hæmoptysis has now been under my observation for nearly five years and I will summarise my notes, which have extended over the whole of this time, as briefly as possible:—

Thomas W., aged, at the present date, 31, described as a fitter, first came under my notice at the Brompton Hospital, in May, 1867. He had been ailing for some years with occasional cough, and had been three years previously under the care of Dr. Stone, at the same Hospital. He complained of pain in the chest, bad cough, but with, he said, no expectoration; he had had streaky hæmoptysis several times. He was doubtful whether he had got thinner; the appetite and digestion were good, the bowels regular, and the pulse slow. The only history of hereditary predisposition consisted in his father, an intemperate man, having died of consumption at the age of 44. The patient himself has always been a tolerably steady man of very active habits. He is very intelligent, of sanguine temperament, clear complexion, of medium height, and slight, though robust build. A striking feature about him, and worthy of note, is his extreme excitability—an almost superfluous energy with which he is gifted, which leads him to do everything with exaggerated effort.

At the date of his first attendance there was present at the left apex some dulness, with a few clicks.

On June 29 he reported having expectorated on the previous day a considerable quantity of blood, and, as he was still spitting some, he was ordered gallic acid powders.

On August 3 he spat more blood, and a note is entered of the existence of a small vomica at the left apex.

8th.—"Hæmoptysis one pint this morning;" repeated powders, and ordered mist. acid. sulph. eo.

On the 10th the hæmoptysis continued in a less degree, and the breath was freer; he was ordered counter-irritation to the left apex, and to continue the medicine.

On the 17th croton oil liniment was applied to the left apex. At this date, regarding the continuance of the hæmoptysis and its repeated occurrence at intervals, together with the absence of any corresponding progress in the pulmonary physical signs, which were still limited to the summit of the left lung, I was first led to suspect the existence of a small aneurism of a pulmonary vessel there.

On the 24th, however, the hæmoptysis had almost ceased, and, as the patient was emaciating, mineral acid and bark, with small doses of oil, were prescribed, and a linctus for the cough, which was troublesome. With the exception of a very trivial attack, he had no return of hæmoptysis, and ceased attending the Hospital, greatly improved in health, at Christmas of the same year.

He returned again in October, 1868, having continued, as he expressed it, "well," and at work until a fortnight previously. He had now slight cough, and had expectorated some blood, but not so much as on previous occasions.

At this date there was "dulness on the left side anteriorly to the mamma, with high-pitched bronchial breath-sound, pectoriloquy, and cavernous cough; sounds very dry; some crepitus at the angle of left scapula." The oil was repeated, and an alkaline bitter ordered, with small doses of iodide of potassium. He again improved, having only one slight attack of hæmoptysis in November; and at Christmas, having an in-patient letter, was admitted into the Hospital under the care of Dr. Pollock, who confirmed the accuracy of the signs as above described. He only remained in a month, however, during which time I saw him on several occasions, and cautioned him against displaying so much energy in doing the most trivial thing, and in coughing with such unnecessary violence. He had no appreciable expectoration, and left the Hospital feeling well.

I did not see him again until August, 1870, when, having remained quite well and at work until the previous Wednesday, he expectorated half an ounce of blood. The physical signs were still limited to the left apex, where there was dulness, bronchial respiration, crepitus, and friction (creaking pleura), and a whiffling murmur, systolic, audible in infra-clavicular region, continuous from subclavian not from pulmonary artery region (and no doubt conducted subclavian murmur). He ceased attendance in October, and continued pretty well until March 4, 1871, when he again attended with hæmoptysis, and was seen by my colleague, Dr. C. T. Williams, in my absence, who ordered gallic acid immediately, and directed him to send in three days' time. With his usual imprudence he attended personally on March 8, having come from Battersea, though still spitting blood freely, and brought up a considerable quantity in the out-patient room. I prescribed \mathfrak{mxx} . of ergot every two hours for twelve doses, and ordered *emp. lyttæ*, four inches by four, to the left infra-clavicular region. This attack proved the most prolonged and desperate one he had yet had, and nearly terminated fatally.

March 11.—Wife attended; hæmoptysis still continues; brought up half a pint of blood this morning at 2 a.m. Ordered six \mathfrak{ss} . powders of gallic acid, one to be taken directly, and one-third (gr. x.) every two hours, with morphia linctus to allay the cough, and a brisk purge.

15th.—Hæmoptysis continues in a less degree. A mixture containing nitro-muriatic acid with glycerine and ipecacuanha (which I have found of great service at the close of an attack of hæmoptysis) ordered, and some more powders and purgative.

On the 22nd he had had three more attacks of copious hæmoptysis three days previously, and was extremely exhausted by the continual loss of blood. Sulphate of iron and alum were prescribed.

29th.—"Hæmoptysis half a pint yesterday; same amount to-day." \mathfrak{ss} . doses of gallic acid ordered every four hours for six doses.

On the 30th, *mist. acid. sulph. co. 3tis horis; pil. plumb. c. opio gr. v., nocte maneque; iodine paint under left clavicle.* From this date the violence of the attacks much abated—I should imagine rather from lack of blood-supply than from the efficacy of the remedies used, which, however, were steadily continued until April 13, when he had had no hæmoptysis in quantity for a week.

On April 20 some small doses of cod-liver oil were ordered and the acid ipecacuanha mixture, with a little morphia. He had no more hæmoptysis after this, and again attended personally, though with great difficulty, from his extreme weakness, on May 4. At this date there was noted at the left apex "retraction of lung, dulness, cavernous respiration, and rhonchus (slight)." Posteriorly there was "diffused crepitation, with some defective resonance." This was the first occasion on which the lung had appeared to suffer from the effects of the hæmoptysis. The cough was troublesome, especially in the morning, and on the 11th he was ordered ether and ammonia expectorant in the morning, lest his violent and unaided efforts at expectorating should lead to a reopening of the broken arterial branch or possible aneurism, which seemed to have

been the only conceivable source of such profuse and repeated hæmorrhage. It was extraordinary to note the rapidity with which the patient regained flesh, strength, and colour, though butchers' meat was only allowed every other day, stimulants were cut off, and abundance of milk alone permitted. He continued to take mineral acids and oil \mathfrak{zj} . a day. He did not at all approve of this diet, but, from previous experience of his rapid blood-making qualities, I was convinced that a more generous regimen would have led to a return of the hæmorrhage.

On June 29, having only (on the 8th) had one comparatively slight attack of hæmoptysis, the physical signs showed enlargement of the right lung, the margin of which reached across the median line; still some irritative bronchitis at the left base, indicated by diffused submucous râles. Compound iodine ointment frictions ordered.

Beyond an occasional tinge of the morning expectoration he has had no more hæmoptysis up to the present time, and has returned almost to his usual health, though the breath is shorter. Since June he has taken no oil; some digitalis was added to his mixture for a few weeks; and the diet has continued restricted, though less so of late.

This case, the great length of which demands some apology to my readers, is one of extreme interest to me, as exemplifying well what I believe to be the main features of recurrent hæmoptysis, viz.:—1. Repeated copious hæmorrhages obviously arising from disease localised at one portion of the lung. 2. Pulmonary disease, chronic in its course, and but little influenced directly by the hæmoptysis, which is accompanied by no severe fever or secondary pneumonia, and from which the patient frequently makes a speedy recovery, though it may prove directly fatal. The pathological condition common, I believe, to all these cases of recurrent hæmoptysis, is that of a slowly formed cavity, or one formed by a very localised process of an active character, in the walls of which pulmonary vessels still patent are exposed. It will be observed that the case above described did not begin with hæmoptysis; the man had had some dry cough and occasional streaky hæmoptysis for some years previously, and a few days after the first considerable hæmoptysis a vomica was found at the left apex, where some two months previously there was consolidation and softening. But the vomica need not be of "tubercular" origin—*e.g.*, a soldier has been under my care at Brompton for the last fourteen months, who, in March, 1869, while blowing the clarionet, in India, was seized with hæmoptysis to the amount of about a quarter of a pint, which did not quite cease for about a week. A month or six weeks later, after having suffered for four or five days from severe pain and oppression in the right infra-mammary region, he suddenly brought up about a pint of "corruption" and some more blood, and since that time he has had hæmoptysis every few weeks. Since he has been under my notice, the attacks of hæmoptysis have usually been preceded by severe oppressive pain in right mammary region. The pulmonary disease is mainly at the base or rather the middle of the right lung, there being scattered moist crepitation over the lung, with dulness, most marked at the base. Within the angle of the scapula, and also at the corresponding point in front, opposite the fourth rib, tubular respiration with some large click is heard. This case appears, then, to have begun with abscess in the lung—whether secondary to pulmonary apoplexy or not it would be difficult to say—which has probably left behind a chronic deep-seated cavity. (a) The patient, Thomas W., whose case is above related, has never appeared to be febrile, and during the short time he was in the Hospital, on one occasion when he had hæmoptysis, though to a much less degree than usual—*viz.*, one ounce—my friend, Mr. Bartlett, the Assistant Medical Officer, found his temperature to be normal. In two other men now under my care as out-patients, who, while in the Hospital, suffered from severe hæmoptysis, this same gentleman found no elevation of temperature—*e.g.*, one case, James A., a stonemason (who had previously been under my care for some time with a vomica at the base of the lung, and induration at the apex, and who had several times had copious hæmoptysis while in the Hospital under Dr. Quain) on November 14 brought up half a pint of blood at 10 a.m., repeated half a pint at 7.30, temperature 97.8°; 10 p.m. four ounces, temperature 99.2°. 15th.—10 a.m., temperature 98.8°; 5 p.m., temperature 98.2°, hæmoptysis three-quarters of a pint half an hour before; 7 p.m. and 9 p.m., temperature 98.2°. He had no more hæmoptysis, and the temperature (taken twice daily by Mr. Bartlett, up to the 21st) never

(a) He was discharged from the army, from Netley Hospital, with "abscess of the liver and phthisis."

rose above 98.4°. The physical signs were not altered, and the patient rapidly improved in general health.

The danger in these cases is from the abundance of the hæmorrhage, which in a great number is the cause of immediate death on the first occasion. It is surprising this should not be so in almost all, (b) and nothing is more striking than the recovery of some patients from (apparently) the most hopelessly profuse hæmoptysis, nature apparently seizing the moment when, from faintness, the blood is at a standstill to heal the breach by the formation of a coagulum. Hence the importance of withholding all stimulants till the latest moment. Rokitansky refers to another mode of arrest of the hæmorrhage from a large vessel in a cavity—viz., by the cavity becoming blocked by coagulum, which thus compresses the vessel. I have seen an instance, post-mortem, in which the apex of the right lung was converted into a blood-cyst, quite closed, as large as a lemon, which had been produced by hæmorrhage into a cavity.

In the form of hæmoptysis now under consideration, besides the general principles of absolute muscular rest, etc., before referred to, we must be more diligent with astringents and remedies which control the heart's action and allay cough: ergot acting upon the muscular walls of the arteries, digitalis diminishing the frequency of the heart's action, and opium lessening excitement and allaying cough, are of the greatest value. Ipecacuanha emetics, admissible in certain cases of primary hæmoptysis, would be certainly harmful in these. Our object is to allow the blood to coagulate at the seat of rupture, and faintness short of actual syncope should be encouraged, rather than prevented by stimulants. Nauseant remedies, however, from their relaxing effects on the vessels, are inadmissible. Interrupted cold applications to the chest may be tried in these cases more usefully, I think, than in those in which the hæmorrhage is capillary.

With reference to prophylactic treatment, patients the subjects of phthisis (particularly with chronic cavities) should be cautioned against muscular efforts, such as running upstairs or walking fast. The experiments of Colin (c) show that on exertion the pressure of blood in the pulmonary artery increases in greater ratio than that in the aorta. In those patients, too, who are gifted with rapid blood-making powers, and who pick up flesh with great rapidity after hæmoptysis, a timely partial abstention from butchers' meat, and the complete withdrawal of stimulants, may ward off or postpone the next attack.

Having dwelt at considerable length upon two classes of cases in which copious hæmoptysis is a very prominent and important symptom—in the one class because it is the first symptom, and, though never directly fatal, is yet often attended with secondary results which endanger the life of the patient; in the other, because the hæmorrhage is always extremely dangerous, and may at any time prove directly fatal, while its secondary results are, as a rule, trivial, and but slightly influence the progress of the disease, which is usually one of the very chronic forms of phthisis—we must not omit to point out, for fear of misconception, that the cases which constitute these two classes are few and exceptional. Hæmoptysis, as a rule, whether very slight or moderately copious, is a merely casual, though very important symptom, in the course of phthisis.

I must, in conclusion, further state it as my firm conviction, that, take hæmoptysis from what point of view we may, its genuine occurrence in any degree beyond a mere streak in the expectoration is a symptom the gravity of which has not been in the least exaggerated by the much-abused Laennec and others of equal experience—i.e., so far as it is significant of positive disease—in the enormous majority of cases. (d) Putting the matter in the most practical form, I presume there are very few Physicians who would venture to consider a candidate for life assurance as a "good life" who had the history of a distinct attack of hæmoptysis. But, on the other hand, by fully recognising the gravity of this symptom, and by, at the same time, bearing in mind the often-proved results attained by due pre-

(b) In cases of fatal hæmoptysis, with very few exceptions, aneurism or erosion of a branch of the pulmonary artery has been found post-mortem at the Brompton Hospital. In some of these cases there had been previous attacks of hæmoptysis of the same character as the fatal one, while in several of them other vessels were found broken across, and occluded only at the very points of the fragments. Other observers (notably Dr. Rasmussen) have insisted on the frequency of pulmonary aneurisms in fatal hæmoptysis.

(c) *Compte-Rendus*, p. 759, 1864.

(d) Having redistributed the many diseases collected together by Laennec under his comprehensive term "tubercle," we must beware lest, in our criticism of the symptoms attached by Laennec to the disease tubercle, we do not make sufficient allowance for our very restricted use of that term.

cautions and improved treatment, we may justly give that very decided and conditionally hopeful advice which is most likely to meet with obedience and to be followed by corresponding success.

(To be continued.)

NOTES ON INHALATION, FOMENTATION, DISINFECTION, Etc., WITH MEDICATED STEAM AND VAPOUR

By J. WILLIAMS, M.D.

IN general practice we meet with numerous throat and chest affections, and also some forms of neuralgia, where urgent symptoms seem to require the use of some local agent acting more directly upon the parts affected than the ordinary administration of drugs by the stomach can possibly do. The difficulty is increased where inability to swallow is added to the other symptoms of the case, and makes it next to impossible to introduce any internal medicines. In quinsy, common relaxed throat, inflamed tonsils, some cases of diphtheria, laryngeal, tracheal, and bronchial affections, as well as in ulcerations of the pharynx, etc., this mode of medication by inhalation is peculiarly effectual. In numerous asthmatic and pulmonary affections, with deficiency of secretion from the mucous lining, I have seen more benefit derived by the plan of local medication than by any medicines given in the usual way.

It will be quite evident, upon consideration, that expectorants—such as squills, ipecacuanha, lobelia, digitalis, antimony, and other drugs—must, even after elaboration with the food, produce nausea, with loss of appetite, even if we wait for their arrival by the circuitous route of the circulation of the blood to the part affected. Moreover, when it is considered that Majendie established by undoubted evidence and experiment the fact that medicated gases and atmospheres produced, when inhaled, very rapid and certain effects upon the blood, and can be detected in many instances in that fluid, after even one inspiration, it seems remarkable that the Profession should not have availed themselves more extensively than they have hitherto done of the avenue thus existing for the introduction of medicines into the system.

The knowledge of these facts has induced me to make numerous experiments with medicated vapours; but with the ordinary inhaler I have found that in the use of hot water (either simple or medicated), without a lamp to sustain the heat, the vapour or essence very quickly subsides as the fluid cools down; and, as a matter of course, this takes place more rapidly in winter (which is the time it is most required, as a rule) than in warmer weather. The use of atomised fluids, as described by Beigel in his excellent treatise, appears to me also a very partial application of the remedies in many of these local affections, especially those of the air-tubes and pulmonary tissues themselves, though I do not for a moment undervalue his system for purely pharyngeal and laryngeal complaints.

A more complete investigation of the subject has enabled me to construct an inhaler, with a lamp, which fulfils nearly every possible requirement for all parts which we have mentioned, and certainly combines many points of importance unattainable by any other system with which I am acquainted. My invention enables the Practitioner to introduce nearly all the substances and fluids which could be given by the atomiser, and at the same time continues the inhalation of all vapours and medications at a uniform heat to the lungs and breathing surface, fomenting, as it were, the whole mucous lining of the air passages, which has a very important and soothing influence. The influence upon the nervous system is equally certain in spasmodic cough; and in nervous asthma, especially, the action is very striking and satisfactory. I may mention that volatile substances, such as camphor, carbolic acid, hyssop, anthemis, etc., are peculiarly efficacious and agreeable when introduced in the form of vapour, which, by the arrangement I have proposed, does not in any way interfere with the digestive organs. In fact, if any doubt could possibly exist as to the action of medicated inhalations upon the system, the common daily use of chloroform, nitrous oxide, methylene, etc., would answer the question in the affirmative. Besides, the introduction of poisonous gases—hydrocyanic and carbonic acid—are well known to be rapidly fatal in this mode of administration; therefore, by a parity of

reasoning, we may assume that the introduction of vaporised medications must, if pursued and investigated, become an extremely valuable means for the introduction of numerous medicines into the human body.

In localised neuralgia, face-ache, ear-ache, etc., a jet of steam directed against the part affected gives almost instantaneous relief, entirely superseding fomentations, mustard, and other burning plasters: these latter remedies, in many instances (in my own experience), serve only to increase the original pain. After the action of the steam-jet, the part affected may be gently rubbed with chloroform, aconite, or camphor liniment, to prevent undue action upon the skin by damp, cold air, etc.

As a disinfecting and fumigating agent I find this lamp superior to all other means, as the chemicals are converted into subtle vapour, which seems instantly to destroy unpleasant odours in the sick-room, and in a far more perfect manner than by sprinkling the fluids or powders about the room.

Directions for Using the Inhaler or Fomenting-Lamp.

Having first fixed the wick in the lamp, pour into it about an inch deep of methylated spirit; then in the pan over the flame place about half a tumbler of warm water, and in the perforated plate a few herbs, such as hyssop, senega, camomile, pennyroyal, etc. These may be used several times without renewing. The apparatus now being ready for use, light the spirit-lamp, and as soon as the water boils a stream of medicated steam will issue from the spout. As the steam would be too hot next the spout, it is better to use a tin or paper tube, expanding to about two inches at the open end. This tube has holes in it to allow the atmosphere to mix with the steam. By this arrangement, and by turning the holes round, the temperature may be very nicely regulated. As the

Lamp-inhaler, made by Mr. Sparkes, Malvern.

steam ascends rapidly, the open end must be held below the mouth or part to be acted upon, and at a little distance from it. A folded piece of paper from the tube resting on the nose, or a loosely rolled tube in the mouth, in some cases is an extra advantage, and excludes the vapour from the eyes, if desired; but in many cases it is of most service when inhaled rather hot. In using carbolic acid and some other ingredients it is better to add them to the water before applying the lamp-flame to it. The tube used for conveying the steam has holes in it; these should be turned round to the lower side, but, if too hot, brought half round, and if required still cooler, to the upper side.

Malvern.

ON A CASE OF

SUPPURATING BUBOES WITH DIFFERENT PLANS OF TREATMENT.

By ALFRED S. BOSTOCK, M.R.C.S.

SUPPURATING buboes being of so common occurrence, I thought the notes of the following case might be interesting to the readers of the *Medical Times and Gazette* :—

A coolie woman was admitted by me into the Colonial Hospital, Trinidad—when I had charge—with a suppurating bubo in each groin.

On May 16 I opened one of the buboes with a curved bistoury, and as I knew by that process buboes were a long time in healing, I determined to try another plan on the other side; therefore, on May 19, I opened the other bubo with a trochar and canula, and by that means evacuated the contents; then I injected a solution of sulphate of zinc, gr. iv. ad. ʒj., and put on pressure with some lint in the form of a pad covered with a bandage. On the following morning there was occasion for an aperient, and the ordinary black draught was administered.

May 21.—I removed the dressing, and found some very thin purulent secretion, which I pressed from the bubo by the aperture made when removing the canula. I then replaced the bandage over a fresh pad of lint. There was no complaint of pain during this treatment.

24th.—The bubo opened with the trochar was quite healed up. The other bubo was looking very healthy.

26th.—On pressing the bubo a thin serous-looking fluid came out at the opening left by the canula.

28th.—The bubo was quite healed. So that this bubo healed in nine days; whereas the bubo which I had laid open with the bistoury was not healed until July 4, taking in all fifty days.

Midhurst.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

THE LONDON HOSPITAL.

SYPHILIS INOCULATED ON THE HAND, BY SCRATCHING THE KNUCKLE AGAINST AN OPPONENT'S TOOTH.

(Under the care of Mr. HUTCHINSON.)

WE saw the other day a remarkable case under Mr. Hutchinson's care, illustrating one of the many unusual modes in which syphilis may be acquired.

The patient, a policeman, aged about 30, at present has a very copious secondary syphilitic eruption of the mixed tubercular and squamous types, and in some parts, especially on the lower extremities, tends to become rupial. He states that it has been out for about five weeks. He denies having had any sore on the usual position, and a careful examination of his genitals convinced Mr. Hutchinson that no trace of a chancre existed there; and the same remark applies to his mouth and lips. There are no enlarged inguinal glands. On searching for a chancre in other parts, Mr. Hutchinson found an open sore on the dorsal surface of his right middle finger, near to the metacarpophalangeal joint; it is now of irregular shape, about as large as a fourpenny-piece, and does not present any induration characteristic of syphilis. He was also found to have a bullet-like enlargement of the axillary glands on the same side. On being questioned as to the origin of the sore on the finger, he stated that it originated in a scratch made by the tooth of another man, whom he struck in the mouth with his closed fist while taking him prisoner; this was about three months ago. He noticed that he made the man's mouth bleed a little, but cannot say whether there were any sores about his mouth or lips. The scratch on his finger bled slightly at the time. It healed up, but remained for some time (as he expressed it voluntarily) "a hard substance," and red; it then ulcerated. The sore is now rapidly healing.

Anyone interested in seeing the man will be able to do so on Monday next (11th inst.), when Mr. Hutchinson will give a clinical lecture on the case, at two o'clock.

UNIVERSITY COLLEGE HOSPITAL.

TWO RARE FORMS OF SYPHILIS; ONE TREATED BY IODIDE OF AMMONIUM, THE OTHER BY IODIDE OF POTASH.

(Under the care of Mr. BERKELEY HILL.)

Case 1.—A lad of 17 had had for years pains in his shins, and for months similar pains in his elbows and collar-bones, worst at night, when they often kept him awake; they were represented as an aching and a sense of weakness in his legs by day. His parents being dead, no history of the lad's infancy could be obtained, but the corneæ had opacities, the irides were irregular, the bridge of the nose sunken, and there were scars along the neck, beneath the jaws, where he said he had had abscesses when a boy. The teeth were of normal shape. Though soft nodes were present on the clavicles and ulnæ, the most remarkable alteration existed in the tibiæ. These were bowed forwards in a regular sweep from the knee to the ankle, the curve being partly due to actual bending of the bones, but chiefly to

thickening of the periosteum along the shins. The epiphyses were not enlarged, nor the joints distorted. The lad had been treated for scrofula, with iodide of iron, cod-liver oil, etc., without benefit, and iodide of potash, it was said, had been tried in vain. This being so, he was ordered to take iodide of ammonium in eight-grain doses three times daily. This was followed by improvement; the pain soon left, and in a fortnight the soft nodes had almost subsided. Since then the lad has grown strong and active, though the tibiae are, of course, still distorted.

Case 2.—The next case is that of a boy, aged 8, who came to the Hospital with aphthæ of the mouth, superficial ulceration of the gums, and a deep sinuous ulcer along the dorsum of the tongue, which was lined with dirty sloughy matter. The boy was ill-fed, thin, and pale; he had also severe photophobia. The corneæ were muddy, the conjunctival vessels enlarged, but no more decided traces of corneitis were detected. The teeth, nose, and complexion had no syphilitic character, and the mother said his infancy had been healthy. As the lad's condition might be due to debility and starvation, though the probability of a syphilitic origin was not forgotten, the lad was first treated on general principles. The ulcers were touched with strong solution of nitrate of silver; a wash of chloralum gr. x. ad. ʒj.) for the mouth, and quinine with iron, cod-liver oil, and nutritious diet were ordered. Ten days elapsed while this treatment was continued, and though the mouth got cleaner, the ulcer of the tongue had enlarged; the eyes remained pretty much the same; iodide of potash in four-grain doses was then given, and all the other remedies abandoned. At his next visit, four days afterwards, the tongue was healing, much less swollen, the soreness gone, and the boy's appearance somewhat better, though the photophobia continued. Five grains were this time given, and in ten days after the iodide had been commenced the tongue was well. The eyes, however, had advanced; iritis and increased opacity of the corneæ were evident; for this special treatment was directed, while the iodide was continued.

WEST LONDON HOSPITAL.

COMPOUND FRACTURE OF THE ANKLE-JOINT—AMPUTATION—RECOVERY.

(Under the care of Mr. TEEVAN.)

J. D., aged 48, a healthy-looking man, following the occupation of stationer, was admitted into the Hospital at 7 p.m., August 5, with a compound fracture of the right ankle-joint, which occurred through missing his footing in descending from the roof of an omnibus. On admission the patient was found to have a good pulse, which probably might be accounted for by the little blood that was lost, but the foot was almost at right angles to the leg, and the ankle-joint was exposed on the inner side by a crescentic wound four inches long; the internal lateral ligament, the anterior one, and posterior also seemed quite destroyed, so that the foot appeared attached to the leg by the integument and external lateral ligament only. The patient was seen by Mr. Teevan the same evening at 10 p.m., and as he had completely rallied, Mr. Teevan removed the foot just above the ankle-joint, making a long anterior flap and a short posterior, utilising the crescentic wound on the inside. Very little blood was lost at the operation, as the tissues had been extensively ruptured subcutaneously. The after-progress of the case was uninterrupted by a single drawback, and in the first week of September the wound was quite healed, and the patient left the Hospital a few days later with a good firm stump that was even then able to sustain pressure. The line of cicatrix was almost removed from the face of the stump, as its covering was entirely made up of the long anterior skin-flap.

An examination of the foot showed that all the ligaments at the ankle-joint were destroyed, with the exception of the middle piece of the external lateral; the lower end of the fibula was broken up into six pieces.

INJURY TO FOOT—CHOPART'S OPERATION—RECOVERY.

(Under the care of Mr. TEEVAN.)

D. H., a pale, unhealthy-looking labourer, aged 20, was admitted into the Hospital, on February 2, for an injury he had sustained to the anterior part of his left foot, which had been crushed a few days before by an engine. When he was seen by Mr. Teevan, on February 4, there was such an amount of local and constitutional disturbance as to entirely

preclude any operative procedure. The skin and nails had been torn off the great-toe and the two adjoining toes, the metatarsal bones of all the toes except the little one had been fractured in several places, and the tendon of the extensor pollicis had been torn off at its insertion, and for several inches exposed. The whole of the foot was much swollen, and the integuments over the instep looked tense and inflamed. As the patient was suffering from irritative fever, Mr. Teevan ordered his bowels to be well opened, and to have full doses of chloral given him every night. On February 15, the skin over the great-toe and up to the middle of the metatarsal bone had become gangrenous, and in the course of a week had involved the other toes, with the exception of the little one. The patient's constitutional condition, however, had been slowly improving, his pulse had become quiet, and his tongue had nearly lost its brown appearance; his nights, too, were good. By March 2 it was clear that the healthy integuments were becoming separated from the gangrenous, by a distinct line of demarcation across the highest part of the instep.

On March 9 Mr. Teevan amputated the foot by Chopart's method, the patient being under chloroform. The integuments were considerably infiltrated, and there was very free bleeding from the surfaces of the flaps, which was checked by firm bandaging. On the following day the flaps were united at their edges by the silver wires which had been passed through at the time of operation. The sutures were allowed to remain in for nearly a fortnight, as there was much swelling of the stump and a tendency to eversion of the lips of the wound. The patient's convalescence was slow, and when he left the Hospital on April 20 there was still a narrow line across the face of the stump which had not healed. Ten days later cicatrization was complete. The face of the stump was made up almost entirely of the posterior flap.

Remarks on both Cases.—Mr. Teevan stated that one great object to be attained in this kind of operations was, so to fashion the flaps that when union had taken place the line of cicatrization should not, if possible, be on the face of the stump, but removed either forwards or backwards. In both cases that object had been carried out; for in the first case the line of union had been carried to the posterior edge, and in the second it had been brought forward to the anterior edge.

EDINBURGH ROYAL INFIRMARY.

CASE OF FIBROUS POLYPUS OF THE UTERUS—REMOVAL BY EXCISION.

(Under the care of Dr. DUNCAN.)

[Communicated by Dr. J. R. HARDIE.]

A. R., aged 47, married, has had four children—the last child six years ago; never had an abortion or miscarriage. She was admitted into Ward 16, October 16, 1871, complaining of occasional pain in the lower part of the belly, a discharge (which she described as being generally red, but sometimes white in colour), and difficulty in walking. Patient enjoyed good health until four years ago, when her present illness commenced. She first became aware that there was something wrong with her on noticing that at the monthly periods she lost more blood than usual. The periods, however, were not more than a week in length, which was the ordinary duration of her natural illness. Previous to this circumstance her menstruation had been regular and healthy in every other respect. About two years ago A. R. began to be subject to a white discharge during the interval between her monthly periods. This has gradually become greater in quantity, and is frequently replaced by a red-coloured discharge. On physical examination per vaginam, the vaginal canal was found to be occupied by a hard, smooth, rounded mass, about the size of an orange of ordinary dimensions. It protruded through the cervix uteri, which was dilated around it. A pedicle was observed to pass from the tumour through the dilated cervix uteri into the cavity of the body of the uterus.

October 26.—It was decided to remove the polypus to-day. For this purpose the patient was placed on her left side on a conveniently high table, and Dr. Duncan, seizing the polypus by means of a volsella, cut through the pedicle with a pair of strong curved probe-pointed scissors. The volsella was entrusted to an assistant, who pulled on the tumour downwards in order to bring its pedicle within reach of the operator. The polypus was, however, not pulled down beyond the orifice of the vagina. There was little bleeding. Before performing this operation, the probe was introduced into the uterus. It was observed to pass three inches and a half. Immediately

after the removal of the polypus—on examination per vaginam—the uterus was found to be occupied by a fibrous tumour.

27th.—Patient passed a good night, and has had no bleeding; she had a slight discharge on rising to make water.

30th.—Uterus feels large; probe enters three inches and a half

November 5.—Discharged to day.

Of the various kinds of polypi which affect the uterus, the fibrous polypus is the most important. It more than any other variety renders the subject of it liable to depraved health. From the hæmorrhage and leucorrhœa which its presence for any lengthened period entails, the patient gradually becomes exhausted, or a fatal issue may ensue from a more than ordinary large bleeding. In some cases, however, fibrous polypi give rise to no symptoms whatever; their presence may be unsuspected by the patients themselves, and they may be detected by the Physician while conducting an examination for other purposes. Dr. Duncan recognises two varieties of the ordinary fibrous polypus—the true and the false. The former possesses an external investment of mucous membrane identical with that lining the cavity of the body of the uterus; within this is a covering of muscular tissue. Occasionally this second envelope cannot be detected over the whole surface of the true fibrous polypus. The latter, or false fibrous polypus, Dr. Duncan considers to be merely a fibrous tumour which is undergoing the process of spontaneous enucleation; it has, therefore, no covering of mucous membrane, and is attached to the uterus by muscular tissue. Excision is the method of removal almost invariably employed by Dr. Duncan. Contrasted with other modes, it is at once simpler, more efficient, and attended with less risk to the patient. Hæmorrhage after this operation is very rare—it scarcely ever occurs immediately after the excision, certainly not to any great extent—but an oozing of blood some hours afterwards is not so uncommon; this is readily arrested by the local application of the perchloride of iron. The results of this operation are highly satisfactory. In cases where the polypi are very large, and require a great degree of force to be used in order to extract them from the genital passages, there is danger to the person operated upon; but in the great majority of cases of polypus of ordinary size removed in this manner, the risk to life is very small, the patient being able to go about in a week or ten days afterwards. In the case described, although the uterus contained one or more fibrous tumours, A. R. was out of bed on the fifth day, and proceeded home—a considerable distance by rail and steamboat—nine days after the operation. An independent feature of the case under discussion—namely, the presence in the uterus of fibrous tumours—is worthy of remark as illustrating incidentally the great value of the uterine sound to gynæcologists. Their presence was suspected while Dr. Duncan was perfecting his diagnosis by introducing the sound: it was observed to enter three inches and a half—a greater length than it would be expected to pass if the hypertrophy of the uterus was solely owing to the presence of the polypus. Subsequent internal and external examination by the finger and hand revealed the presence of the fibroid. In this case the Physician was enabled to warn the patient that her cure was not complete, and to desire her to return again in order to ascertain if one or more of the tumours might not be removed by enucleation or otherwise.

ANTIDOTE TO CARBOLIC ACID.—Dr. T. Hasemann, from numerous careful experiments, both chemical and medicinal, advocates the use of a strong solution of saccharate of lime, of course to be taken as soon as possible.

THE LATE MR. DE LA GARDE.—At the last monthly meeting of the Committee of the West of England Eye Infirmary the following resolution was passed:—"The Committee desire to record their sense of the great loss which the Eye Infirmary has sustained in the demise of its Senior Surgeon, Mr. P. C. De la Garde, F.R.C.S. His devotion to its interests continued to the latest moment of his life. His eminently skilful treatment of diseases of the eye, and his anxious solicitude for the welfare of the patients, to whom his kindness of manner greatly endeared him, combined, during the long period of thirty-five years, to render Mr. De la Garde a most valuable officer to this institution. His death is felt by the Committee to be an event that calls for an expression, on their part, of sincere regret at their loss, and at the same time of their cherished recollection of his eminent services to this Infirmary."

SATURDAY, DECEMBER 9, 1871.

THE ILLNESS OF H.R.H. THE PRINCE OF WALES.

THE Prince of Wales is now in the fourth week of the severe attack of typhoid fever under which he is labouring. Professional readers will know that this is necessarily a period of great anxiety. It is about the time when any sloughs which have formed during the ulcerative process in the intestinal mucous membrane are separating, and when, therefore, two of the great dangers in typhoid fever—hæmorrhage and perforation—are most to be dreaded. Still, it is most satisfactory to know that the Prince is thus far progressing favourably, and is certainly in a much better condition than he was on Thursday and Friday last week. On the latter day his temperature rose to 105.6°, and his condition was undoubtedly very grave. In a few hours, however, the temperature again fell, and it has since remained at a much lower standard, falling in the morning below 100°, but rising towards night. The pulse averages about 96 in the minute. Notwithstanding all the enormous drain on his constitutional powers, however, it is gratifying to be able to state that the Prince's strength continues good. Of course, he is still very ill; the functions of the sensorium are not fully restored, and days, if not weeks, must elapse before he can be pronounced out of danger. But, considering that his Royal Highness has thus far withstood the brunt of the attack, that he has an excellent constitution, fortified by an active life of out-door exercise, and that this week there has been a decided and progressive amelioration in his worst symptoms, we are warranted in affirming that the prognosis is decidedly favourable.

The proof that the fever was contracted during the Prince's stay at the Earl of Londesborough's receives further confirmation from the fact that a man-servant, who was in Lord Londesborough's house during the Prince's visit, is now in London suffering from typhoid fever. It is easy to conceive that the very means taken to insure the perfect salubrity of the house may have led to a temporary escape of sewage matters. It would not be the first time that having the drains of a house put to rights has been followed by an outbreak of enteric fever. The Profession and public will hardly be satisfied with the report of the architects on the condition of Lord Londesborough's house. To us it appears very unsatisfactory. It would be to the interest of Lord Londesborough to have a searching investigation made under the direction of the Medical Department of the Privy Council. The suspicion that the fever was contracted in his house almost amounts to a certainty.

Three adults, in perfect health, who were visiting there, were simultaneously attacked, and there can be no reasonable doubt that they were exposed to one and the same cause.

The Earl of Chesterfield died, most probably, from perforation of the bowels. Up to the day of his death he was progressing most favourably—his pulse was quiet, and his temperature not much above 100°; when suddenly his temperature rose three or four degrees, the abdomen became tympanitic and meteorised, profuse perspiration supervened, and he died in two or three hours. As there was no post-mortem examination, and no alvine evacuation, it is uncertain whether there had been internal hæmorrhage. The character and sudden accession of the symptoms pointed to perforation.

In reference to the illness of his Royal Highness, we may remark that his chances were doubtless much improved by the careful Medical treatment to which he had been subjected when suffering, during the week previous to the accession of fever, from suppurating whitlow, which threatened to attack both hands. The attack of shivering which ushered in the fever commenced on November 13, but for a week previously he had been under Medical guidance.

A remarkable fact in proof of the fæcal origin of typhoid fever has lately been observed. An eminent London Physician has been called to visit in consultation the inmates of a religious house, forty-two of whom have been struck down with typhoid fever since November 1. The cause of this outbreak was traced to a drain which had been opened up, and a grating fixed in it, to prevent rats making their way into the house. The result was that all the solid excrementitious matter was kept back, and accumulated in the basement of the building and yard, and there was distinct leakage into the house. Sixty baskets of sewage were removed from the house side of the grating, and in close proximity to it was a well which supplied the house.

The groom at Sandringham who has been suffering from typhoid fever came there direct from Scotland on October 20, and was not at Scarborough with his Royal Highness. On November 24 he had rigors for the first time. On the 25th rose-spots were present. He had severe symptoms at the commencement, but has steadily improved, and is going on well. There have been no other cases at Sandringham besides those of the Prince and the groom in question.

PROFESSOR LAYCOCK'S LECTURES.

In our first volume for 1862, we had the pleasure of publishing an important series of lectures on "Physiognomical Diagnosis," by Dr. Laycock, Professor of the Practice of Medicine in the University of Edinburgh. During the current year it has been, further, our good fortune to publish another series of Dr. Laycock's lectures, comprising the "Method of Clinical Observation of Diseases of the Nervous System," and "Systematic and Practical Consideration of the Influence of the Nervous System on Diseases of Organs and Tissues." These, and minor contributions which have at intervals appeared in our columns, embrace a variety of views so original and suggestive, and of such high importance to the Profession and to the Practice of Medicine, as to merit special consideration.

The first and most important point is the method by which Dr. Laycock has worked out his views. Careful clinical observation has led the Professor to the conclusion that diseased states of organs and tissues are reversion or degenerations to a lower form of evolution of tissues and organs. Hence, the principle of evolution may be said to be the key to his pathology—from mental derangements at the one extreme, to the production of uric and lactic acid at the other.

It is right to observe, however, that this method has been followed by Dr. Laycock long before the recent discussions as to evolution, to which the promulgation of the Darwinian doctrines has given rise. It may be traced in Dr. Laycock's

earliest works—as, for example, in his treatise on the "Nervous Diseases of Women," published in 1840. His early doctrines regarding the reflex function of the brain are specifically founded upon the doctrine of evolution. His lectures on "Physiognomical Diagnosis," published in our journal in 1862, afford numerous illustrations of this point. We specially refer to the lectures on the "Degenerations of the Nervous System, and the Definition of the Strumous Diathesis." In these will be found illustrations of reversion to both lower races of man and lower animals. The doctrines regarding diathetic diseases which Dr. Laycock has introduced into the study of Clinical Medicine differ widely from those current, inasmuch as they are founded on the evolution of tissues and organs, and have, therefore, a solid basis in histological anatomy, instead of merely the course and symptoms of diseases. Thus, for example, when Trousseau speaks of an asthmatic diathesis, referring to a symptom, Dr. Laycock would speak of vesicular emphysema complicated (or not) with pneumogastric hyperæsthesia, in a person of the atheromatous and nervous diathesis. Those who have witnessed Professor Laycock's treatment, as based upon these wide philosophical principles, can testify to the great advantage which therapeutics have derived from their introduction into the clinical practice of Medicine. By a consideration of diathetic principles, medicines formerly administered with great doubt can now be administered less doubtfully, and diseases uncontrollable by ordinary routine treatment more readily succumb to the influence of diathetic remedies. In the exercise of diagnosis, also, Dr. Laycock's intimate knowledge of the physiognomical appearances, based on evolutionary anatomy, which characterise each respective diathesis, combined with a clear understanding of the tissues which are liable to be affected in each, is used by him as an accurate guide to sound and definite conclusions. Former pupils of Dr. Laycock must recall repeated instances of correct diagnosis based exclusively upon such considerations, and amply confirmed by oral, physical, and post-mortem examination. Perhaps the best illustration of this point is the arrangement of the various forms of diathetic phthisis founded on the particular tissue of the lung involved, of which Dr. Laycock is the author. Thus, the rheumatic form of consumption is that in which there is the greatest tendency to fibroid degeneration of the parenchyma of the lung.^(a) This has since been discussed under the name of "fibroid phthisis." Not less important is his diathetic diagnosis of pulmonary hæmorrhages, in which he not only distinguishes rheumatic pulmonary hæmorrhages from other and more dangerous forms, but indicates the influence of the nervous system on the production of pulmonary hæmorrhages and of hæmorrhagic phthisis as a distinct form.

Another important point to which we would direct attention is, the result of Dr. Laycock's method in the classification of skin diseases, according to the tissues affected in each group. Such an arrangement not only simplifies diagnosis, but connects intimately the skin affection with the diathesis which predisposes to its development. Dr. Laycock represents the skin as a complex secreting and excreting viscus, expanded in such a manner as to display its different elements, and associated with structures homologous with protective appendages. He looks upon the pathology of the skin as of special importance, as it may to a certain extent be regarded as a convenient and typical representation of the pathology of other viscera. He bases his classification on the threefold nature of the tissues, which, each or all, may be affected. These are the mucous, vascular, and fibrous or connective, including the muscular tissue. Along with these primary textures he classes the products which have their origin in each. He traces an intimate relation between leprosy, syphilitic affections, and some forms of psoriasis, based upon the diminution in sensibility which characterises each; and upon historical and

(a) See *Medical Times and Gazette*, April 5, 1862, and May 3, 1862, p. 451.

evolutional grounds, which corroborate the existence of such a relationship.

But we must not omit to mention another result of Dr. Laycock's method—namely, the elucidation of physiological laws by clinical research. It is in this way that he has formulated clinically a trophic nervous system. He has called attention to the fact that the unity of function of the trophic system over an extensive and complex series of areas suggests the idea that a trophic centre, or series of centres, must exist for the maintenance of so conspicuous a harmony. He teaches that there are distinct cerebro-spinal centres set aside for the regulation of distinct trophic areas. It must be admitted that this view, applied clinically, not only throws considerable light on many obscure diseases, but dispels various erroneous views. For instance, by demonstrating the direct influence of the nervous system on nutrition, and on the production of diathetic diseases like gout and rheumatism, he shows the true nature of metastasis. Regarded from his point of view, the doctrine of a transference of *materies morbi* from one part of the body to another becomes untenable. An appreciation of the facts that, first, the morbid products are produced in the tissues themselves, and, secondly, that the products in the tissues are due to various conditions of the nerves and nerve-centres, leads to a clear perception of the true nature of metastatic phenomena.

From this point of view the therapeutical doctrine of "elimination" passes into the region of the mystical. This point is particularly illustrated by Dr. Laycock's theory of the causation of dropsies, and the phenomena of so-called "serous metastasis." He has proved by clinical facts that dropsical effusions do not result, as is generally held, merely according to the action of physical laws, but that the nervous system primarily influences the condition of both the capillaries and the lymphatics—thus both causing and inhibiting dropsical effusions. He, therefore, classifies reflex and centric forms of dropsy, which are totally inexplicable except on the principle of nervous causation.

Closely allied

to metastasis is the process of "counter-irritation." Dr. Laycock shows clearly that this involves, not merely a local action, but a trophic alteration, produced by the influence of the central trophic system. Extend to the trophic system the laws of reflex action, and it will be found that influences conveyed to a definite nutrient centre result in a reflex production of those local changes which have been recognised as characteristic of counter-irritation. When sensibility is impaired, counter-irritants sometimes act with great intensity in very brief periods. This depends upon the fact that impairment of sensibility implies to a certain extent a loss of that central energy by which the body resists the inroads of disease.

Guided by the law of evolution, Dr. Laycock works out a still more interesting point in therapeutics. Many years ago the late Dr. Turner, Professor of Chemistry in the University of London, and Sir Robert Christison, made experiments on plants with opium and similar drugs. They showed that a community of influence of the drugs existed as to the tissues of plants and animals. According to Dr. Laycock's method, the motor *vis nervosa* is an evolution of vital energy, manifested in the tissues of plants as well as animals, and the sensory *vis nervosa* is an evolution of the directive and "purposive" qualities also shown in plants as well as in animals—in short, in all living things. Hence it follows that drugs believed to act exclusively on the nervous system, according to Dr. Laycock's views, act also on the tissues. In this way he explains the action of strychnine in certain forms of vesicular emphysema with bronchitis, and refers to colocynth, aloes, senna, wormwood, and camomile as drugs possessing a combined action on the tissues and the nervous system. It is obvious that such a principle must modify all our therapeutical views.

We have not space to dwell on other points, but we may refer briefly to the views promulgated by Dr. Laycock as to the evolution of the trophic nervous system into sensorial centres,

which regulate the appetites for nutrient materials. It is well known to physiologists that plants select suitable nutrient material, independently of a nervous system. In animals, these trophic centres for the appetites direct the selection of suitable materials both in health and disease. Morbid sensorial conditions of these centres, as Dr. Laycock shows, are very well illustrated by the thirst, bulimia, pica, and anorexia manifested in diabetes, hysteria, and numerous other diseases and disorders of the nervous system.

In his concluding lectures (August 19 and September 2), "On a Clinical, Trophic, and Vaso-motor Anatomy of the Brain and Cord," Dr. Laycock, guided by the principle of evolution, develops a complete system of neurotic trophic anatomy. Such a wide view must necessarily have its weak points, and no doubt exception may be taken to details; but as a generalisation of great principles, and of laws applicable to pathology and the diagnosis and treatment of cerebral disease, it cannot fail to be found of great value. We know it has been thus applied to epilepsy and its influence on the development of insanity.

CERTIFICATES OF DEATH.

WHEN the Act for the Registration of Births, Deaths, and Marriages was passed, the Government wisely made the issuing certificates of death a voluntary act on the part of the Medical Practitioner. It was wisely determined not to make the giving of such certificate compulsory, but it was left to the good-feeling and honour of the Profession to assist the Government in the very important subject of registration, without fee or reward. The remarkable success of the Registration Act has sufficiently shown that the Government of the day did not over-estimate the good feeling and honour of the Profession. The refusal to give a certificate of death is so rare, that it is amongst the "curiosities of experience" to find one. There can be no valid or just excuse for such refusal, unless in the case where a coroner's inquest is deemed necessary and is not held. Doubts as to the exact nature of the disease of which the patient died, would not be considered a sufficient bar to the issue of the certificate, though undoubtedly, where

doubts do exist, it would be better for science that a post-mortem examination should be made. But it is to be borne in mind that the Practitioner gives the certificate of the cause of death for which he treated the patient, which treatment he had reasonable and rational grounds for employing. We regret to record a case in which the House-Surgeon of University College Hospital refused a certificate of the cause of death of a woman who died in that institution, because the husband would not allow an examination of the body to be made, though the Surgeon declared that he was unable to determine the precise cause of death without such examination. The consequence was, the body remained unburied, and threatened to be of injury to the living. The man, under these circumstances, applied to Mr. Vaughan, the magistrate of Bow-street, for advice in the matter. The newspapers say that, after hearing the applicant, Mr. Vaughan ordered the Surgeon to attend. He arrived soon after, and explained his reason for not giving the certificate. Mr. Vaughan, after addressing the Surgeon severely, directed him at once to make out a certificate, or a summons would be issued. The Surgeon, the report says, did not think he was responsible, but bowed to the decision of the court, and the certificate was subsequently granted. His Worship observed that this appeared an "important question." Yes, a more important question than Mr. Vaughan probably imagines. We should be glad to know on what authority Mr. Vaughan "ordered" the Surgeon to attend. He had certainly no legal power to do so. He might have respectfully requested his attendance; and if he had refused, does Mr. Vaughan attempt to say that he had the power to compel him? Is Mr. Vaughan aware that the Registration Act is permissive or voluntary, and not compulsory on the part of the Practitioner

to give a certificate of death? We regret that he should have made such a mistake. If this case had occurred in the early career of the Registration Act, it is impossible to over-estimate the mischief it might have done. An understanding had been entered into between the Government and the Profession, that each should assist the other in carrying out an important Act of Parliament, whose only object was the good of the public. It was stipulated that the services rendered by the Profession should be entirely voluntary, and that there should be no legal power to compel them to act. Imagine a Practitioner, under some misapprehension as to the exact meaning of the Act, refusing a certificate; imagine him "ordered" to a police-court, "severely directed" at once to make out a certificate, and threatened with a summons if he did not comply. Fortunately, the Act is now too well established to be injured either by the foolish refusal of a young gentleman to give a certificate, or the more foolish and not less reprehensible conduct of a magistrate, who seems to have been under the conviction that the law enabled him to compel a Practitioner to give a certificate, when, in reality, it could not. But if such cases were to become common—if the example set by Mr. Vaughan should unfortunately be followed by others—then a great blow and discouragement will be given to the working of one of the most valuable and beneficial Acts that was ever passed by the Legislature. It is too much to expect that we should give our time and labour for nothing in the public cause, and that if we believe we have a good reason to refuse to do that work, that refusal should involve an "order" to appear before a police magistrate, to be "severely" rated, and threatened with a "summons" for not doing that which the law does not compel us to do!

MEDICINE AS A LEGAL STUDY.

THERE is one feature in the projected education of lawyers under the New Law Association which has our hearty commendation. We allude to the requirement from a candidate for examination that he shall have attended at least two courses of lectures on MEDICAL JURISPRUDENCE. For a long time this rule has been in force in the Scottish Universities, and has been found to answer well. Every man of any experience in our courts of law must have been occasionally struck with the lamentable want of knowledge displayed by lawyers and advocates in cases involving questions of Medical Jurisprudence. This is more frequently observed in cases of contested wills, and in those of criminal lunacy. The lawyers have, as a rule, taken their stand on what may be called the *litera scripta* of the diseased or disordered condition, as if the symptoms of lunacy were like the laws of the Medes and Persians, unchanged and unchangeable. No greater mistake could be made than to accept this as an axiom. And yet, when the scientific Medical witness gives evidence on those fine partitions which divide "great sense" from "madness," how is he liable to be sneered at! How the rough-and-ready cross-examiner can attempt to ridicule him and abase him in the estimation of the audience! In the vast majority of cases, this unseemly proceeding has had its origin in the absolute ignorance of the advocate of what really constitutes insanity. No doubt, in some instances the Medical witness is to blame, particularly if he fence with plain questions, or attempt to evade the responsibility which he has undertaken. Future lawyer-coroners—for this peculiar kind of judge must still be in existence—will derive great benefit from the new regulations to be enforced; and the more they become acquainted with the subject of jurisprudence in its Medical aspects, the more they will find how vast, how important are the advantages to be derived from it—advantages to science, justice, and public safety. When the new regulations of the Law Association shall have had time to come into full operation, it is to be hoped that the unseemly contests which now so often take place in courts of law between advocates

and Doctors will cease. Nothing can be more derogatory than these combats to both professions. With a profound knowledge of the requirements of the age, and of the means essential to make the lawyer as useful as possible, and law as great a blessing as it can be to society, Sir Roundell Palmer has urged the necessity of the regulations which we have mentioned. He is entitled to the gratitude of his own brethren, and to the commendation of ours.

THE DUTIES OF POOR-LAW MEDICAL OFFICERS.

WE have reason to think that the duties and responsibilities of Poor Law Medical Officers will before long be revised by the Local Government Board.

Our readers are generally acquainted with the duties of the "parish Doctor," and so far as visiting and examining the sick, and prescribing medicine, are concerned, the duty is simple and clearly defined; but upon another point, which we conceive to be of as great or even greater importance—viz., the ordering and regulation of the patient's diet—there is great divergence of opinion and practice amongst the Medical Officers; there is ambiguity in the instructions of the Poor-Law Board; and we believe that the Inspectors under the Local Government Board entertain somewhat different views on the subject. We will first endeavour to explain the view taken by the majority of the District Medical Officers.

In treating of the responsibility of the Medical Officer it is necessary first to distinguish between the cases of patients attending personally at the Dispensary and those attended at their own homes. A patient able to attend personally is first required to obtain a Medical order—signed by the relieving officer, who is expected to make every inquiry necessary to determine whether the applicant is really a pauper. It is the obvious duty of the Medical man, upon receipt of this order, to investigate the Medical aspects of the case, and to prescribe suitable medicine. An important question then arises as to the patient's diet. The usual practice is to make no inquiries on that point, unless the patient (himself or herself) ask for nourishment. In that case, the Doctor is not supposed to order the ordinary and common articles of food—for example, bread, milk, sugar, oatmeal, butter, and tea; he is expected to assume the existence of these necessaries, and, upon that assumption, he proceeds to order such additional medical extras as he may think fit—those extras being generally limited to meat, wine, and spirits, and occasionally eggs, arrowroot, and milk.

We fear that the above-named assumption—viz., the existence of common necessaries—is very often mistaken. Responsibility on that point is generally supposed to rest with the relieving officer; but we think the practice requires to be more definitely settled. That the Local Government Board will take a view of the Medical Officer's responsibility different from the one usually entertained is probable from a circumstance which has come to our knowledge.

Mr. Corbett, Government Inspector, invited representatives from the guardian boards of the metropolis to a conference on Monday last on the subject of out-door relief. Mr. Corbett then submitted a number of propositions to their consideration, and amongst others he proposed that a Medical Officer seeing patients at the Dispensary should not order any kind of food or stimulant, however satisfied he may be of the Medical necessity, without first making a visit to the patient's home, and entering upon a careful inquiry into the means of the patient, in order to satisfy himself that the patient is unable to procure such things at his own expense.

There can be no doubt that the investigation suggested by Mr. Corbett is a necessity; but we deprecate the imposition of such inquiries upon the Medical Officer. The patient, be it remembered, brings to the Medical Officer a certificate that he is a pauper, and therefore presumably unable to procure the

necessaries of life, much more such additional comforts as may be rendered necessary by disease; moreover, it is at present held by every relieving officer that the order of the Medical Officer is to be regarded simply as a recommendation or certificate of Medical necessity, subject to subsequent inquiries as to the ability of the patient to procure the necessaries or comforts ordered. The relieving officer reserves to himself the right of granting or withholding those articles upon further inquiry.

It is quite evident from Mr. Corbett's suggestion that he takes a different view of the responsibility of Medical Officers; for if it be the duty of the Medical Officer to visit and personally inquire into the circumstances of the patient before certifying the Medical necessity of meat and wine, then the certificate must have the force of an order, and not be subject to subsequent inquiry on the part of the relieving officer—if not, there will be a constant conflict of opinion, and the Medical Officer will be degraded to a position of subordination to the relieving officer.

We are very far from thinking that a thorough investigation is carried out under the present system. The time of the relieving officer is so completely taken up in keeping the complicated books—which are probably quite necessary—that he cannot find leisure sufficient to visit and inquire into the circumstances of all persons who apply for a Medical order; and his duty in this respect is undoubtedly very much neglected. It is equally certain that if a Medical man be required to visit the homes of all patients who present themselves at the Dispensary, and enter into personal investigation of their means, it will be absolutely necessary—at least, in metropolitan districts—that the Medical Officer should devote the whole of his time to parish work, and, as a consequence, that he should be properly paid for his services.

We will now speak of the sick poor visited and treated at their own homes. Under the present system an order is presented to the Doctor requesting him to visit; this order is signed by the relieving officer, who is supposed to have made every necessary inquiry respecting the patient's means. It is also supposed that after the Doctor has made a visit, and ordered some meat or wine for the patient, the relieving officer also visits the sick person, and, after making every inquiry, proceeds to order for the patient the common necessaries of life, and also to furnish the Medical comforts set forth in the Doctor's certificate. Let this be distinctly understood: the Medical Officer assumes, and is legally warranted in assuming, that the relieving officer visits the sick and provides them with necessaries; however imperfectly, this duty is, in fact, carried out.

Now, we most thoroughly agree with Mr. Corbett that the amount of investigation is insufficient, and we think that improvement is required; but we do not think it a dignified or becoming occupation for a Medical man to hunt out information respecting the earnings of the poor. We do think this ought to be done more thoroughly than it is done, not only for the prevention of imposition, but also for the more perfect treatment of the sick. The most important part of the treatment of the sick poor undoubtedly frequently consists in the provision of necessary and suitable diet. We desire, therefore, to extend the powers of the Medical Officer with respect to the ordering of food, and at the same time we would increase the examining power by the employment of special officers, whose sole duty it should be to regularly visit the sick, ascertain the pecuniary position of the patient, and see that the orders of the Doctor as to diet be carried out. The Doctor would then become the chief of a staff, all of whom would labour to solace suffering and effect the cure of disease as quickly as possible, whilst attempts at imposture would be at once detected. A more liberal remuneration to the Medical man would secure the devotion of a larger amount of his time, and prove by no means an additional expense to the burdens of the ratepayer.

THE WEEK.

TOPICS OF THE DAY.

WE are not great admirers of the coroner's court. Together with many other old institutions, it is emphatically on its trial. But it is certain that, in the present state of science, pathological and toxicological, the public value of the coroner's court is not in proportion to the number of inquests held, but rather to the number of post-mortem examinations made under the coroner's order. The inquiry, without a post-mortem examination, and the Medical evidence based on it, is, for all real purposes of usefulness, practically nothing better than was the crowner's quest in Queen Elizabeth's time. A court, composed of a presiding officer (who may or may not be qualified for his post, and is tolerably certain to be wanting either in legal or Medical knowledge), twelve petty tradesmen, and the beadle, is not likely to retain public confidence, unless it be understood that its president has the power to obtain the fullest scientific evidence and guidance. Nothing can be more damaging to the court as an institution than the knowledge that the full particulars of the cases brought before it are not to be investigated with all the light that science can throw upon them. This, however, does not seem to be the opinion of the Middlesex magistrates, as the following Report of the Session on November 30 will show:—

“The Committee of Accounts and General Purposes recommended the payment of the following accounts of the coroners of the county:—Mr. Humphreys, for 143 inquests held between October 9 and November, £296 11s.; Dr. Lankester, 139 inquests in the same period, £358 1s.; Dr. Diplock, for 38 inquests in the same period, £87 12s.; Mr. Bedford, for 24 inquests in the same period, £57 10s. 6d. The Clerk of the Peace called the attention of the Court to the fact that, although Dr. Lankester had held four less inquests than Mr. Humphreys, he had incurred a greater expense by 60%. This arose from Dr. Lankester insisting on holding post-mortem examinations in almost every case, which appeared to him a very improper application of the public money. Mr. T. Turner said if such a state of things continued the magistrates must communicate with the Home Secretary, with a view to put a stop to it.”

We regret to see that the sum of money hitherto subscribed for the Goodsir Memorial Fellowship is only £700. At least £2000 would be needed to found the Fellowship originally proposed. At a general meeting of the subscribers it has been therefore determined to establish a prize, to be called the Goodsir Memorial Prize, which is to be awarded under the following regulations:—

1. The prize to be awarded triennially.
2. To be of the value of £60, or such further sum as the funds may admit, but not to exceed in value £100.
3. The prize to be open to all graduates in Medicine in the University of Edinburgh of not more than three years' standing, and to Licentiates of the Colleges of Physicians and Surgeons of the same standing who have attended within the University the same number of classes as are required for the M.B. degree.
4. That the prize shall be awarded for an essay or treatise containing the results of original investigations in Anatomy, human and comparative, either normal or pathological, or in Experimental Physiology.
5. That three examiners shall be appointed—viz., the Professor of Anatomy *ex officio*; one by the Senatus Academicus of the University of Edinburgh; one conjointly by the Presidents of the Royal Colleges of Physicians and Surgeons.
6. That essays or treatises intended for competition shall be sent in to the Professor of Anatomy not later than March 31 of the year in which the prize falls to be awarded, and that the result shall be intimated on August 1 of the same year.
7. That the prize shall be awarded to the best essay or treatise on a subject embraced by any of the departments of Anatomy and Physiology mentioned in Clause 4; but that if, in the opinion of the examiners, a sufficiently deserving essay or treatise be not sent in, the prize will not be awarded.
8. That a small honorarium be paid to each examiner.
9. That if, after payment of the prize and any reasonable expenses connected therewith, a balance remain, this balance be invested to add to the value of the capital.
10. That the Principal of the University of Edinburgh, the Dean of the Medical Faculty, and the Presidents

of the Royal Colleges of Physicians and Surgeons, be trustees of the capital sum. 11. If from the non-adjudication of the prize or other causes the capital sum should accumulate to an amount greater than is needed to provide for a triennial prize of £100, the trustees and examiners conjointly are empowered to award a second prize should an essay or treatise of sufficient merit be presented."

We regret to have to announce that Dr. Davidson, a promising young Physician, filling the post of Resident Physician to the Middlesex Hospital, has died of typhoid fever.

The Charity Organisation Society has issued invitations for a conference to be held on Tuesday, December 12, at 3 p.m., at the house of the Society of Arts, John-street, Adelphi, to consider the best methods of checking the abuses now incidental to Out-patient Hospital Relief, with special reference to the expediency of extending the Provident Principle. The chair will be taken by W. H. Smith, Esq., M.P., and it is expected that Lord Lichfield, the Right Hon. J. Stansfeld, President of the Local Government Board, Sir Charles Trevelyan, Mr. Kennaway, M.P., Mr. Fowler, M.P., Mr. Randolph Robinson, Dr. Acland, Dr. Sibson, Dr. Fuller, Dr. James E. Pollock, Dr. John Ogle, Mr. Charles Hawkins, Mr. Holmes, and many others will be present. We are requested to intimate that the conference is open to all ladies or gentlemen interested in the subject.

PRESENTATION TO DR. BALLARD.

ON Wednesday evening last a meeting of the Medical Practitioners of Islington was held, for the purpose of presenting to Dr. Ballard, the late Medical Officer of Health of that parish, a Ross's microscope, with the needful appurtenances in the shape of objectives, eye-pieces, etc., in token of their appreciation of his services during the fifteen years that he has held that appointment. The meeting, which was held at the residence of N. H. Clifton, Esq., very emphatically recognised the value of Dr. Ballard's labour in carrying out sanitary measures, and in tracing out the sources of disease, as well as in suggesting the means of disarming the virulence of epidemics. The microscope, which bore on its stand a suitable inscription, was presented by W. Harvey, Esq., in the name of the subscribers. This is what should be. The Medical Practitioners of Islington have only done justice to their good sense and good feeling in thus giving evidence of a grateful recognition of a difficult service faithfully and ably performed, giving entire satisfaction, through many of the best years of a life that has ever been devoted to the prosecution and advancement of Medical science.

SURGEON-MAJOR WYATT AND THE DUBLIN TRIAL.

We are always glad to set ourselves and our readers right in any case involving a matter of fact. In some remarks we made in the *Medical Times and Gazette* for November 25, respecting some documents which had appeared in the *Times* on the treatment of Constable Talbot's gunshot wound at Dublin, we intimated that perhaps "Mr. Wyatt's opinion had not been asked by the distinguished Surgeons who framed that memorandum,"—we refer to the memorandum vindicating the treatment pursued by the Dublin Surgeons. The fact is, that Mr. Wyatt was one of the first invited by the eminent Surgeon who originated the manifesto to allow his name to be added to the list of signatures which appeared in the *Times*. We are glad thus to rectify anything disparaging to Mr. Wyatt's Surgical position, which needs, in truth, no adventitious support. We are further informed that Mr. Wyatt, who was in North Wales when the request reached him, at once stated his willingness to testify to any expression of conviction that the utmost *bona fides* had been observed with regard to the treatment of the unfortunate wounded man, but that he regretted to be unable to sign the document for reasons which were stated in reply. Moreover, we are informed that his original

letter to the *Times* was forwarded to that paper through the eminent Surgeon before alluded to. We are most glad to rectify any matter of fact, however trifling, and to express our sense of the high position which Mr. Wyatt's skill and experience enable him to claim in military Surgery; still, we think—and we know that our sentiment is shared by numbers of our Surgical brethren, military and civil—that it was quite unnecessary for Mr. Wyatt to write to the *Times* at all, and that it had an ungracious look. Can Mr. Wyatt suppose that if he himself had treated Talbot he would have been spared the sarcasms, inuendoes, and impudent insinuations which, for political purposes, were heaped upon the Dublin Surgeon?

PROVIDENT DISPENSARIES.

AT the invitation of the Charity Organisation Society, a number of Medical men connected with Free and Provident Dispensaries met at a preliminary conference at the Society's rooms, Buckingham-street, Adelphi, on Saturday, the 2nd inst. The chair was taken by Alsager H. Hill, Esq.

Mr. Fairlie Clarke opened the proceedings by stating that it was the intention of the Society to invite to a conference all ladies and gentlemen interested in Hospital reform, the meeting to be held at the house of the Society of Arts on Tuesday, December 12, at 3 p.m., for the purpose of discussing "the province of the Poor-law Board, the Dispensary, and the Hospital, with reference to the sick poor, and to promote concerted and harmonious action amongst these agencies." According to the present system of indiscriminate relief, the out-patient departments are overburdened, the Medical men overtaxed, and, after all, the boon is in many cases given to those who are the least entitled to it. To meet this evil, he proposed a large extension of the Provident principle; in particular, he suggested that the Free Dispensaries should be converted into Provident Institutions. Some statistics were quoted showing the enormous number of persons who now receive gratuitous Medical treatment, and the very large percentage which they form upon the population of this metropolis. Now that the Poor Law Board is establishing Dispensaries of its own in every district of London, the Free Dispensaries, he remarked, are less needed than ever, and this time seems opportune for placing them on the Provident basis.

Mr. Hemming mentioned that it had been determined to convert the Notting-hill and Shepherd's-bush Dispensary into a provident institution, and that the rules of the Charity Organisation Society had been adopted with some modifications.

Sir Charles Trevelyan was of opinion that the class of *malades imaginaires* was not confined to the upper classes; that among the poor there are a number of people who attend at Dispensaries and Hospitals for the shelter and warmth they can obtain while waiting to see the Doctor, and others for the chance of getting pecuniary relief from the donor of the letter. Medical relief as now carried out has proved to be one of the most pauperising and pernicious systems of abuse; it breaks down a habit of self-reliance and dependence, and acts as a propaganda of poverty.

Dr. Drysdale was of opinion that the mass of Medical men approve the principle of Provident Dispensaries, but they are likely to be opposed by the governing body of the free institutions, who fear a falling off of the funds if the subscribers do not have letters to distribute gratuitously. Generally three or four governors rule the roost at the public Hospitals and Dispensaries, and they strenuously oppose any suggestions from without. At the Metropolitan Free Hospital a rule was recently made to admit only twenty-five new patients daily to each Medical man. The governors have recently taken off this restriction, and Dr. Drysdale has frequently to see sixty new cases a day. In Paris the staff of every Hospital and Dispensary is salaried.

Mr. Parker Young applied for the appointment of Medical Officer to the Westbourne Dispensary for the purpose of getting

it placed on the Provident system. After much opposition he succeeded in carrying his point, and this Dispensary has now been in full working order for eighteen months. The number of patients has not fallen off. They receive £20 a month from the poor. The duties are just the same. The House-Surgeon usually visits urgent cases outside.

The Chairman asked how the difficulty with regard to funded property could be got over—legacies bequeathed for the gratuitous relief of the sick poor. Several gentlemen replied that such money was usually spent on the *plant* of the Dispensary. The Chairman also asked whether Doctors would consider it *infra dig.* to attend at Provident Dispensaries. There was some difference of opinion on this point. Probably Dispensaries in the outlying districts would not find this a difficulty, but in the central parts of London, Dispensaries are generally worked by consultants, who might object.

Sir Charles Trevelyan paid a worthy and fitting tribute of praise to the Medical gentlemen who have devoted their time and energies for years to the gratuitous relief of the poor. The rule that unpaid work was bad work could not apply to the Medical Profession. He thought the public must be educated up to the advantages of the Provident system. All the artisan class should be encouraged to become members of a Provident Dispensary.

Some of the Medical gentlemen present urged the importance of a careful superintendence in the practical working of such institutions, and the necessity of providing some check to the admission of members who were well able to pay for private Medical attendance. The Medical relief of the artisan class ought not to be monopolised by one or two Medical men in the district providing for them medicines and attendance at a nominal fee.

COLLIERS AND LONGEVITY.

THERE are exceptions, it is said, to all rules. Are not the statistics of the health and mortality of convicts in the main very different from the following? It is stated on good authority that at the Pinxton collieries eight men are at work at the pits whose united ages amount to 536 years, averaging 67 years per man; there are also eight old colliers off work whose ages amount to 558, averaging nearly 70 years of age, and fourteen labourers receiving daily wages whose united ages amount to 1008, being an average of 72 years per man. These are probably exceptional figures, but they are remarkable.

FATAL INJURIES TO A LUNATIC.

CASES are constantly occurring to show that in our public institutions for the reception and cure of the insane, injuries are inflicted, and fatal results supervene, of which it is difficult, if not impossible, to determine the cause. Whatever may be the vigilance displayed by those in authority, it is all but impossible to prevent cruelty in some instances on the part of the attendants; but it is almost incredible that an instance of extensive and fatal injuries should have occurred, and no evidence be forthcoming to show in what manner, or by whom, they were inflicted. On Monday last an inquest was held at Hanwell Lunatic Asylum, on the body of a patient named Lutage, who died from violence in that institution whilst in the refractory ward. After death, the Surgeon found a sear on the left knee, one higher up, a bruise on the chest, and a large one on the chin. There was a comminuted fracture of the jaw, a fracture of the tenth and eleventh ribs, an old fracture of the fifth rib, and the right kidney was torn across. Death resulted from laceration of the kidney and hæmorrhage, caused by violence of some kind or other. The jury returned a verdict, "That the deceased died from the effects of the injuries he received, but how those injuries were caused there is no evidence to show." This is certainly a most unsatisfactory verdict, and reflects little credit on the management of the Hanwell Asylum.

HEART DISEASE IN THE ARMY.

WHATEVER causes may be assigned for the prevalence of heart disease in the army, the fact cannot be ignored that it does prevail to a very remarkable extent. Dr. Jenkins, Staff Surgeon, in his Report on the Health of the Artillery Division of the Royal Marines, says that in the year 1869 seventy-seven cases of heart disease and aneurism were under treatment, and caused a loss to this branch of the service by invaliding of thirty-eight men, or 22.45 per 1000 of mean force. Nearly one-third of all cases of invaliding suffered from disease of the heart, and one-third of the deaths were from the same cause. Dr. Jenkins adds:—"Efforts at improvement already made have not been without fruit; but much remains to be done before the soldier can be freed from those trammels which so literally bind him, and before he can—like other hard-working men—be said to 'strip to his work.'"

THE LIVERPOOL NORTHERN HOSPITAL.

THE proposed alteration of rules, which would have thrown open the office of Physician to the Liverpool Northern Hospital to general Practitioners, has been abandoned, and it is now determined to convene a general meeting of the trustees for the 18th inst., for the purpose of endeavouring to modify the existing laws in such a way as to admit any gentleman as a candidate who, having been engaged in private practice for a period of two years, shall be willing to abandon Midwifery, Pharmacy, and Surgery from the time of election.

VILLAGE HOSPITALS.

GREAT success having attended the establishment of Village Hospitals at Cranley and Bourton-on-the-water, a number of gentlemen of Tewkesbury and neighbourhood some time ago determined to try a similar experiment in that town, and on the 30th ult. the foundation-stone of a new Hospital was laid by John Surman, Esq., of Tredington.

SMALL-POX JOTTINGS.

Two men, last week, were fined 10s. each at the Marylebone Police-court for neglecting to have their children vaccinated. The summonses were taken out by Dr. W. Hardwick.—In consequence of small-pox and diphtheria in an epidemic form, the Communal Schools of Florence have not been opened for the winter. There are 13,000 pupils in attendance at these schools.—The disease is very prevalent at Norwich.—At Sneinton, a suburb of Nottingham, fifty cases are reported.—In the Poplar Union there had been one death from small-pox last week, and twelve new cases. During the week thirty-one persons had been vaccinated.—The disease has within the last few days made its appearance in the garrison at Woolwich, and several cases have already been reported. In one of the streets adjacent to the barracks it is very bad, and several fatal cases have occurred, principally amongst young children.—The *Birmingham News* says that the *Anti-Vaccinator*, a journal started in the interest of those who dispute the efficacy of the discovery of Dr. Jenner, has disappeared from a want of the "sinews of war."—Mr. Edward Brown Taylor, the owner of considerable house-property in the City, was on Tuesday fined by Sir Robert Carden 40s., and 20s. costs, for neglecting to cleanse and disinfect one of his houses in which small-pox patients had died, and otherwise purify the house according to the certificate given by Mr. Clarke, one of the Sanitary Inspectors for the City.

HEALTH OF TROOPS IN CEYLON.

WE hear from Ceylon that during September last a remarkable outbreak of fever of the remittent type, attributable, apparently, to local causes, took place in one company of the 73rd Regiment at Colombo, quartered in a barrack in close proximity to a canal, the shallowness of the water in which caused a large extent of muddy margin to be exposed to the

action of the sun. The constant passage of barges, also, and the dredging necessary for maintaining a channel, disturbed the water, and exposed fresh quantities of mud. The purely local nature of the outbreak is shown by the facts that all the other troops at the station continued in their average health, and that, on the removal of the men among whom the disease appeared to a more healthy situation, only two fresh cases occurred among them. Seventeen cases and three deaths occurred. The remissions were, as a rule, irregular, and badly marked; headache, delirium, and irritability of stomach were prominent symptoms. The vomited matter was generally of bilious character. The bowels were usually inactive. In several cases there was slight jaundice, the appearance of which was usually marked by a reduction in the pulse from 120 to 90. In the fatal cases, congestion of liver and spleen and mucous surfaces of stomach and bowels was generally observed.

PROFESSOR HUXLEY AT THE LONDON INSTITUTION.

ON Monday, the 27th ult., in his fifth lecture, which, according to the programme, was to have been on the subject of "Smell, Taste, and Touch," Professor Huxley, referring only cursorily to the physiological history of these sensations, took his hearers over the more purely abstract ground of the metaphysical classification of Psychoses. He divided the original Psychoses into two groups, primary and secondary—the former requiring no antecedent psychosis, the latter only occurring after a primary. The primary original psychoses he roughly classified as Sensations, Emotions, and Volitions; or, as he considered a better classification, Sensations, Pleasures, Pains, and Efforts. These we share with the lower animals in kind, though differing in degree. In many of the lower animals there is every reason for thinking that the sensations are very intense. In sensations of all kinds there are grades, passing on from the very slightest perception to actual pain. He classified the sensations into Indefinite, Thermic, Olfactory, Auditory, Tactile, Visual. The *indefinite* are exemplified in the dim consciousness of existence which everyone feels without being able to specify—such as the sensation for the first few moments between sleeping and waking. The *thermic* present themselves to us in our feeling of a general sense of heat and cold, without localisation, as felt by himself, and no doubt by each of his audience, in the warm crowded lecture theatre. The *olfactory*, referable to the nose, which, however, is not the actual seat of the organ by which the sensation is produced. The immense variety and extreme diversity of odours are well known, as may be exemplified by the violet and assafoetida, but in each we can appreciate and distinguish different degrees of intensity; but the source of an odour is more general or diffused than localised. In the *auditory*, the same degrees may be observed; every note in the gamut, for instance, is absolutely distinct from every other. The localisation, also, of the source of a sound is not very definite, but when it becomes so, the psychosis passes from primary to secondary. The range of *tactile* sensations is very great; they admit of more definite localisation, but the seat of the sensation is not in the part touched. The *visual* sensations are exceedingly diverse in kind and intensity, from the sense of the slightest gleam of light, to the actual pain caused by gazing at the sun or a brilliant flame. The source of the sensation is also referred to something outside of and beyond the body, and in a definite direction. This is experienced with reference even to the flashes of light caused by pressing on the eyeball when the eye is closed.

Pleasures and Pains may be divided into *bodily* and *mental*. The confusion of language which applies the same term to a toothache as to the feeling of remorse, to the pleasure of eating one's dinner as to the pleasure of doing right, causes also a confusion of ideas. It is advanced as a reproach against a certain school of philosophers that they base our motives of action upon the pleasurable or painful nature of the results of our deeds. This misapplication of terms, however, is the fault,

not of the moralists, but of language. The introduction of the class of Efforts may seem an innovation. The bodily effort necessary for sustaining an object steadily in the hand implies a consciousness of resistance, known as the "muscular sense," by which we are enabled to distinguish objects as regards the property of weight. The seat of this sense of resistance and effort has never been exactly defined. Professor Huxley appeared to think it might be a secondary sensation conveyed to the brain from the skin overlying the muscles employed. Volitional or mental effort is exerted in two different ways—namely, for the control of the mental state (the shutting out of external objects and the concentration of thought upon a fixed subject), and for the production of bodily motion. Consciousness gives no clue as to how this controlling power of volitional effort is exerted.

The secondary original psychoses are those which come into operation in the exercise of judgment or acts of reasoning. By them we become aware of Succession, Co-existence, Similarity, Dissimilarity, and Locality, as respects external objects or mental phenomena. The philosophy which derives all states of mind from sensations, cannot get rid of the above, and cannot trace them to association or sensations. In defining the locality, for instance, of an external object by touching it directly with the hand, the sensation does not really exist in the hand any more than in the point of a poker, supposing the external object to have been touched through that instrument held in the hand. The sense of contact is conveyed as a neurosis from the point touched along the nerves to the central organ, and referred thence back to the point touched as an actual primary psychosis. The sense of light, also, is not in the eye, nor that of sound in the ear, as he had already shown. Now arises the question as to the connexion between neuroses and psychoses. Experiment can reply only to a certain extent. It has, however, been established beyond a doubt that, to enable a neurosis to pass on to a psychosis, the activity and integrity of the nervous system and of the cerebral hemispheres must be complete. This is exemplified by the loss of consciousness consequent on injury of the cerebral hemispheres, and on the operation of certain drugs or anæsthetics. Chloroform, up to a certain point, does not interfere with the action of the spinal cord or medulla oblongata. The individual to whom it is being administered is excited, and loses his power of self-control in consequence of its action upon the central nervous organ, but may still be able to struggle or even walk about before he loses consciousness or sensibility to pain. Mesmeric phenomena likewise are produced by a certain state of the nervous system which abolishes or suspends the activity of the cerebral hemispheres. Alcohol also acts in the first place on the cerebral hemispheres by its cheering and exhilarating influences—as, in the words of the Psalmist, "Wine that maketh glad the heart of man"; it accelerates the succession of ideas in the train of thought, and, if pushed beyond the limits of prudence, it will run that train off the rails altogether.

It has, therefore, been demonstrated by experience that, for sensation and motion, integrity of the afferent and efferent nerves is respectively essential—that for psychoses of all sorts integrity of the whole nervous system is essential. At this point positive knowledge ceases. The substratum through which we become conscious of external objects, and recognise succession, co-existence, similarity, dissimilarity, and locality, remains unknown. When, however, a close and invariable connexion is observed between two sets of phenomena, they are classed respectively as cause and effect. Professor Huxley concluded with an illustration of the hypothetical connexion between neuroses and psychoses, by saying that the whole nervous system may be compared to a clock showing the hour and other events on its face, and consciousness to another superadded clock or piece of mechanism, which strikes the hour or plays tunes, but whose action is not essential to that of the other clock.

We regret that Professor Huxley was prevented by indisposition from delivering his sixth lecture on Monday, the 4th inst.

FROM ABROAD.—SALE OF AMERICAN DIPLOMAS—THE VACCINE VIRUS AS A FERMENT—EXPLOSIVE BULLETS—SUBCUTANEOUS INJECTION OF MORPHIA IN ERYSIPELAS.

THE success of the bogus "American University of Philadelphia," in palming off its hundreds of mock diplomas upon the credulous, has been so great that the real University of Pennsylvania, which has suffered much in reputation in consequence of having been mistaken for it, has at last taken energetic action in the matter, by informing the unwary, and meeting the machinations of the swindlers concerned by legislative enactments. The efficacy of any measures of the kind would be more probable if those who have received, or are desirous of receiving, such documents were merely dupes, devoid of ordinary caution; but there is too much reason to believe that most of them know too well what they are about, and are only too willing to be deceived. However this may be, the University of Pennsylvania can do no more than disavow all complicity in such transactions, and warn, by a wide publicity, all concerned in the matter. This, at all events, will make generally known the true character of these mock diplomas, and cover the holders of them with the disgrace they justly entail. In its circular, the University informs the public that its Honorary Degrees can only be conferred by a *mandamus* signed by two-thirds of the whole number of the trustees, and that the Candidate must receive an unanimous vote by ballot before the degree can be granted. The penal Act which it has procured the passing of runs as follows:—

"An Act to Prohibit the Sale of Academic Degrees.—Section I.—Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it is hereby enacted by the same—That it shall not be lawful for any University, College, or other Institution incorporated under the laws of this State with power to grant Academic Degrees, honorary or otherwise, to confer the same upon any person or persons upon the payment or promise of payment by any person in consideration thereof; and any person knowingly signing a diploma or other instrument of writing purporting to confer an Academic Degree when such consideration has been paid shall be guilty of a misdemeanour, and on conviction thereof be sentenced to pay a fine not exceeding 500 dollars, and to undergo an imprisonment not exceeding six months, or both or either, at the discretion of the Court.—Approved, May 19, 1871."

M. Melsens, in an article on the "Vitality of the Vaccine Virus," published in the Brussels *Journal de Médecine* for October, observes that, without entering into any discussion concerning the different opinions which have been advanced as to the nature of this virus, he wishes to state that he is engaged in investigating whether it may not be regarded as a *ferment*, susceptible, when placed in suitable conditions, of reproduction, like the alcoholic ferment. In this case it should prove capable of being destroyed or rendered inactive by the same bodies which destroy the alcoholic ferment, as also by certain physical agencies, such as exposure to humidity and an elevated temperature. On the other hand, the virus should be able to resist very low temperatures, as M. Melsens, in his communications to the French Académie des Sciences, has shown the alcoholic ferment can. In order to test this last point, he placed glass tubes containing fresh vaccine virus in a freezing mixture, and retained them there for about an hour and a half, at a temperature of 78° C. below zero. The virus which had been so exposed was afterwards employed for vaccination with complete success. "I am still pursuing these researches," M. Melsens adds, "in order to ascertain whether there may not exist additional points of contact between this virus and certain ferments which are capable of reproduction outside the economy—in other words, whether the vaccine virus may not be 'sown' and multiplied in the vessels of the laboratory.

Some of the results of my experiments authorise me in entertaining hopes that this may be the case."

In a communication addressed to the Académie des Sciences, November 20, M. Coze offers an explanation of a circumstance occurring in certain gunshot wounds, which, he believes, has been erroneously attributed to the action of explosive bullets. When a projectile, impelled with very great velocity, strikes against a hard obstacle capable of resisting its progress, the momentum which animated it is transformed into caloric, and the projectile itself becomes, in consequence, heated and fused. From this a double result may be produced; for the ball may undergo fragmentation, while the wounded tissues undergo all the consequences of a burn of a more or less considerable extent. Such effects, from the want of a due appreciation of the conditions under which they have been produced, have been attributed to the action of explosive bullets, and have in the late war given rise to unjust recriminations on the part of both the belligerents. M. Larrey pointed out the desirability of investigating the matter experimentally, with a view of setting at rest this vexed question of explosive balls, and the Academy appointed a committee for this purpose.

M. Nicaise, in a communication to the *Gazette Médicale*, March 18, had, indeed, arrived at very similar conclusions to those advanced by M. Coze with respect to the circumstances which had led to the suspicion of the employment of explosive bullets. The bullet, he observes, having become heated, may, on striking a hard bone, undergo change in its form, or have fragments split off from it and embedded in the tissues, although these constitute but a small portion of its entire mass, and are usually mere lamellæ. Owing to the less purity of the lead from which they are fabricated, some projectiles are much more friable than others. M. Nicaise does not, however, allude to the actual fusion of the metal described by M. Coze.

In the *Deutsche Klinik*, No. 39, is a paper from the pen of Professor Estlander, of Helsingfors, upon "The Subcutaneous Injection of Morphia in Traumatic Erysipelas." He states that he employed this injection originally in his clinical practice, in combination with the so-called abortive treatment (chiefly by means of tincture of iodine), mainly with the view of relieving the heat, tension, and pain of the inflamed skin. It was soon found, however, that the morphia must have exerted other effects also, so quickly was the course of the disease mitigated. It was therefore used in a series of cases as the sole local remedy, and the conviction became established that it must have exerted a direct influence on the inflammatory process, diminishing its intensity and arresting its progress. When the limits between the inflamed and healthy portions of the skin are not very clearly defined, and the process manifests itself in the form of large red spots gradually approaching each other, if we inject near the affected parts we usually find next day that the erysipelas has not extended farther, or has done so only to an insignificant extent. In cases in which the limits of the reddened and swollen skin are well marked, if we make some injections in its vicinity, we may find that the inflammatory process, which during the preceding twenty-four hours had made considerable progress, is sometimes at once arrested, but more frequently it continues in a diminished degree, gradually yielding in the course of a few days to a continuation of the treatment.

In the worst cases of erysipelas ambulans, as in the severe epidemic form, or where a peculiar disposition of the individual prevails, the morphia exerts as little effect as any other of the so-termed abortive remedies. In estimating how far the results depend upon the peculiar nature of the erysipelas itself, and how much they are ascribable to the injections, Professor Estlander has undertaken many comparative trials, and he could relate many cases in which, while a rapid improve-

ment followed the use of morphia, other cases treated at the same time, either expectantly or by means of other remedies, were much slower in their progress. Still, he is too well aware of the capricious character of erysipelas to venture to deliver any categorical judgment upon the subject. But a five-years' experience has convinced him that these injections constitute a better mode of treating erysipelas than many other means.

For the injections, two grains of the chlorate or acetate of morphia are dissolved in a drachm of water; and as Luer's syringe holds about a quarter of a drachm, of which a quarter or a half is injected, it follows that the dose varies from one-eighth to one-quarter of a grain. As, so far from the erysipelas ever appearing at the small puncture-wounds, these and their immediate vicinity are always respected by it, the dose may be distributed over different parts of the healthy skin, at a distance of one or two inches from the limits of the inflammation. Usually the injection is made only once in the twenty-four hours.

Professor Estlander has no intention of proposing this as an exclusive method of treating erysipelas, believing, on the contrary, that one of its advantages is that it admits of the simultaneous use of other means. He has tried, indeed, all the various other remedies which have been recommended, and regards the tincture of iodine as the best of these. As soon as from shivering and the appearance of the wound erysipelas seems threatening, he administers an emetic, a means which he believes is nowadays too much neglected, and one which he believes conduces to moderation of the disease. The morphia is next injected, either as the sole means or in conjunction with a daily painting with iodine, employing afterwards wadding and compression by a roller where practicable. Ipecacuanha with phosphoric or sulphuric acid may afterwards be administered. The sesquichloride of iron, once regarded as a specific, is of no real utility.

CHURCH OF ENGLAND SOCIETY FOR MEDICAL STUDENTS.

(From a Correspondent.)

A BODY of Associates of St. Luke has lately been established and held its first ordinary meeting on Monday, December 4, at the rooms of the English Church Union, Burleigh-street, Strand. The members already include representatives from most of the metropolitan Schools. An animated discussion took place last Monday upon the religious aspects of the subject of the Destruction of the Fœtus in Utero. All the Associates are communicants of the Church of England, and it is intended to hold monthly meetings for the consideration of religious subjects specially affecting the Medical Profession, and for the further purpose of affording to such students as profess definite Church principles opportunities of social intercourse and any other advantages which may attend such association. To judge from the success of this first meeting, the Society seems likely to prosper, and all those who are acquainted with the peculiar difficulties and temptations of a Medical student's life in London will, we are sure, heartily join with us in wishing such an attempt Godspeed.

THE LATEST VIEWS REGARDING THE RED BLOOD-CORPUSCLE.

MR. E. RAY LANKESTER, Radcliffe Travelling Fellow, University of Oxford, has published "Observations and Experiments on the Red Blood-Corpuscle, chiefly with regard to the Action of Gases and Vapours."

The object of these observations was threefold—first, to ascertain whether certain vapours and gases having marked physiological influence on animals exert any direct action on the red blood-corpuscles, and to determine whether those known, by investigation with the spectroscope, to affect the hæmoglobin produce visible changes in the corpuscle; secondly, to examine into the chemical and formal structure of

the red corpuscle; thirdly, to obtain, by a detailed examination of the influence of reagents, and especially gaseous reagents, on a typical histological element, a starting-point for further micro-chemical studies.

In his remarks on "the use of gases and vapours as a means of micro-chemical research," he claims for gaseous reagents the following advantages—apart from the fact that some bodies are necessarily only to be used in the gaseous state—firstly, that in this manner the agents are applied to the microscopic particle under observation without a deluging stream being produced so as to carry the particle right out of the field of the microscope. Such a stream is produced when a liquid is allowed to pass under the thin(a) glass cover as ordinarily used; but with the gas-chamber the reagent acts quietly, and without the least inconvenience to the observer, so that he is able to retain one individual particle under observation through the process. A second advantage in the gaseous method over that of solutions is, that the action of the diluents, water or spirit, is avoided. A third, and perhaps the most striking, is, that exceedingly minute traces of a reagent can thus be brought to bear and very gradually increased in strength whilst the observer is watching the object submitted to the reagent. At any moment the action may be stopped, and with the greatest facility and rapidity a second counteracting or other reagent introduced, by the use of the second tube of the chamber.

Among the reagents which may thus be used, and of which trial has been made, are water, hydrochloric acid gas (by current of air drawn through its solution), carbonic acid gas, acetic acid, osmic acid, nitrogen tetroxide, hydrogen sulphide, chlorine, iodine, bromine, ammonia, alcohol, ether, chloroform, carbon bisulphide, carbonic acid, and other gases and vapours of volatile liquids.

After discussing at considerable length "the opinions and doubts of numerous physiologists concerning the red blood-corpuscle," and giving his own history of the "normal appearance of the frog's red corpuscle," he proceeds to describe in the following terms the "normal appearance of the human red blood-corpuscle":—"The human red blood-corpuscle is a circular biconcave plate. It is, however, erroneous to regard this as the only normal form. In the blood of perfectly healthy persons I have frequently noticed the 'thorn-apple form' so immediately after the shedding of the blood, that I do not doubt that these forms existed in the circulating fluid. My own blood almost invariably presents these thorn-apple forms in large numbers, and I have not yet been able to connect their presence, or greater or less quantity, with any particular condition of health or nutrition. In addition to the thorn-apple form, my own blood frequently presents what I will term the 'single' and 'double watch-glass forms.' In these corpuscles, in place of a concavity on each face of the disc, we have a very large convexity, of delicate appearance, and paler than the rim or margin of the corpuscle. Sometimes only on one face of the corpuscle is there this swelling out, and then the appearance is that of an old-fashioned watch, seen from its side, the darker-coloured rim of the corpuscle representing the metal watch, and the swelling representing the convex glass. Often these convexities appear on both sides of the corpuscle. I do not see any reason for attributing these forms to changes occurring in the corpuscle after it has been shed. I have observed them (with Hartnack's No. 10 immersion) with the greatest rapidity possible, after being shed from the finger, and do not doubt that they exist in their peculiar form whilst within the body."

The writer then adverts to the great neglect that is universally shown in the examination of the blood-corpuscles in disease. It can hardly be doubted, he thinks, that the Physician may thus receive as important information as he gains from the examination of the urine. The reason of this neglect is—firstly, that the microscopes in common use are quite inadequate to the investigation of the corpuscles, which require a power of 450 diameters; and, secondly, that even if the examiner can accurately sketch corpuscles that have been sufficiently magnified, the changes that take place are so rapid that the task is one of extreme difficulty. This difficulty has recently been overcome by the discovery of a reagent which enables us instantaneously, on removing a drop of blood, to preserve all its form-elements *absolutely* unchanged, and in such a condition that the specimen may be put aside and examined at leisure. Such a reagent, he observes, exists in the so-called hyperosmic or osmic acid, introduced as a preservative agent by Professor Max Schultze. It is sufficient to expose a thin film of

(a) The gas-chamber used by Mr. Lankester is a modification of the apparatus employed by Schweigger-Seidel.

blood on a glass cover to the vapour arising from a bottle containing the two per cent. solution of osmic acid during three minutes, to ensure complete preservation. "Every corpusele," says the author, "becomes thus 'set,' as it were, in its living form—there is no coagulation, no shrinking, no dissolution; but, as the corpusele was at the moment of exposure to the vapour, so it remains. The white corpuseles even exhibit their pseudopodial processes arrested in the act of movement. It is as though the osmic acid bottle contained a Gorgon's head, which freezes the corpuseles as they face it into stone. Having been thus acted on by the osmic acid, the cover-glass with the blood on it is placed on an ordinary glass slide, on which is a drop of a nearly saturated solution of acetate of potash, as recently recommended by Max Schultz, and there it may remain unchanged for as long as the Physician wishes. The whole process is so simple that, in less time than it takes to examine the chest, a drop of blood may be taken, thus prepared, and placed on one side for examination at a later moment. One may have perfect confidence, from careful comparative observations, that the osmic acid does not change the form of the corpuseles *at all*; and thus all the advantages are obtained for a leisurely and deliberate study, which otherwise are only to be obtained by most inconvenient haste and precipitation. At the same time, the indispensable opportunity is provided of retaining the corpuseles in their living form for *comparison*, from day to day and from case to case."

We have not space to follow Mr. Lankester in his remarks on the effect of pressure on the red corpuseles, or on "the effect of isolation from the plasma by adhesion to a foreign body, by mixture with salad oil," or on the effects of watery vapour and other vapours and gases on the red corpuseles, but must content ourselves with quoting his own "general conclusions," which will serve to give the reader some idea of the wide scope of his observations:—

"The red blood-corpusele of the vertebrata is a viscid and, at the same time, elastic disc, oval or round in outline, its surface being differentiated somewhat from the underlying material, and forming a pellicle or membrane of great tenuity, not distinguishable with the highest powers (whilst the corpusele is normal and living), and having no pronounced inner limitation. The viscid mass consists of (or rather *yields*, since the state of combination of the components is not known) a variety of albuminoid and other bodies, the most easily separable of which is hæmoglobin; secondly, the matter which segregates to form Roberts's macula; and, thirdly, a residuary stroma, apparently homogeneous in the mammalia (excepting so far as the outward surface or pellicle may be of a different chemical nature), but containing in the other vertebrata a sharply definable nucleus, this nucleus being already differentiated, but not sharply delineated, during life, and consisting of (or separable into) at least two components, one (paraglobulin) precipitable by CO₂, and removable by the action of weak NH₃; the other pellucid, and not granulated by acids.

"The chemical differentiation of the outer pellicle is rendered probable by the behaviour of the corpuseles under weak NH₃, which appears to dissolve this pellicle, and so loose the viscid matter from that which restrained it to its oval shape; also from the inability of CO₂ to act on the corpusele until it has been subjected to the influence of aqueous vapour, which may be supposed to remove or render permeable this pellicle; also from the action of chloroform, oil, and cyanogen, which cause the discharge or diffusion of the hæmoglobin from the corpusele, perhaps by first removing or rendering permeable—at any rate modifying—this outer pellicle.

"Steam, chloroform, benzine, bisulphide of carbon, ammonia, and cyanogen act on the red blood-corpusele so as to cause the escape of the hæmoglobin.

"The further action of these reagents causes the elimination of what may be called Roberts's constituent, that which is stained by magenta and set by tannin.

"A still further action of chloroform, of water, or of ammonia dissolves first the stroma, lastly the nucleus.

"Carbonic oxide and sulphuretted hydrogen produce their respective changes on the hæmoglobin, as demonstrated spectroscopically, without altering the form of the corpusele, merely effecting the radiation of its body."

For further details we must refer to the memoir itself, which is published in the last number of the *Quarterly Journal of Microscopical Science*.

ON EMBALMING.

THE art of embalming, as is well known, is very old; even the ancient Egyptians had introduced the practice from Ethiopia, a country abounding in various gums, which served them to preserve the remains of their relatives. The transparency of these substances had induced some travellers to assert that the bodies were embedded in glass, like insects found in amber. De Pau and many other writers have exposed the absurdity of such a report, since it is more than probable that glass was scarcely, if at all, known amongst them. The Persians enveloped their dead in wax, and the Scythians sewed them up in skins.

The operators were the priests, who persuaded the multitude that the immortal part of our being was retained within its earthly house so long as the corporal form could be preserved entire, and a belief in the transmigration of souls naturally led to the desire of retaining them as long as it was possible in their former bodies; and the words of Virgil—"animamque sepulchro, Condimus,"—would seem to warrant this belief amongst the ancients.

The operator, or "*incisor*," as he was called, appears to have been considered a degraded being; for Diodorus tells us that, after the operation, he was pursued by the relations of the defunct, and pelted with stones, as having polluted the remains of the dead.

As to remuneration, Diodorus Siculus states that the first class of embalming cost a silver talent, the second twenty minæ, and the third scarcely anything. In Rymer's "*Fœdera*," vol. i. p. 1001, will be found a letter from the Keeper of the King's Wardrobe to Sir Ralph de Stoke, Clerk of the Great Wardrobe, stating that Richard de Montpelier is going to London on account of the king's (Edward I.) illness, and desires that every facility may be afforded him to procure and make up the medicines. "*Propter Infirmatē Domini Regis per ordinationem Magister Nicolaus de Tynwick*" (*sic*). Richard de Montpelier's account for this illness and subsequently the embalming the king amounted to £134 16s. 4d., a considerable sum in those days. Amongst other curious items we find:—

	£	s.	d.
Pro Emplastris Cironeis	4	0	0
Item pro Terebintine destillato	0	40	0
Item pro uno Emplastro pro Collo Regis cum Ladano et Ambras Orientalis	0	60	0
Item pro vj. Malis Granates	0	60	0
Item pro sex unciis de Balsamo ad Corpus Domini Regis unguendes	13	0	0
Item pro pulveri aromaticæ de Aloëis Thuris Myrrhæ ad ponendum in Corpore Regis	4	0	0
Item pro Musco unciâ iiij. ad Ponendum in Membris Regis(a)	0	60	0

A curious fact with relation to the embalming of Edward I. will prove that Master Nicolas of Tynwycke (who, the king said, "was more learned and fit to have the care of his health than any one in the realm"), Master Peter, the Surgeon, and Richard of Montpelier, the *Espicer* (or apothecary), did their duty well, for about fifty years ago the tomb of Edward I. was opened and the body found entire. A zealous antiquarian, Sir J. Ayscough, was induced to taste the "pickle" or fluid in which the royal body was preserved, and even then, more than 500 years after the embalment, it showed traces of the spices used, and of which we have just given the charges and accounts.

In modern times we find that Edmond Phillips had £40 4s. 8d. for embalming the body of Thomas Sutton, the benevolent founder of the Charterhouse. In the case of George II. the two Sergeant-Surgeons had £122 8s. 9d. each for "opening and embalming," and the apothecary £152 for "a fine double cerecloth and a due quantity of rich perfumed powders."

Our great Hunter was engaged to embalm the body of the Earl of Moira, and dictated the *modus operandi* to the late Sir John Doratt, his last surviving pupil, by whom the original document was presented to Mr. T. M. Stone, to whom we are indebted for its publication.

The whole of the viscera, thoracic and abdominal, having been removed, the entire inside of the trunk was well washed with cold lime water, and afterwards well dried with cloths: when dry the cavities were actually soaked in rectified spirit of wine. On the removal of the contents of the abdominal cavity, incisions were made into the intestinal canal, to give

(a) The original Latin is preserved.

vent to the faecal contents, as also to the gas that might have been contained within them; they were immediately immersed into cold lime water, well washed, and the blood that appeared well squeezed out; this effected, the whole were again immersed into lime water, and allowed to remain for a time; this last being finished, the whole was thrown into rectified spirit of wine, and suffered to remain for some time. The abdominal cavity having been prepared as directed, and a bed of spices being laid to receive the viscera, the latter was then returned or replaced. The whole cavity with its contents was entirely filled with the spices and alum, so as not to leave a vacant space. The abdominal integuments were then closely drawn together, and strongly sewn with twine well waxed.

The thoracic viscera were in part treated in the same manner as the abdominal viscera, as also was the cavity of the chest, the lungs having been replaced, and the cavity completely filled with spices, etc., the integuments closely drawn together, and sewn with twine well waxed (the blood well squeezed from the lungs before immersion, and incisions having been made, friar's balsam was poured into them).

The heart, after having had several incisions made into its substance, was immersed as before described in the lime water and spirit of wine; a considerable quantity of the friar's balsam was poured into all the openings, and the arteries and veins plugged with spices, etc., well wetted or soaked in the balsam; the heart was then placed in the urn well filled with spices, and again soaked with the balsam. The urn was then hermetically closed. The scalp being most carefully removed, the cranium was sawn through, so as to remove the upper and larger portion, the brain carefully removed; the bony cavities were treated in the same manner as the other cavities. The brain was divided in many parts by small incisions or deep punctures, and a considerable quantity of friar's balsam poured into them; it was carefully replaced within the cranial cavity, well covered with the balsam, so as to envelope the whole mass, the scalp well drawn over the whole cranium, and closed, by being closely sewn with twine well waxed. The mouth and throat were crammed with the spices wetted with the balsam, as also the nostrils. Nothing was done to the lower parts of the body that I remember, neither have I any note of such. The body was well washed with lime water, and when perfectly dry, every member was separately rolled in waxed cloth, and afterwards the whole body closely enveloped in the same.

I forgot to mention the bladder was treated in the same manner by the different immersions, and crammed with the spices. Performed by Mr. Home, myself acting as assistant. The body was an Earl of Moira, all under the immediate direction of Mr. John Hunter.

The apothecary who supplied all the materials that were necessary by tenure of office, was Mr. Wainwright, who resided in Pall-mall, opposite to Carlton-house, within a door or two of St. Albans-street, as it was at that period.

The spices were composed of the more aromatic and pungent order, as cloves, nutmeg, cinnamon, pepper, frankincense, etc., etc., added to which was a large portion of alum in powder; all were reduced to a coarse powder.

JOHN DORRAT.

ST. ANDREWS MEDICAL GRADUATES' ASSOCIATION.

THE fifth anniversary session of this Association—Dr. Day (Stafford), President—was held on Friday and Saturday, December 1 and 2, at the Freemasons' Tavern, Great Queen-street, Lincoln's-inn-fields.

The following were elected Officers and Council for 1872:—

President: *Deputy Inspector-General Gordon, C.B., Dover.

Vice-Presidents: Dr. Crisp, London; Dr. Black, Chesterfield;

Dr. Cholmeley, London; Dr. Wynn Williams, London; *Dr.

Balfour, Edinburgh; *Dr. Lush, M.P., Salisbury. *President of*

Council: Dr. B. W. Richardson, F.R.S., London. *Council*: Dr.

Ballard, London; Dr. Dudfield, London; Dr. Goss, London;

Dr. Cleveland, London; Dr. Buchanan, Glasgow; Dr. W. H.

Day, London; Dr. J. T. Griffith, London; Dr. Wiltshire,

London; Dr. Barnard Davis, F.R.S., Shelton; Dr. Jencken,

Dublin; Dr. Ross, London; Dr. Royston, London; Dr. G.

Bird, London; Dr. Brewer, M.P., London; Dr. Lockhart

Clarke, F.R.S., London; Dr. Cooke, London; Dr. Wharton

Hood, London; Dr. Murray Lindsay, Hanwell; Dr. Nicholls,

Chelmsford; Dr. Semple, London; Dr. Stedman, Guildford;

*Dr. Christie, Royal India Asylum; *Dr. Bower Harrison,

Manchester; *Dr. Samuel Hill, London; *Dr. Humby,

London; *Dr. Lipscombe, St. Albans; *Dr. Macdonald, R.N.,

F.R.S., Woolwich; *Dr. Moon, Brighton; *Professor Norris,

Birmingham; *Dr. Painter, London; *Dr. Waring, London.

Honorary Treasurer: Dr. Paul, London. *Honorary Secretary*:

Dr. Sedgwick, London.

A gown and hood of the Doctor of Medicine of St. Andrews was presented to Dr. Richardson, F.R.S., as a slight acknowledgment of the eminent services which he has rendered to the Association during his four years' tenure of office as President.

The report of the Council dwelt chiefly on the mode of

* Those marked thus have not held this office during the previous year.

taking Medical evidence in courts of law, and on the regulations for the degree of M.D.

In regard to the latter subject the Council reported that they were taking steps to circulate largely among non-graduates the following—

“Memorandum of Medical Degrees.

“The University of St. Andrews is the only British University where a legally qualified Medical Practitioner can obtain, after examination, the degree of Doctor of Medicine without keeping terms at a University or attending anew courses of lectures at a Medical school; but candidates must be forty years of age, and only ten such degrees can be granted annually.

“The Scottish University Commissioners of 1858 reported that the power possessed by the University of St. Andrews, to grant, after examination, the degree of Doctor of Medicine to Medical Practitioners, who, after a successful career of some years, are desirous of obtaining a higher Professional position, is proper and advantageous if confined within due limits; and that, in order to prevent any abuse of the privilege, they had required the candidates to be forty years of age, and had limited the number of degrees which should be so conferred to ten annually, being assured, on the best Professional authority, that this number would be quite sufficient to include all persons so situated who could present any reasonable claim for admission to a degree.

“The University has recently attempted to amend the regulations for the degree of Doctor of Medicine by substituting, for the provision that the candidate shall be forty years of age, one requiring him to have been in possession for five years of a Medical or Surgical qualification which would entitle him to be registered under the Medical Act, and by abolishing the limitation in the number of degrees to be granted annually.

“The consent of her Majesty the Queen in Council, which is needed to render any new regulation of this kind valid, has been refused, for the reason that no sufficient ground has been shown for any further extension of the privileges possessed by the University in granting Medical degrees.

“This Association has contended that the Report of the Scottish University Commissioners as to the sufficiency of ten degrees annually (which has doubtless influenced the decision of the Privy Council) is based on untrustworthy authority; that these arbitrary limitations as to the age and number of the graduates exclude from the degree many candidates who by their position and acquirements are entitled to offer themselves for examination; and that the true and only limit to the number of degrees granted to already legally qualified Medical Practitioners of acknowledged respectability and position should be afforded by an extended and searching examination.

“Under these circumstances the Association is wishful to ascertain, as nearly as may be, the exact amount and nature of the injurious effect of the present regulations; and for this purpose it is endeavouring by means of the accompanying form, which it is hoped will be largely used and promptly returned, to collect the opinion of those most intimately concerned—the opinion, that is, of those legally qualified members of the Profession, who may now, or in a short time, desire to obtain the degree of Doctor of Medicine.

“The Association, pressed by various and conflicting opinions and statements concerning the matter in hand, is only anxious to determine on absolute facts what is the true Professional requirement. It is not, therefore, intended to publish the names of those who are good enough to express in this manner their opinion on this subject, but merely to furnish the University Court, and, if necessary, the Privy Council, with accurate data.”

A discussion on “Habitual Drunkenness and its Treatment, Medical and Legislative,” was introduced by Dr. Swete, and continued by Dr. Griffith, Dr. Richardson, Dr. Lush, M.P., Mr. Hepworth Dixon, Dr. Seaton, Dr. Crisp, Dr. Thomas Ballard, the President, and others. The majority of the speakers considered that in any legislative enactment that might be considered desirable a distinction should be drawn between drunkenness as a disease and drunkenness as a vice, and that the former might well be treated under similar regulations to those provided by the Lunacy Acts. On the other hand, it was contended that dipsomania, if there were such a disease, had no recognisable characters, and that the description given of it was vague and unsatisfactory. Great sympathy with the efforts of Dr. Dalrymple was expressed, and emphatic approval of the object he had in view, but there was a general opinion that many modifications were necessary in the provisions of the Bill. A strong opinion in favour of legislation of this character was given by Mr. Hepworth Dixon, as one outside of the Profession, and he asserted his emphatic belief that there

was a good in what might be called mechanical or mathematical legislation, a legislation of hard lines and rules whereby a man might see for himself that he was outside a standard of right, and was branded as a wrongdoer. In a new path like this many mistakes would be made at first, no doubt, and watchful attention would be essential to good progress. On the motion of Dr. Richardson, seconded by Mr. Hepworth Dixon, it was unanimously resolved—"That the Council of this Association be requested to watch the progress of Dr. Dalrymple's Bill, and, at the proper time, to prepare an analysis of, and an opinion concerning, the probable working of the Bill; and that the Council be also empowered to communicate the same to a public meeting of the Profession at large and of the public, if the proceeding be considered advantageous."

The following day the PRESIDENT delivered the anniversary address on "The Historical Steps of Modern Medicine." After describing the modern progress of natural histology, he said, in regard to the study of diseases by synthesis,—

"By ancient usage the disease was, in every case, accepted as though it were, if I may say so, an experiment projected by nature, out of the knowledge of the Physician, but sought after, as to its cause, by an examination of the external conditions under which it occurred. By modern usage the experiment of disease is made by the observer; the synthesis of disease, as it is said, is practised, and, from a given known cause, suggested by theory, morbid changes are produced, which changes resemble those that take place under what have been before considered as the hidden workings of nature. Of the results of these synthetical researches the world at large has no knowledge, and the Profession, taking it as a body throughout the world, but little knowledge; and, indeed, the study of disease by synthesis has been cultivated for so few years there is small reason to wonder it should be so little, so indifferently recognised. There is as yet about it hardly sufficient information to produce a decent volume, and yet how rapidly has it led us towards generalisations in all the directions in which it has been applied. That diabetes should be producible, synthetically, by the process of irritating the floor of the fourth ventricle, by the inhalation of carbonic oxide, and by other agencies affecting the nervous centres, thereby proving the true neurotic origin of this formidable malady, is one of those rapid strides by direct experiment which could not be accredited had it not actually been done, and which, instead of running counter to the previously recognised but obscurely understood morbid states of the ailment, runs with them, and explains them, as they were never explained before. That the disease so long known as cataract should be synthetically producible by the simple process of charging the circulatory current with an excess of crystalloidal matter; that different forms of cataract should positively be producible by the action of different crystalloids; that the well-known diabetic cataract should be producible by the mere introduction of glucose, the crystalloid which the diabetic patient is throwing off; and that, by placing the body of the animal, in which the morbid state has been generated, in favourable circumstances for recovery, recovery should follow—that all this should happen, opens up to us a series of truths so startling that one almost hesitates to accept them in full, lest, by some accident of experiment, an error should have been committed. That epilepsy, and the chronic epileptic condition, should be producible by the division and removal of portions of nerves; that the epileptic seizure, in the prepared animals, should at once be made evident by the disturbance of motion in the peripheral nervous matter at some given point of the surface of the skin; and that the tendency to the produced disease should be transmitted by hereditary descent—these, again, are facts so extraordinary, that we feel we have yet to wait for a knowledge of the true meaning of nervous lesions, for a knowledge which does not now exist; that is to say, for the discovery of lesions which are not detectable by our present instruments of research—our chemical tests, our microscopes—refined as these may be. That all the conditions of disease, once known by the name of apoplexy, or apoplectic convulsion, but now called uræmia, should be producible by the process of dividing the nerves of the kidney, by separating the vessels of the kidney from the organ, by introducing the nitrogenous product of the kidney—uræa—in excess into an animal, or, lastly, and most wonderfully of all, by making the nitrogenous substance from inorganic materials out of the body, and then occasioning the disease by its introduction into the body—these are facts certainly not less strange, not less remarkable, than those which have preceded. After describing the great advance made in Surgery, he proceeded—"As, for a postscript, the lover cherishes his choicest words of admiration or trust, so, under the section of Surgery,

I retain to the last a reference to the prime Surgical work of this era—I mean the advance made in the introduction of ovariectomy as a Surgical cure. That out of a hundred women, who thirty years ago would have died, had they suffered from the disease known as ovarian dropsy, seventy should now be saveable by the interposition of the art of the Surgeon, is a triumph unmistakably grand. Let us assume that the operation shall not last—let us assume that, in the progress of physiological science, some simpler cure than that of laying open the abdominal cavity, and removing the ovarian cyst, and firing the pedicle of the cyst, shall be discovered—that discovery itself will not conceal the greatness of the operation I name. For to prove, as it has proved, how the viscera of the abdomen may, *in extremis*, be exposed and explored, is in itself a sufficient event to fix the attention of the after-ages. Meantime, too, while we wait for new light, we have the practical results of the operation for our own satisfaction, and for our warrant to the wiser men, the magisters of the future, that the intrepid skill of our Surgeons who perfected this operation, was guided by the steadiest principles of art, is to all of us, their fellow-workers, an honour, to them a pure, an enduring fame. Let me, herewith, pass from the field of Surgery of our time. The workers in it have left two relics at least—namely, subcutaneous incision and ovariectomy—that shall be long remembered, and shall wear enduringly, as historical steps of modern Physic." He concluded with a graphic description of the progress of modern threapeutics.

Sir THOMAS WATSON proposed a vote of thanks to Dr. Day for his important and admirable address.

The anniversary dinner took place in the evening.

REVIEWS.

Pathological and Anatomical Researches on the Inflammatory Changes occurring in the Intra-ocular Terminations of the Optic Nerves as a consequence of Cerebral Disease. By Dr. HERMANN PAGENSTECHER (of Wiesbaden.)

THIS PAPER, which appears in the present number of the Royal London Ophthalmic Hospital Reports, November, 1871, is of great interest to Physicians as well as to ophthalmologists. When in London last summer, Dr. H. Pagenstecher was most assiduous in visiting several Hospitals in order to obtain specimens. He obtained eyes from patients who had been under the care of Dr. Andrew, Dr. Hughlings-Jackson, and Mr. Bader. The paper is of most value on account of the very elaborate and careful microscopical examination of these eyes. Dr. Pagenstecher seems to have arrived at results of great value. But we prefer to extract from the article, as being of more general interest, that part which gives the author's views on the connexion between brain disease and the changes he describes, so well:—

"Another very important question appears to me to arise, in the explanation of the connexion between brain disease and the changes in question which affect the optic disc. I naturally consider here only those cases in which the communication (optic nerve) is not to be regarded as the originator or principal agent (*Fort-leiter* in the morbid process). (a) Up to the date of this, three different explanations of this have been given, of which the first two presuppose an increase of the intra-cranial pressure. They are as follows:—

"1. Through the increased pressure within the cranium, pressure is brought to bear upon the cavernous sinus, which induces venous congestion in the central vessels of the optic nerve, which is also increased, as regards this, by the scleral ring (von Graefe).

"2. The intra-cranial pressure must force the fluid from the arachnoid space along the sheath of the optic nerve into the canal-like system present in the lamina cribrosa; and thus swelling, congestion, and the inflammatory symptoms dependent upon these, take their origin (Schmidt).

"3. The third explanation, propounded by Benedict, asserts that the symptomatic neuro-retinitis (neuro-retinitis as a symptom of a vaso-motor disturbance) depends in the majority of cases upon a morbid innervation of the sympathetic, which

(a) "As mentioned before, I have, up to this time, never had an opportunity of examining an eye of which I could safely assert that the morbid process had crept from the brain along the optic nerve till it reached the disc. But the more I have employed myself in researches of this kind, the more doubtful do I become as to this mode of origination of the changes met with in the disc. However, as regards this, we shall derive the best assistance from those colleagues who specially interest themselves in diseases of the brain and nervous system, and have a large material to draw upon."

is again itself a symptom of the most varied cerebral disorders (Processe).

"Against the first theory there are the following objections:—

"1. The cavernous sinus is a blood canal, surrounded with such impervious walls as are rarely to be met with, and a pressure sufficient to really compress this must, since the pressure within the cranium must be regarded as equal in all directions, exercise enormous pressure on all the other blood-vessels.

"2. The vena ophthalmica superior and vena ophthalmica inferior anastomose extensively both with one another and also with the facial vein; and although the vena centralis retinae empties itself almost immediately into the cavernous sinus, yet it previously anastomoses freely with the vena ophthalmica superior. But besides these anastomoses, it is quite indifferent whether the discharge takes place at the vena ophthalmica or into the cavernous sinus, since both are continuous, and the return of the blood suffers no hindrance so long as the way through the facial vein is patent (Sesemann).

"3. Not every increase of cerebral pressure is followed by neuritis, and undoubtedly neuritis occurs where there is no such increased pressure.

"4. Optic neuritis is sometimes one-sided, and indeed has been often observed on the side opposite to the cerebral lesion, whilst the eye on the same side has remained perfectly normal (Case II.).

"The above-quoted 3rd and 4th facts may be adduced against the second theory. Yet, apart from these, one would be inclined to accept the theory, as soon as one became convinced of the existence of such a system of canals in the lamina cribrosa as are presupposed. Hitherto I have not been so fortunate. The dilatation of the inter-vaginal space (between the outer and inner sheaths of the optic nerve) was indeed revealed in a very suggestive (*prägnante*) manner, yet it would not be difficult to explain this by a surmise that it had its origin in an inflammatory process previously existing in the disc.

"Case V. lends most countenance to this view—namely, in regard to the lacunous formation somewhat above the level of the choroid; yet since even here we have to do with a really atrophic process, this also is by no means conclusive.

"The third explanation actually gains strength from the objections made against the two others, and Benedict especially calls attention to his successes with the constant current. From the point of view of pathological anatomy, nothing special can be said either for or against it, since points of contact are wanting. However, in the majority of cases we shall do best to content ourselves with this, if we must have an explanation at all, although it is partially inaccurate, and also requires further confirmation. In my view, then, the affair stands thus: The irritation conveyed through the nerve-tract of the sympathetic to the disc, induces the changes of the nerve-fibres, the hyperæmia, and even the development of new vessels, and in this manner a swelling and obfuscation (*Trübung*) of the disc and the adjacent parts of the retina is brought about. The latter may then for its part have, as a consequence, an extreme degree of congestion of the venous system of the retina.

"In any case it is very easy to bring the analytical facts in accordance with this explanation; and the very often asserted facts of the swelling of the optic disc of one eye only are most easily explicable on this hypothesis."

Elementary Treatise on Physics, Experimental and Applied, for the Use of Colleges and Schools. Translated and Edited from Ganot's "Éléments de Physique," by E. ATKINSON, Ph.D., F.C.S., Professor of Experimental Science, Staff College, Sandhurst. Fifth Edition, revised and enlarged. London; Longmans. Pp. 828.

This capital text-book, which we have long been wont to use as a study companion, has now been so thoroughly naturalised to our tongue by its talented translator, that we have come to regard it rather as an English than as a French treatise. Indeed, were it not for the French names and titles which still appear on many of the woodcuts, we should be fairly tempted to consider it of indigenous origin. Of the new edition there is not a great deal to say. As a volume, it is perhaps more elegant than the old; a somewhat larger type is employed, but, perhaps from using a somewhat thinner paper, certain of the woodcuts lack that clearness and crispness which used to characterise them.

As a text-book introductory to the study of Medicine,

this work well deserves the confidence of the public; for though written without any special application to Medicine, the plan of handling the subject adopted in it is well adapted to the wants of the student of Medical science. Certain works on the subject of Physics incline too much to mathematical demonstration; and though, without doubt, knowledge formulated in terms of mathematical precision is more exact than that conveyed in ordinary language, nevertheless exactness may not be possible in every branch of knowledge, and so the student fails to obtain a knowledge of those not capable of being so expressed. Among young students, too, such as those preparing for the Medical curriculum, the stock of mathematical knowledge necessary for the study of Physics in that way is not generally available, and so a plan such as is adopted in this volume—that is, neither too loose nor too mathematical—is that which is best for them. The tendency of modern physiology is more and more to take advantage of physical science to explain the phenomena of living beings, and, with a view to a right understanding of what goes on in such mechanical processes as respiration and circulation, a knowledge of mechanics is absolutely necessary. Still more is this so when treating of the movements of the living body and in dealing with the organs of sense. Where would our knowledge of ophthalmology be but for a profound knowledge of the laws of optics? And though our knowledge of diseases of the ear is less exact than is that of diseases of the eye, what exactness it does possess is due to a knowledge of acoustics.

We have long contended for an improved preliminary education in our Medical youth, and in no department is this more necessary than in Physics. The time devoted to Medical studies strictly so-called is all too short, and it is hard for a teacher of anatomy or physiology to have to teach that which might have been taught at school, but which, nevertheless, he must teach if his pupils are to have a right understanding of their subject. A proper knowledge of Physics ought to be exacted from everyone entering on the study of the Medical Profession; and at all events it cannot be urged in excuse that there is no proper text-book, for it is rare to find on any particular subject two works so well adapted to the use of the student as that whose title heads this notice and Charles Brook's "Natural Philosophy."

COLONIAL CORRESPONDENCE.

AUSTRALIA.

MELBOURNE, September 9, 1871.

THE chemists and druggists of Victoria have lately been bestirring themselves to obtain an Act similar to the Act which has been working so well in England, for the regulation of those practising pharmacy. After some trouble, a Bill has been drafted and submitted to the Medical Society of Victoria, who have made some important alterations, most of which, it is expected, the Pharmaceutical Society will adopt. Such an Act is much needed here, both for the protection of the respectable chemists and druggists themselves, and also for the better defining of their own functions; for it is pretty well known that a good many of these gentlemen do a large amount of surreptitious practice, not only over the counter, but in the way of visiting, notwithstanding that the Medical Act, however deficient in some particulars, is tolerably express in defining irregular practice. The amended Medical Bill, also, has been for many months in the hands of the Medical Board, pending the settlement of an objection raised by the Government to introduce it into the Assembly. The Government are disposed to regard it as a private measure, but offer to give it their support.

In a general way, it is here very much the rule for people to take a man at the value at which he appraises himself; but this principle reaches its excess of application in respect of the Medical Profession. A very shrewd observer belonging to our order in this city says that no social infamy is so infamous as Medical infamy; and, if one may judge by examples, which are here abundant, he is right. The impunity with which Professional ethics may be defied is not quite encouraging to those who endeavour to act honourably, and its bad effects are seen throughout a too large section of the Profession here, not always in an exaggerated form, but almost infinitely modified; so that the chivalric sense of honour which one tries to believe ought to distinguish the cultivators of Medicine, is found to be only exceptionally illustrated. It is true that Medical men in Australia have to fight very hard the battle of life. Not only

is there a spirit of very keen competition at work, but the rage for cheap Medicine is continually on the increase. It would seem as if, very shortly, what with clubs and what with charitable institutions, there will be very little private practice left; so that, unless a man be exceedingly high-principled indeed, his virtue cannot resist the temptation of securing an advantage when it offers, no matter at what sacrifice of Professional ethics. For example, at this very time, there is a vacancy in the Assistant-Physicianship of the Melbourne Hospital, for which several candidates are in the field. Of these, notably the most ineligible man is known to be the most industrious canvasser. He obtained an appointment to another charity in this city simply by force of diligent personal solicitation, and the general belief is that he will succeed in a similar manner this time.

Apropos of the Melbourne Hospital, the Committee have just decided upon accepting the services of a young lady of great intellectual culture, and highly connected socially, to train the nurses according to the better method which Miss Nightingale's intelligence and experience have suggested. Hitherto the nurses in this institution, if not exactly of the "Mrs. Gamp" class, have, at any rate, undergone no sort of preparatory training, and this determination on the part of the Committee has created a very favourable opinion of the management.

On the subject of the Medical charities of Victoria there is, however, just now among their several Committees something like consternation. It is known, probably, to your readers that these institutions are, for the most part, maintained by the State, the subscriptions forming a comparatively small percentage of the whole income; but the Treasurer of the Colony has just announced that, for the future, Government aid will be granted only in the proportion of two-thirds to one of subscriptions. It is perhaps desirable that the voluntary system should be more largely applied; but to suddenly insist upon its larger adoption is felt to be something more than inconvenient, and it is not unlikely that some special means will be adopted to bring pressure to bear upon the Government to resume the hitherto prevalent custom of supplementing the funds to the extent of their needs. Our Legislature, however, continually shows itself prone to indulge in wild economies. During the recent debates on the estimates, an almost frantic endeavour was made to abolish all coroners, and also the office of Chief Medical Officer. The design, however, was frustrated, but not until a promise had been given that the whole system of coroners' inquests should be submitted to a commission of inquiry.

I am glad to be able to announce that the Medical Benevolent Association, which commenced its existence six years ago very unobtrusively and modestly, has, after relieving many cases of need, nevertheless accumulated a permanent fund of £500, which it is determined shall form the nucleus of a widows' and orphans' fund.

WEST INDIES.

TRINIDAD, November 8.

SMALL-POX has been epidemic here for nearly three months. It originated with a passenger by the Royal mail steamer *Nile*. It appears that a fatal case of small-pox occurred on the Transatlantic passage of the *Nile* from Southampton. She left that port on July 17, and the passenger in question, a negro, was landed here on August 4. Three days after landing he was attacked with fever, and three days after the fever the eruption appeared. No Medical man was called in until the case was reported to Dr. Bakewell, the Medical Officer of Health for the colony, by whom it was immediately reported to the Governor. The patient was then in the eleventh day of the eruption, and fourteenth of the disease. His sister, living in the same house, who had washed his clothes for him, was then suffering from a discrete form of small-pox, and a few days subsequently a child in the next house was attacked. From these cases the disease spread into the town of Port of Spain, and has now reached the country districts. Unfortunately, the Board of Health declined to comply with the recommendations of the Medical Officer of Health, who advised complete isolation of the first cases, and a rapid vaccination of all unprotected persons, and revaccination of all who had passed the age of 12 years. House-to-house vaccination of the whole unprotected population was adopted, but revaccination, unfortunately, was not. The consequence is, that, though the epidemic is not likely to prove severe or very fatal, it will probably spread over the whole island, and the colony is suffering the inconvenience of being put in quarantine by

all the other islands. Up to this date there have been (from August 24) 152 cases; of these 28 have died (among whom 3 were unvaccinated persons), 82 have recovered or are convalescent, and 42 remain under treatment. Upwards of 2000 persons were vaccinated in Port of Spain in the course of six weeks. The epidemic is marked by no peculiar features. The health of the colony is in other respects good, and, strange to say, the mortality of Port of Spain has rapidly decreased since small-pox became epidemic. In August there were 102 deaths registered, in September 91, and in October 73. Small-pox has also appeared in Jamaica. The weather is now intensely hot.

GENERAL CORRESPONDENCE.

ALCOHOL INCONSIDERATELY PRESCRIBED.

LETTER FROM DR. LIONEL S. BEALE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I was to-day asked to sign a paper in which objections are very properly made to the inconsiderate prescription of alcohol by members of the Profession; but when I inquired for the evidence that alcohol had been inconsiderately recommended, it was not such as to satisfy me, and in the absence of the most convincing evidence, it cannot be right to imply that any members of our body advise *inconsiderately*, either as regards eating, drinking, or the administration of medicines. That many of the public eat and drink too much, is well known to us all; but can it be supposed that any expression of opinion upon our part will reduce the number of courses at fashionable dinners, or persuade persons to drink water while they can get wine? No doubt many people would live longer if they drank less alcohol; but can we, by signing an expression of opinion, however strong and unanimous, hope to influence them? Many persons enjoy their wine—they find by experience that it suits them; they like it and take it. Are we to be held responsible for the morals, manners, and customs of the times in which we live? It cannot be our business to attempt to regulate the general consumption of wine, beer, and spirits!

What, therefore, is likely to be gained by some of us coming forward to protest against habits which all people know to be wrong? By taking this step do we not incur the imputation of responsibility, or, rather, do not those who sign the paper accuse some of their own body of contributing to the creation of habits of intemperance? Some people seem to fancy that drinking goes on in many London counting-houses and in not a few drawing-rooms to a terrible extent; others assert that chloral is all the fashion; and there is no end to the extravagant improbabilities that are put forward as if they were actual facts. Surely it cannot be right on the part of certain members of a Profession like ours to suggest publicly that others administer a remedy inconsiderately or indiscriminately! If a case of inconsiderate alcohol-giving comes within the knowledge of one of us, would it not be better to write to or see the culprit, or discuss the matter with him in a Medical journal? Simply to state or imply that there are amongst us men who, by the advice they give, knowingly or unknowingly encourage their patients in acquiring habits of intemperance, seems very ungenerous and, I venture to think, unjust. Some of us do not believe that there is any real foundation for so serious a general charge. People who drink do so knowingly, in spite of the strong advice given them by others not to drink. They will, of course, try to shift the blame upon their Doctors or their friends, or on fortune or misfortune, or upon anyone or anything except upon themselves, who alone are really responsible.

I am, &c.,

61, Grosvenor-street, Dec. 1.

LIONEL S. BEALE.

MEAT EXTRACT.

[To the Editor of the Medical Times and Gazette.]

SIR,—You have accomplished a good work in taking up the question of meat extract; for the truth ought to be known, even should it prove fatal to the grocer-enterprise of one or more celebrated chemist.

You ask whether it be true that the meat extracts contain no appreciable quantity of albuminous matter, and, therefore, are not superior, in nutritive power, to *unscientific* beef-tea?

Not superior? I answer: *far inferior*. For, not only are they deprived of albumen, but even of *colleine*, which is con-

tained in beef-tea, and causes this to coagulate when cold. In fact, meat extract is almost exclusively composed of salts. I do not say by this that it is quite useless—for why should not the salts of meat have some therapeutical properties?—I only protest against the quackery of ascribing to any article of trade those properties which it does not possess. And it seems to me that the jury of the Exhibition in Amsterdam have exhibited themselves in a manner far from splendid when they assigned a golden medal for the meat extract of Baron von Liebig. If this learned gentleman wishes to provide us with a meat extract *really nutritive*, he should invent a method of preparing it in such a manner that at least the *colleine* is preserved. At all events, some slices of tender roast beef or roast mutton will always be far more nutritive than the best meat extract in the world. It must be kept in mind that meat extract acts as a purgative, and, for invalids liable to diarrhoea, is decidedly unadvisable.

Pau.

I am, &c.,

BEEF-EATER.

LINES BY RICHARD BANISTER.

LETTER FROM DR. W. NEWMAN.

[To the Editor of the Medical Times and Gazette.]

SIR,—The enclosed lines may amuse some of your readers. The reprint is word for word taken from a curious octavo work on "Diseases of the Eyes," by Richard Banister, London, 1622. The book itself is rare, and has little of interest to the modern oculist, except that, speaking of "gutta serena," the author refers to the greater hardness or softness of the eyeball in different cases—a dream, so to speak, of the modern value of greater or diminished tension. The lines are not claimed as original, and the idea has, I believe, been worked out by more than one writer—a testimony hardly needed to its substantial truth.

I am, &c., W. NEWMAN, M.D. Lond.

Barn-hill House, Stamford.

"THE PRACTITIONER'S CAVEAT.

"Dvm nigris ægrum prope mors circumuolat alis
Funestamq; aciem, funera jamq; parat:
Tum me promissis beat, & domus omnis adorat,
Meq; salutiferum clamitat esse Deum.
Paulò vbi conualuit, paulum de numine nostro
Cessit, & in nostris auribus ista sonant:
Tu cœlo nobis demissus es Angelus alto:
Præmia quæ vestri, quanta laboris erant?
Jamq; Machaoniâ magis, et magis Arte leuatus,
Cum sedet ante focum, progrediturque tripes.
Oh homo, non frustra, tantos subiisse labores;
Nosces, quod restat, tu modò tolle malum.
Ast ego si penitus jam sanum præmia poscam,
Ille Deus pridem, mox Cacodæmon ero:
Cautior exemplo tu (dum dolet) accipe nostro,
Qui medicè exercet, gnauiter artis opus."

"A SURGEON DIVIDED INTO FOURE PARTS: OR THE SURGEON'S COMMENT.

- " 1. A Surgeon's like a God whom they adore:
When death about the sicke man's bed doth sore,
Then hath he great respect, and high regard,
Fed with the smoaky promise of reward.
- " 2. But as the Patient doth begin to mend,
So doth the Surgeon's God-head straightway end:
Yct such attendance on him still is given
As if he were an Angel come from Heauen.
- " 3. When health and strength the Patients doth inspire
To sleepe, cate, walke, and sit vp by the fire;
Then strait the Surgeon's state Angelicall,
In their respect vnto a man doth fall.
- " 4. Last when the sicke or sore are heal'd againe,
And that the Surgeon seekes reward for 's paine;
Hee's neither counted God nor Angel than
Nor is he intertained as a Man.
But (through ingratitude) that hellish euill,
They bid the Surgeon welcome as the deuill."

Richard Banister was a Surgeon and oculist residing in Stamford.

THE Mile-end Board of Guardians have voted a gratuity of twenty-five guineas to Dr. Cæsar for extra services performed during the prevalence of small-pox, and increased his salary from £200 to £220 a year.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, NOVEMBER 21.

Mr. HILTON, F.R.C.S., President, in the Chair.

THE PRESIDENT referred to the cases of Epithelioma which had been brought before the last meeting of the Society by Mr. Hulke, and gave some particulars of an analogous case which had been treated by Sir Astley Cooper fifty years ago, and had since come under his own notice. The subject of the disease was a gentleman, who suffered from an active epithelial growth over the shin-bone. As he wore knee-breeches and silk stockings, and as the disease caused considerable disfigurement, he was anxious to have it removed. He was jocularly recommended to use a bone-rasper, advice which he actually put repeatedly into force; and although its use produced pain, he by this means kept the growth down for years. A few years ago this gentleman consulted Mr. Hilton for cancer affecting the tibia, from which he ultimately died.

Dr. DICKINSON exhibited a Small Aneurism affecting the Left Middle Cerebral Artery. The patient was an elderly female, 72 years of age, who had always enjoyed good health. She expired suddenly while at dinner, her head falling on her plate. The effusion on the brain was not sufficient to cause death by cerebral pressure. Dr. Dickinson believed, therefore, that she had died of shock. The arteries of the brain were rather atheromatous, but elsewhere they were not very much affected. The heart and coronary arteries were healthy. The chief interest and rarity of the case was its proving fatal so suddenly.

Dr. GREEN related the case of a gentleman, aged 38, who had died suddenly from cerebral aneurism while drinking a glass of sherry.

Dr. HUGHLINGS-JACKSON mentioned the case of a woman who died in five minutes during, or after, a convulsive seizure; there was rupture of an aneurism of the middle cerebral artery. In this case there had been for several years epileptiform seizures. The association of epileptiform seizures with intracranial aneurism was pointed out by Dr. John W. Ogle and Dr. Murchison at this Society some years ago. It would seem that death by rupture of cerebral aneurism might be exceedingly slow or exceedingly rapid. Dr. Hughlings-Jackson had never seen a case of so rapid death from intracranial hæmorrhage as that related by Dr. Dickinson. He asked if there were vegetations on the valves of the heart.

Dr. DICKINSON, in answer to Dr. Jackson, stated that there were neither vegetations of the valve, nor was there any history of convulsions.

Mr. BRUDENELL CARTER exhibited, by means of the reflecting ophthalmoscope in the ante-room, a case of Double Optic Neuritis in a man. He said that Dr. Hughlings-Jackson, who had examined the patient, believed that a cerebral tumour was present, but that the cerebral symptoms were in abeyance.

Dr. HUGHLINGS-JACKSON considered Mr. Carter's patient's case to be one of great interest, because there were not any marked cerebral symptoms. The headache and vomiting the patient had had were very significant, but these symptoms were so slight in degree, and so transitory, that it would be scarcely safe to rely on them in the diagnosis of the presence of a coarse cerebral lesion. It was, however, certain that such ophthalmoscopic appearances as Mr. Carter demonstrated frequently did occur in association with adventitious products within the cranium, and it was equally certain that the absence of special nervous symptoms did not of necessity negative the existence of severe cerebral disease in this case. Probably the patient would have special nervous symptoms after a while.

Mr. HULKE pointed out that tumours growing inwards upon the brain gradually produce waste, and that there are frequently no symptoms until a few hours before death. We should be careful, therefore, in attacking tumours on the outside of the skull, as we frequently cannot tell whether they penetrate or not.

Dr. BAÜMLER brought forward a specimen of Aneurism of the Innominate Artery pressing on the common carotid artery. It chiefly affected the anterior circumference, so that the sac extended upwards to the right and left. The pneumogastric, sympathetic, and recurrent nerves were involved in the wall of the sac. The left recurrent nerve was intact. The specimen was taken from the body of a labourer, aged 53. Three weeks previously to death he began to suffer from aphonia; he could

not close his glottis, thus showing paralysis of the vocal cords. It was complete on the right and partial on the left. The diagnosis was verified after death, and the muscles of the larynx were found to be thin, pale, and flabby. Dr. Bäumlér wished to know if bilateral paralysis of the cords occurred from paralysis of one recurrent?

Dr. WILKS had known several cases where the discovery by the laryngoscope of paralysis of the vocal cord led to the diagnosis of aneurism. At the Veterinary College he had been lately told that roaring in horses was produced by pressure on the recurrent laryngeal.

Dr. CRISP said that aneurism in the horse was very rare. The old notion was that roaring was produced by emphysema, but this idea was now given up.

On allusion being made to the treatment of roarers by shot, Mr. HULKE referred to a gamekeeper who, he knew, was in the habit of taking shot for "rising of the lights"; and

The PRESIDENT referred to a similar practice of taking vinegar in addition to shot.

Dr. RISDON BENNETT remarked that many horses roared after a certain amount of exertion, and that paralysis of the recurrent laryngeal nerve was only one explanation of the disease.

Dr. DICKINSON exhibited a specimen, for Dr. Hawkes, of Horse-shoe Kidney.

Mr. ARNOTT exhibited a specimen showing the results of Excision of the Elbow-joint. The subject of the disease was a boy, who had been admitted into the Middlesex Hospital two years ago, when two and a half years old. He had strumous testicle, and other strumous symptoms. The joint was diseased, and was excised. Considerable portions of the bones were taken away. In two or three months he had fair use of his arm. In September, 1870, the testis was removed. In May, 1871, the boy showed cerebral symptoms, convulsions, and paralysis, which ultimately carried him off. After death, the bones of the ulna, radius, and humerus were found to be restored, and the ends of the bone were united by means of strong fibrous bands, with cartilage embedded and apparently becoming bone. The limb was half an inch shorter than the other. In the brain were found three tumours in the right cerebral hemisphere, from the size of a walnut to that of a hen's egg, made up chiefly of cheesy substance, and coated with grey transparent material, but there were no miliary tubercles in the brain. The skull was perforated. There was tubercle, however, in the lung. The microscopical examination of the tumour showed it to be similar to lymph-gland structure.

Mr. MAUNDER said that new bone was thrown out in quantity in these cases, because the limb was not allowed to rest.

Mr. DE MORGAN referred to a case in which the radius had been removed, and the ulna had thrown out a large quantity of new bone, which could not be explained by Mr. Maunder's theory.

Mr. WARRINGTON HAWARD asked Mr. Arnott whether he had taken any special care, in excising the joint, to preserve the periosteum, as he had seen, after the subperiosteal method of resection, an unusual generation of bone, in one case so much as to interfere with flexion of the joint. Though he did not think such precaution was necessary in ordinary cases, it seemed to him well adapted to such as, from the extent of the disease, required the removal of a large portion of the bones. Mr. Haward had recently practised that method in such a case with very good results. The mobility of the elbow-joint after resection was generally very good, in some cases even more than the natural movements being obtained—as, for instance, the power of placing the hand flat on the shoulder, which could not be done in the natural condition.

Mr. JOHN CROFT had followed out the plan of saving the triceps insertion.

In answer to Dr. DOUGLAS POWELL, who asked how the skull had become perforated, Mr. ARNOTT replied that he believed the inflammation had extended to the dura mater and skull from the tumours.

Mr. ARNOTT, in reply to Dr. Bäumlér, said he did not know whether the child had suffered from acquired or hereditary syphilis.

Dr. DICKINSON exhibited the larynx and trachea of a man, aged 52, on whom Laryngotomy had been performed for Acute Œdema of the Glottis. He died ten days after the operation, with pneumonia and symptoms of delirium tremens. There was minute injection of the air-passages below the opening, but above it the mucous membrane was of the ordinary pale colour. This inflamed state was, he believed, the result of the air passing, cold and unmoistened, immediately into the trachea and air-passages. At the Hospital for Sick Children, out of thirty-six

fatal cases of tracheotomy, pneumonia was present in seventeen, bronchitis without pneumonia in five, and congestion of the lungs in two. To prevent these complications, he had invented a respirator to be applied to the wound. The plan generally adopted, of making a tent by means of the bed-curtains, and keeping it filled with steam, was not good, as the body was also kept under the influence of the steam, which was objectionable.

Mr. SQUIRE said that he thought diffusing the steam in the room was better than by the tent method. He believed that chloroform was not employed so frequently as it ought to be in performing the operation of tracheotomy. The pulmonary affection was, however, not always due to the cold air, as bronchitis naturally arises in many cases in consequence of the disease.

Dr. WILKS agreed entirely with Dr. Dickinson in his opinion about the effects of the operation. He believed tracheotomy to be a formidable operation.

Mr. THOMAS COOKE said he had operated on five cases in Paris, and four of these proved successful. He covered the canula with a piece of thick gauze. Mr. Cooke also alluded to the case of a gentleman who had worn a canula for years, and who had an indiarubber tube attached to the canula, the mouth of which he kept under the waistcoat, so that the air was thus rendered warm.

CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 24, 1871.

Dr. OWEN REES, Vice-President, in the Chair.

Dr. MOXON related a case of Intracranial Disease cured by Iodide of Potassium. A young man, aged 21, was admitted into Guy's Hospital, under Dr. Moxon's care, having been ill six months. The illness came on with severe headache; in about three months ptosis and ocular paralysis of the left side commenced, and as it went on the left fifth nerve also became involved, and the right hand grew partially numb. When admitted he had agonising pain in the head. The left eye was intensely red, and its cornea ulcerated; it was almost immovable, and the lid was dropped. He could not feel moderate touches on the left face, nor taste salt on the left tongue, nor use left masticating muscles. He had two slight seizures of a doubtful kind on the first two days after admission. Iodide of potassium was given in three-grain doses thrice daily, and the dose increased to a scruple. He gradually got better of all his symptoms. The pain left him very soon; the other symptoms more gradually. He was in attendance at the Society's rooms, and the state of his left face and eye was practically normal again. The points to which attention was directed were chiefly these. That this is the third case of syphilitic disease about the sella Turcica Dr. Moxon had met with. This he connected with the growth of the sphenoidal sinuses there, bringing in illustration the occurrence of exostoses very frequently about the frontal sinuses, and of exostoses on the long bones at the region of the epiphysal cartilage; all these facts going to prove that the seats of late development are unusually liable to disease. Dr. Moxon believed that it was incumbent on everyone who had a case of local intracranial disease come under his care, to treat it at once with iodide of potassium, without waiting to make out its nature. He had not seen any serious ill-effects from the iodide when taken to the extent of a drachm in the day for long periods. Slight salivation, a red rash, and catarrh were not common, though they occasionally occur; and they are by no means to be compared with local intracranial disease as alternatives. As to absorption of the testes, he had never seen it. The iodism of old authors was probably referred to the poisoning of the blood by the absorption into it of broken-down matter of goîtres during their cure.

Dr. ANSTIE read the further and concluding history of a case of which the earlier notes were read last session. It was an example of neuralgia of all three branches of the fifth nerve, immediately excited by constitutional syphilitic infection, and which was of recent date. The case is one of a remarkable character. The nerve had been predisposed to neuralgic pain; many years before the syphilitic infection it had been the seat of an ordinary typical mygrane of great severity, and at present it was very noteworthy that the painful and tender points were distributed, not according to the type of tertiary syphilis, but according to that of ordinary neuralgia. Moreover, a number of secondary lesions (unilateral facial anæ-

thesia, unilateral loss of taste in the tongue, unilateral spasm of muscles, etc.) were distributed exactly as such secondary affections are in severe neuralgias where there is no question of syphilis. Besides these curious phenomena, there were a series of paralyses of the ocular muscles, quite of the ordinary syphilitic type. Thirty grains of iodide of potassium daily completely cured the neuralgia, the anæsthesia, the loss of smell and taste, and the muscular spasms, in little more than a fortnight. The ocular paralysis proved exceedingly obstinate; but the prolonged use of iodide in larger doses (forty-five and then sixty grains) daily at last completely removed them. It was a singular fact that, during the full progress of the muscles towards recovery, unmistakable symptoms of iritis made their appearance; they were checked by a short course of mercury. Such a case as this is sure to be marked in the future by the repeated recurrence of tertiary syphilitic nerve-lesions.

Dr. HUGHLINGS-JACKSON thought there could be no reasonable doubt as to the correctness of the diagnosis of syphilitic disease, since several cranial nerves were paralysed on but one side. Moreover, the palsies had passed off under anti-syphilitic treatment. Dr. Moxon's remark, that patients who are cured of syphilitic affections of the nervous system are liable to suffer again, was of great practical importance. He (Dr. Jackson) thought unfavourably of cases of syphilitic affections of the nervous system, even after the symptoms had been promptly removed by drugs. The author's observation on the indirect way in which nervous centres suffer from syphilis, by plugging of syphilitic arteries, was very important. Although patients would recover from hemiplegia, the result of any kind of pathological change, provided the lesion was very limited, he (Dr. Jackson) did not think the iodide was of value in removing hemiplegia, the result of plugging of a syphilitic vessel, any more than in removing hemiplegia the result of embolism from heart disease. He asked if the patient had had a blow on the head, as he (Dr. Jackson) had frequently seen cases in which syphilitic affections of the nervous system followed severe blows on the head. In illustration, he mentioned the case of a woman whose life-history he had related two years ago at this Society, who, after a severe blow on the left side of her head, had double optic atrophy (the sequel of neuritis) and convulsions, beginning in the right hand. At the autopsy there was found syphilitic disease of the surface of the left hemisphere, and also of the liver and spleen.

Mr. BRUDENELL CARTER said one feature in Dr. Moxon's case told against his diagnosis—viz., Mr. Bader's Report on the Condition of the Optic Discs. Were there pressure on the cavernous sinus, one would expect congestion of the central vein, which would set up œdema of the disc, and would leave traces behind it. If the mischief had been inflammatory, the inflammation might not have had time to creep down to the discs. This was a more likely solution of the difficulty than a tumour. As to the effects of iodine, most products would go with its use. He thought it would not do to call it an invariable rule that iodine should be given for syphilitic formations—in some it was advisable to use mercury. Tolerance of iodine was largely increased by the use of barley-water. It was often, also, a good plan to diminish the dose for a time.

Dr. BROADBENT thought that implication of the inferior maxillary pointed rather to inflammation than tumour. The case reminded him of one he had read to the Society, where the two upper branches of the trigeminus were affected. He had seen two other cases similar, but could get no post-mortem examination. In both there was rupia. In several cases he had seen a kind of purpura by iodine. He preferred to give ammonia with the iodine, and to give it after a meal. He had given as much as a drachm every four hours.

Dr. ANSTIE used to feel some hesitation in prescribing iodine in large doses; but his experience had shown the extreme rarity of troublesome symptoms. He now began with ten grains, and often gave a drachm a day.

Dr. BUZZARD remarked that from Dr. Moxon's title the term "syphilis" was expressly excluded. In many cases he had failed to get any history of syphilis; and yet the patients got well with iodide of potassium. It was, therefore, a question how far iodide of potassium was capable of removing other growths. One might give this drug almost as largely as bromide of potassium.

Dr. ALTHAUS considered large doses better borne than small. He had seen rashes follow their use. He had recently seen a child with paraplegia from rheumatism. Ten grains of the iodide three times a day caused its disappearance. He thought it interesting that in Dr. Anstie's case the symptoms should

disappear after such a length of time. He was surprised he had not used the constant current. The question had been raised as to how a local remedy like the constant-current could affect such maladies. Dr. Hughlings-Jackson had pointed out that local injury often produced such conditions; and so local remedies might remove them.

Mr. HOLTHOUSE asked how they were to account for paralysis of the orbicularis? He had seen petechiæ produced by iodide of potassium. He looked on the iodide as a kind of test for syphilis, as in ulcers. He referred to a case where nothing did good till black-wash and iodide of potassium were used.

Dr. MOXON, in reply, said there was no history of a blow. Mr. Bader had only very recently examined the eye. He thought they must not conclude, because iodide of potassium cured the condition, that it was due to syphilis.

Mr. GEORGE LAWSON remarked that it was rare to have congestion, etc., with ptosis; and Dr. ANSTIE, that exposure was by no means necessary to produce corneal ulceration.

Mr. CARTER said No, certainly not, if the inner portion of the ophthalmic were affected.

Dr. GLOVER described a case of Aphasia in a patient under his care at the Holloway and North Islington Dispensary. G. P., aged 63, an intelligent workman in a varnish and colour manufactory, came under treatment in the beginning of September with a very imperfect power of expressing himself, a furred tongue, high-coloured urine, and a weak pulse. The affection of the faculty of language was peculiar. Many words the patient could say quite well, but he was greatly embarrassed for want of the proper words. This appeared in his attempt to answer questions, and especially when asked to say what the names of particular objects were. Dr. Glover gave several curious illustrations. One day, on being shown a book and asked what it was, he said "good," "house," "butter." On being asked to write the name, he said, "a good"; then he remembered the right word, and said "book." On a watch being shown to him, and being asked for the name of it, he said "*Tempus fugit*," but could not say the proper word; but, on being asked to write it, he wrote "watch." He called a ring "a knife," and purse "bug," "book," "bug," "a pocket-book." One day, after naming the door and the fire, and being asked the name of the window, he was greatly puzzled, and said "five," "glass and sash"; he was then quite confused for a few minutes, and being asked to write it, he put "fire-away," "fender," "windway," "windway," "shot," "lock." Ten days later, being asked the same question, he said "windle," and quickly "a window." He seems at present to know when he answers wrongly, and is sometimes impatient, and sometimes amused at his errors and his embarrassment. There was no other symptom of cerebral disease, no hemiplegia, and either none or but the slightest difference in the sensation of the two sides. He walked well, wrote fairly, shaved well, and protruded his tongue straight. Dr. Glover remarked that the case was especially interesting for being simple and uncomplicated with any lesion of intelligence or of motion, such as right hemiplegia. There was nothing to indicate any affection of the left hemisphere more than one of the right, as M. Broca's remarkable theory supposed, which localised this disease in some lesion of the third left anterior convolution. Seven or eight months ago the patient had had a similar attack, which only incapacitated him for work one whole day, by reason of the way in which he put wrong names on the varnish cases. The present attack began about eight o'clock one morning in the water-closet. He seemed to lose himself. He foamed at the mouth and fell down, but not quite unconsciously, for he tried to save himself. He lost his speech, but spoke a little, cried a little, and seemed inclined to fret. He walked home with the help of a young man, who gave these particulars of the attack, and who thought that at the time the face was drawn to the left side. There was no drawing of the mouth since Dr. Glover attended him, and he saw him the day after the attack. Occasionally, the heart and pulse were irregular; at other times, and generally, they were regular, but weak. There was no abnormal sound. Mr. Carter had kindly examined the eyes, but the existence of lenticular opacity made it impossible to get any help in diagnosis from the state of the fundus. The patient's previous health had been good, excepting yellow fever in 1833 or 1834. He never had rheumatism or syphilis. The treatment at first was chiefly expectant. Latterly, ammonia and a little wine and beef have been its principal features. The aphasia had become rather less, though still persistent. Dr. Glover thought the symptoms might be attributed to either softening, or embolism, or slight extravasation affecting a very limited portion of the brain, and inclined rather to extravasation, from

the persistence of the aphasia and the nature of the attack. The patient was present, and was examined by various members of the Society.

Dr. BAÜMLER asked if there was any lead-poisoning.

Dr. HUGHLINGS-JACKSON thought that since the patient made mistakes in words, and could not express himself correctly in writing, the author was justified by usage in calling the very interesting case he had related one of aphasia, but he (Dr. Jackson) suggested that this term should be restricted to cases of more or less *loss* of speech. He thought a term was wanted for the other condition, that of disorder of speech—mistakes in words, for instance. He believed these two conditions were fundamentally opposite conditions, and that the mental states of the patients were different. For example, in cases of loss of speech the patient readily understands what is said to him, whereas in cases where making mistakes in words is the chief phenomenon it frequently happens that the patient does not readily understand what is said to him. He supposed that disorder of speech was more frequently the result of plugging of vessels, in young people especially, than of other pathological lesions, such as *elot*; but would not speak so confidently on this point as he had formerly done. The absence of hemiplegia in cases of affection of speech was very uncommon. It occasionally happened that the hemiplegia passed off when even complete loss of speech remained, but it was very rare for there to be absolutely no one-sided symptoms at first. Dr. Hughlings-Jackson mentioned a case in which the only paralysis in a patient who could say but one word—"yes"—was of the right side of the face, of the kind and degree usually found in cases of hemiplegia.

Dr. BROADBENT remarked that here the man's account was taken, and yet the man was making mistakes in words. The condition was rather amnesia than aphasia, and he would not expect to find the third frontal convolution affected. It reminded him of a case where a man had a good vocabulary, yet could not name a single object. There had in that case been two hæmorrhages near the lateral ventricle, destroying the perforating fibres.

Dr. ANSTIE had seen confusion of words from temporary depression, as diarrhœa. He thought this was a case of right hemiplegia, of embolic origin, with little confusion and loss of memory.

Dr. MOXON asked if the suggested words were immediately accepted; if so, that would remove the case from the region of aphasia. Sometimes one can induce an aphasia to use a word by frequent repetition.

Dr. ALTHAUS had seen aphasia without right hemiplegia, but with affection of the fifth.

Dr. GLOVER said there was no lead-poisoning, and no affection of the fifth.

OBITUARY.

THOMAS STAWELL BARRY, M.R.C.S. ENG., STAFF-SURGEON,

DIED on November 21 last, at Charles-street, Cavendish-square, aged 36. He entered the service in February, 1855, and became Surgeon in October, 1869. He served in the Crimea from May 8, 1855, and was present at the capture of Kerteh and Yeni Kale, the siege and fall of Sebastopol, and storming of the Redan on September 8 (medal with clasp and Turkish medal). He was with the Central India field force under Sir Hugh Rose, and was in Medical charge of the 86th Regiment at the action of Koonah, the operations before Calpee, battle of Gowlowlee (on which occasion he was mentioned in dispatches), the capture of the town and fort of Calpee, battle of Morar, battle before Gwalior, and capture of the town and fortress. He was subsequently in Medical charge of a flying column in the Jhansi and Gwalior districts. He received the medal and clasp.

PUREFRY HUDDLESTON DICKEN, M.R.C.S.

THIS promising young Surgeon was the third son of the Rev. Dr. Dicken, of Norton Rectory, near Bury St. Edmunds, Suffolk, and died from disease of the heart at his father's residence, on October 24, aged 22 years. He received the first part of his education at the Charterhouse, of which his uncle, the Rev. C. R. Dicken, was then one of the masters. He afterwards went to Ipswich under the Rev. Dr. Holden, whence he proceeded to study Medicine under T. C. Crosse, Esq., one of the Surgeons of Norwich Hospital. He pursued his studies

at St. Bartholomew's Hospital, and was elected a Scholar of that College in September last. He took great delight in entomology and botany, in which he had made some rather extensive collections.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members of the College, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board on the 6th inst. :—

Bodman, Francis Henry, M.D. Aberdeen, Devizes, Wilts, diploma of Membership dated July 28, 1871.
Harbinson, Alexander, M.D. Queen's University, Ireland, Newry, county Down, November 17, 1871.
Hughes, Evan Thos., L.R.C.P. Edin. and L.S.A., Tanyralt, Llanfachraith, Anglesea, July 25, 1871.

Two candidates, having failed to acquit themselves to the satisfaction of the Board, were referred.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, November 30, 1871:—

Dickson, Thomas, Preston, Lancashire.
Oates, James Pimlott, Stourbridge.

As Assistants in compounding and dispensing medicines—

Pattinson, Dan, Dearham, Cumberland.
Simpson, John, Colchester.
Williamson, Nicholas, Harrington, Cumberland.

The following gentlemen also on the same day passed their first Professional examination :—

Bevers, Edmund Augustine, Guy's Hospital.
Cornfield, Thomas, London Hospital.
Manser, Robert, Guy's Hospital.
Vowell, Charles Martin, King's College Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BRAITHWAITE, JAMES, M.D. Lond., M.B., M.R.C.S.E., L.S.A.—Assistant-Surgeon to the Hospital for Women and Children, Leeds.

BURROUGHS, GEORGE EDWARD ELTON, L.K. & Q.C.P. Ire., L.M. of the same College, M.R.C.S.E., and L.S.A. Lond.—Medical Officer of the Prees District of the Wem Union, *vice* Mr. Wetherhead, deceased.

CARTER, ALFRED H., M.B. Lond., M.R.C.S., L.S.A.—Assistant-Physician, Medical Registrar, and Pathologist to the Wolverhampton General Hospital, *vice* Dr. A. Bottle, resigned.

DOBSON, NELSON C., F.R.C.S.E.—Surgeon to the Bristol General Hospital, *vice* H. Marshall, M.D., F.R.C.S., F.R.S. Edin., resigned.

EAGAR, R. T. S., M.B., L.M. Edin., M.R.C.S.E.—Assistant House-Surgeon to the Public Hospital and Dispensary, Sheffield.

FAIRBANK, JOHN, M.R.C.S.—Surgeon-Dentist to Charing-cross Hospital, *vice* Mr. G. A. Canton, M.R.C.S., resigned.

HAMMOND, EDWARD BECK, M.R.C.S.—Medical Officer and Public Vaccinator for the Claydon District, Bosmere and Claydon Union, *vice* H. O. Rowland, deceased.

MARSHALL, HENRY, M.D., F.R.C.S., F.R.S. Edin.—Honorary and Consulting Surgeon to the Bristol General Hospital.

NOAKES, S. S., L.R.C.P. Lond., M.R.C.S., L.S.A.—House-Surgeon to the Teignmouth, Dawlish, and Newton Infirmary, Devonshire.

PEACOCK, EDWIN, M.R.C.S.E., L.S.A.—Certifying Factory Surgeon for the Nuneaton District, Warwickshire.

MILITARY APPOINTMENTS.

9TH REGIMENT OF LANCERS.—Staff Surgeon Robert Lewer to be Surgeon, *vice* Surgeon-Major John James Clifford, M.D., who retires upon half-pay.

6TH FOOT.—Staff Assistant-Surgeon Richard Exham to be Assistant-Surgeon, *vice* John Joseph Crean, appointed to the Staff.

48TH FOOT.—Staff Assistant-Surgeon Arthur Wellesley Roche to be Assistant-Surgeon.

66TH FOOT.—Staff Assistant-Surgeon Henry William Joynt to be Assistant-Surgeon, *vice* James Aloysius Joseph O'Brien, M.D., appointed to the Staff.

87TH FOOT.—Staff Assistant-Surgeon George Bedford Sanders to be Assistant-Surgeon, *vice* Philip Broke Smith, M.D., promoted on the Staff.

MEDICAL DEPARTMENT.—Assistant-Surgeon Philip Broke Smith, M.D., from 87th Foot, to be Staff Surgeon, *vice* Robert Lewer, appointed to the 9th Lancers; Assistant-Surgeon James Aloysius Joseph O'Brien, M.D., from the 66th Foot, to be Staff Assistant-Surgeon, *vice* Henry William Joynt, appointed to be 66th Foot; Assistant-Surgeon John Joseph Crean, from the 6th Foot, to be Staff Assistant-Surgeon, *vice* Richard Exham, appointed to the 6th Foot; Staff Assistant-Surgeon James Duhay has been permitted to resign his commission.

BREVET.—Surgeon-Major John James Clifford, M.D., retired upon half-pay, late 9th Lancers, to have the honorary rank of Deputy Inspector-General of Hospitals.

BENGAL ARMY MEDICAL OFFICERS.—To be Surgeons-Major: Surgeons Edward M'Kellar, M.D., Ancesley Charles Castriot de Renzy. To be Surgeons: Assistant-Surgeons Charles Cameron, John Richardson, M.B., Arthur Parker Holmes, M.D., Robert Grey, M.B., John M'Naghten Fleming, M.D., Charles Frederick Oldham, Edward Ambrose Fitzgerald, George Henderson, M.D., John Reid, Peter Cullen, M.D., James Richard Johnson, Isaac Newton.

BOMBAY STAFF CORPS.—To be Surgeon-Major: Surgeon Francis George Joynt. To be Surgeon: Assistant-Surgeon Abraham Nickson Hojel.

BIRTHS.

BROADBENT.—On December 2, at 44, Seymour-street, Portman-square, the wife of W. H. Broadbent, M.D., F.R.C.P., of a daughter.

GROVES.—On November 30, at 13, Silver-street, London, the wife of Edward Groves, L.R.C.P., M.R.C.S., L.M., of a son.

KNAGGS.—On December 5, at 72, Kentish Town-road, the wife of Dr. Knaggs, of a daughter.

LIDDON.—On December 3, at Silver-street House, Taunton, the wife of Edward Liddon, M.D., of a son.

MACKENZIE.—On December 3, at Sidmouth, the wife of Dr. Ingleby Mackenzie, of a son.

MARRIAGES.

BUCHANAN—KENWAY.—On November 23, at St. Saviour's, Paddington, Walter Buchanan, M.R.C.S.E., etc., Chatham, to Jessie Wilmshurst Kenway, youngest daughter of the late John Seymour Kenway, Esq., of Bridgeport.

LEE—BLIZARD.—On December 4, at the parish church, Killcooly, William E. Lee, M.R.C.S.E. and L.S.A., of Moore-park, Fulham, Middlesex, to Fannie Jane, eldest daughter of Mr. George Blizard, Killcooly, county of Tipperary, Ireland.

MARSHALL—CLOSE.—On December 2, at All Saints' Church, Clifton, Bristol, Henry Marshall, M.D., F.R.S., youngest son of the late Rev. James Marshall, to Constance Ellen Douglas, only surviving daughter of J. Douglas Close, Esq.

DEATHS.

BOXWELL, RICHARD, M.B., son of the late William Boxwell, M.D., of Abbey Leix, Queen's County, at Gorey, county Wexford, on November 28, aged 39.

CALLAGHER, JOHN, M.D., of Lima, Peru, and county Sligo, Ireland, at Lima, on September 29, aged 69.

COLLINGS, ADOLPHUS, M.D., formerly Surgeon 40th Regiment, at Grange-hill, Guernsey, on December 1, aged 56.

ELLIOTT.—On December 2, at Manor-road, Forest-hill, the infant daughter of Mary and John W. Elliott, M.R.C.S.E.

GILDER, WILLIAM TROWARD, late Assistant-Surgeon Scots Fusilier Guards, at Margate, on November 19, aged 83.

HENDERSON, EDITH, third daughter of the late Dr. Henderson, and the beloved step-daughter of Alexander Robertson, Esq., J.P., at Wellington-terrace, Berwick-on-Tweed, on November 29.

MILES, ERASMUS MADDOX, M.D., at Homefield-place, Heavitree, Devon, on December 1, aged 71.

WILKINSON, ABIAH, widow of the late J. Sheldon Wilkinson, Surgeon, at Brighton, on December 3, aged 52.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

AMERSHAM UNION.—Medical Officer wanted for the second Medical District of Chesham, in this Union. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. Henry Bedford, Clerk, on or before December 12.

BLYTHING UNION.—Medical Officer for the Wrentham District. Candidates are required to possess the qualifications prescribed by the General Orders of the Local Government Board, and to be registered. Applications and testimonials to Mr. C. White, Clerk, on or before December 9. Election on the 11th.

BRADFORD FEVER HOSPITAL.—Resident Medical Superintendent. Gentlemen applying for this appointment must be duly qualified Medical Practitioners. Applications and testimonials to Mr. C. Woodcock, on or before December 11.

CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House-Surgeon. Must be a registered Medical Practitioner. Applications and testimonials to the Secretary, Infirmary, Bangor, on or before January 2, 1872.

DENTAL HOSPITAL, 32, SOHO-SQUARE.—Lecturer on Dental Surgery and Pathology. Applications and testimonials to the Honorary Secretary, on or before December 12.

EARLSWOOD ASYLUM.—Assistant Medical Officer. Must be duly qualified and registered. Applications and testimonials to the Secretary, on or before December 18.

HOSPITAL FOR SICK CHILDREN, 29, GREAT ORMOND-STREET, W.C.—House-Surgeon. The gentleman appointed must possess some legal qualification to practise. Applications and testimonials to the Secretary, on or before December 12. Election on the 13th; the duties to commence on the 18th.

JERSEY GENERAL DISPENSARY.—Medical Officer. Further particulars of the Rev. P. A. Le Feuvre, Oakwalk, Jersey. The election takes place early in January, and the duties will commence on February 1.

KILBURN, MAIDA-VALE, AND ST. JOHN'S-WOOD GENERAL DISPENSARY, 13, KILBURN-PARK-ROAD.—Resident Medical Officer. A qualification to practise is required. Applications and testimonials to the Secretary, on or before December 13.

LIVERPOOL SOUTHERN HOSPITAL.—Senior House-Surgeon. Must have Medical and Surgical qualifications. Applications and testimonials to Mr. James Houghton, Treasurer, on or before December 13.

MANCHESTER ROYAL INFIRMARY.—Senior House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to Dr. Reed, on or before December 22.

METROPOLITAN FREE HOSPITAL, DEVONSHIRE-SQUARE, CITY, E.C.—Honorary Surgeon. Must be F.R.C.S., or pledged to become such within twelve months. Applications and testimonials to Mr. G. Croxton, Secretary, on or before December 23.

NORTH STAFFORDSHIRE INFIRMARY.—Resident Medical Officer. The qualifications required are as follows:—M.R.C.S. Lond., Edin., or Dub., or one of the Universities; also a degree or license in Medicine from a University or duly recognised licensing body in Great Britain or Ireland. Applications and testimonials to Mr. R. Hordley, at the Infirmary, Hartshill, Stoke-upon-Trent, on or before December 20.

NUNEATON UNION.—Medical Officer and Public Vaccinator for the Nuneaton District. Candidates are required to possess the qualifications prescribed by the Local Government Board. Applications and testimonials to Mr. John Estlin, Clerk, Nuneaton, on or before December 26. Election on the 27th.

SEAMEN'S HOSPITAL (LATE DREADNOUGHT, GREENWICH).—House-Physician. Candidates must possess at least one qualification. Applications and testimonials to Mr. Kembal Cook, House-Governor and Secretary, on or before December 12.

STOCKWELL FEVER HOSPITAL.—Resident Medical Superintendent. Medical and Surgical qualifications required. Forms of application may be obtained at the offices of the Metropolitan Asylum District, 37, Norfolk-street, Strand, on or before January 1, 1872.

UNIVERSITY COLLEGE HOSPITAL.—Assistant Obstetric Physician. Applications to Mr. John Robson, B.A., on or before December 18.

WEST BROMWICH DISTRICT HOSPITAL.—House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to the Hon. Sec., on or before December 16.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

East Retford Union.—Mr. Willan has resigned the Dunham District; area 7001; population 1338; salary £15 per annum.

Oldham Union.—Mr. Charles Murray has resigned the Workhouse; salary £65 per annum.

Pocklington Union.—The Market Weighton No. 2 District is vacant; area 15,361; population 2470; salary £19 per annum.

APPOINTMENTS.

Arcminster Union.—Frederick Augustus O'Meara, L.R.C.P. Edin., L.R.C.S. Edin., L.S.A. Dub., to the Shute and Colyer Districts.

Chorlton Union.—Denis Walshe, L.R.C.P. Edin., L.R.C.S. Edin., Assistant Medical Officer of the Workhouse.

Christchurch Union.—James Henry Cartwright, M.R.C.S.E., L.S.A., to the Eastern District.

Dudley Union.—Thomas Frederic Higgs, M.R.C.S.E., L.R.C.P. Edin., L.S.A., to the Workhouse.

Eastry Union.—Thomas Edward Mason, M.D. St. And., M.R.C.S.E., L.S.A., to the Deal District.

Farnham and Hartley Wintney District School.—Robert Oke Clark, M.R.C.S.E., L.S.A., to the School.

Liverpool Union.—Henry F. Fisher, L.R.C.P. Edin., L.F.P.S.G., to the First District. James Ridley, L.R.C.S. Ire., L.K. and Q.C.P. Ire., to the Second District. Colles L. Anderson, L.R.C.S. Edin., L.R.C.P. Edin., L.S.A., to the Fifth District. Frederick W. Lowndes, M.R.C.S.E., L.S.A., to the Sixth District. Thorburn Paterson, L.R.C.P. Edin., L.R.C.S. Edin., to the Seventh District.

Market Bosworth Union.—Frederic James Orford, M.R.C.S., L.S.A., to the Market Bosworth District. David P. Thomas, M.R.C.S., L.S.A., to the Workhouse.

Monmouth Union.—George A. Norman, L.R.C.P. Edin., L.R.C.S. Edin., to the Rockfield District.

Romford Union.—Albert Wm. Wallis, M.R.C.S.E., L.S.A., to the Seventh District.

Toxteth-park Township.—Robert Atchison Keys, L.R.C.S. Edin., L.R.C.P. Edin., to the Workhouse.

West Derby Union.—Robert John Sprakeling, M.R.C.S.E., L.S.A., to the Bootle-cum-Linacre District.

Wigton Union.—William Brown, L.R.C.S. Edin., L.R.C.P. Edin., to the Caldbeck District.

ARTS EXAMINATIONS.—At the Preliminary Examination for the diploma of Fellowship and Membership of the Royal College of Surgeons, commencing on the 19th inst., 72 candidates have entered their names for the former distinction, and 232 for the latter—making a total of 304, against 337 last December.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, held on Monday, December 4, 1871, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S., President, in the chair, His Majesty Dom Pedro II. d'Alcantara, Emperor of Brazil, K.G., F.R.S., was elected an Honorary Member of the Royal Institution; and John Fleming, Esq., Mrs. G. H. Gibb, Alfred North, Esq., John Penn, jun., Esq., and Col. Edward Webb were elected Members of this Institution. The following lecture arrangements for the ensuing season were announced:—*Christmas Lectures* (adapted to a juvenile auditory): Prof. Tyndall, LL.D., F.R.S., six lectures "On Ice, Water, Vapour, and Air," on December 28, 30, 1871; January 2, 4, 6, 9, 1872. *Before Easter, 1872*: Dr. W. Rutherford, F.R.S.E., ten lectures "On the Nervous and Circulatory Systems," on Tuesdays, January 16 to March 19. Prof.

Odling, F.R.S., ten lectures "On the Chemistry of Alkalies and Alkali Manufacture," on Thursdays, January 18 to March 21. W. B. Donne, Esq., six lectures "On the Theatre in Shakespeare's Time," on Saturdays, January 20 to February 24. Moncure D. Conway, Esq., four lectures "On Demonology," on Saturdays, March 2 to 23. *After Easter, 1872*: Dr. Wm. A. Guy, F.R.S., three lectures "On Statistics, Social Science, and Political Economy," on Tuesdays, April 9, 16, and 23. Edward B. Tylor, Esq., F.R.S., six lectures "On the Development of Belief and Custom amongst the Lower Races of Mankind," on Tuesdays, April 30 to June 4. Professor Tyndall, LL.D., F.R.S., nine lectures, on Thursdays, April 11 to June 6. R. A. Proctor, Esq., B.A., F.R.A.S., five lectures "On Star Depths," on Saturdays, April 13 to May 11. Professor Roscoe, F.R.S., four lectures "On the Chemical Action of Light," on Saturdays, May 18 to June 8. The Friday evening discourses before Easter will probably be given by Mr. W. R. Grove, Q.C., the Archbishop of Westminster, Professors Odling and Humphry, Dr. Gladstone, Messrs. C. W. Siemens, R. Liebreich, John Evans, and Professor Tyndall.

ASSISTANT-SURGEON FRANCIS H. WEBB has been appointed Assistant-Professor of Pathology at the Army Medical School.

THE deaths in Paris last week show an increase as compared with the week previous, the numbers being 800, against 708.

LORD LEIGH laid, on Monday, with full Masonic honours, the foundation-stone of the new building to be added to the Queen's Hospital, Birmingham.

DR. PROSSER JAMES has been elected Corresponding Member of the Academy of Medicine of Madrid.

A SEVERE outbreak of cholera has occurred at Delhi, but is said to be decreasing.

COTTAGE HOSPITALS are to be erected at Sandgate and Trafford-Southwell.

DR. McCORMACK, of Southampton, has been elected Medical Officer of Lambeth, at a salary of 500*l.* a year.

SIR DAVID BAXTER, Bart., has signified his intention to erect and maintain in all time coming a Convalescent Hospital at Dundee, capable of accommodating sixty patients.

MEDICAL STUDIES AT CAMBRIDGE.—Professor Humphry has given notice that, in accordance with the recommendation of the Board of Medical Studies, "that Students of Medicine should be encouraged to remain in the University and pursue their studies during part at least of the Christmas and long vacations," the opportunities for the study of Practical Anatomy, and the superintendence of the same, will be continued during the approaching Christmas vacation. The course of lectures on Practical Anatomy will be continued till the end of the present term, and will be resumed at the beginning of next term—Monday, January 15, at 6 p.m.

CAMBRIDGE UNIVERSITY.—The annual dinner of the Cambridge Philosophical Society was held in the hall of Jesus College on November 24, Dr. Humphry, the President, in the chair, supported by the Earl of Kintore, the Presidents of the Royal Colleges of Physicians and Surgeons, Professors Huxley and Williamson, and Dr. Carpenter. The Master of St. Peter's College proposed the toast of "The Presidents of the Colleges of Physicians and Surgeons," and both those gentlemen expressed their satisfaction at the steps taken by the University in Medical study, and their willingness to co-operate heartily in the promotion of a joint board of the University and other licensing bodies. Professor Huxley, in proposing "The University," complimented them upon the advance they had made in natural science.

MR. WILLIAM ARTHUR BRAILEY, B.A., M.B., was on Saturday last elected a Fellow of Downing College. Mr. Brailey took his degree of B.A. in 1868, and in 1867 was second in the first class of the Natural Science tripos. He also passed the three examinations for the degree of M.B., and was recently appointed House-Physician to Addenbrooke's Hospital. The Fellowship to which he was elected is a non-residence one, tenable for twelve years from election, provided he does not enter into holy orders within the first six years, and is not vacated on marriage. These non-resident Fellowships are intended for persons in the active pursuit of the studies of law or Medicine. *Appropos* of holy orders, the holder of the Fellowship may continue to hold it for the remaining period of six years if he does not enter into orders within the first six years—affording another instance, in such case, of a clerical Physician.

DR. BAKER has resigned his appointment of Medical Officer of Health of the north district of St. George's-in-the-East. At the request of Dr. Sutcliffe, the Board has transferred him to the district rendered vacant by the resignation of Dr. Baker. The election is to take place on the 15th instant.

INDISCRIMINATE GRATUITOUS ADVICE.—Indiscriminate gratuitous Medical advice is most prejudicial to the interests of the public and the Profession. It has formed the theme of many a sermon, lecture, essay, and letter. But it is deeply rooted in the habits of the people, and not sufficiently opposed by Medical Practitioners themselves. It is gratifying to announce that the Camden and Kentish Town Committee have adopted the rules lately suggested by the Medical Committee of the Charity Organisation Society.

A DEFENDANT FINED FOR NEGLECTING TO DISINFECT A BED.—At Marlborough-street, on Friday, the 1st inst., Mary Rennary was charged with neglecting to disinfect a bed upon which a person suffering from small-pox had died. The sister of the deceased gave the bed to the defendant, who promised to take it to the stoneyard, where the parish have provided apparatus for disinfecting bedding and bedclothes. The defendant, however, according to the evidence of Mr. T. Lloyd Lightfoot, Sanitary Inspector of the parish of St. Marylebone, had not used proper means to cleanse the bed in question, and the consequence had been that two persons who had slept on it had been attacked by small-pox. Witness found that a man had been to a person named Aarons, a dealer in second-hand furniture, living near the defendant, and had offered the bed with other articles for sale. Aarons, however, did not buy the bed. Mr. Mansfield fined the defendant 20*s.*, with 5*s.* costs.

UNHEALTHY DWELLINGS.—The following extract from Mr. Liddle's Quarterly Report of the Sanitary Condition of the Whitechapel District gives an admirable summary of the duties of Officers of Health as regards unhealthy dwellings:—"It is the duty of the Medical Officers of Health to bring under the notice of their Local Boards all such houses as are unfit for habitation, so that the Local Board may adopt such proceedings in each case as their legal adviser may recommend. The Artisans' and Labourers' Dwellings Act is not a permissive Act as regards the duty of the Medical Officer of Health in reporting to the Local Board all such houses as are unfit for habitation, but it makes it imperative upon such officer to do so—the word 'shall' being used in the Act; and if the Medical Officer of Health shall fail in his duty in not reporting to the Local Board such houses which are unfit for habitation, then any four householders living in or near to any street in which there are any houses which, in their opinion, are unfit for habitation, can direct the attention of the Medical Officer of Health thereto, who, upon receiving information in writing, signed by them, must make a report to the Local Board upon the condition of the houses complained of. It is of no use in the public saying, as is frequently the case, that half the houses in London occupied by the poorer classes should be demolished, when no one is willing to specify, in the form required by the Act, the particular houses which are unfit for habitation."

THE ADULTERATION OF COFFEE.—The number of *Food, Water, and Air* for this month contains an article on the "Adulteration of Coffee." It shows that while of thirty-four samples examined some years since no less than thirty-one were adulterated, of eighteen samples now reported upon five only were adulterated; that while, in the former case, the adulterants consisted of chicory, roasted corn, beans, and burnt sugar, or black-jack, in the present instance chicory only was met with. These results show a very great improvement in the state in which ground coffee is now sold to the public, and prove that in this article, at all events, adulteration has much declined. The report contains the following exceedingly simple directions for detecting the adulteration of coffee:—"If, then, on opening the package the contents are caked, or show any disposition to cake, chicory is present. If, on adding a few drops of cold water to a grain or two of the suspected article, the water becomes almost immediately of a brown colour, chicory is surely contained in it. If, further, on touching the particles, which have been wetted with water and spread out on a slip of glass, with the point of a needle, some are found which are non-resisting, soft, and yielding, the sample is adulterated. Lastly, the presence of chicory is immediately revealed by the great difference in the forms of the cells as seen under the microscope, these being in the case of coffee coherent and angular, and in that of chicory rounded and vesicular; the differences are so marked that, once seen, they can never be forgotten."

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Mr. S. K. Cotter.—Your letter, with enclosure, has arrived. The request received immediate attention.

Aye or No.—No.

Parents.—The thing is treated of in Copland's "Dictionary," art. "Debility." He says that old people love to have children to sleep with them, and that it robs the children of health and strength. In case of doubt, act on the safe side.

Venator.—Dumb madness is hydrophobia with paralysis of the muscles of the throat and jaws, so that the dog can neither bark nor swallow. It is well known and described in veterinary works—as Youatt's. That Mr. Grantly Berkely never heard of it, can only be explained by himself.

E. B.—Liebig's essence is very valuable. It contains the elements of muscular flesh, but no gelatine nor albumen. It is also rendered dark by the heat employed. Thus, too, it acquires the taste and smell of roast meat—as Liebig says. It is best used not alone, but to enrich soups made with bones and vegetables.

G.—We are acquainted with both processes, and think both good for moderate investment. Jones's meat-preserving process produces meat in tins, but differs from the ordinary way of putting up meat in tins, inasmuch as every tin is subject to exhaustion by a vacuum, so that all moisture is extracted. The meat looks like good roast or boiled meat, and is dry; not immersed in a mass of gravy and jelly. The process of preserving by pressure promises results more economical—and, therefore, important—than any other. We wish them both success.

Melbourne.—Our attention is called by several correspondents to a most objectionable advertisement which appears in the *Pastoral Times* (Deniliquin). It is issued by Mr. Beaney, who styles himself "late Surgeon to the Melbourne General Hospital, and late Surgeon to her Majesty's forces." We can only express our regret that so objectionable an announcement should have been issued by Mr. Beaney.

Cesspools.—The *Builder* has the following important remarks on this subject:—

"Two months ago, after pointing to the condition in which the drains and cesspits of many large country houses are, we wrote, as, in other words, we had written years before:—'To remedy these evils will certainly cost money, and money is more readily spared for fashion than for domestic comfort and means of health. The annual cost of a couple of racehorses would put the family mansion into a sound sanitary state. But the annual vote is for the racehorses, and the foul sewers are left to become still fouler, and the family rats are left in peace. Vast sanitary improvements have been made during the last thirty years, but very much remains to be done. There are buried dumb-wells to be rooted out when discovered, sewers of deposit to be reconstructed, and country mansions generally to be properly sewered and drained. Men have yet this prime lesson to learn—namely, that means of health in their dwelling-houses are worth far more than rich furniture and costly picture-galleries, and that these means of health cannot be secured until all cesspits, cesspools, and dumb-wells have been abolished, and there is a dry subsoil absolutely free from the possibility of sewage taint.' If we had written with a view to the particular incident now before us, other words would scarcely have been used. Will the warning, emphasised as it is, now be taken?"

THE ACTION OF CONDY'S FLUID ON METALS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The statement which was made before the Army Sanitary Commission, by Dr. R. Angus Smith, in answer to a question (No. 2725) put to him by Dr. Farr, and to which Mr. Oakman has called attention in your issue of the 25th ult.—namely, that "Condy's Fluid oxidises metals"—is utterly destitute of foundation in fact. It would not even be easy to imagine how the notion came into the mind of a chemist of some pretensions to practical knowledge, except as a haphazard surmise engendered by the universally known (to chemists) circumstance, that permanganates act readily on oxidisable metals *in solution*. But the object of Dr. Farr's question was to ascertain whether Condy's Fluid was destructive of metal objects, such as ships' fastenings, pump-boxes, etc.; and it is not improbable that he and his brother-Commissioners, erroneously relying on the answer given, were satisfied to believe that Condy's Fluid could not be introduced into some branches of the military service—troop-ships, for instance—on account of its supposed corrosive action on metals, and may have continued in the same belief ever since.

Although we might, in disproof of the statement in question, have appealed to certain iron pans, which we have used, without change or repair, during thirteen years in the manufacture of Condy's Fluid, we prefer to adduce the following report of some experiments which, at our request, were made by a scientific chemist, and which anyone is able to confirm.

December 4, 1871.

We are, &c.,

BOLLMANN, CONDY, AND CO.

"South London School of Chemistry and Pharmacy,
231, Kennington-road, S.E.,

London, March 11, 1870.

"I certify that iron and mixed metals of the nature of brass, as represented by needles and pins, after having been immersed during six months in Condy's Fluid, were, on being withdrawn, found practically intact. The needles came out of the same weight which they had on being introduced. The pins, with the unimportant exception of a very slight iridescent film on their surface, which to the blowpipe showed traces of copper, had otherwise resisted the action of the fluid."

(Signed)
"JOHN MUTER, Ph.D., F.C.S., Professor of Chemistry."

J. G., jun., St. George's.—To soften and clean sponges, put a teaspoonful of the liq. sodæ chlorinat. in half a tumblerful of water, and wash well.

Mr. Maczwell, Barnstaple.—On making immediate application your son might perhaps be in time for the ensuing Examination in Arts at the College of Surgeons.

F.R.C.S. Exam., Devonport.—The Council will meet on Thursday next to receive the report.

George Washington Evans.—The attention of the Council of the Royal College of Surgeons has been called several times to the pamphlets of this person, and at a meeting yesterday it was resolved to take prompt measures on the subject. We shall recur to this matter next week.

Dr. Jackson.—You will find a portrait and biography of B. S. Albinus in Pettigrew's "Medical Portrait Gallery," vol. i.

Oxbridge.—By custom and courtesy the gentleman is entitled to call himself Doctor. It is not, however, very good taste to presume on this; but if a gentleman chooses to style himself in any one way, it is more courteous to accord him that title when meeting than to refuse it. Speaking of him to a third party, an explanation is legitimate.

CELIBACY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall send for the best Physician the place affords. If I am delirious to-morrow, or unable to give my own orders, have the kindness to send express for Dr. Holland; but don't leave yourself, my good fellow. At my age it is a hard thing to have no one in the world to care for me in illness; and—n affection when I am well." This extract from Bulwer hits many an old bachelor who, from force of circumstances or inclination, remains single. Hercules Daddles, C.B., for many years confessed to 55, with (thanks to art) a fine complexion, dark hair, and splendid teeth, not to mention a mellow port-wine voice; during the day enjoying every advantage of the palatial comforts of the club, at night he retires to solitude—never mind where.

At times, specially in foggy December, he feels less juvenile than of yore, and one fine day he trips over a piece of orange-peel, or an attack of bronchitic asthma makes him prisoner. The club goes on the same—his absence possibly a relief; his knife and fork another man takes; and his obituary in the *Times* but excites momentary interest. From the Faculty he will receive the best and kindest attention; equally good nursing can easily be obtained. But in a small room, in a noisy street, the landlady unsympathetic, and the other lodgers afraid of fever, what chance has the poor old fellow of being made comfortable? The rich have many friends, and where the carcass is the eagles will be gathered together; but will these friends personally take their turn of nursing, having their own interests, their families, and their business to attend to? But Daddles, an honourable and gallant gentleman, though from childhood upwards accustomed to superior comforts, is not rich, and the deprivation of these comforts in old age and sickness will be severely felt. In the grave we are all equal; and it did not disturb the sleep of the great Napoleon, who "desired that his body might rest on the banks of the Seine, among the people he had loved so well," when the Commune proposed mixing his ashes with those of Troppmann, the murderer. Some men keep mistresses, others marry cooks, many have drawn prizes in the lottery of life in the shape of happy homes; but I have not been drawing on imagination for the solitary old man with one foot in the club, the other directed towards Kensal-green, whose case deserves consideration. Now, supposing each member of the "Army and Navy," the Senior or the Junior United Service, paid annually a subscription entitling him to Hospital treatment when ill, the sum thus raised would enable St. George's, King's College, or any other institution, to fit up a special ward for gentlemen, and, according to the means of the patient, the talent of the country would be at his disposal, care being taken to prevent abuse. Just now spending a month's leave pleasantly in London, "walking the Hospitals," it is a matter of perfect astonishment to notice the crowds of well-dressed people attending as out-patients who could well afford to pay. It is cruel and hard on general Practitioners that they should be thus robbed. So, in the scheme proposed, these club-men, when able, would be expected to "shell out" handsomely.

"*Libero lecto nihil jucundius.*" remarks the old bachelor—meaning all the time "The grapes are sour." Having bought experience and undergone trials—including one for breach of promise, which swallowed up every single rupee received from the Nizam of Hyderabad—the question is one of vital personal importance, and a great deal more might be written. Unfortunately, the agonies of composition are intensified by a superannuated piano, the cabs driving by, screaming children, and a sewing machine warranted to give one the "devil's jumps"; besides, it is time to prepare to dine at the "Ship and Turtle." Not liking to take a legal opinion, having burnt one's fingers quite sufficiently, could you—as editors are expected to be omniscient—kindly tell me if there is no redress for being nicknamed

OLD SILENUS.

A NEW VACCINATING APPARATUS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have much pleasure in at last being able to present my colleagues with two specimens of instruments for vaccination, although these unique instruments cost me nearly £3 for the pattern, I understand from Messrs. Maw, Son, and Thompson, to whom I am much indebted for the production of so neat and useful an apparatus for the successful carrying out of that most necessary but simple operation—vaccination—which has been so much dreaded by many of late, on account, as they state, of dirty lancets being used, causing an obnoxious eruption of which their offspring had never suffered before vaccination, laying it, of course, to that simple cause, but of which I have carefully explained could not be the case; but all my explanations would not alter their ignorant ideas. Several attempts have been made to produce an instrument such as I required, by many, but all seemed to fail, and even Messrs. Maw, Son, and Thompson made several unsuccessful attempts; yet they were at last enabled with much painstaking to produce these two little instruments. Their costing so much will deter many from purchasing; but I understand from them that if they were generally adopted, similar instruments could now be produced on a moderate scale. I took the hint from my friend Dr. W. S. Playfair, of 5, Curzon-street, Mayfair, who offered to vaccinate me during the dreadful epidemic of small-pox in Islington this year by what I considered a novel method—viz., with a single glass tube containing cotton-wool moistened with strong ammonia

until the cuticle was taken off, and then applying the lymph. This causing much pain in applying the glass tube three or four times to insure three or four vesicles, and also by the length of time—from one to two minutes—in erasing the cuticle, which is not always convenient, and particularly in infants who will not remain quiet so long, induced me to put my wits to work to see if a better and more speedy plan could not be produced, and thence the instrument with the three tubes. Finding still that babies would not remain quiet a sufficient time, induced me to try some more expeditious plan of removing the cuticle, and recollecting that boiling liquid would have that effect induced me to suggest an instrument similar to the one produced in steel. The instruments I have had movable, to enable me to vaccinate adults and infants with the same one. I think, if this plan could be more in general use, that people would not have such a dislike to having their children vaccinated, and I can prove that adults would all submit to it without a murmur. Having vaccinated over 300 during the months of February and March last, and with only three unsuccessful, I can confidently recommend it to the Profession; and when they have once used this method I have no doubt will use no other kind. In one instance I vaccinated a City clerk who had had five or six unsuccessful attempts, but his employers would insist upon the vaccination issue being carried out according to their Medical man's approval. The gentleman having heard from a friend that a Medical man practising in Islington had a novel mode of vaccinating, applied to me after ten o'clock at night, being the only time he could conveniently spare, being in a situation where his arms were always bare. The operation in taking off the cuticle occupied over three minutes; this might have been from the strength of the ammonia having evaporated, or the skin of the man being tougher than usual; but at all events the operation proved quite successful, two very fine vesicles being produced out of the three applications.

I am, &c., J. WHITEHEAD, M.D., L.S.A.

25, Clarence-terrace, Finsbury-park, N.

APPOINTMENTS FOR THE WEEK.

December 9. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

11. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

12. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m. ROYAL MEDICAL AND CHIRURGICAL SOCIETY (Ballot, 8 p.m.), 8½ p.m. Dr. John Harley, "On the Pathology of Scarlatina, and its Relations to Enteric Fever."

13. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m. EPIDEMIOLOGICAL SOCIETY, 8 p.m. Meeting. SOCIETY OF ARTS, 8 p.m. Mr. Robert Johnston, "Observations on the Esparto Plant."

14. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

15. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, December 2, 1871.

BIRTHS.

Births of Boys, 1075; Girls, 1136; Total, 2211.

Average of 10 corresponding weeks, 1861-70, 2021'3.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29.814 in.
Mean temperature	36.4°
Highest point of thermometer	42.9°
Lowest point of thermometer	28.5°
Mean dew-point temperature	33.4°
General direction of wind	NNE. & NE.
Whole amount of rain in the week	0.12 in.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, December 2, 1871, in the following large Towns:—

Boroughs, etc. (Municipal boundaries for all except London.)	Estimated Population to middle of the year 1871.*	Persons to an Acre. (1871.)	Births Registered during the week ending Dec. 2.	Deaths Registered during the week ending Dec. 2.	Temperature of Air (Fahr.)			Temp. of Air (Cent.)	Rain Fall.	
					Highest during the Week.	Lowest during the Week.	Weekly Mean of Mean Daily Values.		Weekly Mean of Mean Daily Values.	In Inches.
London	3263872	41.8	2211	1918	42.9	28.5	36.4	2.44	0.12	0.30

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29.81 in. The highest was 30.16 in. on Saturday morning and the lowest 29.65 in. on Thursday afternoon.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

Natural Mineral Waters of Vals, Vichy, Carlsbad, Seltzer, Kissengen, Homburg,
 PULLNA, FRIEDRICHSHALL, &c., direct from the Springs; also the Artificial Mineral Waters prepared by Dr. Struve and Co. at the Royal German Spa, Brighton, and the Natural Bromo-Iodine Water of Woodhall Spa, Lincolnshire.—Agents, W. BEST and SONS, 22, Henrietta-street, Cavendish-square, London, W.

MELBOURNE MEAT-PRESERVING COMPANY (LIMITED).
COOKED BEEF AND MUTTON, IN TINS,
 With full Instructions for use. PRIME QUALITIES AND FREE FROM BONE.
 Sold Retail by Grocers and Provision Dealers throughout the Kingdom. Wholesale by
JOHN McCALL & CO., 137, HOUNDSDITCH, London.

WESTERTON'S PATENT ZYMOTIC DISINFECTING FLUID

Prevents the spread of infection; protects the nurse and those about the sick-room. Sponging over the body with the Fluid disinfects the emanations from the skin and (being volatile) exhalations from the lungs of the sufferer. Destroys the noxious properties of the excretions, and purifies the atmosphere.

PREPARED BY

W. C. WESTERTON, 85, Abingdon-villas, Kensington, London;
 and may be had of all Chemists, in bottles, 1s., 1s. 9d., and 3s. 6d.; 10s. per gall.

HUBBUCK'S PURE OXIDE OF ZINC.

See Pharmaceutical Journal of May 1, 1856.

Sold in Stamped Boxes of 14 lbs. each, by the following Wholesale Druggists:—

Messrs. Baiss Brothers & Co.	Messrs. Geo. Curling & Co.	Messrs. Hearon, Squire, & Francis.	Messrs. Southall, Son, & Dymond.
" Barron, Harveys, & Co.	" Drew, Barron, & Co.	" Herrings & Co.	Mr. James Woolley.
" Battley & Watts.	" Evans, Lescher, & Evans.	" Hodgkinsons, Stead, & Treacher	Messrs. Wright, W. V., & Co.
" Burgoyne, Burbidges, & Co.	" Evans, Sons, & Co.	" Langtons, Scott, & Edden.	" Wyleys & Co.
" Cox, Gould, & Co.	" Samuel Foulger & Son.	" Preston & Sons.	Glasgow Apothecaries' Co.

Fox's Palatable Cod Liver Oil WITH Quinine

THE NEW SELF-RETAINING CATHETERS.

(Vide "The Lancet," Feb. 19th and May 14th, and "Medical Press and Circular," Feb. 23rd, 1870.)

MR. BARNARD HOLT'S SELF-RETAINING WINGED INDIA-RUBBER CATHETERS,

both for Male and Female use, sold only by

C. BAKER, 244 & 245, HIGH HOLBORN, W.C.

Price, complete with Stilette and Plug, 6s. 6d.—Illustrated Descriptions free by post.

NEW IMPROVED MAGNETO-ELECTRIC MACHINES,

From 18s. to 35s., in handsome Mahogany Cases.

C. BAKER begs to call the attention of the Profession to the above. They are of great power, yet capable of giving the mildest current, and they have the advantage of being clean and always ready for use.—244 & 245, HIGH HOLBORN, W.C.

Special Appliances for Local Application, from 3s. each.

FIRST-CLASS SURGICAL INSTRUMENTS.

The CHEAPEST HOUSE in LONDON is C. BAKER'S, 244 & 245, High Holborn.
 Every article is warranted of the best manufacture.

DISSECTING CASE, in Ivory Handle, 14s. the Set; Ditto, in Ebony Handle, 10s. and 12s. 6d. the Set. POCKET CASE, from 15s. 6d.

All other articles equally cheap.—Catalogues free by post.—Established 1765.

COCKING'S PATENT POROPLASTIC SHEETS FOR SPLINTS

(AS SUPPLIED TO THE ARMIES AND NAVIES OF ENGLAND, FRANCE, PRUSSIA, RUSSIA, AUSTRIA, AND ITALY).

Consists of a felted substance, is plastic when heated, and rigid when cold, rapidly and easily cut to any shape and manipulated.

"We have no hesitation in recommending it as the best and most convenient splint. The country Practitioner will find it a special boon. Mr. Cocking (of Penzance) deserves the thanks of many, inasmuch as he supplies it to Hospitals almost at cost price."—Medical Press, Sept. 27, 1871.

"By attending to the very simple directions for use, the most perfect splint yet known may be made. We earnestly recommend it to army Surgeons, believing that for field hospital purposes it will supersede all others."—British Medical Journal, Sept. 23, 1871.

"Mr. Cocking (of Penzance) has laid the Profession under much obligation by his sheets for splints, which have succeeded admirably, and will prove highly useful to the Surgeon, particularly in the country."—Lancet, Sept. 16, 1871.

Hospital Quality, at 4/ per lb.; substances made, about 1-8 in., 3-16 in., 5-16 in.; in sheets measuring about—size, 4 ft. by 3 ft., 2 ft. by 3 ft., & 2 ft. by 1½ ft.
 Ordinary Quality, at 6/6 per lb.; " " 1-8 in., 3-16 in.; " " " " " " " " " "
 Finest Quality, at 10/6 per lb.; " " 1-8 in., 3-16 in.; " " " " " " " " " "

The average cost of a medium size perfect Splint being from 6d. to 2s.

Wholesale Agents: Maw, Son, and Thompson, 10, 11, & 12, Aldersgate-street, London, E.C.; Weiss and Son, 62, Strand; Coxeter and Sons, 23, Grafton-street, W.C.; Kröhne and Sesemann, 8, Duke-street, Manchester-square, W.; Lyndal and Co., 171a, Aldersgate-street, E.C.; and at the Depot of this Invention, at Benj. Wilson, Walbrook House, London, E.C.

"To Practitioners in the country and colonies 'Cocking's Splint' will be of the utmost service. It has been used with success by our leading Surgeons, and has been found to answer all that was required or expected."—Medical Times, Oct. 7, 1871.

"To country and colonial Practitioners invaluable."—London Hospital Report, by Jonathan Hutchinson, Esq., Senior Surgeon, Sept. 29, 1871.

"A great boon to Medical men in the country. In town and Hospital practice invaluable. Its porosity is one of its greatest advantages."—Report by John Croft, Esq., of St. Thomas's Hospital, Oct. 6, 1871.

"Without doubt the material will come into very extensive use when its valuable qualities shall have become more generally known."—Report by A. E. Durham, Esq., of Guy's Hospital, Oct. 7, 1871.

ORIGINAL LECTURES.

LECTURES ON THE
PRINCIPLES OF THE TREATMENT OF
FEVER

By Dr. LIONEL S. BEALE, F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE I.

ON THE TREATMENT OF THE FEBRILE STATE.

THE feverish condition which is caused by the entrance of disease germs into the organism, and their transmission by the fluids of the body to all the tissues and organs, is essentially similar to that feverish state which not unfrequently originates in changes occurring in the body itself, without being occasioned by the ingress of anything from without. In considering, therefore, the principles which should guide us in the treatment, it will be necessary to discuss the influence of remedies upon the feverish condition generally, irrespective of the causes which may have given rise to it; and it will appear that there are certain general facts of the highest importance, the proper estimate of which will lead to the adoption of certain measures of great practical value in all forms of fever, and which have to be considered even in special cases which demand peculiar and, it may be, exceptional measures.

In conducting the treatment of fever due to the presence of disease germs, we have to determine by what means the patient's life may be preserved while he remains a sufferer from the conditions caused by the growth and multiplication of the living poison within his body, or the lesions which follow in consequence of this process, or which may be brought about during the elimination from the organism of the substances resulting from the death of disease germs and of other forms of bioplasm.

ON TREATMENT BASED UPON THE FACT OF THE RISE OF
TEMPERATURE.

Acting upon the hypothesis that the danger to life from fever depends upon the increased temperature, many Physicians have adopted plans of treatment which have for their object the carrying off heat from the surface. This is accomplished by the external application of cold. Although there is evidence that cold to the surface does good in some cases in which the body-heat is above the normal standard, few Physicians feel sufficiently satisfied that conclusive proof has yet been adduced that this indication for treatment can be with wisdom fearlessly followed out in all cases.

This remarkable increased development of heat in all fevers is probably an immediate effect of another change. It is certainly associated with, and (I believe) due to, very rapid growth of bioplasm, principally in the slow-moving blood in the capillaries; but the bioplasm in the tissues external to the capillaries is also involved, and in some fevers in a very remarkable degree. (a) The increase of the bioplasm continues, as does also the development of heat, for an hour or two (and in rare instances for a much longer period) after death, and occasionally up to a certain time even in an increased ratio; and for this reason: The bioplasm being perfectly still, and everywhere surrounded by nutrient pabulum, is under the most favourable conditions for appropriating rapidly all that lies sufficiently close to it; it therefore rapidly increases until the adjacent pabulum is exhausted. But when this happens, as no fresh nutrient fluid can possibly be brought to it, the bioplasm dies, and the temperature soon falls.

Now (as will be presently explained), there is reason to think that many of our remedies act beneficially by the direct influence they exert upon the process of increase of the bioplasm in the blood and in the tissues. In fever and certain low states of the system, the bioplasm of the tissues and blood invariably increases more rapidly than in health; and, as I showed many years ago, the classes of remedies which experience has proved to be beneficial are those which check the growth of bioplasm. Stimulants effect this change quickly, and many of the so-called tonics possess this property in a very remarkable degree, though they act more slowly.

Cold reduces the temperature, and may also be instrumental in bringing about a state of things unfavourable to the growth of the bioplasm, which is the immediate cause of the rise. If, however, we could prevent the undue growth of the living

matter, or check it before it has proceeded to a dangerous degree, the temperature might not rise so high as to render the external application of cold either necessary or desirable. If we proceed back yet another step in the inquiry, we shall find that the multiplication of the masses of germinal matter or bioplasm is due to the rapid appropriation of excess of pabulum. If, therefore, this pabulum were removed, or its constitution changed, or its formation prevented, there is reason to think that the increase of the bioplasm would be stopped, in which case the feverish state could not be established. Or, if the blood could be urged more quickly through the capillaries, the heat developed would be carried off, and pass away latent in vapour from the skin and lungs. The rise in temperature would not take place so long as the increased rate of the circulation compensated in this manner for the undue development of heat. This remark will appear strange to many readers who attribute increased body-heat to increased oxidation; but there can be no doubt that the view is correct, for the temperature invariably rises as the capillary circulation becomes more feeble, and, as already remarked, often obtains its maximum some time after the blood has ceased to circulate at all—when, in fact, the functions of respiration and circulation, which are specially concerned in oxidation, have ceased.

In health any disturbing influences are compensated with remarkable rapidity. Thus, exposure to degrees of heat or cold differing considerably from the body-temperature will produce very slight change in the internal temperature. The same thing is observed as regards alcohol. In the experiments of Parkes and Wollowicz, moderate doses of alcohol appeared to influence very little the temperature of the body or the amount of nitrogen excreted. Traces of alcohol escaped, but there can be no doubt that the larger proportion was appropriated by the bioplasm of the blood, and afterwards eliminated in the form of excrementitious matters, especially carbonic acid and water. But in fevers and inflammations the mechanism by which this process of compensation is carried out undergoes deterioration or is seriously damaged, so that artificial efforts are required to put it into operation at all. In health it works perfectly well without the introduction of any stimulus from without. (b)

The beneficial effects of external cold in febrile conditions have been long known, and cold was practically employed in the treatment of fever by Currie so long ago as 1789.

Of late years the more careful employment of the thermometer in disease, as proved to be of great value, especially by the observations of Traube, Wunderlich, Ringer, and others, and

(b) The manner in which this compensatory action is effected has been described in my Croonian Lecture (*Proceedings of the Royal Society*, May 11, 1865), and before this in a memoir "On Deficiency of Vital Power in Disease, and on Support," published in the *British Medical Journal* for 1863. The following remarks will serve to explain the matter:—"If you press upon the distended vessels of an inflamed part, as is well known, the blood is driven out of them, and the skin becomes quite pale; but the moment the pressure is withdrawn, the redness recurs, and exhibits precisely the same tint as before. From this it is clear, not only that the capillaries are distended, but that the calibre of the small arteries through which the blood is distributed to them is much larger than in the normal condition. Besides this, the simple experiment proves that the vessels are maintained for a long time of a given calibre. Such a state of things can only result from the influence of nerves which govern the calibre of the small arteries; and thus the quantity of blood permitted to flow through them in a given time is regulated and varied from time to time. The mechanism is such that a small artery is made to assume a different calibre, although this may be momentarily altered by artificial means. I have shown, contrary to the statement of Kölliker, that all the small arteries are abundantly supplied with nerves, and that nerves also ramify in the tissues external to the capillaries, and upon the capillaries themselves. There are the two kinds of peripheral nerve-fibres which take part in regulating the supply of nutrient pabulum to every part of every tissue in the body:—1. The nerve-fibres distributed to the coats of small arteries and veins which ramify amongst the muscular fibres, and are efferent or motor. 2. The nerve-fibres distributed to the capillaries, and in tissues which are altogether devoid of capillaries, and which are the afferent or excitator branches connected with the centres from which the vaso-motor nerves arise. These branches have been demonstrated by me in many tissues, and form a new system of nerve-fibres, not previously described. (See *Archives*, No. xiii.) Now, any alteration taking place in the nutrition of the tissue-elements external to the capillaries must of necessity influence these excitator or afferent branches. The fibres may be subjected to increased or diminished pressure, to the influence of an increased or diminished quantity of fluid; and their numerous masses of bioplasm will necessarily be exposed to the same conditions as those of adjacent tissues. In the inflamed tissue, the bioplasts, like those of the tissues around, would receive more pabulum, and would grow faster; and where growth and increase of living matter are most active, the particular action or function of the tissue is least manifested, because function is the effect of changes in matter which has been already formed. Hence it is not when nerves are growing that we find nervous action remarkably developed, but when they have grown. So in the case supposed the nerves are less active than in the normal state, and, as a consequence of their inactivity or reduced irritability, we have dilatation of the vessels. A further development of the same changes will lead to paralysis, and ultimately the complete destruction of the normal tissue will follow unless the balance of nutrition is restored or death is occasioned.

(a) See my "Report on the Cattle Plague." 1866.

now carried out by the great majority of Practitioners, both in public and private practice, has, as might have been anticipated, led to a revival of the treatment of fevers by cold. In order to form a correct judgment concerning the influence of cold upon the phenomena of fever, I would refer to the results which have been observed to succeed its application in cases of extreme severity, and I doubt if any more to the point could be selected than those which have just been published by Dr. Wilson Fox. (c) I desire more particularly to call attention to these cases, because they also afford an illustration of the free use of stimulants in the very last stage of desperate fever, at a period of the disease when the temperature was so high that a fatal termination was imminent; indeed, it is almost certain that death would have occurred had not the most decisive measures been promptly taken.

Excessive and very rapid rise in temperature is perhaps seen more frequently in acute rheumatism than in any other febrile disease. In very severe cases of this affection it is not uncommon to find a rise of 4° or 5° within a period of a few hours, death usually taking place a short time after a temperature of 107° has been reached, and sometimes before so high a maximum has been attained. The high temperature may persist for some time after death, and a further (post-mortem) considerable elevation has been witnessed. It is, indeed, seldom that recovery occurs after the temperature has reached 106° in a case of acute rheumatism; but Dr. Fox gives a full account of two remarkable cases of the disease which recovered after a temperature of 107·3° and 110° respectively had been attained. Both these cases were treated by the application of cold. In the first, when the temperature was 107°, the patient was immersed in a bath at 96°. The temperature, however, still rose until it was 110° in the rectum, when "ice was fetched; a large lump was placed on her chest, another on her abdomen; a bag filled with ice was tied down the length of her spine; and while two assistants baled the warmer water out of the bath, two others poured iced water over the patient as rapidly as the pails could be filled." *Within half an hour the temperature in the rectum had fallen to 103·6°, and in less than another half-hour to 99·5°.* It is, however, worthy of note that in this instance the patient took *six ounces of brandy during the time (one hour)* that the ice and cold water were being applied, when the temperature fell more than 10°. Subsequently eighteen ounces of brandy per diem were given for several days.

In Dr. Fox's second case, also, in which the temperature was reduced from 107° to 98° within an hour, large quantities of brandy (from twenty-four to twenty-eight ounces in twenty-four hours) were given; and Dr. Fox expresses a doubt whether the man would have recovered at all had the stimulant been withheld.

In a case of Dr. Meding's, (d)—quoted by Dr. Fox—the temperature fell from 108·6° to 99·5° *in five hours* during the application of ice-cold cloths to the body, and enemata of iced water given every half-hour. The pulse fell from 140 to 72, perspiration ensued, and the patient rapidly recovered. In this case no stimulant at all was administered, but the temperature fell much more slowly than in Dr. Fox's cases. It was certainly slight as compared with the two cases reported by Dr. Fox, and many that I have myself seen, and treated successfully with frequently-repeated doses of brandy without recourse to the application of cold.

Dr. Wilson Fox considers that in acute rheumatism active treatment by cold should be commenced when the temperature reaches 107°, and all Physicians who have had much experience in the treatment of desperate cases of the kind will be disposed to agree with him; for although the opinion may be fairly entertained that in many cases the rise of temperature to the danger-point may be prevented by treatment, and particularly by the administration of alcohol, it appears to me to have been fully proved that cold (with or without stimulants) is the only remedy yet tried by which the rise in temperature can be not only quickly checked, but decidedly and rapidly reduced after the high body-heat of 107° has been reached. In moderately severe cases many will doubt if there is any necessity for adopting the treatment by cold; and it is certain that many most serious cases have progressed favourably, and have recovered, under other plans of treatment, and especially under the influence of alcohol. But in such very serious instances of disease as those reported by Dr. Wilson Fox, there can be no doubt that the application of cold should be resorted to. The objections that can be made to the plan are, in my opinion, far outweighed by the circumstance that, if not adopted, the patient will almost surely die, and within an hour or two.

By merely reducing the temperature of the body, however, we do not remove the causes which have given rise to the increased development of heat. The rise in temperature is not the *cause* of the febrile condition, but a concomitant effect, or a consequence of a prior change—the increase of bioplasm. At any rate, in every one of the cases of fever that I have examined, both in man and animals, I have invariably found very considerable increase in the proportion of the bioplasm of the blood and tissues. If the bioplasm did not increase, there would have been no undue development of animal heat—no fever. This, then, seems to be the change of which the febrile or inflammatory state is an immediate consequence, and it is therefore of the utmost importance to consider carefully the various means at our disposal for preventing, or modifying, or cutting short the conditions which favour the occurrence of such a morbid change, or which may modify the intensity of the latter when it has occurred. It is also highly desirable to discuss the circumstances which, in severe forms of disease, occasion the fatal result, either suddenly or more gradually, by inducing structural changes which render impossible the continuance of life.

In all fevers and extensive general inflammations there is more or less failure of the capillary circulation, and the danger varies according to the degree of the disturbance, and the extent of tissues and important organs involved. In very severe cases, what we have to apprehend, and what our greatest efforts should be directed to avert, is *stagnation of blood in the small vessels, and cessation of the capillary circulation over a considerable part of the body.* To bring about this result, the following circumstances contribute:—1. Failure of the force of the heart. 2. Alteration in the composition of the blood. 3. Growth of the bioplasm of the blood, vessels, and tissues.

(To be continued.)

ORIGINAL COMMUNICATIONS.

CASE OF CONTRACTILE PHTHISIS, CAUSING REMARKABLE DISPLACEMENT OF ORGANS.

By C. THEODORE WILLIAMS, M.D. Oxon., F.R.C.P.,
Physician to the Hospital for Consumption, Brompton.

ISABELLA C., a married woman, aged 29, a dressmaker, was admitted under my care, April 18, 1871, and gave the following history:—

There was no consumption in the family, except in a cousin on the mother's side, who died of the disease.

For the last three years she has had cough and expectoration, and about two years ago noticed that she was decidedly emaciating. Hæmoptysis to the extent of ʒiv. came on shortly after the beginning of her illness, and she coughed up the same amount three months later, and again ʒij. two months after, in February, 1869, but has since been free from that symptom. Has had night sweats, which ceased previous to admission, and she once suffered from diarrhoea for two weeks. Lately she has complained of increasing shortness of breath, which has become very troublesome.

In September, 1869, she became an out-patient under Dr. R. Douglas Powell, who found flattening, dulness, and cavernous respiration in the upper right chest anteriorly, and tubular respiration and moist crepitation over the posterior base. He observed that the left lung was enlarged and extended to the right of the sternum, and he detected crepitation at the apex and along the posterior surface. Dr. Powell's diagnosis was, a cavity in, and contractile disease of, the right lung, and granulations in the left. He ordered an iron tonic, and at a later visit cod-liver oil, which the patient took steadily for some time.

In October, 1869, she was admitted into the Hospital under the care of Dr. Cotton, when the right lung was found to be in the same condition, but in the left, harsh blowing respiration had taken the place of the humid crepitus.

She remained in the Hospital for three months, taking phosphorated oil alternately with quinine and other bitters, and at the end of the time had gained seven pounds and a half in weight, the physical signs remaining the same. After this she continued better for some time, but the symptoms returned, and her increasing shortness of breath caused her to apply to the Hospital, where she was admitted under my care in April, 1871. Her cough was very troublesome, expectoration frothy,

(c) "Treatment of Hyperpyrexia." Macmillan and Co. 1871.

(d) *Archiv. für Heilkunde*, 1870, xi., p. 467.

tongue clean, bowels regular, catamenia absent for two years; her countenance was very pallid, and there was considerable emaciation, especially of the thorax. The right side of the chest was found to be considerably smaller than the left; the shoulder greatly depressed, and the upper portion of the chest fixed. Marked depression was visible in the upper right front as low as the third rib, this space being decidedly resonant. Cavernous breathing was heard under the clavicle, though chiefly below the sternal end. From the fifth rib downwards there was absence of breathing and marked dulness, not removable by change of position. Posteriorly, cavernous breathing was audible in the right inter- and supra-scapular regions. The heart's sounds were more audible over the lower portion of the sternum than in the cardiac region, and the apex could not be felt; it was therefore concluded that the heart was displaced towards the contracted side. The diagnosis was, contractile disease of the right lung, with some excavation of the upper portion, and displacement of the left lung, liver, and heart towards the affected side.

The patient was ordered cod-liver oil and quinine, but she did not improve; and on April 27 the evening temperature, which had been normal, rose to 100°, and three days later the morning temperature rose to 101°, and the record then remained between 100° and 101.6°, with the exception of one day, till May 14. The patient became weaker, and the breath shorter; rhonchus and harsh breathing were audible in the left lung.

On May 15 the morning temperature fell to 98.4°, and the evening to 99°; the pulse being 100; respiration 40. After this the morning and evening temperature varied from 98° to 98.5°, and on May 20 the breath became very difficult, crepitation being audible at the left base; dyspnoea increased, and the patient died on the 25th.

The post-mortem examination was made by my Clinical Assistant, Mr. William Rose, in the presence of Dr. Powell and myself, and the following account is taken from our notes:—The body was greatly emaciated; there was marked concavity from the right clavicle to the second rib, and general shrinking of the whole right side of the chest. On removing the cartilages, the right lung could not at first be distinguished, but was afterwards found contracted to about a third of its normal size, occupying the axillary and lateral regions, and not extending lower than the fifth rib. The heart was drawn over to the right side of the sternum, the apex being slightly to the left of the ensiform cartilage. The liver, which was much enlarged, was drawn up, and, owing to the retraction of the right lung, had become superficial below the fifth rib. It did not extend far below the margin of the ribs. The left lung stretched across the median line as far as the costo-sternal articulations on the right side, this being the case as low as the third rib. The right lung, weighing twenty ounces and a quarter, was universally adherent to the chest-wall; the pleura, with intervening adhesions, being on an average half an inch thick, and thickest over the diaphragm, where it contained in its interior a great deal of fibro-gelatinous material. The texture of the lung itself was of a dark grey colour, traversed by whitish fibrous bands proceeding from the pleura, interlobular septa, bronchi, and vascular sheaths. In the upper lobe were the remains of an old cavity, into which some bronchial tubes opened, their mucous membrane seeming to terminate at its entrance. The cavity appeared to have undergone contraction, and was divided by numerous fibrous septa stretching across it, separating it into smooth-walled loculi, which communicated with each other. The left lung was much enlarged and congested, the edges being highly emphysematous. It contained some cheesy nodules, around which were gathered miliary tubercles of recent date. In the portion drawn over to the right side of the median line was a small cavity the size of a walnut, which was doubtless the site of the cavernous respiration heard under the right clavicle. The heart was large, the right ventricle slightly dilated, valves healthy; the liver and spleen were both lardaceous; kidneys healthy.

Remarks.—Cases of phthisis with marked contraction are by no means rare, and have been recorded by various writers; but this instance is interesting on account of the remarkable amount of displacement which occurred. The shrinking of the right lung caused a void which atmospheric pressure had filled up in various ways. The chest-wall was contracted; the liver was pressed upwards, the heart to the right of the sternum, and the upper part of the left lung into the right chest. Owing to this portion of the left lung containing a cavity, it caused cavernous sounds under the right clavicle; from which it was naturally concluded, by those who had examined the patient, that the cavity existed in the right lung, whereas—

strange anomaly—it really existed in the *left lung*, though in the *right chest*. This portion of the lung would doubtless, during inspiration, have reached further to the right side, and thus given rise to cavernous sounds over a wider surface of the right chest than would appear from post-mortem examination. The fact of the remains of an old cavity in the right lung might be used to explain the cavernous sounds heard by Drs. Cotton and Powell at an earlier period in the patient's history than when I examined her. It might be said that they heard a different cavity from that which I did; but this explanation is rendered improbable by the fact that, even at that period, Dr. Powell detected the presence of the left lung on the right side of the sternum, and this displacement would hardly have occurred without a previous retraction of the right lung, including its excavated upper lobe, to the axillary and lateral regions of the chest, where, if anywhere, the cavernous sounds from this source would have been audible. The condition of the pleura indicated that the disease originated in an attack of pleurisy, and that the contractile tissue had slowly extended since, gradually obliterating the lung, and giving rise to increasing dyspnoea. Death was probably caused by the congestion of, and eruption of miliary tubercle in, the left lung, by which the remaining breathing surface was further reduced in extent.

ON THE TREATMENT OF PYREXIA BY A COOLING PAD.

By WILLIAM ROBERTS, M.D., F.R.C.P.,
Physician to the Manchester Infirmary.

At a meeting of the Manchester Medical Society, I exhibited, on October 4, a pad designed to apply regulated and continuous cold or heat to the surface of the body. The annexed figure will aid the description. The pad consists of a close coil of very thin indiarubber tubing, three-eighths of an inch bore, cemented to a strong canvas backing. The terminal portions (composed of stouter tubing) reach a couple of feet from the margin of the pad, and each is closed by a stopcock, *B* and *C*. The inner end of the coil pierces the canvas backing at its centre, and passes behind the pad to its stopcock, *C*. For the

Description of the Tubular Pad.—The coil is cemented to the canvas backing *A A*. The stream enters the circumference of the coil at *B*, and makes its exit at the centre, where the tubing pierces the canvas, and passes along the back of the pad to *C*, and thence to a vessel on the floor.

purpose of experiment, three sizes were made—one a foot in diameter, another two feet by sixteen inches, and a third three feet by two feet. My principal object in constructing these pads was to obtain a convenient means of applying external cold in cases of fever and inflammation. The observations made in Germany on the treatment of typhoid fever by cold baths, and the more recent trials of the same treatment by Meding and Wilson Fox in the hyperpyrexia of rheumatic fever, seem to hold out hopes that we may be approaching a more effective treatment of pyrexia than has hitherto been attained. The cold bath, ice-water affusions,

and iced cloths, are all of them extremely troublesome of application, and wear so heroic an appearance, that any general introduction of them into private practice seems well-nigh impossible. But if some such means of applying cold as I am now proposing could be made effective, it would open an easy way to the study of this method of treatment, and also make it available in private practice. The procedure I have followed has been to place the pad either under the back of the patient or round the trunk next to the skin. A stream of water of any desired temperature is then conveyed through the pad, as it lies under or around the patient's body. This is accomplished by placing a reservoir of water, holding about six gallons, a foot or two above the level of the bed, and connecting this with the stopcock *B*. The most convenient form of reservoir is a tin can pierced near the bottom for a stopcock, to which a length of indiarubber tubing is attached for the purpose of connecting it with *B*. In the absence of a can of this sort, an ordinary toilet-can or large jug may be used, and the water made to flow from it into the pad by a suitable length of tubing arranged as a syphon. When the connexion is made, and the stopcocks opened, a stream of water flows through the coils of the pad, and issues at *C*, whence it is conveyed by an exit-tube to a vessel on the floor of the room. In this way a moving sheet of water, of any desired temperature, is brought into near contact with the surface of the body—only separated from the skin by a layer of indiarubber of one-thirty-second of an inch thick.

Before placing the pad under the patient, it is absolutely necessary to fill the coil completely with water. To accomplish this, the pad is placed on the floor of the apartment, near a table some four feet high. The can or jug which acts as the reservoir is then filled with warm water, and placed on the table. Connexion is now made by means of the attached lengths of indiarubber tubing, and the current is set a-going, the exit tube being placed in a shallow vessel—such as a wash-hand bowl—on the floor. The empty coil soon begins to fill, and the air within it to be expelled. The stream should be allowed to run freely for some ten minutes, in order to drive out all the air from the coil. The two stopcocks are then shut, and the pad is ready to be placed under the patient. To prevent a too sudden shock, the pad should be first filled with warm water, and then gradually cooled by adding pieces of ice to the reservoir, or by filling it up with cold water as the warm water flows away.

My trials have already satisfied me that it is easily possible to reduce the temperature of the body by the means here proposed; but whether the method will prove of practical use in the treatment of fever and inflammation must depend on further experience. The subject is of such great and urgent importance, and demands such multiplied and varied experiments to test its utility, that I have thought it desirable to make public my results at once, in the hope that some other inquirers with more leisure at command will take the matter up and institute a more elaborate research. The following observations can only be regarded as a very crude beginning:

Case 1.—*M. D.*, aged 25. Subacute pleurisy of two weeks' standing, with large liquid effusion on the left side, in a big, robust young woman.

October 19.—6 p.m.: Pulse 108; respiration 36; temperature in axilla 103.7° Fahr. The smallest pad (one foot in diameter) was filled with warm water, and placed under the lower part of the back and buttocks. The stream of water was slowly cooled by putting pieces of ice into the reservoir. The following table shows the progress of the experiment:—

(*Smallest pad, one foot diameter.*)

Hour.	Temp. in axilla	Temperature of		Remarks.
		entering water.	issuing water.	
6.15 p.m.	Deg. 103.7	Deg. 60	Deg. 80	The pulse and respiration remained unchanged throughout the experiment.
6.50 "	103.8	50	70	
7.30 "	103.7	46	63	
7.50 "	103.6	46	63	The pad was removed at 9.
9 "	102.6	44	60	

The patient passed a comfortable night, and the temperature next morning at 10 a.m. was 100.5°. The depression of the temperature only amounted to 1° Fahr., and it took nearly three hours to produce this effect. On October 23 the patient was again more feverish, and the largest pad (three feet by two feet)

was placed under the whole length of the back. The following was the result:—

(*Largest pad, three feet by two feet.*)

Hour.	Temp. in axilla	Temperature of		Remarks.
		entering water.	issuing water.	
Oct. 23—4 p.m.	Deg. 103.0	Deg. —	Deg. —	Pulse 108, respiration 26. Pad put under patient at 4.30, and the reservoir gradually cooled by pieces of ice.
5 "	102.9	60	78	
5.30 "	102.7	40	66	Stream running freely—about ten pints an hour.
6.30 "	101.8	38	62	
7.30 "	101.2	40	64	
8.30 "	100.8	40	70	
9.5 "	100.5	40	70	Stream running more slowly. Stream through pad stopped at 9.5, but pad left under patient.
9.30 "	100.6	—	—	Pad removed at 10.5. Pulse very weak (102). Patient feels cold, with slight tendency to shivering.
10 "	100.8	—	—	
11 "	101.0	—	—	Oct. 24—1.30 a.m. Pulse 112, respiration 32.
10 "	101.4	—	—	

From this date steady improvement set in, with rapid absorption of the fluid.

The table shows that a very decided and long-sustained depression of temperature was produced in this experiment. The cooling of the body went on steadily for four hours and a half, at the end of which time the temperature had fallen 2.5°. Then it gradually rose until 1.30 a.m., when it reached 104°—fully one degree higher than before the commencement of the experiment. Next morning at 10 a.m. it had again fallen to 101.4°.

Case 2.—My next trial was on a boy of 11, who was suffering from cardiac enlargement and valvular disease, the consequence of an old attack of rheumatic fever.

On October 17 this boy began with a sharp attack of pyrexia, of doubtful import.

On the 20th at 10.30 a.m. temperature was 104.8°. At 6 p.m. temperature 104.8°; pulse 146; respiration 50.

On the 21st the smallest pad (one foot) was placed under the lower part of the back at 5 p.m. The temperature was 103.7°; pulse 128; respiration 40. The water was cooled by ice, and entered the pad at 40° and issued at 60°. At first the temperature in the axilla rose to 104.2° at 5.30; then it very slowly fell hour by hour until 9.30, when it reached 103°; the pad was then removed. After half an hour the temperature began to rise slowly. At 11 p.m. it was 103.2°. Next morning at 11 a.m. it was the same; but the day following it fell to 99.9°, and the pyrexial symptoms permanently passed away.

The total depression of temperature in this case during an effective application of the smallest pad for four hours did not exceed 0.7°. I can only explain the temporary rise of the temperature during the first half-hour of the experiment on the supposition that a rapid spontaneous rise was taking place at the time when the experiment was commenced. The pulse and respiration were not appreciably affected during the experiment. The boy soon after left the Infirmary, all his symptoms being quiescent.

The result of this and the previous experiment on the smallest pad seemed to show that so small a cooling surface as this presented is not sufficient to produce an effective lowering of the general temperature of the body.

Case 3.—Typhoid fever at end of second week, complicated with severe capillary bronchitis, in a boy of 16.

(*Large pad, three feet by two feet.*)

Hour.	Temp. in axilla	Temperature of		Remarks.
		entering water.	issuing water.	
Oct. 14—5.30 p.m.	Deg. 104.7	Deg. —	Deg. —	Pad was put under (warm) at 5.30 p.m., and gradually cooled.
6.45 "	103.0	40	70	
7 "	102.6	40	70	Stream running about the rate of ten pints an hour.
7.30 "	101.6	40	70	
7.50 "	100.2	40	70	

The pad was removed at 8 p.m., and no further observations were made.

The next evening, at 6 p.m., the temperature was 104.6°.

Two days after, defervescence set in, and rapidly went on to recovery.

The cooling of the body in this case amounted to 4.5° Fahr. in two hours and twenty minutes. This is the most powerful effect I have seen produced by this method. The approaching period of normal defervescence had probably something to do with this. Ziemssen's observations show decisively that the application of external cold in typhoid is much more effective in lowering the temperature in the later than in the earlier periods of the fever.

Case 4.—A very stout young woman, aged 24, affected with acute articular rheumatism of five days' standing, without complication; nearly all the joints swollen and painful.

(Large pad, three feet by two feet.)

Hour.	Temp. in axilla	Temperature of		Remarks.
		entering water.	issuing water.	
	Deg.	Deg.	Deg.	
Oct. 31—11.30 a.m.	103.2	—	—	
2 p.m.	103.0	—	—	
3 "	103.1	—	—	
5 "	103.3	—	—	Pad put under patient at 5.15 p.m.
5.30 "	103.0	63	83	
6 "	103.0	62	86	Patient felt pad cool and comfortable.
6.30 "	103.1	61	81	
7 "	103.2	61	81	The stream flowing through-out at the rate of seven pints and a half per hour. At 7.30 patient felt better; shortly after fell asleep.
7.30 "	103.2	61	81	
8 "	102.9	59	80	
9 "	102.5	59	79	
9.30 "	102.2	59	80	
10 "	101.7	—	—	Pad was removed at 9.30
10.30 "	101.8	—	—	
11 "	101.8	—	—	
11.30 "	102.0	—	—	
Nov. 1—12.30 a.m.	102.3	—	—	Patient passed a good night.
1 "	102.5	—	—	
2 "	102.7	—	—	
10 "	102.7	—	—	

In this experiment the water was not iced, but used as it was drawn from the main. The utmost degree of cooling was 1.3° Fahr. in about five hours. The stream through the pad was running but slowly. Probably a better result would have been obtained if a swifter current had been maintained.

Two days later, the joints being still somewhat swollen and painful, the cooling pad was re-applied, with the following results:—

(Large pad, three feet by two feet.)

Hour.	Temp. in axilla	Temperature of		Remarks.
		entering water.	issuing water.	
	Deg.	Deg.	Deg.	
Nov. 3—5 p.m.	102.2	—	—	
6 "	102.2	50	70	Pad set under patient at 5.30, but running very slowly until 6.20; then set to run rapidly at rate of about twenty pints an hour to end of experiment.
7.15 "	101.7	45	69	
8 "	100.7	45	69	
9 "	100.4	—	—	Pad removed at 8, patient feeling chilly.
10 "	101.5	—	—	

At 10 a.m. next morning, temperature 101.6°. After this the joint affection subsided. Convalescence was in full progress on November 6.

Case 5.—Typhoid fever (second week) in a young woman, aged 30.

(Medium pad, two feet by sixteen inches.)

Hour.	Temp. in axilla	Remarks.
	Deg.	
Nov. 3—5 p.m.	104.8	Pulse 140; respiration 30.
6 "	104.2	The pad was placed round the back and abdomen at 5.30, and set running at once with iced water, which entered at about 45°, and issued about 55°. The stream ran at the rate of about twenty pints an hour until 6.45. At 6.45, patient complained of cold, and shivered slightly; the pad was then withdrawn from under the body, and placed simply across the abdomen, and the current made to run very slowly. At 7.30 the patient still complained of the cold; the pad was therefore altogether removed.
6.30 "	102.8	
7 "	102.8	
7.10 "	102.7	
8 "	103.0	
9 "	104.5	
10 "	104.3	
11 "	104.4	
Nov. 4—10 a.m.	102.1	

In this experiment the maximum power of the pad was used, the water being iced and the current running very freely. The

effect was proportionally great—the temperature fell 2° in an hour. The pulse fell from 140 to 120; but the respirations rose from 30 to 32. The first sensations of the patient were those of agreeable coolness; but the feeling of cold soon became uncomfortable, and slight shivering occurred, though the temperature was still 102.8°. The patient passed a good night.

On November 5 I went to re-apply the pad in the evening, but I found the temperature rapidly falling, and the patient sweating freely. From this time rapid convalescence set in.

Case 6.—Typhoid fever (end of first week); in a girl of 14. In this case the medium pad (two feet by sixteen inches) was applied on three evenings, with some rather curious results.

On November 17 the temperature ranged from 104° at 11.30 a.m., to 105.7° at 4 p.m.

On the 18th it ranged all day from 104.8° to 104.9°.

Hour.	Temp. in axilla	Remarks.
	Deg.	
Nov. 18—4 p.m.	104.8	The pad was put round the body, and set to work at 4.15. It ran for an hour, at the rate of thirty-six pints an hour, entering at 50°, and issuing at from 55° to 58°. The rate of flow was then reduced to eighteen pints per hour—the entering water being at 50°, and issuing at 59°. This was continued until 8.15, when the pad was removed. The pulse fell from 120 to 112, and became very weak, and at 7 she complained of the cold.
5 "	104.5	
6 "	103.7	
7 "	104.1	
8 "	103.1	
8.30 "	105.1	
9 "	106.1	
10 "	104.8	
11 "	105.4	

The sudden jump of the temperature, when the pad was withdrawn, from 103.1° to 106.1° in the course of an hour, is very remarkable.

On November 20 the same pad was re-applied.

Hour.	Temp. in axilla	Remarks.
	Deg.	
Nov. 20—5 p.m.	105.0	Pulse 120; respiration 40.
6 "	103.5	The pad was put round the body at 5.5, and the stream flowed at the rate of thirty-two pints per hour until 6, entering at 49°, and issuing at 52°. Then it flowed irregularly from 6 to 7, and at 8 the pad was removed. From 5 to 8 the pulse remained steady at 120, but the respiration fell from 40 to 28.
7 "	103.9	
8 "	103.0	
9 "	106.0	
10 "	104.6	
11 "	104.0	
12 "	103.0	
Nov. 21—9 a.m.	103.5	

On November 21 the same pad was again applied.

Hour.	Temp. in axilla	Remarks.
	Deg.	
Nov. 21—4 p.m.	104.4	Pulse 120; respiration 36.
4.50 "	104.5	The pad was put lengthwise under the back (not round the body) at 5.30. The stream flowed at the rate of thirty pints an hour, entering at 48°, and issuing at 52°.
6 "	104.4	
7 "	103.2	The patient slept from 7 to 8, and woke up feeling chilly.
8 "	102.5	
9 "	102.3	
9.40 "	103.6	The pad was removed at 9.15.
10 "	103.9	
10.30 "	104.1	During the experiment the pulse fell from 120 to 112, and the respiration from 36 to 28.
Nov. 22—9 a.m.	102.9	

In the course of November 22 the temperature fell throughout the day, and the defervescence went on during the next three days, the fever finally disappearing on the 25th.

It will be observed that in all the cases the depression of the temperature was only temporary. This has always been found to be the case after the use of the cold bath. It is also seen that as a rule the temperature rises after the withdrawal of the pad to a higher point than before the experiment began. But this appears to be only a temporary jump. The impression on my mind was very decided that the use of the cooling-pad was beneficial on the course of the disease.

It will be interesting to ascertain the effect of a more gradual and more sustained cooling, and to contrast the effect so obtained with the effects of a more rapid and more brief cooling frequently repeated.

In conclusion I must record my obligations to Mr. Buckley, Physician's Assistant in the Infirmary, to whose zeal and accuracy I am indebted for most of the temperature observations. (a)

DR. LYDIARD has been elected Medical Officer for the north-east district of Kensington.

(a) The pads were made by Chas. Macintosh and Co., Manchester. The price of the medium pad, which promises to be the most useful, is about 5s.

CEREBRAL AND GANGLIONIC DISORDERS OF MENTATION.

By METCALFE JOHNSON, M.R.C.S.E., L.S.A.

PART II.

(Continued from page 674.)

It now becomes important to take a more general glance at the cases detailed, with a view to ascertain their practical bearings not only upon the question of present remedial measures, *quoad* the patient, but more especially to inquire whether by ascertaining their causes we have not some clue to a power of adapting such persons to the customs of society through the medium of State interference.

On the subject of present treatment of the patient there is, perhaps, little to be said, except it be to point out how—as in the case of No. 10, C. L.—punishment should never be administered to a pupil until we have fully investigated his character. I grieve to say it, but I consider that, as a rule, schoolmasters ascribe to their pupils an amount of power of volition which they do not possess. Several important cases are on record in which most sad mistakes in this matter have led to most cruel castigation. On this head, also, I would venture to suggest that the subject of physiology should be especially studied by the *παιδαγωγος*, and by the priest in his capacity of public instructor; and to his especial study I would commend the subject of volition. We are all apt to set up ourselves as the standard whereby to judge others, but this is an error; and the more we study anatomy, the more, I think, shall we agree with Condorcet, “*Cette faculté (volition) se développe en lui par l'action des choses extérieures.*”

One important practical suggestion arises, however, out of the consideration of the cases of A. B. and B. B.—namely, that it is desirable as far as possible to cultivate the beautiful and the pleasant during the period of pregnancy—for though we do not expect to find “a coach and horses” as a maternal *nævus*, yet we do find idiocy resulting from maternal intemperance, and much injury done to children, while suckling, from fits of passion on the mother's part. Moreover, every mother desires her baby to be beautiful; and with this view the contemplation of the beautiful by the pregnant mother is likely to assist in fulfilling her desires.

The treatment of these cases by the agency of law, both as preventive and corrective, will form the subject of a few remarks in their proper place. It however behoves us first to consider that the cause of much of this permanent and functional aberration from health is the practice of making use of alcoholic drinks as a daily use and abuse.

Idiocy is traceable to maternal inebriety. I have seen very many cases in which children, not only of a low class of intelligence, but others, in which a low class of *morale* is engendered simply from the fact that during the pregnant period the mother, who is a secret drinker, is obliged to resort to so many subterfuges to obtain ease for her craving without being subject to discovery, that her mind during that important period is filled with craft and guile to hide her fault. What can possibly prevent the child, which at this time is flesh of her flesh, from inheriting some of these mental bendings?—for “as the twig is bent the tree's inclined.” This opinion is not mere theory, but, did not the violation of Professional secrecy forbid such a disclosure, I could adduce instances in some numbers confirmatory of the results.

But as regards the general aspect of the drinking habits of society towards the subject we have now in hand, the question is perhaps paramount in importance; for while it is all-engrossing as one of scientific research, it has a social bearing which claims pre-eminence at all times, but especially at the present; and, had I the pen of a ready writer,—

“I could a tale unfold, whose lightest word
Would harrow up thy soul,
Make thy two eyes, like stars, start from their spheres,

And each particular hair to stand on end,
Like quills upon the fretful porcupine.”

I could summon as dumb but eloquent witnesses the pale wan face and wasted skeleton of the syphilitic baby, the vacant stare and gibbering scream of the idiotic child, the rigid spasms and distorted features of the epileptic youth, the hectic flush and dilated pupil of the consumptive girl, the sunken tear-injected eye of the heart-broken and belated wife, the reeling gait and bedrabbled garments of the victim of the gin-palace, the untaught children, the pauper family, and, indeed, almost every ill that flesh is heir to. These all witness to the

wasting of the talent which is intrusted more or less to every man; and the great symbol of his being “lord of the fowl and the brute,” instead of being cultivated to remain in the image of God, is debased to a lower condition than the animals by which he is surrounded. Here it is to be regretted that for the numberless instances of border-land insanity, which produces all these evils, the law of England offers no remedy, on protection. From too frequent experience I am sadly reminded of the home of a man of great talents, comfortable means of livelihood, and a benevolent disposition, who, by succumbing to the baneful influence of an uncontrolled sympathetic nerve, is suddenly removed from his family, unloved and unmourned. Poverty and crime render the hearth which he should have made sacred the scene of domestic strife, sorrow, and disease; the bed he should have honoured despoiled even of its coverings to satisfy the cravings of his unruly ganglia, leaving the wretched partner of his life to starve and shiver through the cold wintry nights; chairs, tables, carpets—nay, all the household gods—surreptitiously taken one after another to deposit in pledge for his one ruling passion. In the face of such misery one is tempted to exclaim—Where is the law to protect the wife and children; to deal rightly between father and son? Surely our lawgivers do not know the depths of misery and sorrow which these border-land lunatics inflict upon all around them, or there would be more willingness to combine to mitigate these evils by the strong hand of the law. What higher object, I would ask, for the philosophic investigator than to seek the cause and eradicate the curse of such a state of things as this? What better object for the philanthropic lady than to add her mite of advice and assistance in such a cause? What holier end for the disciple of Christ or the worshipper of the God of Nature than to seek to make his fellow-man better than at present? True, a journal of pure science is no place for enthusiastic pleading; but I trust that even amid the hard cold facts of philosophy there is still room for the better and holier part of our nature to develop itself in trying to “do unto others as we would they should do unto us.”

In my paper (*Lancet*, March 19, 1870) I have called attention slightly to the political-economy aspect of the question; and, looking at the Great Commonwealth, as in the view laid down by Thomas Hobbes, in his “*Leviathan*,” we see the position between the State and the individual resembling that between parent and child—the State demanding obedience, the individual asking protection.

There are now several classes of persons against whom the State does not protect the individual—

1. Drunkards, who consume earnings and acquired property, and, finally, are maintained by the State (poor-rates); Nos. 8, 10, 15.
2. Persons who, through drink, become dangerous to themselves and others; No. 15.
3. Persons who, from congenitally deranged hedonism, become injurious to the commonwealth (lunatic asylums, county rates).
4. Persons who are amenable to the laws of their country, and as such are supported by the State (prisons, county rates).

Against these persons the law affords us no protection, but enforces that we shall support them out of our hard-earned gains.

I am satisfied that paupers and prisoners are, taken as a great whole, able to earn more than it would cost to keep them; and until this desideratum is brought about by our Parliament, the State will not have performed her parental duties to the individual.

One suggestion of a practical nature arises out of this subject. To persons of the tradesman class a lunatic relative is often a very terrible burden, costing from 20s. to 30s. a week—often nearly as much as the tradesman can earn of profits. It would be a great relief if such persons could, on proof that their income is insufficient to support a lunatic, be allowed to send such lunatic to the county asylum on payment of all expenses, which would not exceed 12s. or 13s. per week.

One other fact forces itself upon my memory in connexion with this subject. The dwellings of the pauper class are, as a rule, filthy and unfit for human habitation, tending not only to foster disease, but to drive the inmates from home to the streets, the gin-shop, and the gaol. It would be well if boards of health, magistrates, and police authorities could be so combined as to compel periodical whitewashing of these tenements; but it would be still more desirable if companies could be formed to purchase the present sites of these haunts of infamy, and (following the example of London in the Holborn Viaduct) houses now the abodes of thieves, poachers, prostitutes, and paupers, might be turned into habitations for an industrial

population, and the lawless denizens driven from pillar to post, and so hooted, as it were, from off the face of society.

The inquiry into the causes of ganglionic insanity of mentation brings us face to face with a difficulty of no mean dimensions—the subject of genital use and abuse. Hitherto, unhappily, owing to the prejudices of society, the treatment of the maladies incident to genital abuse have been committed to the care of a class of men who are known as “quack Doctors,” and it requires no small amount of moral courage in an orthodox Practitioner to meet this dragon of prudery *vi et armis*. There is no doubt that the derangements of the ganglionic system, known as chorea, hysteria, furor uterinus, nymphomania, etc., are due to use and abuse of the generative function, owing to some misdirected views of morality. The use of masturbation in young men arises generally from a virtuous desire to avoid the sin of fornication; and in escaping Scylla they too often founder on Charybdis.

It were presumptuous to offer a remedy for this terrible evil, but the suggestion may be allowed that the subject should receive more earnest consideration from the respectable members of our Profession than it has hitherto done. The remedies for the cerebral section of our subject are now receiving consideration from our State advisers, and the Contagious Diseases Act will be a step in the right direction. Nevertheless, there is a phase of the subject which the Contagious Diseases Act cannot touch, and that is—the real bearings of the Gamic custom in reference to age and the present habits of society. The Bills of Dr. Dalrymple and Sir Wilfrid Lawson are bringing the question of alcoholism before the Senate, and no doubt but that good will come out of them. Certain it is that in no section of *mores* is State interference more demanded than in relation to the subject of “the narcotics we indulge in.”

But, with reference to the third subject, “maternal impressions,” we have only hope that Mr. Huxley’s proposal to teach the people physical sciences, and among them physiology, may assist in enabling the public so to understand the philosophy of marriage as to teach them to avoid some of the stumbling-blocks of their forefathers. The example of Laban with his pregnant ewes may ere long not be lost upon the present generation, and the subjects of consanguine marriage and scrofulous connexion may also receive due consideration.

There is one other subject which, as it were, evolves itself out of these considerations, and that is—the relation of the female mind to education, and the relation of that education to offspring. There is no doubt that the part played by the female in the period of utero-gestation has an influence upon the future man’s or woman’s nervous system greater than that of the male, and that intelligent sons may generally be traced to intelligent mothers. It becomes, then, a matter of national importance—if we can, by cultivating the physique of our women, so influence their minds as to extend their mental powers to offspring—that we should no longer allow the subject of “women’s rights” to be kept in the background. It will thus be seen that the remedies for cerebral and ganglionic insanity of mentation are in the hands of State Ministers, under the able advice of the Medical Profession, and that one of our pressing needs for national good is a State Health Department and Medical men in Parliament.

ADDENDA.

Since my last paper was in type the two following cases have occurred in my experience, which seem to me sufficiently illustrative of the principle for which I have claimed attention, and so aptly showing the contrast between cerebral and ganglionic insanity as to deserve notice while the subject is under consideration:—

C. D., aged 40, married, and having had a family of very intelligent children (one of whom, however, shows symptoms of hydrocephalus) has been labouring under mental depression of a suicidal tendency, in consequence of a disordered liver. Her symptoms were—loaded tongue, cool skin, yellow conjunctivæ, quiet pulse, loss of appetite, loaded urine, and constipation. Her feelings of despondency were so great that she desired to commit suicide for several weeks, and it was necessary to watch and provide her with cheerful companions. Remedies were administered to relieve the liver, by acting on the kidneys, and by means of cholagogues; and as the liver symptoms disappeared the depression vanished, and she is now cheerful and almost a complete convalescent.

As a contrast to this picture is the case of Y. Z., who, at the age of 59, died suddenly of heart disease. He had been through life a morose, moody, silent man, who drank away what few wits ever belonged to him. His taciturnity pre-

vented any proper analysis of his mind, but his habits were dirty in the extreme, and his manner more like that of a gorilla than of a man. A post-mortem examination of his brain revealed an opaque arachnoid over the whole surface, and on the left side, just behind the intra-parietal fissure, was the angular gyrus wasted away to the thickness of a small goosequill, and having the appearance of a small roll of yellow fat. The rest of the brain, though rather soft in substance, seemed in a fairly healthy condition.

These two cases present an instructive example of the two classes of insane mentation—one dependent on disorder of the ganglionic nerve, acting through the liver and the organs of digestion, while the other had its cause in a disorganised structure of a part of the brain itself; one which, though associated with removal of structure, yet developed no paralysis or loss of motile power; nor has his history presented us with any reason to suppose that such loss was ever experienced. But that some power of perception—some power to receive and convey a sensation (whatever that may have been)—must have been lost, is evident from the structural change in the gyrus referred to. It is much to be regretted that our experience of the brain and its lesions does not enable us to know what loss of sense to expect in such a case; yet I think it may be predicted that by constantly placing on record the exact portion of the cortical substance which is either so diseased or so deficient in formation as to place it *hors de combat*, in every case in which post-mortem examination reveals it to us, in course of time we may expect so to map out the brain, as to function, as once more to place the now slumbering science of phrenology in a condition to enlighten us as to a man’s powers and proclivities by inspection of his central organ of mentation.

FATAL INJURY OF THE PERINEUM.

By J. FAYRER, M.D., C.S.I.,

Professor of Surgery, and Senior Surgeon, Medical College Hospital, Calcutta.

R., a MAHOMEDAN carpenter, a healthy, vigorous man, aged 35, was admitted into the Medical College Hospital on July 21, 1871, with a lacerated and contused wound in the perineum, extending from the scrotum backwards, and a little to the right of the raphe, to within half an inch of the anus.

The accident occurred at Ranaghat, about forty miles from Calcutta: he, with eleven other men, was raising a block of wood to be sawn, when it suddenly fell from off their shoulders, and crushed him violently against another log of wood, the sharp corner of which lacerated his perineum, as above noted. The wound was externally about four inches long, and so deep as to expose the bulbous, membranous, prostatic portions of the urethra, and the neck of the bladder, extending as far as—indeed, above—the symphysis pubis, through the pelvic cavity, without injuring either the urethra, the prostate, the bladder, the rectum, or the peritoneum. The triangular ligament and levator ani were torn across, the anterior ligaments of the bladder were ruptured, and the pelvic bones fractured. The symphysis pubis was separated, and its ligaments torn. The accident occurred at 7 a.m. He was brought down by rail, and admitted about eight hours after the accident. During the journey, his companions say, he lost much blood.

On admission he was much depressed, his pulse being quick and feeble. Blood was still oozing from the depths of the wound. A catheter was passed without difficulty, and some clear and natural urine withdrawn. The wound was filled with lint, and the catheter for a time retained in the bladder, natural urine continuing to flow through it.

By the next morning the hæmorrhage had quite ceased, and he appeared to be much better, his condition having improved under the influence of rest, stimulants, and nutrients.

On July 23 unfavourable symptoms set in. He became low; pulse rapid and feeble; the right thigh swelled, became cold, and rapidly gangrenous.

On the morning of July 24 he died rather suddenly.

On making a post-mortem examination, the posterior and inner aspects of the right thigh were found to be covered with bullæ; the limb was swollen, infiltrated, and gangrenous. The adductor muscles were extensively lacerated and infiltrated, and blood effused into the limb as high as the thyroid foramen. The obturator muscles were also torn, and the obturator artery, as well as the branches of the profunda, torn across. The abdomen having been opened, blood was found to be extravasated into the subperitoneal tissue all round as high as the

level of the umbilicus, and the quantity in the pelvic cavity was so great as very much to narrow its capacity. The viscera and peritoneum were uninjured. On the right side the ascending ramus of the ischium was fractured just above the tuber ischii, and the descending ramus of the pubes was fractured below the symphysis. On the left side the ramus of the ischium was also fractured; the bodies of both pubic bones were fractured just internal to the ileo-pectineal eminence. All five fractures entered the thyroid foramen, and the fractured bones could be moved with considerable freedom on one another. The line of fracture of the two ischial bones traversed the course of the internal pudic artery, which had, on one or both sides, probably been torn across. The viscera were all free from disease, except slight congestion of the lungs.

This is a case of much interest, showing, as it does, how very severe an injury may be inflicted on the pelvic cavity without serious injury to the bladder. The tissues were violently torn, and the bones were fractured and the parts displaced; and yet both bladder and urethra, as well as other pelvic contents, escaped injury. The entire course of the urethra, from the bulb to the neck of the bladder, was, as it were, dissected out by the injury. It appears that he had emptied his bladder about an hour before the accident occurred: had it been distended, it could hardly have escaped rupture. Death was caused by gangrene of the thigh, which resulted from the great violence done to that limb, the muscles being lacerated, and the arteries torn across.

Calcutta.

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

MIDDLESEX HOSPITAL.

TWO CASES OF UTERINE POLYPI.

(Under the care of Mr. HULKE.)

HÆMORRHAGE is usually an early as well as a leading symptom of uterine polypi. The interest of the following case lies in the complete absence of bleeding until the polypus protruded through the vulva, its appearance externally being the first indication to the patient of the existence of the growth.

Case 1.—A tall thin blonde, aged 32, a cook, was admitted into Regent Ward on May 14, for the protrusion of an unnatural substance through the os uteri, followed by bleeding. She related that a fortnight previously she felt some discomfort, and found, on going to the closet, a roundish body, of the thickness and length of the first two joints of her little finger, protruding from her person. Profuse bleeding soon followed. A Doctor who was called to see her applied tannic acid, which checked it, and the protruding body disappeared. On an examination, the os uteri was found slightly dilated, and floating in the vagina was a long, roundish, soft polypus, not very unlike an overgrown uvula, which appeared to be attached just within the os, to its posterior lip. It was pulled down with a loop of thread, and cut off with an écraseur. No bleeding occurred, and in a few days she was discharged convalescent. A small scar marked the point of attachment.

It is commonly taught that the removal of a fibrous polypus from the uterus is never followed by recurrence, any portion of the stalk which may be left withering and finally disappearing. The general truth of this is confirmed by experience; but there are exceptions, and, in the following case, had the patient survived long enough after the removal of the first polypus, a second and even a third might have been evolved out of the original stalk.

Case 2.—A servant, aged 39, was admitted May 30, 1870, in a state of great prostration, into the cancer wards, having that morning had such profuse hæmorrhage from the womb that her Medical attendant had only restrained it by using a strong styptic injection of a salt of iron. He had looked upon the disease as cancer, and had advised her removal into the Hospital. During ten months she had suffered frequent and great losses of blood, unaccompanied, however, by any other vaginal discharge or by pain.

On a digital examination the vagina was found filled with a tough clot overlying a tumour, the nature and connexion of which could not be clearly made out without detaching the

clot, and it was feared this might provoke a fresh hæmorrhage, which in the exhausted state of the patient would very likely be fatal.

Four days afterwards the bleeding recurred, and at a consultation with Dr. Davis and Mr. De Morgan the tumour, being found to be a polypus of the size of a large pear, was at once removed with the écraseur as the best means of arresting the bleeding and saving the woman's life. The removal of the polypus was bloodless, and the bleeding did not again recur, but the patient sank, and died a week later. At the post-mortem examination the stalk of the polypus was found to be attached near the fundus of the uterus, and to contain three small fibromata of the size of peas, each of which might in succession have grown to a large polypus.

Medical Times and Gazette.

SATURDAY, DECEMBER 16, 1871.

THE ILLNESS OF H.R.H. THE PRINCE OF WALES.

THE whole period since our last record of the Prince's condition has been one of very great and continued anxiety. We can hardly say, even, that there have been alternations of fear and hope; for the fear of what the next news might be has all along been the predominant feeling, and but very rarely has any gleam of hope lightened the gloom. The affection with which the Prince is personally regarded, the sympathy felt with the Royal Family, and the warm loyalty and love of the English for the Queen and the throne, have been shown to a degree and universality that will make the past week a memorable one in the national life and history. It is not at all an exaggeration to say that the lightning-rapidity of communication of the day has, as it were, made the British empire, for the time being, the ante-room of the Heir-Apparent's sick chamber; and as bulletin after bulletin has flashed along the wires, the pulse of the whole nation, and, indeed, of all English-speaking people, has throbbed in sympathy with the anxious and loving hearts at Sandringham; and certainly Medical men have been not the least anxious and deeply interested of her Majesty's subjects. Everywhere in their daily rounds—from patients, friends, and acquaintances—the first question has been, "What do you think of the Prince's state?" and very thankful have we all felt when we could point out any grounds of hope.

When we went to press last week we were happy to be able to take a decidedly hopeful view of the condition of the Prince of Wales. The fever appeared to be running a regular course without any complications, though the attack was evidently a severe one. The bulletin issued on the morning of the 7th stated that his Royal Highness had "passed a quiet night,"

and that "the decline of the symptoms continues regularly"; and that issued in the evening of the same day told us that the day had been a quiet one, and that there was "no material change in the symptoms." The general tenor of the official Medical reports, added to the facts that the Prince's strength continued good, and that he took nourishment freely, enabled us to feel warranted in saying at that time that the prognosis was decidedly favourable. At the same time we reminded our readers that his Royal Highness was far from being out of danger, and that that period of the fever, the beginning of the fourth week, was one during which the gravest complications might occur.

This warning was, alas! only too soon and too fully justified. The night of the 7th was a very unquiet one, and there was "a considerable increase in the febrile symptoms"; and in the afternoon of the 8th the bulletin spoke of the Prince's "precarious state," and stated that the febrile exacerbation had been "attended by great prostration of the strength." Throughout Friday, the 8th, the bulletins were of a character to excite the gravest anxiety and alarm, but on Saturday, the 9th, our apprehensions were somewhat relieved; the Prince was able to sleep at intervals, passed the day "quietly," and the mid-day report stated that the "febrile paroxysm" of the previous day was subsiding, and there was no increase of exhaustion. This improvement continued through Saturday night, and up to mid-day on Sunday, the 10th, at which hour the Medical report was that the general condition was "somewhat more satisfactory than yesterday"; but the same evening brought again unfavourable tidings, and the bulletins reported "a return of the more urgent symptoms," and of restlessness. On Monday, the 11th, the bulletin dated 8 a.m. caused still greater alarm, for we learned from it that the night had been "restless, with a further recurrence of the graver symptoms," and again the Physicians spoke of the Prince's state as "precarious." But, at the same time, the Medical world were not a little relieved by the assurance that the complication which had excited, and was still exciting, so much anxiety, was not abdominal, but pulmonary. From the necessarily guarded expressions of the bulletins, we had not been able to gather from what the dangerous condition arose, and, naturally, we dreaded intestinal hæmorrhage or perforation (the most frequent and most fatal complications of enteric fever), and in this fear we could hardly find a ray of hope. The pulmonary complications—bronchitis and pneumonia—are, indeed, full of danger, and very often are the immediate cause of death in enteric fever; but neither of them is so fatal as severe or recurring intestinal hæmorrhage, and of course still less deadly than perforation. When, therefore, we learned that no grave abdominal complication existed, we were able to take fresh courage, and to hope that the Prince's vigorous and unimpaired constitution would still enable him to "pull through." It must be said, however, that the character of the bulletins from Monday morning till the Wednesday night made it very difficult to continue to hope; they did not, indeed, say that there had been any recurrence of the attacks of pulmonary congestion and bronchial engorgement, but they spoke of constant restlessness, of continued prostration and exhaustion, and we ceased entirely to get the welcome tidings that "the pulse continues good." We have said that on Monday morning the Prince's condition was "precarious"; since then, the expression used in the bulletins has ever been, till to-day (the 14th), "The general condition continues unchanged," or "There is no abatement of the gravity of the symptoms." No words of ours are needed to point out the extreme peril indicated by such a state, continued into the fifth week of the fever. There appears to have been no marked remission of the grave symptoms from the morning of the 11th inst. up to the morning of the 14th; there are still, we must fear, abnormally high temperature, and bronchial irritation; and these, with restlessness, must be fearfully exhausting. On the other hand, we believe that the Prince continues able to take food and

stimulants well, that he has intervals of consciousness and clear intellect, and that there are no new complications; and we know that he does still live, and that, in enteric fever, while there is life there is hope. And, above all, we learn that at last the long-continued obstinate restlessness has yielded. Late last night—we are writing on the 14th—we were gladdened by the report that the Prince had "passed a less unquiet evening"; and this morning the bulletin told of quiet sleep, and of some abatement of the gravity of the symptoms. We need not enlarge on the great value of this rest and sleep—

"Sleep, death's twin brother, knows not death;"

and, especially in such a case as the Prince's, sleep may, above all other helps, save from death. There is now stronger ground of hope. The latest bulletin reports that "the gain during the night is maintained"; and we know, from a source which, were we at liberty to name it, would command absolute confidence, that the Royal watchers at Sandringham are feeling "more hopeful." It would be a specially happy recollection should the commencement of the Prince's recovery date from the morning of the day on which, ten years ago, his father died from the disease against which he himself is still struggling.

We are very glad to be able to close with words of renewed hope; but no words are needed to remind our Medical brethren that the battle is still far from won.

We have at present no time, and not much inclination, to discuss the sanitary conditions of Londesborough Lodge, and the question whether it is fairly well or very badly drained. But as two of our Medical contemporaries have sent "sanitary commissioners" to examine and report on these matters—and their reports have excited not a little discussion—we must just refer to them. There can be no question that these commissioners conducted their inquiries in the utmost good faith, with perfect impartiality, and without any prejudices; but we must take leave to think that their reports will not much increase the public faith in Medical sanitary inquiries, and are not altogether creditable examples of scientific investigation. They have no doubt been very generally and carefully perused, with the replies to them. Both seemed to prove that the sanitary state of Londesborough Lodge was very bad indeed; and the wonder is, not that some of Lord Londesborough's guests contracted enteric fever, but rather that any inmate of his house escaped it! The *Lancet* commissioner especially pointed out that there were no ventilation-pipes to the sewers, and that sewer air must almost of necessity have entered the Prince's bedroom. But we are informed, in a report signed by Mr. Dale, of Scarborough, by the Medical Officer to the Local Board, the architects, the contractor, the clerk of works, and the plumber, that there were two ventilation-shafts to the drainage system, that the soil-pipe from the water-closet used by the Prince runs up to, and opens freely to the air on, the roof of the house, and that "all the drains inside that part of the house receiving water-closet soil-pipes are glazed sanitary tubes, that they are from four to nine inches in diameter, have a fall of one inch and a half to ten feet, and that there was no deposit or smell in the drains;" and these facts are confirmed by the sanitary commissioner of the *Lancet*, he having been "present at, and taking part in, the re-examination" of the Lodge. And, further, we are informed that, when reporting that there was no ventilation to the Prince's closet, "the *Lancet* commissioner has been misinformed by"—God save the mark!—"the plumber's man"! The *British Medical Journal* commissioner stated that there were two cesspools inside Londesborough Lodge, and that one of these was under the Prince's bedroom. Mr. Dale says there are no cesspools, and the report we have above quoted from affirms that "there is no cesspool of the kind described by the *British Medical Journal* commissioner inside the house, or anywhere about the premises! In reply to this, the commissioner says—"When I requested him (the contractor), on the strength of a letter I had received from Lord Londesborough, authorising my examination of the drains at Londesborough

Lodge, to open in my presence the cesspool which he described as existing beneath the Prince's bedroom, he declined to do so;" and the commissioner was satisfied. We fear the "plumber's man" will often be quoted against us when we speak against sanitary defects, and that it is too evident that the "commissioners," when conducting scientific investigations, took much too easily the evidence offered them.

We must all feel sincere sympathy with Lord Londesborough,—for what has happened, apparently, at his house may happen to any of us, seeing the sanitary ignorance and carelessness of architects and builders—but we hold that Lord Londesborough did all that man could do to protect his guests, and that he is entirely free from blame. At the same time, it is to be observed that the very fact that his Lordship thought it necessary to take all the precautions that he did take, seems to show that there was something suspicious about the drainage of his house. For, to say the least, it is not the custom for English gentlemen, when about to receive guests, to have all their sewers and drains inspected, and to retain a man to flush them during the stay of visitors. And, again, the facts—if they are facts—that Lord Chesterfield succeeded the Prince of Wales in occupying one particular suite of rooms, and that some other inmates of Londesborough Lodge have suffered from enteric fever, or diarrhoea, are very damning of the sanitary state of the house. We hope that Lord Londesborough may yet think it right to request that the Privy Council will order a strict inquiry into the whole matter.

THE PUBLIC SERVICES.

EVERYONE is aware of the long-established axiom of political economy, that the demand creates the supply; the truth of a corollary to the same, that as demand increases quality deteriorates, has also unfortunately been so frequently recognised, that even the most sanguine and confiding individuals are compelled to acknowledge it. The Indian Government, however, in the management of its Medical Service appears to have entertained some doubts upon this subject, and, having for about three years discontinued its demand for Medical officers, is now about to re-establish the reciprocal currents of demand and supply, by throwing open in February next to public competition at least forty vacancies in its Medical Service. The supply, we have no doubt, will be fully equal to the demand so far as quantity is concerned; the quality, also, we are equally certain, will be in conformity with the usual law. The Naval Medical Service is likewise beating up for recruits in the advertising columns of the various papers, and it is, we believe, not unlikely that the Medical Service of the Army will also compete for a limited number of candidates in the Professional labour market.

This is a state of affairs which cannot be otherwise than exceedingly gratifying to a large number of students, particularly to those whose aspirations for employment in the public services have hitherto been baulked by the obstacles presented by really competitive examinations. During the next six or eight weeks the Professional "crammers," also, are likely to have a busy and profitable time; so that, if the interests of these two classes were the only objects to be held in view, there would be every reason for congratulations all round. Unfortunately, however, much more serious and extensive interests are involved; and it appears to us that the official advisers of the Indian Government in this matter should be called upon to explain their principles of action in the past, and their intentions as regards the future management of the Indian Medical Service. By closing the doors of admission to the Service for such a lengthened period, and now suddenly throwing them open to the influx of such a large number of candidates, they are about to deprive the Service, whose interests are in their charge, of all the advantages which might have been obtained by the admission of a limited number of candi-

dates, through genuine competitive examinations at short but regular intervals.

This mismanagement on the part of the Indian authorities reflects also its injurious influences upon the Medical Services of the Army and Navy. And it becomes a question for consideration what may have been the exigencies which could have rendered either advisable or justifiable such manifestly injudicious vacillation on the part of the Indian Government. It would be well, we think, that the Directors-General of the Medical Departments of the Army and Navy should address to the War-office and Admiralty a vigorous remonstrance, with a view to prevailing upon the Indian Government, even at this late period, to reduce by one-half or one-third the number of places to be competed for in February. Failing in this, there should be no admissions to the Medical Services of the Army and Navy until such a date as may be necessary for the re-establishment of the normal rate of competition, which is now likely to be seriously disturbed by the large number of vacancies thrown open by the Indian Government.

It may be thought that a good deal will depend upon the examiners as to whether the candidates are to be submitted to really competitive tests. It is, however, we believe, the fact that even at the last examination for the Army Medical Service, where the number of candidates was nearly three times greater than the number of vacancies, only one was found not to have attained the minimum number of qualifying marks. It is evident, therefore, that when the number of vacancies at all approaches the number of candidates, the whole scheme of competition falls to the ground.

THE WEEK.

TOPICS OF THE DAY.

THE conference which took place at the house of the Society of Arts on Tuesday last, under the auspices of the Council of the Charity Organisation Society, "On the best methods of Checking the Abuses now incidental to Out-patient Relief, with special reference to the expediency of extending the Provident Principle," is perhaps destined to mark an era in the history of our public Medical institutions. The attendance of Mr. Stansfeld, the President of the new Board of Control; his expression of sympathy with the views and purposes of the Charity Organisation Society; his pledge of sanitary legislation in the coming session, and the consideration which he promised he would give to the suggestion of Dr. Acland—"that it might be well in the organisation of the Hospitals and Infirmarys, whether belonging to unions, or parishes, or to towns, that provision should be made for the treatment in the same building and under the same management, not only of those who were professedly and acknowledgedly paupers, but also of the great mass of the community who could not afford in their own homes to secure the conveniences and accommodation which might be afforded to them in the Hospitals, even if they contributed somewhat to the support of those institutions"—afford evidence that if nothing which Mr. Gladstone and his colleagues deem of more importance than the health of the people intervene, we may at least expect that Parliament will be early called on to consider the questions involved in the Medical relief by Government and by voluntary charity of the poor. The fact is, that the present crying evils of the out-patient system, both to the sick poor (whom it demoralises and pauperises) and to the Profession of Medicine (whom it directly injures), are beginning to attract attention in non-Medical circles. We fully admit that the Profession of Medicine is not free from all blame in the development of the present system. There has been too much desire on the part of some of its younger members to render charity subservient to their own success, and, failing to obtain public appointments in recognised institutions, to start fresh ones, for the purpose of bringing themselves into notice. That great harm has been

done in this way we are compelled to confess. But we may hope that these illegitimate modes of attracting attention have had their day. They have been denounced by the general voice of the Profession and the public will soon learn to discountenance them. At the same time, the large Hospitals are not blameless in the matter. They have opened their out-patient rooms indiscriminately—as Mr. W. H. Smith said on Tuesday—to all comers. “No matter how many patients sought relief, no matter whether the sickness was severe or light, no matter whether the means of the applicants were large or small, they appealed to the Physician or Surgeon, and they were seen in turn.” We thoroughly agree with Mr. Smith, that it is impossible to deny there are great evils mixed up with this work of “charity”; but the difficulty is, to introduce a reform which shall not interfere with the real work of Medical charity. That the system of Provident Dispensaries may help to reform the evils we think possible, provided that the Provident Dispensary be established on the broad principle of including all the legally qualified Practitioners of the town or district. Otherwise, the establishment of a Provident Dispensary is simply the establishment of a gross monopoly, ruinous to the Medical practice of the neighbourhood, and unfair alike to the Profession and to the working-classes. For this reason Medical Practitioners will, we are certain, oppose Dr. Acland’s proposition of erecting a sanitarium, in connexion with a rate-supported Hospital and Dispensary, for patients who can contribute to their own support, unless it be clearly understood that such patients are at liberty to choose their own Medical attendant, who should be remunerated at a fixed rate. We believe that it is most desirable that the working- and lower middle-classes should be encouraged to combine to obtain Medical attendance at a stated and fair payment, instead of being pauperised by Free Hospitals and Dispensaries; but such combination must not be allowed to establish a monopoly of Medical practice, and thereby to bring ruin on the neighbouring Practitioners.

The Naval Medical Department has advertised a competitive examination of candidates for appointment as Assistant-Surgeons, to be held in the course of February next. Application for admission to the examination is to be made in writing, to the Director-General, at Somerset House.

The Council of the Geographical Society has asked Government aid to obtain the means of communicating with Dr. Livingstone. The Foreign Office has been applied to, and it is suggested that native messengers should be despatched by different routes to the country of Manyema, where Livingstone is supposed to be, or that a qualified European, with a party of natives, should be sent. The rewards of the natives are to be contingent on their bringing back letters from Livingstone.

On Wednesday, the 13th inst., a large number of the past and present students of St. Mary’s Hospital met in the Board-room to present a piece of plate to Dr. Sibson, and a handsome timepiece to Mr. Lane, on their retirement from the respective offices of Physician and Surgeon, after twenty years of valuable service in the School and Hospital. The presentation was made on behalf of the students by Mr. Gascoyen, whose observations, together with the replies of Dr. Sibson and Mr. Lane, were received with warm demonstrations from the large number of students the occasion had brought together. Mr. Lane’s earlier reputation was connected with that School of Anatomy in Grosvenor-place which was the lineal descendant of the Windmill-street School, rendered illustrious by the Hunters.

UNPROFESSIONAL CONDUCT.

The Council of the Royal College of Surgeons having had attention drawn to a most extraordinary pamphlet from George Washington Evans, of Reading, a Member of the College, which for some considerable time past he has been circulating

largely in this metropolis and the provinces, and to which attention has been drawn several times in the *Medical Times and Gazette*, it was resolved to appoint a committee to investigate and confer with the solicitor on the subject. This having been done, Sir James Paget, Bart., as chairman, submitted the following report to the Council, on Thursday last, the 14th inst., viz.:—

“Your Committee—appointed on the 8th of June last, to consider and report to the Council upon the letter of the 4th of May last from Mr. J. P. Wilton, Honorary Secretary to the Gloucestershire Medical and Surgical Association, and the previous correspondence in relation to the pamphlets issued by Mr. George Washington Evans, of Reading, a Member of the College—have taken the subject into consideration at two meetings, viz., on the 5th of July last and on this date, and have agreed to the following report, viz.:—‘That, in the opinion of your Committee, the pamphlets issued by Mr. George Washington Evans are, in the words of Clause 2, Section xvii. of the By-laws, ‘prejudicial to the interest’ and ‘derogatory to the honour of the College,’ and ‘disgraceful to the Profession of Surgery.’ And that your Committee accordingly recommend that notice should be given to Mr. Evans that such is the opinion of the Council; and that if there be any further distribution of these or similar pamphlets, the Council will proceed to deal with him under Section xvii. of the By-laws. “JAMES PAGET, Chairman.

“November 20, 1871.”

Whereupon the Council resolved that the Secretary be directed to furnish Mr. Willan with a copy of the proceedings and to communicate with Mr. Evans on the subject. It is to be hoped that the Council will at once proceed against him, if it should be proved that he disregards this important By-law, viz.:—

“2. No Fellow or Member of the College shall advertise or publish any matter or thing prejudicial to the interest or derogatory to the honour of the College, or disgraceful to the Profession of Surgery; and any Fellow or Member, who may in any manner offend herein, shall be liable to removal, by resolution of the Council, from being a Fellow and Member or a Member of the College.”

DR. PHILIP FRANK.

AMONG our list of marriages this week, there is one which we should not have felt it right to notice in more than the ordinary manner, if it had not been publicly alluded to as follows in the *Times* of Wednesday:—

“Our columns yesterday recorded the marriage of Lady Agnes Campbell, widow of Sir Archibald Campbell, of Succoth, and daughter of the late and sister of the present Lord Westminster, to Dr. Philip Frank, late of the Army Medical Staff, a gentleman who was employed last year in the service of the National Red-Cross Society for the Aid of the Sick and Wounded, of the Ladies’ Committee of which Lady Agnes, it will be remembered, was one of the most active members. Of the daughters of the late Marquis of Westminster, the eldest, Lady Eleanor, is Dowager Duchess of Northumberland; the second, Lady Mary Frances, is Countess of Macclesfield; the third, Lady Elizabeth, is the wife of Lord Wenlock; the fourth, Lady Caroline Amelia, is the wife of Lord Leigh; the fifth, Lady Octavia, is married to Sir Michael Shaw Stewart; another, Lady Jane Louisa Octavia, is the widow of the fourth Lord Muncaster; and one, Lady Theodora, is still unmarried. Dr. Frank, we hear, is in practice as a Physician at Cannes, in the south of France.

Dr. Frank is so well known to all the leading members of our Profession that we have little to add to the above announcement. But it will be a source of general satisfaction, and another proof of the recent rapid advance of Medicine in social standing, if we add that it is generally understood that this marriage between a Physician and a member of a very wealthy and powerful aristocratic family, has been received by that family with warm and general approval.

THE LOCAL TREATMENT OF OPEN CANCERS.

A correspondent asks if any of our readers have tried the plan of treating open cancers with alcohol or a mixture of alcohol

and chloroform, as recommended some years ago by Professor Beneke, of Marburg. This Physician stated that he had discovered a large quantity of myelin in cancers, and that the peculiar offensive smell of suppurating cancerous sores is partly owing, at any rate, to the decomposition of this substance. It struck him, therefore, that as myelin is easily soluble in spirit containing 80 to 85 per cent. of alcohol, the soaking the sore with spirit might be useful. On trial, this proved to be the case, both as regards cancerous ulceration of the tongue and of the breast. The addition of chloroform to the alcohol (one-third chloroform, two-thirds spirit) was found to be also useful in relieving pain. Our correspondent would be glad to know if anyone in England has tried this treatment, and with what result. He also mentions that, in a recent private communication from Professor Beneke, a vegetable diet, with little nitrogen, is recommended in cancers, on the ground that cholesterine and the nitrogenous cholin, which form a constituent part of the lecithin which occurs in cancers, are chiefly derived from nitrogenous food. Professor Beneke describes a case in which a patient lived well on an exclusively vegetable food. The vegetable food must not, of course, include much pea or bean, or lentils, as these are rich in nitrogen. If any similar observations have been made, our correspondent would be obliged if they could be communicated to the *Medical Times and Gazette*.

THE SOLLY TESTIMONIAL.

A SUM approaching £400 has been received towards this fund, which is to be applied to the establishment at St. Thomas's Hospital of an annual prize or scholarship, bearing the late Mr. Solly's name. The prize is to be awarded for the best reports of Surgical cases, preference being given to those accompanied by drawings. It is well known that Mr. Solly attached great importance to this method of illustration.

THE HAMPSTEAD HOSPITAL INQUIRY.

GREAT dissatisfaction has been expressed at the "delay" of the Commissioners in issuing their report with respect to the above inquiry. We think the dissatisfaction has been without reasonable cause, and that the Commissioners were justified in not arriving at a hasty conclusion. We understand, however, that the report has been forwarded to the Local Board, and that it will be transmitted to the managers of the Hospital without delay.

A GOOD EXAMPLE.

No greater boon could be conferred on workers in dangerous trades than some discovery for the prevention of mischief arising from their calling. Our neighbours across the Channel, through the Société d'Encouragement of Paris, have offered a prize for an invention to protect the cutters of millstones from the dust produced in the process, which causes such distressing diseases of the lungs. M. Catilliers and a Commission have been making a series of experiments on the effects of ventilation, and the most satisfactory results have been obtained. By means of a fire and a tall chimney a current of air is produced in the dressing-shop, having a rate of ten feet per second, from the men, and it is found that by this simple method all the dust is removed. There are many trades in this country to which a preventive of a like kind would be a great boon.

JEWISH MEDICINE.

WE have observed in a religious contemporary devoted to the conversion of the Jewish race (the *Scattered Nation*), some papers by one of our fraternity, Mr. Gaskoin, on "Medicine as Practised by the Jews." The September number contains an article under the heading "The Foundation of the University of Cordova," which has an original stamp, and which sets things in a new and as yet unconsidered light. We hope to see these papers continued. From the December number of the

same publication, we are fain to borrow a few "Talmudic Gleanings." These passages are of an extremely biting character, and serve to show the priestly race of yore in strong antagonism to our art:—

"Talmudic Gleanings.

"14. A Doctor that heals for nothing, his cure is worth nothing.—*Bava Kama*, fol. 85, i.

"15. Most donkey drivers are wicked, most camel drivers are worthy, most sailors are pious, but the best of Doctors are for hell.—*Kidushin*, fol. 82, i.—*Note*.—A Doctor, says a certain writer, has the advantage over the Angel of Death. The latter kills gratis, but the former is paid for it.

"16. Seven have no portion in the world to come—the legal writer, the scribe, the best of Doctors, etc.—*Avoth. Drb. Nathan*, c. 36.

"17. When a patient says, I am in need of (certain food), and the Doctor says he is not in need of it, the patient is rather to be listened to; for (Prov. xiv., 10) the heart knoweth its own bitterness.—*Yoma*, fol. 83, c. 1.

"18. If there be no Israelitish Doctor in a city, but there are in it a Samaritan Doctor and a Gentile Doctor, the latter may circumcise (a Jewish child), but not the former.—*Avodah Zarah*, fol. 26, c. 2.

"19. Physician, heal thy lameness.—Fol. 23, c. 2."

ASSUMPTION OF A MEDICAL TITLE.

A CASE of considerable importance came before the Shrewsbury County Court on Monday last. It was the case of a person of the name of Thomas Andrews, against Mr. F. H. Davies, for £4 13s. 6d. This is a copy of the bill delivered—

"Shrewsbury, November, 1871.

"Mr. Frank Harry Davies—

"To Thomas Andrews, M.D.

"To Professional attendance, medicine, etc. . . £4 13s. 6d."

It appeared in evidence that the plaintiff had been in business as a chemist and druggist for some time; he had obtained a diploma lately, but the debt was contracted before he obtained the diploma. He had in his bill only charged as a chemist and druggist. On cross-examination, he said the diploma was an American one—in fact, he had two diplomas; but he did not produce either. A long contest ensued between the lawyers as to the diploma—the advocate for the defendant insisting he had a right to know where the alleged diploma was obtained; the lawyer for the plaintiff contending that, as his client sued only as a chemist and druggist, therefore it was not necessary to produce the diplomas, or answer questions as to whence they came. Eventually the judge allowed the plaintiff to withdraw the case on the payment of costs, observing, that as the plaintiff had admitted he was not a Medical Practitioner, there was an end of the case. But surely the case is too clearly an infringement of the 40th clause of the Medical Act to be allowed to rest where it is. There is *prima facie* evidence of the Act being infringed.

HAMPSTEAD-HEATH.

WE are very glad to see the powerful influence of the *Times* is being brought to bear upon the Metropolitan Board of Works, to encourage the Board so to improve Hampstead-heath that it may become a real place of "recreation" for the public. Mr. Le Breton, Chairman of the Open Spaces Committee of the Board, recently showed that he understands the real meaning of the term *recreation*—the renewal, restoration, or *recreation* of the force used up in the daily toil of city life; and he has now the power of showing whether he has the will and the ability to give practical effect to his knowledge. Parliament has made the Board of Works the steward of the public, for whom Hampstead-heath has been secured for ever. The Board has great powers, but, since the passing of the Act last June, it has literally done nothing, though directed by the Act to prepare and preserve the Heath "for the purposes of health and of unrestricted exercise and recreation." The Board have only six months left, if they intend to comply with the Act, to level, drain, plant, and improve the Heath; and they have not shown yet what

are their ideas of exercise and recreation. There are ponds which might be converted into swimming-schools and bathing-places; open spaces which a little draining and levelling would make into excellent grounds for cricket, bowls, or football; courts for tennis and fives could easily be planned, open-air gymnasia erected, good roads made for carriages, rides for horsemen, and walks for pedestrians, while all the existing depredations and nuisances ought to be stopped, and ornamental planting carried out in a manner which shall not injure the natural aspect of the Heath. The *Times* suggests that the Board should offer three prizes for the best plans by which these objects might be attained, and we cordially support this suggestion. It would be certain, at a small expenditure, to bring a number of valuable hints before the Board, who might adopt or reject exactly what they please from any plan; and it might be the means of bringing forward some able man now kept in obscurity for want of the opportunity of distinguishing himself by good work. The principle of open competition for national works is one which ought to generally encouraged.

HEALTH OF SALFORD.

THE Salford Board of Guardians do not appear to have a strong notion that they have any sanitary duties to care for. At a meeting held on the 7th, Dr. Syson, the Medical Officer of Health, wrote thus to the Clerk of the Guardians:—

“Before the small-pox epidemic visited Salford, I took the liberty of writing to your board, warning them of its certain approach, and suggesting the immediate vaccination of our unvaccinated population. My letter you did not think required any notice at your hands, but nevertheless the small-pox came. May I now again call your attention to the large number of unvaccinated in Salford, and also to the fact that, although small-pox has been, and still is, so rife, there is an utter absence of placards—save a few old and worn ones—calling on the people to protect themselves by vaccination and revaccination. As I said in my previous letter, I am strongly averse to prosecutions except as a very last resort, but I think suasion properly applied would insure at least 90 per cent. of vaccination. I thank you, on behalf of my committee and myself, for your prompt information as to all fever and small-pox cases.” After some discussion, the Guardians came to the conclusion that they had done all they could do, and thus the matter dropped.

SMALL-POX JOTTINGS.

SMALL-POX has broken out at Wold.—Dr. Lankester reports that there had been more cases of small-pox in St. James's, Westminster, the last fortnight than the preceding one.—Small-pox is very prevalent, and increasing in severity, at Leeds. The sheds on the workhouse estate are, in consequence, to be used as a Small-pox Hospital.—The disease, after having for several weeks caused scarcely any deaths in Camberwell, has within the last three weeks broken out afresh in some parts of the parish, more especially in the neighbourhood of Beckett-street and Nelson-street, and has caused there a comparatively heavy mortality.—At Kensington, during the last month, there was one fresh case, but no deaths from small-pox; 137 persons had, during the same time, been successfully vaccinated in the parish.—At Marylebone, the disease is still prevalent; and, independently of the large number of cases sent to the Small-pox Hospital, no less than eight deaths have occurred in the parish in the last four weeks, being an increase of four above the number of the previous month.—At St. George's-in-the-East, there were last week six fresh cases reported.—Small-pox is prevailing in part of New Brompton, and, in consequence, an order has been issued that the men, women, and children at the School of Military Engineering at Chatham are to be vaccinated. These precautionary measures are taken on account of a large number of the married men of the Royal Engineer Corps living out of barracks in New Brompton.—104 deaths occurred in London last week from small-pox, showing another further decided increase.—The Homerton

Small-pox Hospital is now full, as regards male patients.—Small-pox is spreading in New York, and in the opinion of Dr. Morris, the City Sanitary Inspector, is likely to become epidemic.

SMALL-POX IN DUBLIN.

THE epidemic is still increasing in extent and frequency. The number of patients suffering from the disease in the Dublin Hospitals in the week ending November 25, was 170, of which number sixty-one had been admitted during that week. Numerous cases, too, have occurred in private practice, and in the fortnight ending December 2 thirty deaths from variola were registered. All the beds set apart for the reception of small-pox cases in the Cork-street and Hardwicke Fever Hospitals are now occupied, while the sheds provided by the Guardians of the North and South Dublin Unions are largely filled.

PATHOLOGICAL SOCIETY OF DUBLIN.

AN adjourned meeting of this Society was held on the 9th inst. in the Anatomical Lecture-room of the School of Physic, Trinity College, the chair being taken by Sir Dominic Corrigan, Bart., M.P. The objects of the meeting were (1) to consider certain notices of motion by Dr. Barton, and (2) to proceed with the election of officers for the present session. The notices of motion—three in number—had reference to the mode of conducting the annual election of officers; to a proposed introduction of discussion at the Society's meetings; and to an alteration of the time and place of meeting, together with the exclusion of students. The last two proposals, in which was contemplated the introduction of radical changes in the method of working the Society, were negatived; but it was agreed to alter the mode of election to office. The members subsequently elected the following officers for 1871-72:—*President*: Joliffe Tufnell. *Vice-Presidents*: Thomas Beatty, Samuel Gordon, Edward Hamilton, Henry Kennedy, John T. Banks, and John Denham. *Council*: Robert Adams, Sir Dominic J. Corrigan, John Hamilton, Thomas Hayden, James S. Hughes, George Kidd, Robert Law, Benjamin G. McDowel, Robert M'Donnell, William Moore, George H. Porter, and James H. Wharton. *Honorary Secretary*: William Stokes. *Secretary and Treasurer*: Robert W. Smith. *Secretary for Foreign Correspondence*: Robert D. Lyons. Sir Dominic Corrigan having then vacated the chair, it was taken by the incoming President. A vote of thanks to Sir Dominic Corrigan was unanimously carried, and the Society adjourned.

SURGICAL SOCIETY OF IRELAND.

THE opening meeting of the present session took place on the evening of Friday, the 8th inst., in the Albert Hall of the Royal College of Surgeons. The attendance of members and visitors was very large. Dr. James H. Wharton, the incoming President, occupied the chair, and delivered an inaugural address. He sketched the progress of the Society, and pointed out such subjects as still afforded opportunity for advancement in Surgical science. Mr. Croly afterwards presented a number of interesting specimens, including two polypi of the rectum, a large-sized chronic mammary tumour, and a section of a diseased tibia. Mr. Joliffe Tufnell read an account of a successful case of radical cure of scrotal hernia, effected according to Mr. Syme's modification of Wurtzer's operation. A prolonged discussion ensued, after which some patients on whom Mr. Croly had performed tenotomy were presented to the notice of the members.

PROFESSOR HUXLEY AT THE LONDON INSTITUTION.

PROFESSOR HUXLEY, on Monday, the 11th inst., commenced his sixth lecture by a reference to the observations with which he had closed his previous lecture, on the difficulty of defining the relation between neuroses and the higher mental phenomena. It is, in fact, unknown. But in the lower class of

psychoses, such as the sensations, it is possible, in some measure, to trace the connexion between the physical agency through which the initiatory step is effected and the mental result. Taking as an instance the pain produced by a prick with a pin, there is first a physical lesion or condition, arising from the contact of the sharp instrument with the nerve-fibres distributed throughout the papillæ of the true skin; there is next the neurosis conveyed along the nerve-fibres to the central organ; then the psychosis, by which the pain is referred to the seat of the lesion; and, finally, the origin of the pain is referred to an external cause. In illustration of this part of his subject, Professor Huxley exhibited a diagram of a section of the skin, showing the epidermis, composed of horn-cells, quite devoid of sensation, the underlying *derma* or true skin, projecting in papillæ into the epidermis, containing blood-vessels, fat in meshes, sweat-glands and ducts, and nerves. The termination of the nerve filaments in the papillæ is not yet completely understood, but so far as present knowledge goes no special termination has been discovered; it is supposed that they are confined to the papillæ of the derma, and that mere contact with them is sufficient to produce a neurosis, no special arrangement of their terminating points being necessary. Going again over old ground, Professor Huxley impressed upon his audience that the actual seat of the pain is not in the point at which an injury is inflicted; that if the afferent nerves from the part be cut across, any amount of injury may be inflicted without the sensation of pain being produced; also that the central nervous organ must be intact and active. It is only necessary to refer to one's self-consciousness to satisfy oneself that pain apart from oneself has no existence—that it is a sensation *in* oneself. Hence the foundation of a convenient terminology, by which affections of oneself are designated *subjective phenomena*, as distinguished from things outside oneself, which are known as *objective phenomena*. There is in reality no connexion or parity between the physical agent which inflicts an injury and the sensation resulting therefrom—between, for instance, the point of a pin and the pain experienced on the skin being punctured with it. As to the actual seat of the pain, consciousness gives erroneous information. The pain is *not* in the finger pricked with a pin, but is in the brain, and by an act of primary mental activity is referred to the part touched. This is an important point, as it establishes the fallacy of the common notion that our sensations are taken in passively from without, or, according to the ancient idea, “as copies of external things.” There is nothing passive in our sensations. The localisation of sensations has been explained as the result of experience; but, to convince his hearers that this is improbable, he had only to remind them of the experiment which he had exhibited to them of touching with acetic acid the skin of one of the legs of a frog, separated from the body, but still connected with the lower part of the spinal cord. They would remember the distinct rubbing motion with which the other leg was applied, as if with the purpose of removing the cause of irritation. It is therefore evident that in the physical organisation of the nervous system there is something independent of cerebral action, capable by some automatic action of defining the locality of tactile sensations. The reference of the origin of pain to an external cause affecting a particular part is indubitably due to the association of ideas; but strictly *subjective* pain sometimes so strongly resembles that produced by an external cause, that it cannot be distinguished from it. It is well known, for instance, that after amputation of a limb irritation of the nerves of the stump frequently produces pain, which is referred by the patient to the fingers or toes formerly supplied by the terminating filaments of the irritated nerve.

Proceeding to another slightly more complex instance of cutaneous sensation, Professor Huxley suggested the supposition of a smooth, round body at a high temperature being brought near the skin at any particular point without actually

touching it. A diffused sense of warmth is then referred to that part. But there is a difference in this case from that in which the skin is punctured by a pin—the terminating nerve-filaments are untouched. Again, if the little and ring fingers be held for some time in ice-cold water, numbness will be felt in them from the cooling down of the nerve-filaments distributed to them; but if the elbow only be immersed in the cold water, although numbness—at last actual pain—may be felt in the skin covering the elbow (near which the trunk of the nerve supplying the little and ring fingers lies very superficial, and is, therefore, much cooled down by the water), no similar sensations will be experienced in the little and ring fingers. It appears, then, that reduction of temperature does not produce the same effects when acting on the trunk of a nerve as when applied to its terminal filaments. It is, therefore, concluded that an intermediate apparatus between the nerve-filaments and the epidermis is necessary for our appreciation of the varying sensations of heat and cold. It is also well known that, if the epidermis be destroyed or removed, as by the action of a blister, the tactile sense is lost, while the sense of pain remains. It has hence been inferred that there may be an extension of nervous filaments in the papillæ of the skin, towards the epidermis. This has even been described as existing in the form of “tactile corpuscles,” the existence of which, however, has not yet been satisfactorily demonstrated, and may be considered dubious. Consequently, Professor Huxley did not deem it necessary to dwell upon recent speculations on the subject.

Reverting to the consideration of the terms “heat and cold,” in the use of which, as applied to our sensations, there exists in many minds a confusion of ideas, Professor Huxley pointed out that, outside ourselves, the qualities signified by them have no existence; that the heat which we feel on approaching a fire is not in the fire, but in ourselves. So likewise other qualities of external objects, such as the hardness and roughness of a piece of chalk, are *subjective phenomena*, or activities awakened in ourselves by external causes. The apparent paradox of there being nothing whatever in the external world answering to the *subjective* psychoses of heat, hardness, roughness, etc., which we experience on contact with external objects, is nevertheless nothing more than the truth. The relation between our psychoses and the external world is similar to that between a person playing on a piano and the sound produced. There is no parity or similarity between an overture or symphony and the person playing. A person seeing a piano for the first time, and minutely examining its internal mechanism during a performance, while the performer was concealed from view, could never form any idea, or draw a sketch of the originator of the sounds. Thus the sensational philosophy, which traces all our states of mind to sensations passively received from external objects, if logically carried out to its conclusion leads to idealism.

The next primary psychosis is the sense of *Taste*, which Professor Huxley said he had in some unaccountable way omitted from the list of primary psychoses given in the previous lecture. The analogy between this and the tactile sense is very close. The nervous and vascular structures in the papillæ of the tongue were illustrated by diagrams. Sapid bodies are all more or less soluble in water; so that the dissolved material soaks through the epithelium to the papillæ of the tongue, and the series of neuroses and psychoses is set into action, as in the sense of touch. There is at present no actual knowledge as to the existence of any intermediary apparatus between the terminating nerve-fibres in the papillæ and the epithelium of the tongue; but it probably exists. As in the phenomena of the tactile sense, so in the gustatory—*tastes* do not exist in the substances tasted, but are *subjective* psychoses.

In illustration of the sense of *Smell*, large-sized diagrams were employed, shewing lateral and transverse sections of the internal cavities of the nose, the arrangement and relative

positions of the turbinated bones, the peculiar mode of exit of the olfactory nerve by several filaments through the perforated plate of the ethmoid bone, and its distribution over only the superior nasal cavities and the upper and middle turbinated bones. Professor Huxley also demonstrated by chalk drawings on the black-board the modification in structure of the epithelial mucous membrane investing the superior nasal or olfactory fossæ, showing that between its cylindrical cells are peculiar spindle-shaped prolongations of the fibres of the olfactory nerve, presenting minute bulbous enlargements on their surface. In these prolongations of the olfactory nerve, an intermediary nervous apparatus is more easily recognisable than in the papillæ of the skin and tongue. The extreme tenuity of the particles of matter, contact of which with the sensitive extremities of the olfactory nerve produces the sense of smell, is amazing—a piece of musk, for instance, will retain its odorous properties for years, without the slightest appreciable loss of weight. For the production of the sense of smell it is necessary that a current of air should be drawn upwards into the proper olfactory fossæ. The sensation is referred by most persons, Professor Huxley is inclined to think, not to the exact spot in the internal structures of the nose at which the minute particles come into contact with the sensitive mucous membrane, but rather to the root of the nose; and this, he thinks it likely, is attributable to the influence of the current of cold air on the nerves of ordinary tactile sensation extending to the proper olfactory region.

Before the lecture it was announced that, in order to terminate the course on the date fixed, Professor Huxley would, on Friday, the 15 inst., at 4 p.m., deliver the lecture which—had he not been compelled by illness to omit a lecture during the preceding week—should have been delivered on that day, instead of that of which we have given the above notes.

MEDICAL SPIRITUALISM IN AUSTRALIA.

SPIRIT-RAPPING and table-turning appear to be rampant in Melbourne. Many of the better classes are disciples; but the most singular phase of the delusion is that which appertains to certain members of our Profession who have become converts to the new doctrine. These gentlemen associate with themselves in practice some of the most eminent Professors of the healing art in ancient and modern times, from Æsculapius down to Sir Astley Cooper, whom they spiritually consult.

FROM ABROAD.—PROFESSOR BILLROTH ON OVARIOTOMY—M. FAUVEL ON THE PROGRESS OF THE CHOLERA IN 1871-72—M. REVERDIN ON SKIN-TRANSPLANTATION.

In his "Surgical Reminiscences," now publishing in the *Wiener Med. Wochenschrift*, Professor Billroth thus speaks of ovariectomy:—

"I recently received a visit from one of my former assistants, who had just returned from England, and he informed me that he had been present at the performance of his 427th ovariectomy by Spencer Wells. Truly, we Surgeons of the Continent cannot deal with proportions like these when appealing to our experiences in order to decide upon this or that mode of procedure; and just as Paris, Berlin, or Vienna are mere small towns compared with London, so the total number of ovariectomies performed on the Continent is trifling when we consider the frequency of this operation in Great Britain. And yet we should relate our cases also, and especially for the sake of the unfortunate women who are the subjects of ovarian tumours, and who, remaining unoperated upon, or only submitted to tapping, almost all die in the course of a few years; for most of these might be saved by operation, and enjoy a long life afterwards—and the more so, inasmuch as these ovarian tumours are seldom combined with other diseases, and most of these women, with the exception of the ovarian affection, are in good health.

"First of all, Surgeons must dismiss from their minds that ovariectomy is a dangerous operation; and, through the medium

of well-informed Practitioners, this conviction must make its way with the public. After ovariectomy skilfully performed according to the rules of art, recovery is the general rule, and a fatal issue the constantly diminishing exception. Comparing it with some other operations, ovariectomy, taking the mass of cases, is shown by statistics to be less dangerous than amputation of the thigh, disarticulation of the shoulder and hip-joints, or excision of the hip or knee. Its danger is about the same as that of amputation of the arm, excision of the shoulder, partial excision of the jaw, lithotomy in the young, and similar operations. We must, however, perform ovariectomy strictly according to the rules laid down by the English operators in their classical works; and only after having attained the same results should we venture to practically put into force our own ideas, in order to improve upon these. I had the good fortune to see Spencer Wells operate upon two complicated cases, and from them, as well as from oral communication with this remarkable man, I learned much. I constantly follow his precepts, knowing that he has long since thoroughly thought out and tested all that can happen to myself. I shall willingly regard myself during my lifetime as his scholar; and contented shall I be if it falls to my lot, by means of this operation, to snatch from certain death one-half the number of lives he has been enabled to save.

"Up to the present time I am tolerably contented with my results. I give here a short account of them, in order to encourage the performance of these operations, and especially to inform the colleagues into whose hands these lines may fall that I have, personally, no reason for supposing that the results attendant upon ovariectomy will be less cheering in Vienna than they are in London. Hitherto I have performed it nine times; and of these patients only two have died, giving, therefore, only a mortality of 22.2 per cent. The first four cases recovered one after another; then two fatal cases occurred, to be followed again by three recoveries. The first case is related in my Zurich 'Chirurgische Klinik,' and the second, third, and fourth cases in the 'Chirurgische Klinik' published at Vienna in 1868; of the remaining five cases the narration is now given."

M. Fauvel, in a communication to the Académie de Médecine, December 5, terminates an interesting account of the progress of cholera during the present year with the following *résumé*:—

"The cholera, then, the invading progress of which towards the North-east of Europe has for the time been suspended, still prevails with some intensity at Constantinople, menacing thence all the basin of the Mediterranean, which to the present time has remained intact. On the other side, the disease, advancing through Arabia to the holy places of Islamism, threatens the invasion of Egypt, and consequently the shores of the Mediterranean, as in 1865. This is the present position of Europe with regard to the cholera; and it follows that, if we have some chance of escaping a scourge which presses on us on several sides, there is also a strong probability that we shall be subjected to its invasion. This the year 1872 will decide.

"There is, however, some compensation in this perspective. If we cast a comprehensive glance on the invasion of the cholera in 1871, we perceive, without any doubt, that at no epoch has the disease prevailed over so vast a space; for we find it prevailing with varying intensity along an undulating line, which is scarcely interrupted, from Archangel to the southern extremity of Africa. But, then, in compensation, never has an epidemic of cholera shown itself so benign in Europe as that of 1871. It is not that the malignity of the disease has diminished, for the gravity of the attacks has continued the same; but, with certain exceptions, their number has been much more limited than usual. In other words, individual resistance opposed to the action of the morbid principle has been more extended than in former epidemics. The progression towards Western Europe has also been less active, and—a fact to be noted—it would seem that, wherever the means of disinfection have been employed with energy and intelligence, they have greatly contributed to the extinction of epidemic foci, and, consequently, to attenuate their effects. The conclusion to be drawn from this last fact is, that if the cholera should unfortunately visit our country, it ought to find us prepared beforehand to oppose it with those prophylactic measures which experience has proved to be of service."

At the meeting of the Académie des Sciences, November 27, M. Reverdin presented an additional communication on

greffe épidermique, or skin-transplantation. He observes that since his first paper was read (in December, 1869) he has repeated the experiments on a great number of wounds, and the procedure, susceptible as it is of various practical applications, has been adopted by many Surgeons, both in France and abroad. Latterly, in experiments upon animals, he has been investigating the histological process which is set up, and the results thus attained form the subject of the present communication.

"It is to be observed, in the first place, that these flaps comprise not only the epidermis, but also a more or less thick stratum of the dermis, and that it is well-nigh impossible in practice that it should be otherwise. Our experiments demonstrate that these flaps may be derived either from different individuals of the same species or from individuals of different species. In white men we have succeeded in grafting flaps procured from other white men, from negroes, and from rabbits; and on the rabbit we have grafted with success flaps obtained from the rabbit, from man, and the cat; while on the sheep we have grafted from man.

"When a graft succeeds, it becomes adherent at the end of twenty-four hours, being then swollen and wrinkled. Towards the third day a smooth red circle begins to form around it, the graft sinking below the level of the granulations. Next day this circle has become of a pearly grey, which gradually becomes white; the red areola advances, and so it goes on exactly as in the marginal cicatrix. The islets so constituted are tolerably circular when the graft is placed at a distance from the edge of the wound. If it be near this, or if two grafts are near each other, the development of the epidermis takes place more rapidly on the side on which the two cicatrices approach each other, the islets become elongated, the marginal cicatrix sending out a prolongation; and at a given moment there are formed at these points cicatricial points, which are sometimes very long and very narrow. When the grafts have been derived from a pigmented skin, as in the negro and black cat, we have found that the flap becomes gradually decolorised until it is quite white. The islets formed around do not present any particular coloration.

"As to the microscopical examination, it proves—1. That the adhesion of the grafts is first produced through the epidermis, and only secondarily by the dermis. 2. That the epidermis operates by contact action (the catabiotic action of Gubler) in determining the transformation of the contiguous embryonic surfaces into epidermis."

POOR-RELIEF IN SAXONY.

No. I.

THE President of the Local Government Board has just received from Mr. Andrew Doyle, Poor-law Inspector, an interesting Report upon the Poor-law System of Elberfeld. Mr. Doyle recently visited that town, and, in conjunction with Mr. Crowe, H.M. Consul-General in Saxony, instituted a very minute investigation into poor-relief, including in his inquiry, for the purposes of comparison, the towns of Barmen, Crefeld, Düsseldorf, and Aix-la-Chapelle. It appears that in 1852—the year before the present system was adopted—the total number of persons relieved in Elberfeld, out of a population of 50,364, was 4000, or just 8 per cent., at a cost of £7072 7s. In 1853-4 the system under consideration was established. With an increase of population to 52,590 in 1857, the number of paupers had decreased from 4000 to 1528, or from 8 per cent. to 2·9 per cent., whilst the expenditure was reduced from £7072 7s. to £2623. Such figures as these make the mouth of a British ratepayer water, and prompt the inquiry, "How is it done?" and "Is what is possible in Elberfeld not possible in England?"

The change was effected in this wise. In 1850 the town was divided into but sixty districts; the number of visitors—one for each district—proved much too few; the duties were neglected; the pauperism and expenditure increased; and the complete demoralisation of the pauper population caused much uneasiness. So far the parallel seems to run very closely with our own condition at the present—so far as regards, at least, the inadequate number of visitors and the demoralisation of

the pauper population. Much uneasiness naturally resulted, and the Municipality determined to effect a complete revision. Then the matter was taken up by Daniel von der Heydt, a distinguished banker and citizen, who appears to have thought out the existing system, and to have succeeded by his personal influence in securing its efficiency. Under the *Armen Ordnung*, or Poor-law, suggested by Von der Heydt, the administration devolves primarily upon the *Armenverwaltung*, consisting of a president, four members of the Municipal Council, and four citizens. Subordinate to this body are the *Armenpfleger*, or visitors, and the *Amenvorsteher*, or overseers—each class being *unpaid*, and compelled to serve. The selections of persons to fill these offices are made in the most liberal spirit, and, to quote the words of the Report, "without reference to politics or religion, or to any consideration save fitness for the office. The 'oath of office' is simply a *handschlag*, or grasp of the hand, which is possibly found to be not less binding than the more solemn form of obligation so often exacted from English officials." Each visitor (and there are 252) has under his charge a section of the town, and fourteen sections are under the charge of an overseer. The visitors meet once a fortnight, under the presidency of the overseer, and submit for confirmation their grants of relief and reports of application. Each application for relief must be made to the visitor of the section, and forms the subject of most searching investigation. If the visitor is satisfied that there are just grounds, he is authorised to give relief at once, but subject to such restrictions as to obviate as far as possible the risk of abuse or imposture. The general rules within which the administration of relief is restricted are the following:—

"1. Every person who is destitute and unable to procure work shall, upon application by himself, or by another on his behalf, be relieved from the town funds, except when other persons bound by law to relieve him(a) possess the means of doing so, or except when he is in receipt of relief from private charity.

"2. Any able-bodied person, being destitute and unrelieved by private charity, may, by applying personally or through friends for relief, and upon proof that he has tried unsuccessfully to obtain work, be entitled to receive temporary relief until such time as he can earn a sufficient livelihood, he being bound, in the meantime, to perform such work as may be assigned to him.

"3. Single persons and heads of families whose income suffices to procure for themselves the absolute necessaries (*das unabweislich Nothwendige*) of life are not to be considered as destitute—that is, entitled to relief from the public funds. The weekly sum to be considered sufficient for procuring the absolute necessaries of life in respect of food, clothing, lodging, furniture, and education is, as a rule, to be measured thus:—25 sgr. or 2s. 6d. for the head of a family; 19 sgr. or 1s. 11d. for his wife when living with her husband; 17 sgr. or 1s. 8½d. for a child of 15 or upwards; 15 sgr. or 1s. 6d. for each child from 10 to 15 years; 11 sgr. or 1s. 1¼d. for a child from 5 to 10; 9 sgr. or 10¼d. for each child from 1 to 5; 6 sgr. or 7¼d. for a child under one year; 3 th. 12 sgr. or 10s. 2¼d. for a family with five children; 25 sgr. or 2s. 6d. for a single person.

"4. Poor-relief, in case of persons earning less than the means of subsistence, may be administered as out-door relief by grants of money, soup, clothes, and bedding, indispensable articles of furniture, free schooling, Surgical, Medical, and midwifery attendance, medicine, cost of funeral; or it may be administered in-door in the town poor-house."

It is by adherence to such rules as these, and by requiring the most minute inquiry into each application, that the change already mentioned in the number of poor and their cost has been effected. That the inquiry made by the visitors is excessively minute may be judged from the fact that *four* is a usual number of cases to be under the care of each.

How little prospect there is that the Elberfeld system can be adapted to our needs here, pressing as they are, will be allowed at once when, as Mr. Doyle says, "the counterpart to it with us would be a meeting of fourteen relieving officers,

(a) Under the Prussian law, parents, grandparents, and great-grandparents are bound, if capable, to support their children, grandchildren, and great-grandchildren. A corresponding obligation is thrown upon children, grandchildren, and great-grandchildren. Man and wife to support each other. Children-in-law, with certain exceptions, to support their parents-in-law. Parents-in-law, with similar exceptions, to support children-in-law. Persons hiring domestic servants are bound to support them, or pay the cost of their relief, for four weeks after they become destitute through sickness; so also the obligation to support a destitute person may be incurred by contract, as in cases of benefit societies, burial societies, etc.

unpaid, each with a district comprising not more than four cases, bound to administer relief in accordance with certain fixed and very stringent rules, each responsible to the majority of his fellows, and all responsible to the higher administrative tribunal, the town administration or *Verwaltung*. It may be further observed that these relieving officers should be selected from amongst well-to-do citizens, shopkeepers, manufacturers, master mechanics, and men engaged in various professions, and that they should be selected upon the simple ground of their fitness for the office." It is to be feared that in England—or, at all events, in the metropolis—the pursuit of wealth or of pleasure effectually precludes the adoption of an unpaid administration of relief, and experience of selections for existing unpaid local offices leaves but little hope that in England any man would be chosen to a new post of the kind upon the simple ground of fitness.

How Medical relief is given at Elberfeld we must see on another opportunity.

(To be continued.)

ATHETOSIS.

THE term "Athetosis" (from *'Atheros*, without fixed position) has been devised by Dr. Hammond, of New York, as suitable to a rare class of cases in which the most characteristic symptoms are an inability to retain the fingers and toes in any position in which they may be placed, and their continual motion.

As far as he knows, only three cases have as yet been observed—namely, one by himself; one by Dr. Hubbard, of Ashtabula, Ohio, who sent Dr. Hammond an excellent report of it, accompanied by two photographs; and one by Professor F. Barker, of the Bellevue Hospital Medical School, of which no details have yet been published, and of which Dr. Hammond had not heard till after he had written his chapter on Athetosis in his "Diseases of the Nervous System."

The following is the history of the case which originally called Dr. Hammond's attention to the subject:—

J. P. R., aged 33, a native of Holland, consulted him September 13, 1869. His occupation was bookbinding, and he had the reputation, previous to his present illness, of being a first-class workman. He was of intemperate habits. In 1860 he had an epileptic paroxysm, and, since that time to the date of his first visit to Dr. Hammond, had had a fit about once in every six weeks. In 1865 he had an attack of delirium tremens, and for six weeks thereafter was unconscious, being more or less delirious during the whole period.

Soon after recovering his intelligence, he noticed a slight sensation of numbness in the whole of the right upper extremity, and in the toes of the same side. At the same time severe pain appeared in these parts, and complex involuntary movements ensued in the fingers and toes of the same side. At first the movements of the fingers were to some extent under the control of his will, especially when this was strongly exerted and assisted by his eyesight, and he could, by placing his hand behind him, restrain them to a still greater degree. He soon, however, found that his labour was very much impeded, and he had gradually been reduced, from time to time, to work requiring less care than the "finishing," at which he had been very expert. The right forearm, from the continual action of the muscles, was much larger than the other; and the muscles were hard and developed, like those of a gymnast. When told to close his hand, he held it out at arm's length, clasped the wrist with the other hand, and then, exerting all his power, succeeded, after at least half a minute, in flexing the fingers; but instantaneously they opened again, and resumed their movements.

Dr. Hammond treated him with galvanism, primary and induced, for four months without notable result. His fits were, however, arrested with bromide of potassium. His memory began to fail him soon after the attack of delirium tremens, and his intellect was obviously weakened before he first consulted Dr. Hammond.

On January 17, 1871, he entered the Hospital for the Diseases of the Nervous System; and Dr. Cross made the following report of his case:—

"The head is symmetrical, but is peculiar in shape, the posterior portion rising to a much higher point than the anterior,

while the latter slopes downward and forward, giving the cranium the form of that of a Flathead Indian. The special senses are normal. The intellect is somewhat impaired, and his ideas are not so vivid at one time as at another. His memory is much enfeebled. There is slight tremor of both upper extremities, but there is no paralysis of any part of his body. There are, however, involuntary grotesque muscular movements of the fingers and toes of the right side; and these are not those of simple flexion and extension, but of more complicated form. They occur not only when he is awake, but also when he is asleep, and are only restrained by certain positions, and by extraordinary efforts of the will. Thus, those of the fingers are arrested when the wrist is firmly grasped by a strong hand, or when it is less forcibly held in a vertical position. But if the arm be extended horizontally, the fingers at once begin their movements. During their continuance the arm is hard and rigid, and the calf of the leg is also in the same state of tonic spasm while the toes are in motion. The movements are somewhat paroxysmal, being worse at times than at others. During the remissions the power of the will over the muscles is more effective than when the paroxysms are at their height. Sensibility to touch, pain, tickling, and temperature is normal in all other parts of the body. There is slight tremulousness of the tongue, but no difficulty of articulation. There are no oscillatory movements of the eyeballs (nystagmus). The involuntary contractions of the fingers and toes do not take place quickly, but slowly, apparently as if with deliberation and with great force. The numbness and pain in the arm, hand, leg, and foot have increased in proportion to the increase in the contractions. The toes are not involved to the same degree as the fingers. Position does not, however, afford the same relief to them as to the fingers, and the spasms are more tonic in character. The muscular development is greater in the right arm and leg, from the almost continuous muscular action. The toes are kept restrained to some extent by the boot, but as soon as it is removed they become flexed, and take on their peculiar movements. When, by a strong effort of the will, he succeeds for an instant in arresting the movements in the hand, the little finger at once becomes strongly abducted, the third finger participates to some extent, the second finger is slightly flexed, the index-finger is extended, and the thumb is extended to its very utmost."

In these peculiar positions the patient is able to quiet the action of the muscles, and to allow his hand and forearm to be photographed; and the peculiar position of the fingers, both in this and in Dr. Hubbard's case, is admirably illustrated in copies of photographs given in Dr. Hammond's volume.

On account of the severe pain in the whole arm, caused by the spasms in the muscles, the patient is at times unable to go to sleep until quite exhausted. On awaking, however, after a few hours' repose, although the actions have continued during his sleep, they are not so severe as at any other time through the day or night. This state of comparative repose lasts for about half an hour.

"His habits," says Dr. Hammond, "are bad. He boasts that he has often drunk as many as sixty glasses of gin in a day, and it is therefore doubtful whether the tremulousness observed in the tongue and the muscles generally is the effect of the disease or of drink, or of both combined. I have never, however, seen him drunk, or even under the influence of liquor. His mental faculties are decidedly more obtuse than when he first came under my observation. Under the use of the primary galvanic current to his brain, spinal cord, and affected muscles, and the internal use of chloride of barium, he is certainly improving; but I have little hope of any permanent result being obtained. His epileptic paroxysms are kept down with bromide of potassium."

The history of the case recorded by Dr. Hubbard shows that in this instance the disease was more advanced, the distortion of the hand being obviously greater; but, on the whole, the two cases are so similar that we need not enter into any details regarding the latter.

"Both cases," says Dr. Hammond, "came on with epileptic paroxysms—a feature accompanying other organic diseases of the brain and spinal cord. In both there are similar head-symptoms, tremulousness of the tongue, numbness on the affected side, pains in the spasmodically-affected muscles, and especially complex movements of the fingers and toes, with a tendency to distortion. In neither case is there any paralysis. Relative to the character of the lesion producing these symptoms, and its exact seat, I am not yet prepared to speak with any degree of certainty. The phenomena indicate the implication of intra-cranial ganglia and the upper part of the spinal

cord. The analogies of the affection are with chorea and cerebro-spinal sclerosis; but it is clearly neither of these diseases. One probable seat of the morbid process is the corpus striatum."

Dr. Hammond has published these cases with the view of directing the attention of his Professional brethren to an affection that seems hitherto to have been overlooked or confounded with some other disease.

THE HISTOLOGY OF FATTY TISSUE.

FATTY TISSUE has been made the subject of an elaborate memoir by Flemming, in which its formation, its relation to connective tissue, and its retrogression into the latter are discussed. His observations were made on embryos and newly born animals (guinea-pigs and puppies), and also on animals artificially fattened, in order to make sure that the fatty tissue should be in the condition of increase; also on animals in a state of progressive emaciation. He is in agreement with most of the physiological and pathological observers on the point that fatty tissue is nothing but a modified connective tissue. Flemming finds that the development of fat is always dependent on vessels. The first deposit of fat takes place in the *tunica adventitia* of the bloodvessels, so that adipose tissue might in fact be called a loosely spread adventitious coat of the vessels. Moreover, the fat does not accumulate round newly formed outgrowths of vessels, but rather round those which are completely formed and comparatively thick. The production of fat takes place only in isolated foci, round certain vessels of the fatty lobule, while other quite similar vessels show nothing of the kind. The fat does not appear at first, as observed by Czajewicz, in the periphery of the lobules, nor is it contained, as has been asserted by other observers, in special smaller cells. A certain quantity is accumulated in the walls of the larger completed fat-cells, and a small number of fatty molecules are seen free, perhaps in consequence of the mode of preparation; but most is seen in what are believed to be fixed connective-tissue cells. Migratory cells are seen in great abundance, but are not different from the white corpuscles of the blood, and do not contain fat. The genuine young fat-cells have no membrane, and look at first sight like a heap of fatty molecules, varying in size; they are angular, or spindle-shaped, or polygonal, and only when they contain several larger drops of fat are they round. The smallest of them hardly exceed in size the normal fixed connective-tissue corpuscles.

In his observations on the wasting or absorption of fat, Flemming comes to the conclusion that the fat-cells become ultimately converted, not into a "serous fat-cell," as has been said, but simply into the ordinary flattened connective-tissue cell; in fact, that the process is precisely the converse of that seen in the production of fat.

His general results are, that fat-cells are formed out of the ordinary fixed elements of connective tissue, and can, by the loss of their fat, return to the condition of such connective-tissue cells again, and that there is no special preliminary tissue, and that the name of adipose or fatty tissue is accordingly superfluous. The "mucous tissue" of Virchow has no special relation to fat; it has merely the characters of all embryonic connective tissue.

The passage of fat into the fixed connective-tissue cells is not to be explained by its transmission through plasmatic channels communicating with connective-tissue corpuscles. The existence of these channels Flemming does not admit; but he proposes the hypothesis that fat circulates in, and passes out from, the vessels in a liquid form, and then, being absorbed by the connective-tissue cells, is precipitated in their substance.

The remarkable localisation of the production of fat, he thinks, depends upon the dilatation of the vessels at particular points, and he sees another evidence of this dilatation in the large number of migratory (extravasated) cells at these points.

CANCER *v.* CONDURANGO.—The curative powers of this root for cancer on both sides of the Atlantic begin to be viewed in the light of another huge mare's-nest. The German papers have received a communication from Prussia House to say that the reports of the English Practitioners applied to by the German Embassy go to deny entirely the curative power of the condurango.

REVIEWS.

Neuralgia, and the Diseases that Resemble it. By FRANCIS E. ANSTIE, M.D. Lond., F.R.C.P., Senior Assistant-Physician to Westminster Hospital, Lecturer on Medicine in the Westminster Hospital School, etc. London and New York: Macmillan. Pp. 296.

A BOOK on the subject of neuralgia from the pen of Dr. Anstie is sure to be well worth reading, and we think we may also say of the present one that it is well worth careful study. The nature of the disease itself is at once so vague, and it is so excessively painful, that its study, though eagerly called for by the sufferer who desires relief, is far from easy, there being so few objective indications of the cause of the pain which is its prime feature.

Pain may, indeed, be said to be the essence of neuralgia; and, as in so many diseases it is a symptom of paramount importance, itself deserves careful study. To pain, indeed, Dr. Anstie first turns his attention; and he does well to draw a distinction between pain and hyperæsthesia. The two are certainly not identical, and, though they are often associated, they are also encountered apart—in point of fact, pain often coincides with diminution of sensibility, as is seen when pain of one kind or from one cause is used to neutralise that the product of another. In cases of defective nerve-supply, it is often our lot to encounter much pain at a spot so anæsthetic, that a hot iron may be applied to it for a moment without the individual perceiving it.

As to the etiology and pathology of neuralgia, Dr. Anstie holds that the disease is invariably connected with atrophic change in the sensory root of the nerve, which in some portion of its course is painful. Tendency to this change, or to some other form of neurosis, is, he thinks, hereditary; and, farther, that this inherited tendency may in the same individual manifest itself in various ways. This is clearly a matter of importance; and we see no more reason to disbelieve the transmission from parent to child of a tendency to certain neurotic diseases, than that mental and moral qualities are within certain limits hereditary. Next to hereditary tendency, Dr. Anstie considers bad early training, whether physical or moral, a potent cause of neuralgia.

Of mere purely physical causes, cold comes in for a large share, in the production of neuralgias which are connected with peripheral irritation; but it would seem that to induce it to set up neuralgic pain there must be something more than mere cold in most cases. It must be persistently applied to one spot, as in a draught; or there must be some local defect to constitute a vantage-ground for the influence of cold. Injuries to nerve-substance, or prolonged pressure of tumours on nerve-tracts, are undoubted causes of neuralgia. Examples of the former are afforded by what frequently occurs after amputation or excision of joints; of the latter, by the so-called neuromata. Debility is a powerful agent in the production of neuralgia, but rather, perhaps, by securing a good soil for other influences than by trophic change. To conditions not of anæmia but of toxæmia, such as occur in gout and rheumatism, we should most certainly be inclined to relegate alcoholic neuralgia, which Dr. Anstie considers apart, and which he thinks is due to mere degeneration, induced by the action of alcohol. The condition of the circulating fluid has, we think, unmistakably some influence in the production of neuralgic pains, even though indirect. The remainder of this interesting chapter we have hardly time to discuss.

The complications of neuralgia constitute an exceedingly valuable chapter. The first here mentioned is vaso-motor paralysis. This we would be inclined to expect, from the known influence of irritation on a sensory nerve. Such changes cannot take place without affecting nutrition—the hair turns grey, the periosteum and skin become thickened, the epithelium of the mucous membranes, too, accumulates, whilst not unfrequently erysipelas shows itself. Affections of the eye, referable to a like cause, are far from uncommon. Secondary to neuralgia there is not unfrequently some muscular paralysis, as in the case of the bladder from pelvic irritation. So, too, convulsion may occur; whilst impairment of sensation, as we have seen, is frequently encountered. The profuse lachrymation connected with some forms of frontal neuralgia is also worthy of attention.

A word as to the diagnosis of neuralgia. The first thing, to our mind, is, that there is so little to show for the severe pain, either locally or constitutionally; and that the pain intermits. Of course there are some regions, especially those to which the fifth nerve is distributed, which are so frequently the site of

neuralgia, that we are perhaps too prone to attribute any pain in their vicinity to neuralgia; nevertheless, neuralgia is confined to specific nerve-tracts, and it is mainly unilateral. Dr. Anstie places some reliance on the fact that neuralgia is aggravated by depressing agencies; but in this it is not peculiar, though, of course, it is an element in the case by no means to be neglected, either in diagnosis or treatment.

As to the treatment of neuralgia, Dr. Anstie divides it into four branches—by constitutional remedies, by narcotic stimulant remedies, by local applications, and by a prophylaxis. Improved diet (short of over-eating) he considers of very great importance, and fatty matters (which are often repugnant to the patient) are to be insisted on. For syphilitic neuralgia, iodide of potassium, in large doses, is of course the remedy; for malarial neuralgia, quinine and arsenic should be given; when there is gout, colchicum, but only in small quantity, and associated with other remedies. Strychnia and iron are invaluable medicines in appropriate cases—that is, when there is depression and anæmia. In angina, the author says arsenic is invaluable. Hypodermic morphia is wisely commended; so, too, in certain cases, is atropia (we prefer the extract of belladonna reduced with water). Belonging to remedies of this class are chloral and Indian hemp; perhaps, too, bromide of potassium. Blisters and other counter-irritants have their uses—so, too, have their opposites, aconite and veratria; but, of late years, no therapeutic agent has been so frequently or effectually used as electricity. The kind of electricity is important—induced electricity does harm; the constant and continuous current does good. Details of the mode of using galvanism in neuralgia we cannot give here, but its importance and utility are very great.

We have briefly alluded to some of the most prominent characteristics of Dr. Anstie's work, but there is one feature it possesses which will perhaps commend it more to some readers than all we have said: it is, in many respects, a narrative of personal experience. We should not have been justified in alluding to the fact had not the author himself so freely done so; but in his own system Dr. Anstie has, unfortunately for himself, a convenient field for study, he having been from time to time a martyr to this malady. Be this as it may, the book is well deserving attention, and doubtless will obtain what it justly merits.

The Skim-milk Treatment of Diabetes and Bright's Disease; with Clinical Observations on the Symptoms and Pathology of these Affections. By ARTHUR SCOTT DONKIN, M.D. Edin. and Durham, Lecturer on Medical Jurisprudence and Toxicology in the University of Durham, late Physician to the Sunderland Infirmary and Dispensary, etc. London: Longmans. Pp. 317.

DR. DONKIN made and published, some time ago, a few observations on the use of milk as an article of diet, in certain affections characterised by defective nutrition, coupled with abnormal excretion. The two diseases he mainly dwelt upon were diabetes and Bright's disease.

Now, this we hold to be highly praiseworthy, even though the use of milk under such and similar circumstances is not new. Whey and milk cures have long been heard of on the Continent, just as grape cures, hunger cures, and water cures have been in vogue. Even Dr. Donkin, in point of fact, gives what purports to be a history of the milk treatment. Nevertheless, he claims originality in having applied it to diabetes; and if it turns out to be a satisfactory means of dealing with this troublesome malady, he will deserve to be regarded as a benefactor of his kind. But, this said, we fear we have said all we can with justice say in favour of the book. The treatment of a few cases of diabetes and chronic albuminuria with skim-milk cannot, we think, be considered at the present day equivalent to every other qualification for writing a treatise on either subject. Nevertheless, Dr. Donkin tells us that there is no very good treatise on the subject of diabetes in our language; and, as we understand him this volume appears to remedy that defect in our literature, he cannot therefore complain if we take him at his word, and test his production accordingly.

In doing so, it is somewhat difficult to know where to begin, for inaccuracies or deficiencies are "thick as leaves in Vallombrosa." First, however, so far as we can make out, Dr. Donkin seems to be unaware that sugar, or, at all events, a copper-reducing body, is found in normal urine; so that it is not the presence of sugar, but its presence in excess, which is the main feature of saccharine diabetes. As to the detection of this sugar, Dr. Donkin seems to rely on Moore's and Trommer's tests; but we fail to discover any account of any

means whereby the quantity of sugar present in any sample of urine may be estimated. The test nowadays most frequently employed by those daily engaged in the examination of urine is Fehling's. To this there is no allusion. The two means most commonly used for the quantitative estimation of sugar are fermentation or the polariscope. According to Dr. Donkin, neither of these is in use. The one "has fallen into disuse," the other "is not generally known in this country." He himself relies on specific gravity alone—surely a most unsatisfactory way of estimating sugar; yet there is not in the book a single complete analysis.

"Our knowledge respecting the amount of urea excreted in the urine in diabetes is very indefinite and unsatisfactory," says Dr. Donkin. That being so, from the opportunities afforded him we might have expected to learn something with regard to it from the author of what aims at being a "comprehensive account" of the disease. Instead, we have merely records of the experiments of Mr. Sydney Ringer, as quoted by Dr. Parkes.

With regard to the pathology of diabetes, we had hoped to find something new in the way of observation; but here, too, the work of others is alone submitted to us, Dr. Pavy's researches being made to play a prominent part, although we had been led to conceive his book was useless, or next to it. We, further, have some important quotations from various other authors, among others one whose works are referred to in the following cabalistic formula—"Greifswald's Medicinische Beiträge, B. III. II. I."—which, we confess, we do not understand.

We might say more on this head, and pick out many more faults, but we turn with more zest to what is really valuable in Dr. Donkin's book—we mean his cases treated by skim-milk. The cases here recorded are seven in number, and full details of the treatment are given. In every instance the patients benefited, in some they got quite well. Now, this part is very good and useful, and had Dr. Donkin contented himself with its publication he would have done well, but he has unfortunately chosen to overload his book with second-hand material, and we have, as a direct consequence, been obliged to condemn it.

But this fault is even more apparent in the latter part of the volume referring to Bright's disease. What on earth has the fact that certain patients having albumen in their urine improved on skim-milk to do with the anatomy of the kidneys?—yet we have that lugged in. Still more is the author at sea when he begins to group Bright's diseases pathologically. The forms he recognises are the cirrhotic kidney, the waxy kidney, and the fatty kidney. The last he apparently makes co-extensive with chronic tubular nephritis, and not an accident to which all imperfect new-formations are liable. But the most curious idea is that the epithelium of a kidney undergoing fatty degeneration may proliferate, and beget new fatty cells under the use of any fat; so that the process of fatty degeneration would be favoured by the use of fat. This is fairly on a par with the pathology that refers the fatty liver of phthisis to the cod-liver oil used to check the disease.

We think Dr. Donkin's suggestions as to the use of milk both practical and valuable—we are prepared to put them to the test on the first convenient opportunity; but we do utterly object to have a treatise, poor in quality and insufficient in quantity, on anatomy, physiology, pathology, and things in general, inflicted on us for their sake. Dr. Donkin would do well to cut all that out.

Medizinische Jahrbücher. Herausgegeben von der K. K. Gesellschaft der Aerzte. Redigirt von S. Stricker. Jahrgang, 1871. Heft I.

Year-book of Medicine. Published by the K. K. Gesellschaft d. Aerzte, Vienna. Edited by S. Stricker, for 1871. Part I.

THIS is the first quarterly division of the Year-book of the Association of Physicians in Vienna, who have entrusted their highly accomplished member, Professor Stricker, with the editorship of their organ. The book closely resembles in its external appearance the "Studies from the Institute for Experimental Pathology," which was brought out in 1869 by the same pathologist, and which has been incorporated with this new series, where the continuation of the subjects treated of in its predecessor will be found.

As might be expected, when we remember that the editor is Professor of Experimental Pathology in the University of Vienna, most of its pages are filled with the accounts of investigations on morbid processes in the various tissues, and with the conclusions to be deduced therefrom. But we shall find that this is not exclusively the case.

The Introduction, by the editor, is a brief expression of his opinion on the relation of pathology to practical Medicine. Contrasting chemistry, as a science, with pathology, he shows how there is a want of scientific theory in the latter. This is, however, supplied by the practical Physician, and the result is—what we have so much to lament—the present mixture to be found in Medicine of theories, hypotheses, opinions, and beliefs. Medicine suffers accordingly, and this condition reacts upon pathology. The morphography of diseases and the statistics of their course, leading respectively to diagnosis and prognosis, comprise the first part of pathology; but these according to Stricker, are at the present day kept in the background by irrational treatment, thus preventing real clinical advance, and turning away many of our best men from a pursuit which seems to them so superficial. Pathology, he continues, is as distinctly to be separated from pathological anatomy as is physiology from anatomy; and, while pathology joins physiology, and avails herself of the numerous means of research, morbid anatomy and anatomy must together forego altogether the use of these. The attempt made to establish a theory of disease as an independent doctrine has resulted in the introduction of the terms “pathological physiology” and “general pathology.” Stricker shows the entire dependence of “general pathology” on special pathology, and draws attention to the work done during the last ten years—how it has taught us the value of “dry facts,” and the utter uselessness of purely speculative general pathology. To the term “pathological physiology” he most strongly objects.

Finally, he says, pathology must settle with the other sciences in working laboratories if it would exist independently of practical Medicine and of anatomy—*i.e.*, it must be made experimental. He cites the cases of Magendie and C. Bell, as showing examples of what experiment may achieve. Yet experiment is but one thing; and he who would be an experimenter in pathology must be a pathologist to begin with.

The first paper is contributed by Dr. Genersich, on “The Doctrine of the Lymphatic Canals in the Cornea.” It is written in support of Von Recklinghausen’s views on the nature of the appearances produced by staining the fresh cornea with nitrate of silver; which views, although now almost universally accepted, met at first with more extensive opposition. Genersich carried out for this purpose two series of experiments, which he fully describes, with the results obtained. For the first, by inducing simple inflammation, he was able to make out changes in the protoplasmic contents filling the spaces—*i.e.*, in the corneal corpuscles. This speaks in favour of the spaces not being artificial products. In the second series, by transplanting the cornea of a frog with a lymph sac, he found leucocytes passing in and out of the canals or spaces, following exactly in their course the branches of the same. He never saw a wandering cell break through the walls of such a space.

Dr. Heiberg, in his article on the “Repair of the Corneal Epithelium,” combats the statements of Julius Arnold, published in 1869, and founded upon certain observations on traumatic inflammation of the anterior epithelium of the cornea. In these statements Arnold expresses his belief that the tissue referred to is repaired from a blastema, which collects in the injured spot; that this blastema is a finely granular mass, that it becomes epithelium, and that this epithelium breaks up into portions separated by furrows. This opinion it is hardly necessary in the present day to disprove. We give, however, Heiberg’s experiments and results:—Working with Stricker, he found (1) that, on scraping away a portion of the anterior corneal epithelium, and observing closely the various stages of the regeneration of the cells, no mass corresponding to Arnold’s blastema was to be seen; (2) that, instead of it, a number of processes from the surrounding cells occupied part, at least, of the cavity; (3) that these processes went on to farther change; and (4) that from the processes portions are separated on the side towards the focus of reparation, and that these portions in their turn send inward processes till the cavity is filled up. After very many long, patient, and careful observations, Heiberg failed to see a wandering cell in any single instance pass into the focus of inflammation and become an epithelial cell.

The third paper is written by Güterbock, and is designated “Investigations on Inflammation of Tendon.” The author starts with the assumption that the corpuscles of tendon are compact rod- or spindle-shaped cells linearly arranged, and not united into cylindrical tubes, as Ranvier contends. For this we do not believe Güterbock has sufficient ground, and the value of the present paper, considerable though it may be, is, in our opinion, diminished very much on this account. Under

Stricker’s direction, the experimenter induced inflammation in the tendo Achillis of the rat, rabbit, and guinea-pig by passing a thread through it, examining the injured tendon after certain intervals. He made out these successive changes in the tissue:—(1) Swelling of the cells, especially of the nuclei; (2) multiplication of the nuclei: in elongated cells the nuclei, when dividing, presented a peculiar rosette-shaped appearance; (3) after eighteen hours: disappearance of the fibrillar ground-substance, cells alone being to be seen lying in heaps, with yet more extensive proliferation and peculiar bunch-of-grape-shaped masses, instead of rosettes; (4) after twenty-four hours: presence of what might be called pus-cells; the source of these, though probably the previously-present rosette-shaped masses, was now almost impossible to discover.

Mr. Yeo’s “Investigations on the Structure of Inflamed Lymphatic Glands” determined the occurrence of peculiar changes in the reticular connective tissue of glands during the inflammatory process. The pancreas aselli of the cat was the particular gland experimented on, by opening the abdominal cavity of the chloroformed animal, and passing a thread through the exposed body. After a certain time portions were removed, and examined, by hardening in alcohol, cutting sections, and agitation to wash away the proper gland-substance from the supporting framework. The fibres of this became, after from three to five days, thicker, and less distinctly defined, while nuclei came prominently forward in the swollen points of junction, and passed through the various stages of inflamed cells up to the fatty granular corpuscle. Of the changes in the proper gland-tissue, Dr. Yeo cannot speak; but the determination of the above is alone an important addition to our knowledge of gland-inflammation.

Lang publishes his “Investigations on the First Stages of Inflammation of Bone.” The plan he adopted was the simple fracture of the bones of rabbits, with daily rubbing of their broken extremities upon each other. After about a week the changes upon the tissue were most decided; and Lang came to the following conclusions:—That the bone corpuscles are changed in inflammation, which has as its consequence an increase in the number of the cells within the bone tissue; that these cells can have but three possible sources—the blood, the connective tissue around the vessels, the bone corpuscles; that there is nothing in favour of either of the first two sources, but very much for the third. All the changes on the corpuscles progress with the appearance of the cells, increasing as they increase, and finally disappearing, with no residue to be found if the cells do not represent it.

The two following papers relate to the severe and somewhat peculiar discussion which raged in Vienna in the spring of this year between Professors Stricker and Billroth on the subjects of Pyæmia and Inflammatory Fever. These papers are exceedingly interesting to the pathologists of this country in several ways, and we propose for this reason deferring our notice of them to a future number.

One of the most interesting investigations described is that of Riegel “On the Reflex Innervation of the Bloodvessels.” The experimenter proposed to himself two questions:—

1. Whether the changes to be seen on the vessels of inflamed tissues may be regarded as the direct consequence of the inflammatory stimulus, or whether the stimulus passes circuitously through the nerves. 2. Whether it is possible to have an exact knowledge of these changes—the changes referred to being both those of the lumen of the vessels and those of the velocity of the blood-current within them.

Riegel measured the velocity of flow in the vessel under the microscope by comparing it with a stream of known rapidity which he ingeniously passed through the objective and across the visible field, so as to appear side by side with the one to be investigated. The particular tissue experimented on was the web of the frog’s foot, and the nerve irritated the great, sciatic in the thigh, which was cut after careful exposure. Here we can but mention the results he obtained, and they were briefly these:—That a moderate current applied to the stump causes not sloughing but acceleration of the velocity, and a moderate narrowing of the lumen of the arteries; that these increase with continuation of the irritation, to a certain degree; that in arteries, veins, and capillaries, by such stimulation, the velocity may be so much increased that it is almost impossible to estimate it. These results are quite opposed to those of Saviotti, at Würzburg, published some time before. He found a retardation of the flow accompanying the narrowing of the lumen. In a note to this paper, Stricker says he has tried to reconcile these opposite statements, and believes that they might have agreed had the same stimulus been used in the two cases. Riegel followed

up these experiments on reflected irritation by some on direct stimulation of the web of the foot. We recommend these to the reader.

The volume ends with a fragment by Rokitansky, on "Defect of the Inter-auricular Septum of the Heart."

COLONIAL CORRESPONDENCE.

AUSTRALIA.

MELBOURNE, October 10.

IN consequence of the resignation, about a month ago, of Dr. Wilkie, one of the Physicians of the Melbourne Hospital, the election of an Assistant-Physician became necessary. This event took place on the 26th of last month, and resulted in the return of Dr. Neild by a large majority. As Dr. Neild had declared from the outset his determination not to canvass the contributors, his return was considered doubtful; for the system of personal solicitation has been so long regarded as an established rule here, that it was supposed he, like most innovators, would suffer for his departure from an acknowledged custom. Upwards of 700 of the contributors voted, and the excitement in connexion with the election was unprecedentedly great. The large majority gained by the successful candidate is very properly regarded as not only a success of which individually he may be proud, but as a triumph of that better principle which condemns the practice of the Medical candidates for Hospital appointments waiting personally upon every voter, and so encountering personal mortification, and lowering the dignity of our calling. Dr. Neild's election to the Hospital causes a vacancy in the staff of the Benevolent Asylum, with which he has been connected for six years. For this appointment there are several candidates, among whom is Professor Halford. He, also, is very properly resolved to abstain from a personal canvass, and to rely solely upon his merits.

Dr. Rees, the late Resident Surgeon of the Alfred Hospital, has severed his connexion with that institution. The committee, composed principally of persons having very little perception of what is due to a Resident Surgeon, annoyed and harassed him by a series of petty restrictions, and he resigned, rather than be subjected to treatment which could only be regarded as degrading.

The subject of Hospital maintenance has, for the last week or two, served as the occasion for public comment and journalistic animadversion in this colony. You are already aware that the revenues of our Hospitals are principally derived from the State, but that the control of them is altogether in the hands of the contributors. For some time the unreasonableness of this arrangement has been pointed out, and it has been contended that as the State has contributed such a large share of maintenance, it ought to have some part in the government of these institutions. It has been the custom hitherto for the State to give exactly as much money as was required to make up the difference between the expenditure and the amount of private contributions; but the present Treasurer of the colony has lately issued a memorandum to the effect that, for the future, the rate of State subsidy will be in the proportion of two-thirds to one of contributions, and that the rule will take effect at once. This determination is regarded as the beginning of a desire on the part of the Government to take the whole of the Hospitals under its care. Meantime it is considered as very arbitrary to enforce it without having given sufficient notice. The Government urge that more money should be raised in the shape of private subscriptions; but the truth is, the public have been so long accustomed to look to the State for the maintenance of the charities, that they have become habituated to the practice of not giving much. The immediate consequence of the partial withdrawal of State aid is seen in the determination of the Committee of the Melbourne Hospital to close up some of their wards, while the Committee of the Benevolent Asylum declare their intention of resigning, and so of throwing the responsibility upon the Government of taking charge of this vast Hospital for incurables, now containing upwards of 600 beds.

Meantime, as the business of our charities must go on, whoever votes the money for their maintenance, the new operating-theatre just built in connexion with the Melbourne Hospital, at a cost of about £1000, has been opened. This took place on the 5th inst., Mr. James, one of the honorary Surgeons, performing the first operation. It is a substantial, commodious structure, on the ground-floor, quite detached from the main building;

and though this arrangement is a considerable disadvantage, yet the part for the spectators has been contrived with particular care for their convenience. A new operating-theatre was very greatly required. The old operating-room was quite at the top of the Hospital, and was in every respect inconvenient and unsuitable. The operation of ovariectomy has been performed at the Lying-in Hospital four times within the last five months—twice by Dr. Tracy, and once by Dr. Martin and Dr. Fetherston. Three of these cases have been successful, and the fourth—the last one, done by Dr. Tracy a fortnight ago—was perfectly successful so far as the operation was concerned, but death took place thirty-two hours afterwards, apparently from uræmic poisoning.

The movement for the establishment of a Hospital for inebriates does not make much progress. Public meetings have been held, and much spurious sympathy expressed for the inebriate; but the mistake made seems to be that of regarding the proposed asylum as a means of moral reformation, rather than as affording an opportunity for subjecting inebriates to scientific treatment. It is felt, too, that some of the promoters of the Hospital are using the occasion of its advocacy rather to give prominence to themselves than to help on a useful institution.

Among miscellaneous items, it is to be recorded that Dr. J. K. Ramsey has been appointed to the House-Surgeonship of the Alfred Hospital; that Dr. Fetherston has been appointed Physician to the Institution for the Deaf and Dumb, and Assistant-Surgeon to the Torpedo Corps; and that Dr. William Smith has resigned his several offices of Demonstrator of Anatomy in the University, Curator of the Pathological Museum in the Melbourne Hospital, and Surgeon to the Hospital for Children.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

EDINBURGH, December 11.

ONLY a few weeks ago, while small-pox was epidemic in the surrounding towns and villages, Edinburgh could boast an all but entire freedom from the disease. Now and then one or two cases were met with, contracted, for the most part, by communication with infected villages in the neighbourhood; indeed, there was good reason to hope that Edinburgh might escape the disease to any serious extent. It was, therefore, with feelings of unpleasant surprise that the public learned through the newspapers, three weeks ago, that many cases of the disease were being conveyed from the surrounding towns and villages into the Royal Infirmary, which lies in the very heart of the densely crowded old town.

The propriety of thus carrying into the midst of a large and populous city, hitherto comparatively free from it, so virulent a disease, was very properly called in question at the time by Dr. Gairdner, of Glasgow, in a letter addressed to the *Scotsman*.

Within the last three weeks, the disease has spread rapidly in Edinburgh, and is now assuming the proportions of an epidemic. That this increase has been to any extent directly due to the cases brought from the country, I do not affirm; but this is unquestionably the fact, that the available accommodation has been to so large an extent encroached upon by cases from a distance, that within the past fortnight there has not been room in the Royal Infirmary, or in the King's Stables Hospital, to meet the requirements of Edinburgh. Many cases of small-pox have consequently had to be treated at their own homes, and the rapid spread of the disease is no doubt in a great measure owing to this.

The great prevalence of typhus, typhoid, relapsing, and scarlet fevers, in addition to the small-pox, has given rise to much anxiety; and the city authorities have at last applied to the managers of the Royal Infirmary for, and have been granted, the use as a temporary Small-pox Hospital of the now unoccupied building of Watson's Hospital, which stands on the site of the future Infirmary.

It is to be hoped that now every case of small-pox which occurs will be promptly removed to the new Hospital, and that thus the risk of the disease spreading indefinitely will be greatly lessened.

If all the cases of small-pox are removed to Watson's Hospital, greatly increased accommodation will be available elsewhere for the fever cases.

GENERAL CORRESPONDENCE.

ENTERIC FEVER.

LETTER FROM DR. FRANCIS R. HOGG.

[To the Editor of the Medical Times and Gazette.]

SIR,—On reference to the invaluable Reports of the London Fever Hospital, it appears that from 1848 to 1864 the total number of cases treated amounted to 3076, the average for each year being 176, excepting in 1860—remarkable for its cold and rainy summer and autumn—when the numbers fell to 94. Conversely, the admissions (very low in spring) rise at the end of autumn after a hot dry summer. Many of the patients were servants in private families, or had been in good circumstances. The sexes, taking the general average, appear to have been evenly divided. In 1862, of 220 admitted, 30 died; in 1863, of 170 admitted, 24 died; in 1864, of 252 admitted, 50 died; in 1865, of 520 admitted, 96 died; in 1866, of 575 admitted, 108 died; in 1867, of 378 admitted, 55 died; in 1868, of 461 admitted, 71 died; in 1869, of 368 admitted, 62 died; and in 1870, out of 595 admitted, 93 died. Making a general total during this period, the admissions amounted to 3543, of whom 589 died.

The characteristic eruption of the disease was noticed from 1862 to 1870, both years inclusive, in the following percentage:—88, 88, 93, and 61 per cent. in 1865; 65, 77, 71, 68, and 57 per cent. in 1870.

In 1862, death in seven instances was attributed to perforation and peritonitis, in five instances to hæmorrhage from the bowels, and in seven instances to inflammation of the lungs.

In 1863 mortality was high amongst males. In 1864 a large number of cases came from Greenwich. In the autumn of 1865 yellow fever appeared in Britain; and in October, after six weeks' want of rain, and with a mean temperature through two of those weeks of $66\frac{1}{2}^{\circ}$, enteric fever acquired a new power. In July, 1866, Asiatic cholera broke out in London. In the Report for 1867 it is interesting to quote from the table of ages. Four cases were under 5 years of age, no deaths; from 5 to 9 years, 58 cases, 6 deaths; from 10 to 14 years, 75 cases, 6 deaths; from 15 to 19, 100 cases, 15 deaths. The numbers then decline until we reach the ages of 50 to 59—2 admissions, no deaths. In 1868 the summer was particularly hot, and the numbers rose; but in 1869, coincident with cold weather, the fever diminished. In 1870, the prolonged drought and summer heat telling on bad drainage and equally bad drinking-water, the admissions rose to 595.

Fatal Complications.—Calculating from 1863 to 1870, both years inclusive, it appears that, out of 757 cases complicated with pulmonary affections, 231 died; hæmorrhage of the bowels, 132 instances, 52 deaths; peritonitis, 54 instances, 51 deaths; perforation, 26 instances, all fatal; erysipelas, 19 instances, 6 deaths; parotid swellings, 15 instances, 8 deaths; cancerum oris, 3 instances, all fatal; jaundice, 6 cases, 1 death; convulsions, 4 cases, 1 death; gangrene, 2 cases, both fatal; relapses, 59, of whom only 4 died; of thrombosis of femoral vein and nephritis, each a fatal case; of 18 instances of bed-sores, 1 died; of 8 complicated with otorrhœa and 9 with epistaxis, a case of each died; out of 17 instances of pregnancy, 10 aborted and 3 died.

Non-fatal Complications.—Instances are recorded of phlegmasia dolens, phlebitis, laryngitis, tuberculosis, rubeola, variola, typhus, glossitis, purpura, scarlatina, rheumatism, epilepsy, synovitis, abscesses of the neck and breast, retention of urine, necrosis of the tibia, cardiac disease, etc.

Health of Officials.—From 1855 to 1864, during which period 1500 cases were treated, only one nurse was attacked; but in 1864, owing to defective drainage, a cook, a child, a Medical officer, and a patient contracted enteric fever. From that time until 1870 a scarlet fever patient, three nurses, and two servants also caught the fever; but from 1855 until 1870 no death either amongst the Medical officers, nurses, or servants from this disease appears recorded.

It may not be generally known that the London Fever Hospital, founded in 1802, has no endowment, and is the only institution in the metropolis for the treatment of patients (not paupers) suffering from contagious fever, and that since the establishment of the Hospital up to December, 1870, the total number of patients treated has amounted to 60,957.

Whilst engaged in the pleasant and interesting task of compiling statistics referring to enteric fever, many of the calculations as to results of complications appear so satisfactory that, up to the very last, almost until peritonitis sets in, one

hopes for recovery. Throughout England, however, there can be but one feeling this morning (December 11) of hoping against hope.

In the summer of 1861 (it only appears yesterday, ten years roll so quickly on) there was a splendid review at the Curragh, nearly all the Royal Family present—Prince Albert on horseback. The Prince of Wales, then a stripling lad, in his scarlet tunic and bearskin, marched past his parents with his regiment, the band playing the "British Grenadiers." The rain came down, and everyone was drenched.

In December, 1861, when war with America appeared impending, the death of the Prince Consort spread universal gloom. The troops marched off silently and mournfully, the bands did not play; and at sea that cold Christmas, and travelling also in sleighs over miles of frozen lakes, one subject of conversation rose uppermost. It just occurs to mention that at one halting-place a bandsman, for a few minutes carrying a bucket in each hand, with his fur gloves off, was frost-bitten, and amputation at each wrist had to be performed.

Apologising for the length of this letter,

I am, &c.,

FRANCIS R. HOGG,
Assistant-Surgeon R.H.A.

THE DECLARATION RESPECTING ALCOHOL.

[To the Editor of the Medical Times and Gazette.]

SIR,—As one of those who signed the paper on alcohol, referred to by Dr. Beale in his letter in your last issue, I cannot help expressing my regret that Dr. Beale should not have felt able to attach his signature.

The declaration is no censure on the Profession, and certainly no imputation that the great national intemperance is owing to Medical men; it is simply an opinion expressed by those of greatest weight in the Profession of the necessity of using alcohol with due caution in disease. It surely cannot be a matter of doubt that some Medical men, by incautious recommendations or insufficient attention, have led some of their patients to take too much alcohol. I know personally some such cases, and I presume instances of the kind must have occurred to many.

I regret, also, I cannot agree with Dr. Beale's other remarks.

Surely, if any body of men are called on to give advice to the public respecting this matter, it is the Medical Profession, which is charged with the health of the public. Dr. Beale quite exaggerates the plain object of the second paragraph of the declaration, which is not to lay down rules for social habits, but to urge on Medical Practitioners the importance of inculcating habits of moderation in the dietetic use of alcoholic liquids.

An expression of opinion by the Medical Profession, that they will gladly support any wise legislation which will introduce habits of temperance, is surely also one which it is at this moment specially desirable should be made by the leaders of the Profession. It will strengthen the hands of Government, and thus indirectly benefit the entire kingdom.

It is very much to be deplored that so good an object should not receive unanimous support.

I do not append my name to this letter, for the declaration is signed by so many men higher in the Profession than I am, that it would be presumptuous in me to make myself their mouthpiece. But I do not wish to be anonymous to Dr. Beale; and, when he learns my name, he will know, not only that it is that of a friend, but of a man who places the highest value on Dr. Beale's opinions. I am, &c., F.R.S.

BRISTOL MEDICAL BENEVOLENT FUND.

LETTER FROM MR. STAMFORD FELCE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you kindly permit me to make a Christmas appeal to your readers on behalf of the British Medical Benevolent Fund, a charity which I venture to say has a strong claim on the practical sympathy of all our brethren.

Help *promptly* given, help *quietly* given, is, I may say, a distinguishing feature of this benevolent fund—and I might add, help *carefully* given and help *inexpensively* given, for I can assure you that I know of no society whose meetings are more regularly or better attended than the monthly committee-meetings at 11, New Burlington-street; while the only paid official is the collector.

The cases relieved by grants during the past eleven months have been 102; but, inasmuch as some of these cases represent

large families of children, the number assisted is really much greater. The sum of 8347. has been thus expended; and, to meet the cases which may crop up this month, our treasurer had at its commencement a balance remaining of about 207. only. If it were not for fear of trespassing too largely upon your space, I should like to give the details of a few cases as specimens of the want and misery I ask your readers to assist in alleviating—want and misery all the more bitterly felt, as in most instances the sufferers have been at some time or other in comfortable circumstances.

Donations or subscriptions, however small, will be thankfully received by the Treasurer, Dr. Hare, 57, Brook-street; the Honorary Financial Secretary, C. S. Webber, Esq., 1, Upper Berkeley-street West; or by

Yours, &c.,

STAMFORD FELCE,
Honorary Secretary.

12, Chippenham-road, W., December 12, 1871.

N.B.—Articles of clothing for men, women, or children I am always glad to receive for our applicants.

MEAT EXTRACT.

LETTER FROM MR. STEPHEN DARBY.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you permit me to call the attention of your correspondent "Beefeater," writing from Pau, to an article in your journal of June 10 last, on the preparation (or rather the changed form) of meat for which I have adopted the above title; and further, to state that in it not only is the "colleine" preserved, but the whole of lean meat—fibrine, albumen, gelatine, and extractives—is offered in a perfectly soluble form, and with this last not trifling advantage: it is quite as "nutritive as slices of tender roast beef." To this most of my Medical friends will bear me testimony, and also that, in many cases where the digestive powers have become so weakened that even beef-tea cannot be taken without causing flatulence and pain, the fluid meat causes no such results, being in a condition admitting of very speedy absorption into the system.

If your correspondent will take into consideration the very small proportion extracted from beef by even long-continued boiling in water, and that the portion rejected is certainly not the least valuable in point of nutrition, the inferiority of "unscientific beef-tea" to a preparation such as I have indicated must be at once evident.

140, Leadenhall-street.

I am, &c.,

STEPHEN DARBY.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, NOVEMBER 28.

MR. CURLING, F.R.S., President, in the Chair.

MR. WILLIAM FAIRLIE CLARKE read a paper

ON A CASE OF UNILATERAL ATROPHY OF THE TONGUE.

Mrs. H., aged 45, the wife of an oilman in the North of London, became aware of a tumour in her right breast in the spring of 1869. In February, 1870, she showed it to Mr. Hume, of Devonshire-street, Islington, and he recommended that it should be removed at once, as it had all the characters of a malignant growth. It was accordingly excised on February 16. The wound healed slowly, but satisfactorily. On April 15 she complained of cough and slight dyspnoea, the latter only noticeable after exercise. Under treatment the cough soon disappeared, but the dyspnoea continued. On October 3 Mr. Hume was called suddenly, and found her suffering from a deep-seated pain on the right side of the head, of a periodic character, returning each night between one and two o'clock a.m., and rendering her for some hours incoherent and unmanageable. Many remedies were tried; but the only thing which gave her relief was morphia in grain doses. It was at this date that the atrophy of the tongue was first noticed, though it was not then so marked as it afterwards became. On March 29, 1871, Mr. Hume was again urgently required to attend, and found the patient suffering from all the old symptoms, but in an aggravated degree; and in addition there was an alarming dysphagia, together with paroxysms of suffocation, which

recurred about three times in the twenty-four hours. On being asked to protrude the tongue, she always appeared unable to do so at first; and, on the request being repeated, would reply, "Wait a minute." Then, after a few moments' deliberation, she put it out very slowly. The tongue was puckered and crimped along its whole right side from base to apex, though these appearances were the most marked at the anterior two-thirds. An actual loss of substance had taken place, but it was bounded exactly by the median raphe; and the contrast between the plumpness of the left side and the shrivelled aspect of the right was very striking. When it was protruded, there was no deviation to either side. Articulation was slow and difficult. There was great pain along the right side of the neck, with a certain fulness and turgescence of the vessels, but no tumour could be felt in any part of the mouth or neck. Together with these symptoms there was general cachexia and great prostration of strength. From this time the dysphagia and dyspnoea gradually became worse; and on June 7, in one of the attacks of suffocative cough, the patient died. At no time during her illness had there been any paralysis of the extremities, and her intellectual faculties remained clear throughout her whole illness. Unfortunately, no autopsy could be obtained; but, looking at all the circumstances of the case, the writer thought there was good reason to believe that the ninth nerve on the right side was involved in a secondary cancerous tumour, such tumour being situated either within the cranium or at the upper part of the neck, and pressing upon the right hypoglossal nerve, and more or less implicating the pneumogastric and glosso-pharyngeal nerves as well. The writer then proceeded to compare with this case two other instances of well-marked unilateral atrophy of the tongue—the one related by Dupuytren in the "Leçons Orales" (Lecture on Hydatid Tumours); the other by Sir James Paget, in the third volume of the *Transactions of the Clinical Society*. The experience of Romberg and of Bidder was adduced to show that this remarkable condition of the tongue may be produced by a lesion of the ninth nerve; and to establish the same point, the author related an experiment that he had made. On October 25 he divided the right hypoglossal nerve in a rabbit, and took out a piece about a quarter of an inch in length. Immediately after the operation, and during the whole time that the animal was under observation, the tongue was strongly protruded to the right side. On November 27 the rabbit was killed. It was found that the nerve had united by a soft, gelatinous, and highly vascular substance, of about twice the ordinary calibre of the nerve. The right side of the tongue, along its posterior half, was slightly wasted and flattened. The preparation was exhibited; and an outline sketch, illustrating the case which had been related, also accompanied the paper.

Dr. JOHN HARLEY acquiesced in the view that the nerve affection was due to a cancerous tumour. It was not unusual in scarlatina, when the glands were swollen, to note deviation of the tongue. He had a case now in hand occurring in a youth of 15. He suffered from occipital headache and vomiting at intervals; his tongue deviated. The glands were swollen on both sides, especially the right.

Dr. BASTIAN was by no means certain that tongue atrophy was always associated with paralysis of the ninth. He had a case of paralysis of the tongue where there was no paralysis of that nerve. The deviation was slight. When tested by faradisation contractility was left. Another case reported by Juccoud showed the same. In a case of progressive muscular atrophy there was paralysis of the tongue on one side, and so of the face. These cases had been long under notice, yet no wasting of the tongue followed. After death the anterior roots of the nerves were much atrophied, and so with regard to the facial and hypoglossal, whilst the fifth was healthy. Juccoud thought the sympathetic fibres go with the fifth to the face, rather than with the motor nerves; such, also, was his opinion. There was no atrophy in the rabbit, though there was deviation of the tongue.

Dr. HABERSON referred to the case of a woman, aged 52, who was in Guy's Hospital with a tumour of the breast. This wasted, but the glands in the axilla and neck enlarged, and the right side of the tongue became flaccid. The tip was turned to the left, and she had difficulty in managing her food. Sensation in it was perfect. The right sterno-hyoid was paralysed. She suffered from pain in the back of the head and spine, and she gradually wasted and died. There was found to be cancer of the skull-bones, implicating the orifice of the eighth nerve, and the vertebræ were cancerous.

Dr. HUGHLINGS-JACKSON thought the case a very rare one. In no case had he seen palsy of the tongue either on one side

or on both sides 'without palsies of other parts. Thus, in a case of syphilitic disease there was palsy of the left portio dura and eighth nerve, as well as palsy of the left ninth. In a case of tumour of the medulla oblongata and pons Varolii there was palsy of the fifth, sixth, seventh, eighth, as well as of the ninth on the left, and paralysis of the right arm and leg. He mentioned the case of a man who found out one morning that he was hoarse, and that his tongue was turned to the right side "like a hook." There was palsy, with wasting of one side of the tongue, paresis of the right side of the palate, and palsy of the right vocal cord. As the man was past fifty years of age, as he had albuminuria, and as the symptoms came on in one night, the probability was that they were the result of clot. In one case of sudden palsy of the tongue, palate, and orbicularis oris, which he had seen, Dr. Lockhart Clarke discovered relics of effusion of blood in the medulla. Dr. Lockhart Clarke's researches, showing the close relations of the lingual and spinal accessory nuclei, gave the explanation of cases of lesion in the medulla producing palsies of the several factors concerned in articulation, deglutition, and voice. Dr. Hughlings-Jackson had never seen wasting of the tongue from paralysis of the fifth nerve, although the temporal and masseter muscles wasted.

Dr. WILLIAM OGLE referred to a case reported by Dr. Salter, where the hypoglossal was cut, and paralysis and atrophy followed. The tongue might be protruded straight after section of the hypoglossal, and it was not always protruded to the side of the lesion. The geniohyoglossus protruded the tongue, and that might be paralysed without causing deviation. Withdrawal of the tongue reverses the deviation. In the rabbit the tongue on the injured side was higher than usual.

Dr. HILTON FAGGE said there were two drawings at Guy's of such atrophy, and he had seen one case himself in a boy aged 5½ years with disease of the upper cervical vertebrae. In this case the odontoid process projected through the dura mater. He thought the transverse fibres might push the tongue to the opposite side.

Mr. T. SMITH thought the geniohyoglossus enough to thrust the tongue to the other side.

Mr. H. POWER said Dr. Bastian entered on the question of trophic nerves. He thought they went with the fifth to the tongue, and Mr. Clarke with the eighth. He cited the instance of the ophthalmic of the fifth being divided, and producing destructive inflammation of the eyeball, as showing that sensitive nerves did preside over nutrition. He thought the atrophy must be due to vaso-motor paralysis.

Mr. SOELBERG WELLS said Meissner divided the fifth, it was true, but inflammation only followed section of the inner division of the ophthalmic.

Mr. BRUDENELL CARTER alluded to another class of cases connected with trophic nerves—viz., cases of herpes. With such the ganglia became enlarged. He had seen frontal herpes followed by increased tension and turbidity of the cornea, with exaltation of sensation. This was, perhaps, due to affection of the cavernous ganglion.

Mr. BARWELL said that in this case it was assumed that cancer was the cause of the paralysis, the disease recurring after extirpation. He thought there was no evidence of this.

Mr. HOLTHOUSE had seen a case of strabismus with pain at the back of the head. The left side of the tongue was atrophied, and the patient had difficulty with food. The ninth and sixth nerves were affected, apparently from syphilis. The patient got well.

Mr. CLARKE briefly replied.

Dr. WM. O. PRIESTLEY read a paper on

CASES OF INTER-MENSTRUAL OR INTERMEDIATE DYSMENORRHOEA.

The author pointed out that, although much had been written concerning dysmenorrhœa, and several forms of it had been described in accordance with the pathological views taken of its causes, the description of the several varieties was ordinarily limited to the time of the catamenial period, with the two or three days additional which may precede and follow the menstrual flow. From time to time, however, cases of a more obscure kind presented themselves, in which the chief suffering is remote from the actual menstrual period, but comes on, nevertheless, with the same punctuality, and is probably dependent on organic changes associated with the production of the catamenia. Probably other Practitioners had observed like instances, as they were not unfrequent, but as the author had met with no description of them, he brought the subject before the Society as a fragmentary contribution to the pathology of uterine affections, which might possibly evoke further elucidation by discussion. In all the cases detailed severe pain was experienced by the patients midway in the menstrual interval.

The pain commonly came on about fourteen days after a catamenial period, and, after lasting a variable number of days, ceased before the supervention of the next expected period. In one case the pain, beginning midway in the interval, ran into the following monthly period, and was relieved by its flow. The suffering was constantly referred to one or other ovarian region, and in three cases out of four marked tumour, or thickening from old adhesions, was found in that locality. The reason for the occurrence of pain in the inter-menstrual period, and with such regularity, was not, in the present condition of our knowledge, perfectly obvious. A study of the physiological and pathological conditions left little doubt, however, that it was due to perturbations in the function of "spontaneous ovulation" habitually going on in the ovary. Hypertrophy of the structure of the ovary, or thickening of its indusium, would lead to undue vascular excitement, and impede the advance of ova to the surface in their attempts to attain maturity. It was not unreasonable to suppose, from all the known facts of the case, that preparation for an approaching period began in the ovary ten or fourteen days before the occurrence of the monthly uterine discharge, and if the initial steps in the process of ovulation were opposed by certain pathological conditions, pain would ensue. Nay, in the absence of distinct organic change, it might readily be imagined how special irritability in the ovary would cause an unusual amount of disturbance whenever there was occasion for the exercise of fresh activity in the organ. This latter class of cases would partake more or less of a neuralgic character. The treatment would depend on the pathological condition as ascertained by examination. The pain being only a symptom, it would be needful to inquire into the cause; and, if there were tumour, or thickening depending on former inflammation, absorbent remedies would be indicated. If no organic change of structure could be detected, anti-neuralgic remedies, such as quinine, iron, and arsenic, would best answer the purpose of cure.

Dr. ELAM asked how far this idea would correspond to that commonly entertained with regard to fecundation.

Dr. PRIESTLEY said the facts in nowise militated against the ordinary ideas.

MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 30.

Dr. ANDREW CLARK, President, in the Chair.

M. VICTOR DE MÉRIC narrated the following case:—The patient, aged 45, was forcibly raised from the ground by his assailant, who attempted to throw him into a wine vat. Some of the lower ribs on the right side suffered fracture near their angles. He was sent to the London Hospital to have a broad bandage applied. On the fourth day the bandage was comfortable, and there was no dyspnoea or fever. During the next few days the symptoms became alarming—hurried breathing, severe pain in the left side of the chest, restlessness, anxious countenance, and abundant expectoration. On the eleventh day the patient was in a typhoid state, the whole of the left side of the chest being dull on percussion, and offering no respiratory sounds whatever; the right side sounded well. The respiration being quite puerile, it was concluded that from pressure or shock the left pleura had been injured, that effusion had taken place, and that the case was one of acute pleuro-pneumonia. The negative symptoms were, absence of pain or stitch, and no bulging of the intercostal spaces. The patient gradually rallied, and at the end of two months left his bed. The physical signs varied but little; the cough and dyspnoea were at no time very distressing. It was thought that, since succussion produced no splashing, false membranes were lining the pleura costalis. About ten weeks after the assault, faint gurgling began to be heard towards the apex of the left lung, and it was supposed that the left lung was getting partially freed. The gurgling soon, however, assumed the character of air passing through a small vomica filled with fluid. It was regarded now as a case of phthisis of long standing, followed by the complications described. The fractured ribs had united. The patient gradually sank, and died on the ninetieth day after the accident. Post-mortem examination: Right lung, collapsed, filled two-thirds of the cavity; several tuberculous circumscribed deposits in it varying in size from a pea to a walnut. On the left side lay a large dense greyish-looking mass occupying four-fifths of the whole cavity. It was extremely hard, and had contracted adhesions. The pleural fluid on both sides (four ounces) was reddish, and

small in quantity; the left lung formed a solid mass, composed of tuberculous fibroid infiltration. On section, no trace of vessels, air-tubes, or air-cells could be made out; no oozing was perceived; not a sign of breaking-up or of pus, and of course no vomica; heart atrophied. The man supposed himself to be healthy; his occupation was laborious. There was no family history of phthisis. We must therefore suspect that the pleuro-pneumonia did the mischief, though it is difficult to believe that the induration would be so extensive if some previous pathological changes had not been present. The importance of the bulging of the ribs and dyspnoea is shown in this case. The presence of tubercle in the right lung suggests that it might be present in the left also. Ninety days was hardly sufficient to transmute the left lung from a perfectly healthy state to the mass above alluded to.

Dr. DOUGLAS POWELL was unable to understand why this was called a case of phthisis. He would consider it, from an examination of the specimen and the clinical history, a case of pneumonia in the grey stage.

The PRESIDENT remarked that it was not a case of what he called fibroid-phthisis, which would present ulceration and suppuration of a more or less circumscribed non-malignant deposit in the lung. If there was no cavity there was no phthisis. Some bronchi become blocked by exudation; fluid collects in them, and gives rise to gurgling.

The specimen was an excellent example of the hard form of grey pneumonic consolidation.

LEGAL INTELLIGENCE.

IMPORTANT CASE.—PROSECUTION OF A BOTANICAL PRACTITIONER.

A CASE (*Dalrymple v. Lakin*) was recently heard at the Leicester Police-court, before the Mayor and a bench of magistrates. The defendant was summoned, under the Medical Act, for having illegally practised as a Doctor of Medicine. Last week the judgment, which had been postponed, was read by the clerk, and was as follows:—

“The defendant is charged, under Section 40 of the Medical Act, with having wilfully and falsely taken and used the name and title of a Doctor of Medicine, he not being by law entitled to use such name or title. It was proved, on behalf of the prosecution, that the defendant occupies a house in New Bond-street, Leicester; that in the window are coloured bottles, breast-pumps, bottles of castor oil, Medical pamphlets, etc.; that the shop inside is fitted up in the same manner as open surgeries frequently are in other towns, but of which there are few, if any, in Leicester; that the words ‘Dr. Lakin’ are on a brass plate at the side of the front door; that the words ‘Dr. Lakin, Botanic Practitioner,’ are painted above the window for the whole length of the front of the house (about twelve feet long) in letters about five inches in height; and that the defendant had attended one of the witnesses, in the capacity of a Medical man. A certificate of death, signed by the defendant as M.D. (U.S.), was produced before us by the Deputy Registrar of Births and Deaths. The defendant, in answer to the charge, produced a diploma of Doctor of Medicine, dated October 1, 1870, purporting to be granted by the Eclectic Medical College of Pennsylvania, United States, incorporated by an Act of the General Assembly of the Commonwealth of Pennsylvania, under the seal of the College, and under the hands of six of the Professors. A witness named Crick was called on behalf of the defendant, who was in the possession of a similar diploma to that of the defendant, dated April 27, 1867, and he stated that such diplomas are granted without any personal examination by the Professors, or any attendance at the lectures of the College, although the diplomas recite that they have been granted after the applicant for the degree has attended two full courses of Medical lectures, and passed a successful examination in each department of study ‘before us, the Professors of the College.’ The witness further stated that all that was required from him previously to obtaining the degree was to answer certain questions sent to him by a board of examiners at Leeds, to attend once personally at Leeds, and to pay certain fees, the amount of which he could not recollect. The diploma possessed by the defendant had all the appearance of authenticity, but was not proved in evidence to be genuine. Four cases were cited in the course of the hearing, two of which (*Pedgriff v. Chevalier*, 29 Law Jour. R. M. C., 226; and *Steele v. Hamilton*, 3, L. T., N. S., 322) have no bearing on the present charge, they having turned on the question of the sufficiency of

the evidence as to the defendants not having been in practice as Surgeons before the Act passed, or before 1815; but the other two cases have required our consideration with reference to the facts of the present case. In *Ladd v. Gould* (1 Law T., N. S., 325), the defendant had used the word ‘Surgeon,’ followed by the words ‘Mechanical Dentist,’ on the side of his door, and the justices had dismissed an information charging him with having used the title of ‘Surgeon.’ The Court of Queen’s Bench held that it was a question of fact for the magistrates to decide, whether by the use of these words the party proceeded against was guilty of an offence against the statute; and Lord Chief Justice Cockburn said that there was not, in his opinion, any false pretence in using the word ‘Surgeon’; that he should have come to the same conclusion as the magistrates, that it was like the case of persons calling themselves ‘Surgeon-dentists’ (or, as Mr. Justice Crompton remarked, ‘Surgeon-chiroprudists’), but that there was evidence upon which the magistrates might have come to either conclusion, although, in the opinion of the Court, they had arrived at a correct one. In the remaining case of *Ellis v. Kelly* (30 Law Journal R. M. C., 35, and 6 Hartstone and Norman, 222), it appeared that the defendant, who was a duly registered Surgeon, had used the prefix of ‘Dr.’ to his name for some years before the Medical Act; that he was in possession of a diploma as a Doctor of Medicine of a German university; but that such diploma was not proved to be genuine. The justices had dismissed an information charging him with having used the title of Doctor of Medicine. It was held by the Court of Exchequer that the word ‘Doctor’ must, under the circumstances, be taken to mean a Doctor of Medicine; that a person falsely calling himself a Doctor of Medicine (per Baron Bramwell) would be liable to a penalty, although he was in reality a Member of the College of Surgeons or of the Apothecaries’ Company, and so registered; but that the words ‘wilfully and falsely’ meant ‘wilful falsity,’ and that the possession of the foreign diploma, although not proved to be genuine, so far justified the defendant in using the prefix ‘Dr.’—as he had done before the Medical Act was passed—as to exonerate him from the charge of having ‘wilfully and falsely’ assumed that title.

“It is rather singular that there is no reported case of a successful prosecution under Section 40 of the Medical Act. In the case before us it appears that the words ‘Dr. Lakin,’ are on a plate at the side of the door—that the words ‘Dr. Lakin, Botanic Practitioner,’ are over the window in large letters, extending the whole length of the front of the house. That the defendant is in possession of an American diploma, and that in a certificate of death he describes himself as ‘M.D. (U.S.)’ With respect to this certificate, we think no one can successfully contend that a person who actually describes himself as ‘M.D. (U.S.)’ evidently meaning a Doctor of Medicine of the United States, is guilty of the offence of wilfully and falsely assuming the title of Doctor, so as to imply that he is a recognised Physician in England, and the words ‘botanic practitioner’ would probably be viewed in the same light as ‘mechanical dentist’ were in *Ladd v. Gould*, as they do not appear to be such words as would be used by any Medical man who wished it to be known that he was a legally qualified Practitioner, and registered under the Act. Although we could have wished that the facility with which foreign diplomas are obtained, and their utter worthlessness in many cases as tests of Medical proficiency had been more fully brought under the notice of the Court of Exchequer in *Ellis v. Kelly*, which opened the door for the admission of foreign diplomas for the purpose of negating the charge of a false pretence, and the view of the right to use the word ‘Doctor,’ taken even in a work regarded as one of the organs of the Medical Profession, in which it is broadly stated that a person in the possession of the degree of M.D. under a diploma from the College of Pennsylvania, however obtained, has the right to call himself a ‘Doctor of Medicine’ if he pleases (see *Lancet*, September 23, 1871, page 457), we do not feel justified in convicting the defendant of the serious offence of having, by ‘wilful falsity,’ used the title of Doctor, he being in possession of a diploma from an incorporated college in the United States, which has the appearance of being (although not legally proved to be) genuine, as the possession of such a document may have led the defendant to believe, in common with some members of the Medical Profession in England, as shown by the publication to which we have referred, that he was entitled to use the prefix of ‘Dr.’ to his name, and may, under a penal statute, be an answer to the charge of having ‘wilfully and falsely’ assumed that title. We think it will not be out of

our province to add that, if the Medical Act were intended to give any security to the public that Medical Practitioners should be persons of education and science, it has, to a great extent, failed in its object; and that, to be effectual, it requires material amendment, as the offence created by the Act is not that of practising without being registered, for which there is no penalty, but of wilfully and falsely using a name or title implying that the party had been registered—an offence which, considering the interpretation put on the words 'wilfully and falsely' in the cases referred to, is difficult to prove in a court of law."

At the conclusion, the attorney for the prosecution applied for a case for the opinion of the Court of Queen's Bench, which was granted. The ultimate decision of this case will, in all probability, be attended with important results, as it seldom happens that a case of appeal is asked for by the prosecution except some public interest is at stake.

OBITUARY.

WALTER COOPER DENDY, M.R.C.S., ETC.,

DIED in London, on the 10th inst., in the 77th year of his age. He was born at or near Horsham, in Sussex, and was descended from a family highly respected and long known and located in the county. After an apprenticeship in the locality, he came to London about the year 1811, and entered as a student at the then united Hospitals of Guy's and St. Thomas's—at the time Sir Astley was in his zenith, and when that school was the most famous in England. He became a Member of the Royal College of Surgeons, London, in 1814. He commenced practice in Stamford-street, and here, in 1827, I first became acquainted with him, in consequence of his attending a very near and dear relative of mine. I well recollect him in those days, and, as a boy, was delighted and charmed with his agreeable manners, his wonderful versatility of knowledge, and his charming powers of conversation. A few years afterwards, when I had become a Medical student, and commenced reporting the Medical Society of London, one of the prominent Fellows of the Society was Mr. Dendy. An admirable speaker, always well informed on the subject on which he spoke, I was never at a loss to follow him. If he was occasionally a little theoretical and imaginative, he was in the main practical. Amongst the speakers at the Society, then by far the most important gathering of the Profession, he was second to none. This is no small praise, when his associates were Clutterbuck, Haslam, Uwins, Leonard Stewart, James Johnson, Whiting, Crisp, and Headland, with many "as worthy sons as they." Discussions at the Society at this period were carried on with a spirit and ability which have never been surpassed. The Westminster Society, though much larger in numbers, was *jejune* and discursive when compared with its Bolt-court rival. The Medico-Chirurgical had not at this time emerged from its chrysalis state, and was contented to allow papers of immense importance, from the ablest men of the day, to drop as it were into oblivion—to be read and *not* discussed, and only to be rescued from their obscurity by being printed at some indefinite time after, in the *Transactions* of the Society. It is lamentable to think, by the obstructive arrangements which prevailed with reference to debating the merits of a paper, how much of the experience of the leading men of the time has been lost! What a valuable mass of information might have been preserved to the Profession had the occasional short statements of the leading Physicians and Surgeons who occasionally said "something" been reported in the journals! The Society became at last a mere "tea-meeting," with the solemnity of a secret reading, as it were, of papers, no doubt of inestimable value, but like the "gems of rarest ray serene," or the "flowers born to blush unseen," were, in almost the strictest sense, lost to the world. The consequence was most disastrous to the Society, at whose meetings scarcely a dozen attended. When it had dwindled to nearly a condition of exhaustion, permission was given to reporters to attend, and to publish the proceedings. Great were the revivifying effects of the air of publicity on the Society. It is not too much to assume that the debates in the Medical Society had some effect on the Council of the Medico-Chirurgical in inducing them to consent to a change in their regulations respecting the admission of the press to their meetings. It is a fact that, whilst the library in Bolt-court was attended by a crowded and admiring auditory, that of the Society I am criticising was a mere "hole-and-corner" assembly, without spirit and without interest. It is due to the memory of Mr.

Dendy, and others who were his colleagues, to state that he was one of the first to advocate publicity to the proceedings of the Society in Bolt-court. He was one of the foremost to assist me in my then arduous task of reporting their proceedings. In after years, and even to within three months of his death, the question formed the subject of our conversation on many occasions. In looking back at the early times of reporting for the Medical press, with all its drawbacks, its vicissitudes and difficulties, I must say the evenings in Bolt-court are amongst a few of the "pleasures of memory" associated with the pursuit I followed.

Walter Cooper Dendy was not a mere Surgeon. In days when the Surgeon in general practice was certainly not usually an educated person, he shone conspicuously by his superior acquirements, by his cultivated taste, and his polished manners. He found time, even amidst the toils and struggles all but invariably the early lot of men who engage in our calling, to indulge in his fancy for general literature. Thus, he wrote and published a poem of considerable merit, entitled "Zone;" and "The Philosophy of Mystery," an able and learned treatise on dreams, spectral illusions, and other imperfect manifestations of mind. In this little volume, he advanced some theories which were regarded by hypercritical and shallow thinkers as bordering on Materialism; but the book, taken in its entirety, is one of the most conclusive that could be to prove his belief in a future state. For instance, in speaking of the deaths of little children, their mysterious "forethought," as it were, of their demise, even when those around them had hope of their living—I quote from memory—he says, "In that awful moment when the spirit

'Is soon from its cell of clay
To burst a seraph in the blaze of day.'

who shall say that there is not some communication between the Almighty and the 'cherished ones,' who are called in 'their purity to heaven'?" That Dendy had some peculiar religious views, I know, but his mind was of too grave and reflective a character, too much imbued with enthusiasm, too poetic for him to be a materialist. I mention his literary productions first, not because they are the more meritorious of his contributions, but inasmuch as he prided himself, and justly, upon them. In later life he published a volume under the singular title, "ΨΥΧΗ: a Discourse on the Birth and Pilgrimage of Thought," a metaphysical essay, worthy of being classed amongst the first of such essays on a profound and most fascinating subject. His "Sketches in the Isle of Scilly" are full of truthful fancy; it was followed by other works of singular merit. "The Beautiful Islets of Britane," "The Wild Hebrides," "The Islets of the Channel," and "Legends of the Lintel and the Ley," are the most important. But he was not idle in respect to Medical literature. He was author of a "Practical Treatise on Diseases of the Skin," "Hints on Health and Diseases of the Skin," "The Book of the Nursery," "Portraits of Diseases of the Scalp," "Wonders displayed by the Human Body," "Monograph on the Cerebral Diseases of Children," and "The Varieties of Pock." He contributed largely to the Medical journals, and was the author of some of the most remarkable and interesting of the papers which appeared in the *Psychological Journal*, edited for many years with much ability by Dr. Forbes Winslow. It should be mentioned that he was for a long period Surgeon to the Royal Infirmary for Children in the Waterloo-road, and at this institution he found materials for some of his best Medical works. Dendy was an admirable draughtsman, and illustrated his own works in a manner which elicited admiration from all. His last efforts with his pencil were, I believe, some sketches of the scenes described by the poet Cowper in the neighbourhood of Olney and Weston Underwood. Knowing my early association with these scenes, he kindly brought the sketches to me. Nothing could exceed these in graphic and truthful illustration. His last essay, I think, was "On the Mental Condition of Cowper," that marvellous enigma—the most popular of poets, the simplest and yet one of the profoundest of philosophers—whose life has been written by numerous authors. Was he insane, or was he not? There can be no doubt, I think, that for a time his fine intellect was under a cloud. But it must be remembered that it was a *questio vexata*. Hayley, Johnson, Southey, and other eminent men differed in opinion on the subject. Dendy took what appeared to me a sound view of the question. He steered a middle course, and treated the matter from a Medico-Psychological point of view. The essay was originally intended for publication in Winslow's *Quarterly*; but this having ceased to exist, he brought it to me for publication in the *Lancet*. I felt it was not fitted for a Medical journal, and with great regret returned it to him. I hope it may yet see

the light, as I understand it is the intention of his executors to publish a posthumous volume of his writings. Dendy was almost a recluse, even in his earlier days. With the exception of attending the annual dinner of the Medical Society, and occasionally the biennial festival of the Students of Guy's Hospital, he seldom or never appeared at any convivial meetings of the Profession. I believe he never gave a private dinner-party to his friends. When President of the Medical Society he lived at Storey's-gate, in the house that immediately overlooks the Birdcage-walk. He gave the usual Presidential dinner. I was present. The repast was perfect in its way. The fine old china plates, the glasses of all but mediæval age, the wines old and select, gave to the entertainment a charm and originality which I shall not easily forget. But it was characteristic of the man. He "came out" but "once in his life," but he "came out" not like a hermit or recluse, but with all that could delight or astonish his company. As I have said, Dendy was a retiring man, even in his palmy days. He had no amusements out of doors, and this may explain why he had time for his numerous contributions to literature and to Medicine. He retired from practice some years since, and occupied his time in the reading-room of the British Museum. Daily you might see him coming up from Suffolk-street to the Museum, with his spare figure, his small frame, his reflective face, and his grotesque habiliments, his brown greatcoat, and his huge spectacles. Of late there was a certain kind of melancholy about him, which was "sweeter even than pleasure." He met death at the age of 77, after a short illness, with that "ealm and decorous fortitude" which he had ever evinced during life. I have but one sentence to add to this memorial to my old friend. He died in Suffolk-street, Haymarket, in the house of a patient of mine. On the morning of the day when these reminiscences were penned, I was requested by Mrs. M—— to view the body of my old friend. One of his executors, an eminent pastor of the Unitarian creed, could not convince himself that Dendy was dead, and positively insisted that he should be examined in his coffin by some Medical gentleman. I obeyed the summons. In the second-floor front room at a house in Suffolk-street, Pall-mall, which he had occupied for years, and had endeared himself to those about him by his gentle manner and his kindness of heart, lay all that was mortal of one of the most accomplished and kind-hearted members of our Profession I had ever known. My friend Dr. Routh had attended Dendy with all kindness and attention and skill during his last illness. My visit to the corpse was unnecessary, but I felt I was not doing wrong in taking a "last sad look" at him I had known intimately for upwards of forty years.

J. F. C.

SIR JAMES MURRAY, M.D.

THIS well-known Physician died last week, at the advanced age of 83. His name is more identified in this country with his "fluid magnesia" than for other claims he had to distinction as a writer or a Physician. But Sir James Murray had such claims. For many years he performed the duties of Inspector of Anatomy for Ireland, with considerable tact and ability. When Lord Anglesea was Lord Lieutenant of Ireland, Murray was his Physician, and was knighted in consequence of his position, and of "eminent services" rendered to his Excellency. He was educated in Dublin, and was formerly in the army. He was ordinary Fellow of some, and honorary Fellow of several learned and scientific societies. He was an able chemist, and devoted most of his time to chemical study. He published, amongst other works, essays on the "Air-Pump," on a "New Method of Restoring Suspended Animation," on "Magnesia," "Specific Gravity," "Atomic Changes," and several articles on magnesia. It is remarkable that these contributions to the *Materia Medica* and Therapeutics in relation to magnesia were published upwards of sixty years since, and that he should, a quarter of a century after, patent a "fluid magnesia," by which he obtained reputation and a considerable income. Sir James was a good specimen of "a good Irishman"—a thoroughly Celtic face, with a rich brogue, and a fund of humour and anecdote. He was of herculean frame and strength, and up to within a short time of his death maintained his wonted spirits and vigour.

ADULTERATION OF FOOD AND DRUGS.—The *Birmingham Gazette* understands that this measure will be re-introduced in the House of Commons at the commencement of the ensuing session by Mr. Muntz, M.P. There will be certain modifications, to disarm the specific opposition which Mr. Muntz encountered in Parliament last session.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members of the College, having undergone the necessary examinations for the Fellowship on the 22nd, 23rd, and 24th ult., were reported to have acquitted themselves to the satisfaction of the Court of Examiners, and, at a meeting of the Council, on Thursday, the 14th inst., were admitted Fellows of the College, viz. :—

- Butlin, Henry Trentham, L.R.C.P. Lond., Camborne, Cornwall, diploma of Membership dated November 12, 1867, student of St. Bartholomew's Hospital.
- Hardwicke, Junius, L.K. & Q.C.P. Ireland, Rotherham, June 3, 1844, of the Dublin School.
- Higgins, Charles, L.R.C.P. and L.S.A. Lond., Hambledon, Hants, April 21, 1868, of Guy's Hospital.
- Oldham, Charles James, L.R.C.P. and L.S.A., Lond., Brighton, January 26, 1870, of Guy's Hospital.
- Page, Herbert William, B.A. and M.B. Cantab., Carlisle, November 16 1869, of the London Hospital.
- Partridge, Samuel Bowen, L.S.A., of Her Majesty's Indian Army, August 5, 1851, of King's College.
- Rendle, Richard, L.S.A., Forest-hill, April 22, 1868, of Guy's Hospital.
- Wyman, William Sanderson, M.D. St. Andrews and L.S.A., Putney, April 25, 1862, of St. Thomas's Hospital.

Four candidates, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their Professional studies for twelve months.

At a special meeting of the Dental Board, on Tuesday, the 12th inst., Mr. Samuel Hamilton Cartwright, of Old Burlington-street, having undergone the necessary examination, was admitted a Licentiate in Dental Surgery, his diploma of Membership bearing date May 7, 1867.

APOTHECARIES' HALL.—The following gentleman passed his Examination in the Science and Practice of Medicine, and received a Certificate to practise, on Thursday, December 7, 1871:—

Kilner, Walter John, Bury St. Edmunds.

The following gentlemen also on the same day passed their first Professional examination:—

Collier, Nicholas C., King's College.
Edwards, John Ellis, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- ALLCHIN, W. H., M.B. Lond., M.R.C.S., L.S.A.—Medical Registrar to the Westminster Hospital, *vice* Dr. Lee, resigned.
- ARNOLD, RICHARD ORLANDO, L.F.P.S., L.M., L.S.A.—Medical Officer for the Second Division of the Chesham District of the Amersham Union.
- BEACH, FLETCHER, M.R.C.S.E., 1st M.B. Univ. Lond. (late Resident House-Physician to King's College Hospital)—House-Surgeon to the Hospital for Sick Children, 29, Great Ormond-street, W.C.
- CEELY, ROBERT WALTER, M.R.C.S.E., L.S.A.—Medical Officer to the Infirmary and Workhouse.
- CURLING, HENRY, M.R.C.S.E.—Assistant-Surgeon to the Sussex County Hospital, Brighton, *vice* F. A. Humphry, resigned.
- ELLIOTT, A. BOWES, M.R.C.S., late House-Surgeon at Guy's—Resident Surgeon to the Farringdon General Dispensary and Lying-in Charity, Bartlett's-buildings, Holborn.
- HUMPHRY, F. A., F. & M.R.C.S.E., and L.S.A.—Surgeon to the Sussex County Hospital, Brighton, *vice* Mr. G. Lowdek, deceased.
- LIDDARD, THOMAS, M.R.C.S., L.R.C.P. Lond.—Fifth District Medical Officer for the new district in the north part of the parish of St. Mary Abbott's, Kensington, W.
- SHIPMAN, GEORGE WILLIAM, M.R.C.S., L.R.C.P. Lond.—Medical Officer and Public Vaccinator for the Grantham District of the Grantham Union, Lincolnshire, *vice* Charles Ferneley, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A. Lond., resigned.
- SLATER, JOHN S., M.R.C.S.E., L.S.A.—House-Physician to St. Thomas's Hospital, *vice* E. Cox, resigned.

NAVAL APPOINTMENTS.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of February 22, 1870, Sir Alexander Armstrong, M.D., K.C.B., was on December 4 placed on the Retired List of Inspectors-General of Hospitals and Fleets in her Majesty's Fleet. The undermentioned Medical Officers, on the retired list, have been promoted to the honorary rank of Deputy Inspector-General of Hospitals and Fleets in her Majesty's Fleet:—Robert Grahame, M.D., James Vaughan, Charles Deane Steel, Charles Thomas Simpson Kevern, Andrew Murray, and Joseph Henderson, M.D.

BIRTHS.

DUKES.—On November 28, at Rugby, the wife of Clement Dukes, Esq., M.B., B.Sc. Lond., of a daughter.

FENNEL.—On December 12, at New Wandsworth, the wife of Charles John Fennell, Surgeon, of a son.

JONES.—On December 6, at Grange House, Bromley, Kent, the wife of Alfred Orlando Jones, M.D., of a son.

MOORHEAD.—On December 4, at Clifton, the wife of Dr. T. Moorhead, of a daughter.

MARRIAGES.

ALVES—INGLIS.—On December 6, at St. Andrew's Church, Plymouth, Malcolm Arbuthnot Alves, Royal (late Bengal) Engineers, to Julia Jane, eldest daughter of John Inglis, M.D., H.M.'s Indian Army.

COVEY—MORTON.—On November 15, at the Church of St. Edward, Dringhouses, Yorkshire, Edward Rogers Covey, Esq., of Alderton, to Emily, youngest daughter of the late Hugh Morton, M.D., of Newark-on-Trent, Notts.

FRANK—CAMPBELL.—On December 5, at the British Vice-Consulate, Cannes, France, and afterwards at Christ Church, Philip Frank, M.D., F.R.C.P., late Army Medical Staff, to the Lady Agnes Campbell.

GORDON—WAINWRIGHT.—On December 11, at Hornsey Parish Church, Thomas Shephard Gordon, Esq., Crouch-end, to Kate, sole surviving family of John Wells Wainwright, M.D., Temple, London.

LYONS—SPENCER.—On December 9, at St. George's Church, Hanover-square, Thomas Lyons, Esq., Indian Medical Service, to Martha Elcanor (Pattie), youngest daughter of Mr. Paul Spencer.

MAINGUY—DAVENPORT.—On December 7, at St. James's, Paddington, Ferdinand Beckwith Mainguy, Captain Royal Engineers, to Frances Matilda, younger daughter of James Davenport, M.D., late Bengal Army.

DEATHS.

ATKINSON, JAMES, Assistant-Surgeon, on half-pay, at Cullenswood-terrace, Ranelagh, on November 29, aged 31.

BOXWELL, RICHARD, M.B., T.C. Dublin, L.R.C.S.I., late H.E.I.C.S. (retired list), of Abbeyleix, Queen's Co., on November 28.

BURNETT, MARGARET JANE, second of daughter of the late Sir William Burnett, M.D., K.C.B., Director-General of the Naval Medical Department, at the Treasury, Chichester, on December 12.

COLLINGS, ADOLPHUS, M.D., Surgeon (half-pay) 40th Foot, at Grange-hill, Guernsey, on December 1, aged 56.

DAVIDSON, JOHN, Assistant Resident-Physician at Middlesex Hospital, younger son of George Davidson, merchant, Aberdeen, at the Middlesex Hospital, of typhoid fever, on December 5, aged 24.

DRUMMOND, MINNA, the beloved wife of James Drummond, M.D., at 17, Promenade des Anglais, Nice, France, on December 9.

DUKES, ALICE MARY, the wife of Clement Dukes, at Rugby, on December 12, aged 21.

MURRAY, SIR JAMES, M.D., many years Inspector of Anatomy for Ireland, and Physician to the Lord-Lieutenant, 19, Upper Temple-street, Dublin, on December 8.

NALTY, JOHN, M.D. Edin., M.R.C.S. Eng., at 6, Clare-street, Dublin, on December 7, aged 73.

NORTON, JOHN EDWARD, M.D., at Grey Friars, Chester, suddenly, on December 5.

RAINES, CHARLES, M.R.C.S., L.S.A., at Clarence House, Hull (the residence of his brother-in-law, E. C. C. Hart, Esq.), suddenly, on December 11, aged 21.

SMITH, CAROLINE, wife of Thomas Heckstall Smith, F.R.C.S., of Rowlands, St. Mary Cray, at the residence of her son, Courtney-terrace, Cliftonville, Brighton, on December 8, aged 65.

SPENCER, JOSEPH FROWD, M.R.C.S., formerly of Fonthill Gifford, Wilts, on December 7, at Brompton, in the 90th year of his age.

WALKER, ELIZA, widow of the late Adam Walker, M.D., at the residence of her daughter, Mrs. Tickell, Ravensworth, Cheltenham, on Dec. 10, in her 90th year.

WILLIAMS, CAROLINE ANNE, the wife of John Williams, M.D., of Sudbury, Suffolk, on December 8, aged 31.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House-Surgeon. Must be a registered Medical Practitioner. Applications and testimonials to the Secretary, Infirmary, Bangor, on or before January 2, 1872.

EARLSWOOD ASYLUM.—Assistant Medical Officer. Must be duly qualified and registered. Applications and testimonials to the Secretary, on or before December 18.

EAST SUSSEX, HASTINGS, AND ST. LEONARD'S INFIRMARY.—The appointments of Physician and Assistant-Physician are vacant. The qualifications required are as follows:—Doctor or Bachelor of Medicine of Great Britain or Ireland, or Fellows or Members of the Royal College of Physicians of London, Edinburgh, or Dublin. Applications and testimonials to the Secretary, on or before January 1.

JERSEY GENERAL DISPENSARY.—Medical Officer. Further particulars of the Rev. P. A. Le Feuvre, Oakwalk, Jersey. The election takes place early in January, and the duties will commence on February 1.

MANCHESTER ROYAL INFIRMARY.—Senior House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to Dr. Reed, on or before December 22.

METROPOLITAN FREE HOSPITAL, DEVONSHIRE-SQUARE, CITY, E.C.—Honorary Surgeon. Must be F.R.C.S., or pledged to become such within twelve months. Applications and testimonials to Mr. G. Croxton, Secretary, on or before December 23.

NUNEATON UNION.—Medical Officer and Public Vaccinator for the Nuneaton District. Candidates are required to possess the qualifications prescribed by the Local Government Board. Applications and testimonials to Mr. John Estlin, Clerk, Nuneaton, on or before December 26. Election on the 27th.

ROYAL SOUTH LONDON DISPENSARY.—Honorary District Surgeon. Apply to Mr. Hentsch, at the Dispensary, St. George's-cross, Lambeth, S.E.

St. PANCRAS AND NORTHERN DISPENSARY.—Resident Medical Officer. Must be qualified in Medicine and Surgery. Applications and testimonials to the Secretary, Mr. S. S. Wigg, 33, Gordon-street, Gordon-square, W.C., on or before December 18.

UNIVERSITY COLLEGE HOSPITAL.—Assistant Obstetric Physician. Applications to Mr. John Robson, B.A., on or before December 18.

WEST BROMWICH DISTRICT HOSPITAL.—House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to the Hon. Sec., on or before December 16.

UNION AND PAROCHIAL MEDICAL SERVICE.

** The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Keighley Union.—Dr. Usher has resigned the Bingley District; area 9614; population 12204; salary £50 per annum.

Manchester Township.—Mr. Edmund Manley has resigned the St. Michael's District; salary £170 per annum.

Penistone Union.—Mr. George F. Trotter has resigned the Penistone District; area 17,380; population 4887; salary £21 per annum. Also the Workhouse; salary £30 per annum.

Ripon Union.—Mr. E. Smith has resigned the Third District; area 19,834; population 3269; salary £30 per annum.

St. George-in-the-East Parish.—Mr. Benjamin Baker has resigned the North District; area 108; population 26,000; salary £230 per annum.

Wolverhampton Union.—Mr. H. D. Best has resigned the Sixth District; area 848; population 12,178; salary £77 4s. per annum.

APPOINTMENTS.

Bosmere and Claydon Union.—Edward Beck Hammond, M.R.C.S., L.S.A., to the Claydon District.

Christchurch Union.—James Henry Cartwright, M.R.C.S.E., L.S.A., to the Eastern District.

Shoreditch Parish.—Albert W. Wallis, M.R.C.S.E., L.S.A., to the Brentwood School.

Wem Union.—George Edward Elton Burroughs, M.R.C.S.E., L.S.A., to the Prees District.

West Derby Union.—Wm. Little, L.R.C.P. Edin., L.R.C.S. Edin., to the Workhouse for Sick Poor.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The next meeting will be held on Saturday, December 16, at 7.30 p.m., at the Scottish Corporation Hall, Crane-court, Fleet-street. A report will be read on the "London Water-supply." W. H. Michael, Esq., barrister-at-law, will deliver an address "On Future Sanitary Legislation."

SIR ALEXANDER ARMSTRONG, M.D., K.C.B.—In accordance with an Order of Council, this gentleman has been placed on the retired list, from the 4th inst., of Inspector-General of Hospitals and Fleets.

DR. H. J. DOMVILLE, C.B., Deputy Inspector-General of Hospitals and Fleets, and Chief Medical Officer of Melville Hospital, will, with the sanction of the Lords of the Admiralty, hold that appointment for another year, and so complete a term of five years' staff employment.

THE SYME TESTIMONIAL.—The Surgical Fellowship intended to be founded in honour of this great Surgeon has already received subscriptions to an amount which will yield about £100 a year.

MR. EDWARD COCK.—This deservedly popular member of the Court of Examiners of the Royal College of Surgeons, in resigning his seat at that Board, at a meeting of the Council on the 14th inst., requested he might not be nominated for re-election. Mr. Cock, who has done good suit and service to the College, was elected a member of the Council in 1856; of the Court of Examiners in 1867, with Sir William Fergusson and the late Mr. Solly; and in 1869 was elected President of the College.

INSPECTOR-GENERAL F. W. INNES, M.D., C.B., has been appointed Principal Medical Officer at Netley, *vice* Inspector-General Beatson, M.D.

SCARLET fever in a somewhat virulent form has appeared at Himbleton.

AN Infirmary and Dispensary is being erected in High-street, Shoreditch, and is an extension of the Workhouse. Accommodation is provided for 150 beds.

SICKNESS AMONG THE POOR.—It is stated that the Workhouse at Newington, which is used only for the reception of sick paupers, was last week so full that forty persons had to sleep on the floors.

WILLIAM HEREFORD, a gentleman possessed of extensive property in Southwark, was fined on Monday, by the Southwark police magistrate, three guineas and costs, for refusing and neglecting to perform certain sanitary works ordered by the authorities at 26, Charles-street, St. John's, where fifty girls were employed at staymaking, and the place in a very unhealthy state.

It is telegraphed from India that a Medical committee reports that the Delhi Camp may safely be formed again. No new cases of cholera have occurred.

CHOLERA has appeared in Lucknow. Though very fatal to natives, only one or two cases among Europeans have hitherto been recorded.

THE last quarterly report of the Hospital for Consumption, Brompton, states that the number of patients admitted since August 3 was 276; discharged (many greatly benefited), 239; died, 25; new out-patient cases, 3041.

PROFESSOR LONGET AND BARON PAUL DUBOIS.—During the last week two funereal ceremonies of great interest have occupied the attention of the Profession in Paris. The obsequies of Professor Longet, who died during the siege, were celebrated. He had scarcely reached his 60th year, and during the last ten years he had frequently, on account of ill-health, been obliged to suspend his labours, and his courses on Physiology in consequence excited much less attention than they deserved. His great work on Physiology, produced with an immense amount of painstaking labour, that rendered its production very irregular, and its printer almost desperate, will ever remain a noble monument of which his country may well be proud. Baron Paul Dubois was in his 76th year, but during the last ten years his mental powers have gradually become extinct; and it is remarkable that while, when they were in their vigour, he was dyspeptic and delicate in health, after they had become extinguished his frame entered on the vigorous enjoyment of all its functions. His great success as a clinical teacher, and his extensive private practice, enabled him greatly to influence the progress of Obstetrical Medicine in France, a whole school of now distinguished accoucheurs having served under him as *chefs de clinique*.

WAXED PAPER AS A DRESSING.—A correspondent of the *Deutsche Klinik* (November 18) states that, at the St. Hedwig's Hospital, this has been found of great utility in covering over applications which it is desired to keep in a moist state. It is therefore especially indicated as a covering to wet compresses in suppurating wounds. It is easily adapted to all parts of the body, lying lightly and smoothly. Owing to its lightness, it is preferable to gutta-percha textures as a covering for cataplasms when applied to the abdomen or chest. It is very cheap, and its durability, considering its light texture, is considerable. It may be wetted and dried again, so as to serve for a week. It is sold by C. Geffer, Surgical instrument maker, 2, Schiffbauerdamm, Berlin.

THE ARTESIAN WELL AT ROCHEFORT.—An artesian well, at the Marine Hospital, at Rochefort, has been sunk to the depth of 846 metres, the depth of the wells at Grenelle and Passy not exceeding 700 metres. The temperature of the water is 41° C., and agrees pretty well with the law which attributes 1° for each thirty-three metres of depth. While the waters derived from other artesian wells contain but little of saline matters, that of Rochefort contains a great deal, and, among others, the sulphates of soda and lime, chloride of sodium, iron, manganese, etc. The water is quite unfit for either drinking or washing. A curious circumstance has been observed during the boring—namely, that the tubes became magnetised during the process of perforation, and, when separated, constituted so many magnets, capable of communicating magnetic properties to iron.—*Gazette Médicale*, December 9.

THE disinfecting power of carbolic acid seems yet to be dubious, and certainly not so great as to be relied upon. Dr. H. J. von Ankum inserted a paper in *Morandschrift voor Natuurwetenschappen* stating the following facts:—Atmospheric air, to which are added the vapours emanating from carbolic acid, is unable to hinder the development of lower organisms in water with hay, in milk, and in urine. He put those substances under a glass bell, with an opening at the upper side, and surrounded by little cups filled with carbolic acid. All was placed in a ventilating closet, and the arrangement was such that the air that passed the above-named substances was mixed, if not saturated, with the vapours of carbolic acid. After the lapse of a little time, the development of lower organisms took place just as if the fluids had been exposed to the free air. Von Ankum made use of pure and impure carbolic acid, and only once he saw, in using the impure strong-smelling carbolic acid, the formation of those organisms retarded and not take place in so many forms. He concludes, from his experiments, that no disinfecting action can be expected from the vapours of carbolic acid when they are mixed with the atmospheric air in such quantity that the respirations can take place in it without damage.

MIDWIVES AT KENSINGTON.—The Board of Guardians of this Union have, as we indicated some weeks since, resolved to supply midwives, instead of Medical officers, at a fee of five shillings for each confinement. If a case be urgent, a Medical Practitioner is to be called in—a wise and safe proviso.

DR. HARDWICKE, at an inquest on the body of a woman who was burned to death in a fire which destroyed a house in Peter and Key-court, Cow-cross, said it was a great pity that the whole of the infamous nest of fever, etc., in Cow-cross had not been burned down—the houses were a disgrace to the parish. Verdict, "Accidental death."

A DUST contractor employed by the Camberwell Vestry has been fined £100 for neglecting to fulfil the obligations of his contract. If other Boards would show the same determination in insisting on the performance by dust contractors of the duties they undertake, there would be fewer complaints, and the public health would be more satisfactory.

THE Factory Inspectors, in consequence of the extension of the system of Government inspection from factories to workshops, have written to the Home Secretary, complaining that the new duties imposed upon them are derogatory to their dignity, and that their present pay is insufficient for the duties required of them.

HEALTH OF SCOTLAND.—The deaths of 2611 persons were recorded in the eight principal towns during November, of whom 1302 were males and 1309 females. Allowing for increase of population, this number is 32 above the average number for the month during the last ten years. A comparison of the deaths registered in the eight principal towns shows that during November the annual rate of mortality was 16 per thousand persons in Perth, 23 in Leith, 26 in Aberdeen, 29 in Edinburgh, 30 in Glasgow and in Paisley, 31 in Greenock, and 33 in Dundee. Of the 2611 deaths registered, 1064, or 41 per cent., were of children under 5 years of age. In Perth, 28 per cent. of the persons who died were under 5 years of age; in Edinburgh, 34; in Paisley, 35; in Dundee, 37; in Leith, 38; in Aberdeen, 41; in Glasgow, 44; and in Greenock, 51 per cent. The zymotic (epidemic and contagious) class of diseases proved fatal to 721 persons, constituting 27.6 per cent. of the mortality. This rate was exceeded in each of the following towns: in Aberdeen from the prevalence and fatality of measles, in Edinburgh and in Greenock from that of scarlatina, in Dundee from small-pox, and in Leith from small-pox and scarlatina combined. Small-pox continues greatly on the increase, and is now the most fatal of the epidemics. In the eight towns 157 deaths, or 6.0 per cent. of the mortality were ascribed to this disease. In Dundee 26.0 per cent., in Leith 21.3 per cent., and in Edinburgh 6.3 per cent. of the deaths arose from that disease. Scarlatina caused 136 deaths, or 5.3 per cent. of the mortality. In Leith 9.0, in Edinburgh 10.9, and in Greenock 19.2 per cent. of the deaths were from this disease. Fever caused 129 deaths, or 4.9 per cent. of the mortality. Of these, 54 were ascribed to typhus, 36 to enteric, 32 to relapsing, 2 to simple continued, and 5 to infantile remittent fever.

COMPOSITION AND QUALITY OF THE METROPOLITAN WATERS IN NOVEMBER, 1871.—The following are Dr. Letheby's returns to the Association of Medical Officers of Health:—

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen required by Organic Matter, &c.	Nitrogen.		Hardness.	
			As Nitrates &c.	As Ammonia.	Before Boiling.	After Boiling.
<i>Thames Water Companies.</i>	Grains.	Grains.	Grains.	Grains.	Degs.	Degs.
Grand Junction	—	—	—	—	—	—
West Middlesex	18.97	0.018	0.139	0.000	15.0	3.5
Southwark & Vauxhall	20.33	0.071	0.112	0.005	15.8	3.7
Chelsea	21.17	0.076	0.129	0.005	16.1	3.8
Lambeth	20.33	0.075	0.131	0.002	15.8	3.5
<i>Other Companies.</i>						
Kent	27.87	0.013	0.242	0.000	20.1	5.8
New River	29.77	0.026	0.140	0.001	16.0	3.7
East London	21.79	0.053	0.119	0.003	16.2	4.2

Note.—The amount of oxygen required to oxidise the organic matter, nitrites, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters the quantity of organic matter is about eight times the amount of oxygen required by it.

The water was found to be clear and nearly colourless in all cases. The average quantity of water supplied daily to the metropolis during the preceding month was, according to the returns of the Water Companies to the Association of Medical Officers of Health, 105,645,974 gallons; and the number of houses supplied was 491,485. This is at the rate of 32.4 gals. per head of the population daily.

LORD LEIGH laid, on the 4th inst., with Masonic honours, the foundation-stone of the new wing to the Queen's Hospital, Birmingham. His Lordship made an admirable and effective speech on the occasion. There were great demonstrations of rejoicing. A luncheon at the Great Western Hotel followed the ceremony, and in the evening there was a *soirée* at the Town Hall, presided over by the Mayor. Of the £6000 subscribed, £4000 has been contributed by working-men.

NOTES, QUERIES, AND REPLIES.

Be that questioneth much shall learn much.—*Bacon.*

F. A. B., Reading.—In the volumes of the *Medical Times* for 1849, 1850, and 1851.

LL.D., Highgate.—Apply to the Professor. We should think they would be; yet not, perhaps, till they have been delivered again and revised.

Emigrant.—1. In 1862. 2. The "cottage Hospital system for insane patients," in Australia, is said to have been introduced by the late Dr. Bowie. 3. Clinical lectures were not at the early part of the present year provided for the students at the Melbourne Hospital; we are not aware if they have been subsequently provided.

COMMUNICATIONS have been received from—

Mr. R. E. POWER; Dr. WHITMORE; Mr. P. ROBERTSON; Mr. HOWSE; Dr. DICKEN; Dr. ALLCHIN; Mr. S. WINTERBOTTOM; Mr. CARSON; Mr. WILLETT; Dr. J. M. MINOR; Rev. S. ALLEN SHONE; Mr. T. PIPER; Mr. CLEMENT DUKES; Mr. FELCE; Dr. BRAKENRIDGE; Mr. J. SANDERS; Mr. C. S. JEAFFRESON; Mr. J. S. SLATER; Mr. S. GREEN; Mr. STEPHEN DARBY; Dr. C. T. WILLIAMS; Dr. FRANCIS HOGG; Mr. J. BESWICK PERRIN; Dr. PARKES; Dr. ROBERTS; Mr. WALSH; Mr. G. W. SHIPMAN; Dr. VINEN; Dr. STEVENSON; Mr. BEDFORD; Mr. C. H. JOHNSON; Mr. R. W. TIBBITS.

BOOKS RECEIVED—

Tanner's Memoranda on Poisons—Sure Methods of Attaining a Long and Healthful Life, with the Means of Correcting a Bad Constitution, translated from the Italian of Lewis Cornaro—Gamgee on Fractures of the Limbs—Blackwood's Desk Diary for 1872—Annual Report of the Borough of Salford.

PERIODICALS AND NEWSPAPERS RECEIVED—

Everybody's Year-Book, 1872—Nature—Pharmaceutical Journal—Edinburgh Daily Review—The Salopian—North British Daily Mail.

APPOINTMENTS FOR THE WEEK.

December 16. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m. ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, 7½ p.m. A report will be read "On the London Water Supply." Mr. W. H. Michael, "On Future Sanitary Legislation."

18. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting. Mr. Thomas Bryant will exhibit some Drawings, and make some Remarks, illustrating the Process of Cell-growth in the Operation of Skin-grafting. Dr. Ogle (of Derby), "Preventive Medicine or Medical Reform—not Parliamentary, but Particular and Individual."

19. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

PATHOLOGICAL SOCIETY, 8 p.m. The following Specimens will be exhibited:—Mr. Lawson, "Case of Blood-cyst" (sequel reported in vol. xviii. of *Trans.*). Mr. Spencer Watson, "Ulcer of Eyelid," removed by Dr. Swift Walker. Mr. A. Norton, "Ulceration of Trachea." Dr. Thorowgood, "Large Salivary Calculus removed by Operation." Dr. Southey, "Caseous Degenerative Disease of Supra-renal Capsules." Dr. Peacock, "Plugging of Middle Cerebral Artery." Dr. Payne, "Hæmatoma of Muscle." Mr. Goodhart, "Casts from the Intestine."

20. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1¼ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

21. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

22. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, December 9, 1871.

BIRTHS.

Births of Boys, 1093; Girls, 1033; Total, 2126.

Average of 10 corresponding weeks, 1861-70, 1969.2.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	927	929	1856
Average of the ten years 1861-70	776.8	767.1	1543.9
Average corrected to increased population	1698
Deaths of people aged 90 and upwards

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 30.05 in. The highest was 30.33 in. on Friday at noon, and the lowest 29.87 in. on Sunday morning.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

ORIGINAL LECTURES.

LECTURES ON EXPERIMENTAL AND PRACTICAL MEDICINE.

By BENJAMIN W. RICHARDSON, M.D., F.R.S.

ON THE SCIENCE AND ART OF EMBALMING THE DEAD.

LECTURE I.

(Continued from page 702.)

THE ORIGIN OF THE ART AND THE PRACTICE.

THE first notice we have of the art of embalming the dead comes from the Egyptians, and we are not only well informed of the methods they pursued but are rendered cognisant of the results they obtained, by the specimens of preserved bodies which they have left us. From their time the practice has proceeded with certain modifications of detail, which until lately have been unimportant. On the whole we may divide the practice into three parts:—

1. Into embalming proper, by the introduction into the body of certain odoriferous essences or antiseptics, aided by after-immersion in saline solutions.

2. Into preservation by simple extraction of water from the tissues—desiccation.

3. Into preserving by the injection of preservative solutions into the bloodvessels.

The first of these lines of practice includes the true Egyptian and Græco-Egyptian process of preservation, and it is most carefully retained for us by the Father of History. Herodotus, travelling through Egypt, was struck by nothing more than the divisions of labour in learned work. The Medical fraternity he discovered divided into almost as many specialities as there were parts of the body; a fact to his mind—instructed as it must have been in the harmony and unity of natural phenomena taught by the higher school of philosophy in Greece—presenting a singular anomaly. Amongst other specialists he found the embalmers, a class hybrid between Medicine and Divinity, making a certain profession of both, yet hardly belonging to either. These professors of the art embalmed somewhat differently, according to the wealth of the embalmed and the fee of the embalmer. They were legally appointed to the exercise of their profession, and when a dead body was brought to them, they exhibited to the friends of the deceased different models highly finished in wood. The most perfect of these they held to resemble one whom the *Pater Historiæ* did not think it religious to name—this was the most expensive model; a second was of less price, and inferior in point of execution; and a third was meaner still. They then inquired after which model the deceased should be represented, and when the price was determined on the relations retired, and the embalmers proceeded with their task. In the most perfect specimens of their art, they drew the brain through the nostrils, partly with a piece of crooked iron and partly by the infusion of drugs; they then, with an Ethiopian stone (fact for Darwinians), made an incision in the side, through which they extracted the intestines; these they cleansed thoroughly, washing them with palm wine, and afterwards covering them with pounded aromatics. They next filled the body with powder of pure myrrh, cassia, and other perfumes, except frankincense. Having sewn up the body, it was covered with *natrum* for the space of seventy days, which time they might not exceed. At the end of this period the body was washed, closely wrapped in bandages of cotton dipped in a gum which the Egyptians use as glue, and returned to the relations, who enclosed it in a case of wood made to resemble a human figure, and placed it against the wall in the repository of their dead.

The above was the most costly way of embalming. For such as chose the middle mode, from a desire of avoiding expense, the embalmers first filled syringes with cedar oil, which they injected into the body per anum, without making any incision or removing the viscera; they then closed the apertures of the body and laid it in brine the specified number of days, on the last of which days they removed the cedar oil which they had previously injected, and with it—such was the strength of it, as they thought—the viscera also, in solution; at the same time the *natrum* had dissolved the flesh, so that there was nothing left but the skin and the bones. They then gave back the body without any further operation to the friends who owned it. The third mode of embalming, which was used for such as had still scantier means, was as follows:—

After washing the inside with *symæa* the embalmers salted the body for seventy days, and returned it to those who owned it.

Between four and five hundred years after Herodotus, Diodorus Siculus, writing on the same subject, shows how little the art had changed since the time of the *Pater*. Those, said he, who have the care of ordering the body are such as have been taught the art by their ancestors. These, showing to the kindred of the deceased an estimate of expenses of each kind of burial, asked after what manner the body should be prepared, and when the terms were agreed upon the body was delivered over to them, and they thus proceeded. First, he who bore the name of *scribe*, laying the body upon the ground, marked upon the flank on the left side how much was to be cut away. Then he who was called the cutter or dissector, with an Ethiopic stone cut away as much of the flesh as the law commanded, and presently ran off as fast as his legs would carry him; those who were present pursuing him, casting stones at him and cursing him, thereby turning all the execrations which were due to his office on him: for whosoever offered violence, wounds, or any kind of injury to a body of the same nature with himself, they thought worthy of hatred; but those who were called the embalmers they esteemed worthy of honour and respect, for they were familiar with the priests, and went into the temples as holy men, without any prohibition. So soon, then, as one of these came to embalm the dissected body, he thrust his hand through the wound and drew out all the viscera except the heart and kidneys, after which another operator washed and cleansed the viscera with wine made of palms and of substances of aromatic odour. Lastly, having washed the body, the embalmers anointed it with oil of cedar (or cedria) and other aromatics for about thirty days, and afterwards treated it with myrrh, cinnamon, and such-like matters, which had not only power to preserve it a long time, but to give it a sweet smell; then they delivered it to the kindred in such manner that every part remained whole and entire, and no part of it changed, but the shape and beauty of the face just as it was before death, so that it could be known; even the hairs of the eyelids and eyebrows remaining as they were at first. By this means many of the Egyptians, continues Diodorus, keeping the dead bodies of their ancestors in magnificent houses, see so perfectly the true visage and countenance of those that died many ages before they themselves were born, that in viewing the proportions of every one of them and the lineaments of their faces, they take as much delight as if the dead were still living among them.

We gather from these histories that the Egyptian method of embalming consisted really of eviscerating, of employing aromatic preservatives, and of exposure of the body to a saline solution—in plain English, pickling. It has been argued by some authorities that the exposure of the body to the saline substance was the first part of the process, and the filling of the cavities with aromatics the last; but the whole argument, beyond what is stated by Herodotus and Diodorus, is merely speculative. It seems clear that the Egyptians used an aromatic powder like to the specimen now before us—a mixture of myrrh and cassia—a strongly preservative compound; and it also seems clear that they used the oil of cedar, and that sometimes they injected this oil into the cavities. The saline solution they employed does not appear to have been saltpetre, but either chloride of sodium (culinary salt), or a mixture of that salt with soda. The saline substance taken by Mr. Pettigrew from a Græco-Egyptian mummy, and chemically examined by the late Dr. Ure, proved to be composed simply of common salt. It is clear that in some instances—instances, I presume, where the embalmer received his highest fee—the description by Herodotus does not supply the details of everything that was carried out by the operator, for we find, in the actual mummies still remaining, the most extensive and skilful bandaging, and also evidence of the employment of bituminous substances—*asphaltum* and *pissasphaltum*. The former was a pure bitumen, called in later centuries *bitumen Judaicum* (Jew's pitch), while the latter was a mixture of Jew's pitch and common black pitch. To these was probably added the oil or essence of some aromatic, such as cedar. In some mummies this bituminous matter has been found in the cavity of the skull and in the ventral cavity; in other specimens the whole body had clearly been immersed in the bitumen before it was bandaged. The bandaging was made with light but rather coarse cloth, somewhat resembling canvas, and was carried apparently from the lower limbs to the upper part of the body, including the head itself, and back again, in layers, several times.

In the most costly specimens, gilding of the surface of the

face and of other parts of the body was practised, and with such perfection that it has been retained in good preservation to the present day.

The results secured by the embalmers of Egypt in the ancient times, however crude they may seem, were good when the highest development of the art was practised by them. This is proved by the specimens that have come down to us. My good and distinguished friend George Cruikshank, who to-day honours us with his company, has brought for us to look at the first-proof of a drawing he took of the face of a Græco-Egyptian unrolled by Mr. Pettigrew at the Charing-cross Hospital, on April 6, 1833. Mr. Cruikshank says that the features of this preserved man, preserved over 2000 years, were so perfect, that there was no difficulty in the task of making an accurate representation of them. The soles of the feet were quite soft, and yielded readily to the pressure of the fingers, while, at the same time, they showed elasticity of structure. The face in this case had been gilded, as had also the upper surfaces of the feet, the thighs, abdomen, and chest. The full account of this mummy will be found in Mr. Pettigrew's admirable work on the "History of Egyptian Mummies": suffice it only to add now, on the authority of our friend, that the immortal Græco-Egyptian, embalmed and gilded regardless of the embalmer's highest fee, and lying over two thousand years in useless preservation, passed speedily in this commercial age into a means of affording quick returns on small profits. The last time Mr. Cruikshank met his antique friend, who gave him so strange a sitting, the said antique was enshrined in Seven Dials for the sake of being seen for the sum of one penny per visitor.

"Imperious Cæsar, dead and turned to clay,
Might stop a hole to keep the wind away."

But our friend's antique out-Cæsar's Cæsar.

The term embalming is applied to the Egyptian art of preserving the dead because preservative balsam or balm was used in the process—*baal-samum*, prince of oils. Much speculation has been offered as to the kind of balm used by the Egyptians, and Prosper Albinus, learned in all such matters, describes with infinite care the plant yielding the balsam, the mode of obtaining it by incision of the branches (called *opobalsamum*), and the balm itself. The fluid was whitish at first and turbid, of a strong pungent smell, like turpentine, but much sweeter and more fragrant, and of a bitter, acid, astringent taste; on being kept it became thin, limpid, light-greenish, and then of golden yellow; after which it again became thick, like turpentine, and lost much of its fragrance. Its smell resembled that of citrons, or rather a mixture of rosemary and sage-flowers. The use of this balsam was, I conclude, confined to the highest class of embalmments, and it was probably mixed with the other aromatics with which the cavities of the body were filled. Bodies thus prepared retained longest their natural condition of structure and feature.

The viscera removed from the body by the Egyptian embalmer were placed in a separate vessel, and, with a sort of funeral prayer, addressed to the "sun and all the gods givers of life," were cast into the Nile.

Such in brief was the Egyptian method of embalming, and, with a few modifications of detail, their method was copied by all the neighbouring nations. The Jews introduced aloes into their preparations, and some other changes from the primitive plan were carried out; but on these I need not dwell.

One marked difference of mode does, however, remain to be told. Herodotus records that the Ethiops *desiccated* the bodies of their dead, painted and dried the bodies to represent life, and, finally, enshrined them in columns of transparent solid substance, so that they could be seen by the living. For one year the dead man, thus crystallised, was kept in the house of his friends, after which time he was removed, and was set up in the town where he had lived. What the nature of the transparent substance used to envelope the dead might have been is not known. It has been assumed to have been glass; it has been assumed to have been amber, or a fossil crystal.

We travel from these early times through many centuries, never historically to lose sight of the art of preserving the dead by one or other of the methods named. Camerarius, the author of that quaintest of quaint old books, "The Historical Meditations," tells us that brass was considered to be a preservative of the dead, and that on this belief rests the custom of using brass in the coffins that receive the dead. He, too, quoting from Gyrard de Cambrea, affirms that people in the Isle of Arran will not putrefy after death, so that the bodies of the Arrans are naturally preserved. Further, he tells us, on the authority of Peter Martyr, that the Spaniards found at

Comagna, in the New World, a chamber of a cacique full of the dried dead bodies of his forefathers.

The statement by Peter Martyr is sustained, in respect to the inhabitants of Peru, by Garcilasso de la Vega, who, however, described a process of preservation different from desiccation. The Peruvians, he says, embalmed the bodies of their kings by burying the corpses in snow, to dry them; after which they applied to the bodies a kind of bitumen, which kept them in such entirety, they seemed as if they had been alive. The same people of Peru have continued the practice of preservation, principally by desiccation, until a later day, the bodies of the dead being placed in sand and exposed to the heat of the sun. These bodies have commonly, when they are unearthed, a crouched sitting position; they are little more than skeletons covered with dried skin.

Pettigrew, quoting from Glass's "History of the Canary Islands," takes from a translation of an ancient Spanish manuscript an account of the manner in which the people of the Canaries preserved their dead. They carried the dead body in a case, stretched it out on a flat stone, opened it, and took out the bowels; then twice a day they washed the porous parts of the body—viz., behind the armpits, behind the ears, the groin, between the fingers, and the neck with cold water. After sufficient washing, they anointed those parts with sheep's butter, and sprinkled them with a powder made of the dust of decayed pine trees, and a sort of brushwood which the Spaniards called *bressos*, together with the powder of pumice-stone; then they let the body remain until it was perfectly dry, when the relatives came and swathed it in dressed goat-skins, girding all tight with thongs of leather. The body was finally placed in a cave. In some cases amongst the Guanches, the cavities of the body, after being washed with salt water, were made to receive aromatic substances, and the whole body was then dried in the sun or in air artificially heated. The same authority (Pettigrew) records that at Palermo, at the Convent of the Capuchins, the bodies of the monks were all preserved, the skin and flesh, by some process of putrefaction, being rendered quite hard, so as to resist decay. These bodies, habited in the clothes they usually wore, were preserved in the standing posture. In Burmah the priests of the highest orders are, I learn, still subjected to a peculiar process of embalming. The plan is to eviscerate, to fill the cavities with aromatic spices and honey, and afterwards to coat the whole external surface with a layer of vegetable wax, on which gold-leaf is laid. Another practice by these same people related by Pettigrew, on the authority of Captain Coke, a practice of thrusting hollow bamboo canes from the soles of the feet into the body, and of injecting preservative fluids through these tubes, is now unknown.

The methods of preserving the dead I have immediately sketched have been limited to particular communities. The all but universal method that prevailed for centuries was, practically, the Egyptian. By this method for two thousand years the great potentates of the earth were held in a little longer suspension against nature, the mode of procedure passing down by tradition, and known but to a few practitioners of the art. Such modifications as really occurred in the art are quickly related. Lewis de Bils, in 1750, proposed to embalm without evisceration of the body. After him, Gabriel Clauderus, in 1769, introduced the plan of injecting into the cavities of the body what he called his "balsamic spirit," which consisted of one pound of salt of tartar, half a pound of sal-ammoniac, and six pounds of water. Into this same solution he also immersed the whole body, and allowed it remain immersed eight weeks; after which he dried it in the sun or in heated air. Some time after Clauderus, it became the practice to make incisions into the bodies of the dead that were to be preserved, and to insert into the incised parts tincture of myrrh or other similar antiseptic substance. Lastly, there came into operation an improved covering for the embalmed—a cere-cloth coated with wax, oil, and aromatic preservatives. The whole process, as it was carried out a little more than a century ago, is described in the following directions by one of the ablest Surgeons England has ever produced—I mean Benjamin Gooch, of Norwich; and he is supported almost entirely by the great authority of the last century in class-book Surgery—Benjamin Bell, of Edinburgh.

"After evisceration," says Gooch, "as has been directed in opening a dead body, and continuing the incision farther upwards—even into the mouth, and, if practicable, without cutting the skin of the neck—all the cavities are to be well cleansed, and the humidity sucked up with sponges, then washed with tinctura myrrhæ, and filled with a *species* compounded of fragrant herbs, aromatic drugs,

and gums reduced to powder, not very fine, first restoring the heart to its former residence, after having opened its ventricles, cleansed and washed them with the tincture, stuffed them with *the species*, and sewed them up; and then the cavities are to be stitched very close with the glover's or spiral suture. Large and deep incisions are also to be made in all the most fleshy parts, cleaning and washing them with the tincture in the same manner, filling them with the antiseptic *species*, and stitching them up. Then the head, trunk, and limbs are to be perfectly well covered with cere-cloth; putting a piece under the chin, to be secured by sewing on the top of the head; after having well adjusted the cap of the skull, sewed the scalp together, and cleaned the mouth, as has been directed for the other parts, and putting in some of *the species*. The cere-cloth is to be prepared with a composition made of wax, resin, storax, and painter's drying oil S.A. After the application of the cere-cloth with great care and exactness, cut into suitable pieces, according to the respective parts, and closing them well everywhere, the face, being close-shaved, is to be covered with some of the above composition, melted and laid on with a brush of a proper degree of heat, and of a moderate thickness—and it may have a faint flesh colour given to it with vermilion; and when it has grown cold and stiff upon this part, it may be lightly struck over with hard varnish—or this varnish, applied thick, may here serve the purpose alone. A cap is to be well adapted to the head, falling down upon the neck, and to be sewed under the chin, making a few circular turns about the neck with a roller of a fit breadth. All the rest of the corpse is to be enclosed in a sheet, to be artfully cut, and sewed on very close and smooth with the finest tape, over which an appropriate dress is to be put, as the relations or friends think fit to direct and appoint, and then laid into a coffin, which should be in readiness; but when it is some great personage, who is to lie in state for public view before the funeral rites are solemnised, the dress must be appropriate to his dignity and character. The brain and other viscera are to be put with some of *the species* into a leaden box. Sometimes the heart, prepared as has been directed, to preserve it from putrefaction, is deposited in an urn by itself."

With Gooch and Bell, the ancient process of preserving the dead by embalming proper ceased to be. We reach now to William Hunter, who perceived a way of preservation by injection of the bloodvessels. Hereupon a new era was developed, to which I propose to direct attention in another lecture—a lecture that shall bring the practice from his—William Hunter's—to the latest of our own time.

CLINICAL

LECTURES ON OPHTHALMOLOGY,

DELIVERED AT

St. Thomas's Hospital,

By R. LIEBREICH,

Ophthalmic Surgeon and Lecturer to the Hospital.

ON THE TREATMENT AND THE ORIGIN OF PURULENT OPHTHALMIA IN NEW-BORN CHILDREN.

GENTLEMEN,—You have had the opportunity of observing among the out-patients a series of cases of purulent ophthalmia in new-born children. Several questions have been put to me on the nature of this disease and its treatment: therefore it would be useful to go more explicitly into the subject. Every Practitioner ought to thoroughly understand the principles upon which this disease is to be treated. I am sorry to observe that in England, as well as in Germany and France, old prejudices in regard to the treatment of this disease have for a long time been established in the mind of the public, and have exercised a most pernicious influence. Mothers, grandmothers, nurses, and midwives, and, unfortunately, even Medical men, concurrently destroy by injudicious treatment many eyes which could be saved with ease and certainty.

For, Gentlemen, this is not a disease which is amenable to treatment only up to a certain degree, and which may lead to unfavourable results even under the most rational treatment; but, on the contrary, it is an affection which, even in its worst form, is always perfectly curable.

What, now, is this treatment? It consists, first, in careful cleansing; secondly, in the local application of cold; and, thirdly, in cauterisations with mitigated nitrate of silver (one part of nitrate of silver and two parts of nitrate of potassium fused together). Allow me now to speak of this in a somewhat ele-

mentary and detailed manner. As regards the cleansing, it is above all necessary to explain to the attendants the importance of it, for, ordinarily, the fear of injuring the child prevents them from properly opening its eyes in order to remove the secretion. I do not recommend syringes, so generally used, for cleansing—first, because they are dangerous to the attendants, who, in using them, may easily have some of the contagious matter spattered into their eyes; secondly, because by this method the secretion is not completely removed, even after pouring much water over the child. A fine sponge, if you can rely upon it being kept clean, or, if not, small pieces of moistened linen rag, are preferable for effectually cleansing the conjunctiva.

The application of cold, if made in a careful and suitable manner, is of great assistance in the treatment. In the mildest form of the disease this application alone may even effect a cure in a few days. It is then only necessary to apply, for several hours a day, small linen rags, moistened by being dipped in cold water, changing them constantly. In the more serious cases, on the contrary, when there is much swelling, redness, and heat in the eyelids, and a copious discharge of thick yellow purulent secretion, it is necessary to apply, day and night, without intermission, small rags, previously placed upon ice, and to renew them continually. Later, when the elevated temperature begins to fall, the applications may be discontinued during the night, and gradually reduced, according to the course of the disease. In order to prevent the child from taking cold, it is necessary that the rags should be of a size merely to cover the eyelids without touching the bridge of the nose, and not to make them too wet.

We now come to the real curative treatment—that is, the cauterisation. It should only be done with mitigated nitrate of silver. The eyelids must be reversed one after the other, and, after being carefully cleansed, touched with the caustic, which must be passed over all the swollen and red part of the mucous membrane. Before replacing the eyelids in their natural position, it is necessary to neutralise the free nitrate of silver by a drop of salt water. For the first few days only of the disease we may restrict the treatment to the application of cold, and then commence the cauterisations; repeat them once a day, never more frequently, and, after an evident reduction of the disease, once every two or three days. It is important not to repeat the cauterisation until the scar of the previous one has disappeared.

To drop weak solutions of nitrate of silver into the eye is not advisable, even in the mildest forms; for the graver forms it is completely insufficient. Cauterisation with pure nitrate of silver ought never to be used, neither in this nor in any other disease of the conjunctiva, as it is impossible to limit its effects. The slightest touch with pure nitrate of silver, in fact, produces a strong cauterisation, not only not limited to the surface of the mucous membrane, but attacking the subjacent connective tissue. The cicatrization which is the result of such cauterisations produces a permanent irritation of the eye, which cannot be removed by any possible means. None of the other known caustics can replace the mitigated nitrate of silver in the treatment of purulent ophthalmia. Let nobody avoid the trouble of preparing a pencil of nitrate of silver himself if he has not a suitable one already prepared at his disposal. The sole difficulty lies in procuring an iron mould, into which the mixture of one part of nitrate of silver and two parts of nitrate of potash is to be poured after having been melted over the fire. This difficulty could be avoided by immersing an iron wire repeatedly with one end into the melted mass until, on cooling, a sufficiently thick layer of caustic adheres to it. That is the procedure which I formerly recommended for caustic probes in cases in which it is desirable to cauterise with a very fine point or in a very narrow canal (lacrimal canals, lacrimal sac, ciliary roots, etc.).

In the most difficult cases, cleanliness, cold, and cauterisation are sufficient, and enable you to form a good prognosis. The case is, however, different when children come under your treatment, after a more or less great part of the cornea has already been destroyed, the iris projecting, the capsule of the lens injured; here the prognosis depends entirely, in the individual case, on the existing destructions. Ulcers of the cornea of no great extent, and not too near to perforation, allow of a still favourable prognosis; but it becomes more unfavourable already, when perforation has taken place, and the iris projects. There is a decidedly bad prognosis if almost the greater part of the cornea had been destroyed before the child came under your treatment.

In such grave complications, it is sometimes desirable to cut off the projecting iris, or to let out the lens. But I advise

you generally to abstain from those operations, which require considerable experience and practice. Direct your attention, then, exclusively to the quick cure of the affection of the mucous membrane, whatever the complication may be which neglect and false treatment have caused. You will be astonished to see how quickly even the gravest complications come to a comparatively favourable cure, as soon as the possibility of it has been given by the removal of the affection of the mucous membrane. I have shown you an instance of it in a child, in one of our previous meetings; it was brought as an out-patient, after it had suffered for more than three weeks from a very high degree of purulent ophthalmia, and had been treated during all that time with warm milk.

The corneæ of both eyes were perforated to a great extent, the iris protruding from the corneal wound, and the cornea of the right eye almost destroyed to half its extent. By care and cleanliness, application of cold, and daily cauterisation, the swelling and secretion of the mucous membrane speedily subsided, and spontaneously cicatrised of the corneal ulcers, as favourable as could be expected, took place, although deliberately I limited my treatment exclusively to the affection of the conjunctiva, without touching the protruded iris—nay, even without the application of atropine. Nevertheless, you now see on its right eye only a leukoma, with a fine black dot in its centre, which indicates the place of the previously existing protrusion of the iris. There is, besides, a sufficiently large and transparent part of the cornea for iridectomy to be performed at a later period. As regards the left eye, it is to be expected that without an operation a tolerably good vision will be preserved, because the very much smaller cicatrix of the cornea is situated more towards the side, and leaves the greater part of the natural pupillary region uncovered. The protruded iris of this eye has spontaneously returned, and the previous existence of the protrusion is now only to be seen by the adhesion between a small part of the iris and the inner surface of the corneal cicatrix. If this case had been simply neglected for three weeks, without using warm milk—a popular remedy so favoured in spite of its mischievous influence—the destruction would have probably not reached so high a degree; but if, on the contrary, a rational treatment had been begun eight or ten days earlier, the disease would have been cured without leaving any disagreeable consequences.

If you inquire into the cause why the use of warm milk or of moist heat in general, in spite of its evident mischief, and in spite of the repeated warnings of ophthalmologists, could have gained ground in all countries, amongst the public as well as amongst general Practitioners, you will find that it originated in an erroneous supposition on the nature and origin of the affection.

It has always struck me with what haste relatives or nurses declare, as soon as they bring a case of purulent ophthalmia for treatment, that the affection is due to having caught cold. The same will be told you if you have to examine grown-up people, where you will find the results of an ophthalmia from which the individual has suffered immediately after his birth. In addition to the erroneous supposition of having caught cold in the eye, comes the wrong principle of treating that cold by warmth; and these errors have preserved themselves for generations, in spite of all the opposition against them. Let us, therefore, first of all, understand the pathogenesis, of which, in my opinion, there is not the slightest doubt.

You may accept it as proved that any pathological secretion of any mucous membrane, be it catarrhal or purulent, brought into the conjunctival sac, will cause a pathological condition of the conjunctiva, which will, on the one hand, according to the nature of the secretion, and on the other hand, according to the peculiar disposition of the individual, assume a variety of appearances. On going through the maternal passages, the eyes of the child are exposed to inoculations from two quite different sources. They are—first, gonorrhœal secretions from the urethra of the mother (this causes the most formidable cases of purulent ophthalmia, but only an extremely small percentage of the cases are due to that cause); by far the greater majority of cases are due to inoculation from the second of the two sources—namely, the secretion due to the increased functional activity in which the maternal passages are in the last month of pregnancy. According to the nature the secretion had taken in a given case, and according to the quantity of it introduced into the eye of the child, we shall see a series of affections ranging from simple conjunctivitis up to those forms of purulent ophthalmia which in no way are different from those caused by gonorrhœic secretion.

Whatever cause may have produced the disease, and whatever degree it may have reached, let me repeat to you it must

be cured without leaving any serious pathological changes by a rational treatment, if early directed against it. Let us hope that rational principles in regard to this disease will soon be so generally spread that blind asylums will cease to be filled, as is now the case, by individuals who have lost their sight by purulent ophthalmia.

ORIGINAL COMMUNICATIONS.

A CASE OF

NEURO-SYPHILIS WITH APHASIA.

By RICHARD EATON POWER, L.R.C.P. Lond., etc.

J. B., aged 27, came under my care July, 1870, suffering from ophthalmia, with rheumatic enlargement of the knee.

Previous History.—By profession an engineer; acknowledged to have led a very fast life, and to have suffered severely from syphilis. His Hospital records date from July 21, 1868, when he was under treatment for rheumatism; discharged relieved in October of the same year. In January, 1869, he was re-admitted, and treated for periostitis, and subsequently, in consecutive order, for sorethroat, enlarged glands of the neck, and ophthalmia, with which latter affection and rheumatism he suffered when first I saw him, and was kept under treatment up to November, 1870, when he was discharged, all the prominent symptoms having disappeared. He was again admitted the month following with abscess over the occipital bone, which subsequently left behind a small patch of caries on the left side of the occipital protuberance.

Under treatment, the ulcer healed, and in June, 1871, he had gained thirty-three pounds in weight, looked fat, and felt stronger than at any time since his reception into Hospital. On more closely examining him before discharge I fancied the mouth was slightly awry, but on testing further the muscular contractions were perfectly symmetrical, and, presuming that what I observed was a natural obliquity, and with the hope that fresh air and change from Hospital life might benefit him, I discharged him.

He was carried in the following morning in a state of right hemiplegia, having fallen down a short time previously in a fit. When I saw him two hours after, the paralysis (motor) was incomplete in the lower extremity and complete in the upper. The facial paralysis was well marked on the same side, articulation being much impaired, and partial aphasia present. Whilst undergoing examination he suddenly regained use of the arm, but not of the hand, which yielded a little to the flexors, and by evening his power of articulation was increased. These improvements were, however, but temporary, for another fit was followed by complete motor paralysis (right) with aphasia, which latter remained after he again recovered partial power of articulation. Curious, too, being aware of his inability to remember the word he wanted, he made signs for a pencil, and then found that he could not remember the shape of the letters.

A third fit was followed by complete unconsciousness, which continued until death on September 19, 1871.

On post-mortem examination, the brain was found highly congested, with some serous effusion, but not to any considerable amount. The left middle cerebral artery was atheromatous, and hard as a pipe of macaroni; and on tracing it into the fissure of Sylvius for about an inch, it terminated in a space of white softening, about the bulk of a walnut.

Of the treatment I have said nothing, as, though doubtless the patient received benefit at times, it was powerless to remove the *materies morbi* which was slowly but surely destroying life. Cod-liver oil seemed to be most efficacious in promoting a tendency to health; he also took iron in different forms, phosphorus, iodide of potassium, bark and sarsaparilla, and strychnia in various combinations. At no time since his admission to this Hospital was mercury administered; but I believe he was treated with that drug for the primary disease.

My object in placing these notes before the Profession is, that they may add another item to the statistics of the relation between intracranial changes and their visible expressions.

Invalid Prison, Dartmoor.

THE Newcastle Coroner has been presented with a sword to support his dignity. It will be remembered he lately spoke regretfully of the decay of the ancient custom of coroners wearing swords.

OBSERVATIONS ON

DR. C. B. RADCLIFFE'S THEORY OF THE GENESIS OF PAIN.

By JOHN CHAPMAN, M.D., M.R.C.P., M.R.C.S.,
Physician to the Farringdon Dispensary.

A REMARKABLE theory, elaborated and propounded by Dr. C. B. Radcliffe, (a) concerning the proximate cause of muscular movement, normal sensation, and pain, has recently attracted some Professional attention, and is exerting an appreciable influence on therapeutics both in this country and in the United States. Physiological theories, whether true or false, which to any extent embody themselves in, or determine the character of, Medical Practice, establish, *ipso facto*, an undeniable claim to consideration by Medical men. Recognising this claim in respect to the theory advocated with much ability by Dr. Radcliffe, I listened to his lectures, in which he explained his views to the Royal College of Physicians, and have read attentively the two volumes which he has since published; and, in the hope of at least promoting the discussion of his doctrines, and, possibly, of contributing something towards the formation of a correct judgment concerning them, I propose to examine what seem to me his most important arguments in support of that part of his theory which relates to the genesis of pain.

In respect to sensation, his cardinal doctrine is, I believe, correctly stated as follows:—During each act of normal feeling there is an electric change in the feeling nerve, and in the sensory centre to which it is related. This change consists in a temporary reversal of the ordinary electric state of the nerve and nerve-centre in question. This reversal is accompanied by a discharge, or loss, of "natural electricity." While this reversal obtains, the vitality of the nerve and nerve-centre is lower than it is when the nerve and nerve-centre are not functioning; and hence a diminution of the normal supply of arterial blood, or the circulation of venous blood in the nervous centres, or, in other words, a lowering of their vitality, increases their sensibility or irritability, and therefore constitutes the indispensable condition precedent of pain.

Having propounded this astonishing theory, and having, as he believes, proved its truth, Dr. Radcliffe repeats the expression of it in several successive propositions, involving statements of pathological facts, which are called as witnesses to prove it. I refrain from discussing the significance of the electro-physiological experiments which he either exhibited in the course of his lectures, or has since adduced, in support of it, and I do so the more willingly because the radical elements of his theory seem to be still undergoing transmutation. In his newly published volume, (b) which, though not avowedly a second edition of his previous work, comprises the substance of it, and is intended to supersede it, he records the discovery of new facts, his recognition of which has necessitated a partial reconstruction, at least, of the foundation of his doctrine. He says—"What to think of this state of things I could not at all see at first. The facts would not chime in with preconceived conceptions, and the end was that the conceptions had to be modified to suit the facts"; (c) and believing, as I do, that the "conceptions" will have to undergo several more metamorphoses before they suit all the facts which a true theory of the genesis of muscular motion and of pain must fully explain, I do not think it at present expedient to attempt a critical analysis of those "conceptions"; but, concerning the pathological facts to which he refers, his interpretation of them, and the use he makes of them, I venture to submit to the readers of the *Medical Times and Gazette* the following observations:—

Dr. Bland Radcliffe says:—"Pain of a neuralgic character may be associated with a very depressed condition of the circulation. It is a well-established fact that neuralgia in its most excruciating form may occur again and again without fever or inflammation. . . . Judging from the pale and perspiring skin, and the miserable pulse, which are so generally met with in the actual paroxysm of neuralgia, it may be supposed that this paroxysm is associated with a state of the circulation in which the habitual depression [alleged to exist] is exaggerated. Indeed, the appearances during such a paroxysm

(c) *Ibid.* Preface, p. 7.

are often calculated to remind one of the cold stage of ague." (d) The whole paragraph from which this passage is extracted contains no word distinguishing the simultaneous state of the circulation in the spinal cord and sympathetic ganglia from that here alleged to be generally observable during the neuralgic paroxysm; and the meaning which the author evidently intends to convey is, that this "depressed state of the circulation—a state of anæmia, and not a state of hyperæmia"—obtains in those nervous centres, as well as throughout the periphery of the body generally. Now, whether or not that state does also obtain simultaneously in those centres is the very pith and marrow of the question at issue; and his assertion that it does is not only not proved, but, in my opinion, is actually disproved by thoroughly established facts. Even Dr. Radcliffe probably recognises the fact that the anæmia of the surface of the body, observable in the cold stage of ague, is due to excessive action of the ganglionic nervous centres; for he himself testifies to the truth of the discovery made by Claude Bernard and Brown-Séquard, that the contraction of the arteries in any, or in all, parts of the body is effected by "a state of action" of the ganglionic nervous centres functionally related by vaso-motor nerves to those arteries. He maintains, however, that the more intense this "state of action" is, the less is the supply of blood, or, at least, of arterial blood in those centres! But, though he believes in this continuous miracle—the production of nervous energy in inverse ratio to the quantity of arterial blood supplied to the nervous centres producing that energy—the great majority of neuro-physiologists and pathologists assuredly look upon vigorous action of the vaso-motor nerve-centres as evidence of an abundance of arterial blood in those centres; and therefore, while altogether refusing to admit that "a very depressed condition of the circulation" in the periphery of the body justifies the inference that a like condition obtains in the vaso-motor nervous centres, they will, I doubt not, interpret the state of peripheral anæmia as an expression and immediate product of hyperæmia in those centres. This conclusion is confirmed by numerous post-mortem observations in cases in which sufferers from cholera have died during the cold stage or in "collapse," and when, therefore, the peripheral arteries are contracted to the uttermost: in such cases the ganglionic nervous centres have again and again been found excessively hyperæmic. I may add that when ice is properly applied along any part of the spine, the peripheral arteries of the corresponding segment of the body become relaxed, and that when heat is thus applied the peripheral arteries become contracted. The relaxation is denoted by increased heat, and often by perceptibly increased fulness of the peripheral parts in question, while the contraction is denoted by a fall of temperature, and sometimes by more or less obvious shrinking of those parts. Now, I believe there is no possible explanation of these positive facts, except that which pre-supposes them due to modifications of the state of the circulation of blood in those centres—modifications induced, in the one case, by the application of cold, and, in the other, of heat to the spine; and that whereas the effect of the cold consists in lessening the vitality, contracting the bloodvessels, and lessening the amount of blood, the effect of the heat consists in augmenting the vitality, dilating the bloodvessels, and increasing the amount of blood—or, to use other words, in greatly exalting and quickening the circulation—in those centres. This conclusion directly contradicts, in so far as the ganglionic nervous centres are concerned, the proposition of Dr. Radcliffe at the head of this paragraph, and, implicitly, the general theory of which that proposition forms a part; but it, as well as that part of his proposition which relates to the peripheral circulation only, is in perfect harmony with the doctrine which teaches that the existence of pain is immediately dependent on the presence of hyperæmia in the sensory centre affected. The question whether the spinal cord is anæmic or hyperæmic in cases of neuralgic pain I have elsewhere fully discussed; but I may observe here that the sympathetic ganglia and the cord are intimately connected, structurally as well as functionally—that, in fact, the several parts of the former are said to originate in the latter, and that, as there is a recognised tendency in all parts of the body to assume a condition of circulation or vascularity like to that of immediately neighbouring parts, the inference that when any considerable group of sympathetic ganglia is hyperæmic the proximate segments of the spinal cord are in a like condition, is a valid one.

"Pain of a neuralgic character," says Dr. Bland Radcliffe, "would seem to be antagonised rather than favoured by an

(d) *Ibid.*, pp. 270, 271. This passage is word-for-word the same in the "Lectures," published in 1864, and in the "Dynamics of Nerve and Muscle," from which it is now quoted.

over-active condition of the circulation"; and he tries to establish this proposition by adducing in support of it several pathological facts generally recognised as indubitable, and akin to each other in character. He says—"In rheumatic fever, the rule, I believe, will be found to be this—that the pains which had been torturing the patient for days or weeks or months previously . . . come to an end when the feverish reaction and local inflammation of the fully formed disorder make their appearance." He adds—"It is also difficult to look upon the local inflammation of gout as essential to the existence of the racking pain of this disorder." He quotes Sydenham's description of an attack of gout to prove that the pain precedes the inflammation, and appeals to Dr. Garrod in confirmation of his assertion that, when gouty "inflammation runs higher than usual, *the characteristic pain is less urgent than usual*. . . . It would seem," he says, "as if the inflammation of gout were not essential to the pain of gout. It would seem as if the pain went hand in hand with the rigors which are preliminary to the development of the inflammation. . . . Nay, it would even seem as if the pain were put an end to by the establishment of the inflammation—as if, in fact, the pain were antagonised rather than favoured by the inflammatory condition. . . . There is also reason to believe that pain holds the same relation to fever and inflammation in other kinds of fever besides the rheumatic, and in other kinds of inflammation besides the gouty. Six or seven years ago I had a patient in the Westminster Hospital, who, when I saw him first, complained of violent pains all over the body, especially in the back and loins, and also of chills and shivers. A few hours afterwards he was hot and feverish, and the pain and chills and shivers had all taken their departure. The case was one of small-pox; and the lesson I gathered from it was that the pains and the rigors were symptoms which ought to be classed together, and considered as belonging to the cold and not to the hot stage of the fever. And this case would seem to be a fair illustration of what happens in other fevers; for it seems to be the rule rather than the exception for the pains which attend upon the onset of these disorders to pass away or to become greatly mitigated when the cold stage gives place to the hot stage. . . . Nor is it different with inflammation. In the case of a dislocation or sprain, for example, the acute pain of the accident does not, as a rule, remain after the parts have begun to be hot and swollen and tender; and this case is certainly no exception in the history of inflammation. It would seem, in fact, as if the proper place for the pain was among the phenomena of the preliminary stage—the stage of 'shock'—and not among the phenomena of actual inflammation. . . . Nor is a contrary conclusion to be drawn from the history of certain cases in which pain continues as a permanent symptom after the full establishment of inflammation, as, for example, in deep-seated inflammation of the mamma; for, in these cases, it is a fact that this persistent pain is immediately relieved or removed by those operative measures which diminish the tension or stretching arising directly or indirectly from the inflammation."(e)

Though Dr. Radcliffe asserts that "pain of a neuralgic character seems to be antagonised rather than favoured by an over-active condition of the circulation," he does not say whether he means "an over-active condition of the circulation" in the nervous centres as well as in the periphery of the body; but the general drift of his argument, and especially the whole tenor of his remarks in his article on "Diseases of the Spinal Cord,"(f) make it certain that this is precisely what he does mean. In fact, the proposition, established as he believes himself to have established it, is intended as a conclusive confirmation of his fundamental principle that pain and vitality of the sensory nerve-centres are in inverse proportion to each other. Stated briefly, the argument by which Dr. Radcliffe endeavours to support the proposition in question consists in his assertion that, as a general rule, the pain which is felt in cases of fever does not accompany the fever, but precedes it; that, in like manner, the pain which is felt in cases of inflammation does not accompany the inflammation, but precedes it; and that, moreover, the supervention of the actual fever or inflammation drives away, or antagonises, or, at least, mitigates the pain. The relation in respect to time, or the order of succession of the pain and fever, or of the pain and inflammation, is an exceedingly interesting and instructive one; but its pathological significance seems to me wholly misinterpreted by Dr. Radcliffe, and the following considerations will, I believe, show that, while rightly interpreted it affords no

countenance whatever to his peculiar theory, it confirms in a striking manner the doctrine concerning the proximate cause of pain already mentioned.

It will probably be thought that the exigencies of his theory have tempted Dr. Radcliffe to draw a more distinct line of demarcation between the pain and fever and between the pain and inflammation than is warranted by accurate observation of the phenomena in question—that, in fact, pain co-exists with the fever and with the inflammation more generally, or to a greater extent, than his statement of the case implies; but, whatever may be the exact truth of the matter, I think it expedient, for the sake of the argument, to assume the correctness of that statement, and it seems to me that the facts which it embodies are fully explained by the following propositions:—(1) That all fevers and inflammations begin in the nervous system, and are essentially disorders of that system; (2) That as their exciting cause or causes must first operate on centripetal nerves, the sensory nerve-centres into which they converge are primarily irritated, and therefore give evidence of the morbid excitement which is being wrought in them in the swiftest and most immediate way they can—viz., by functioning so intensely as to produce the consciousness of pain before the other phenomena of the fever or inflammation, which is being developed, are observable; (3) That the excitement of those centripetal nerves which are in the area of operation of the exciting cause of the fever or inflammation, and which terminate in vaso-motor nerve-centres, originates irritation, hyperæmia, and, consequently, excessive reflex action of those centres on the bloodvessels to which they are functionally related, and thus produces that peripheral anæmia and surface-pallor constituting, when obtaining all over the body, the most obvious phenomena of "nervous shock"; (4) That the primary irritation of the sensory nerve-cells in some part of what Marshall Hall called "the true spinal cord"—viz., the conjoint spinal cord and medulla oblongata—in cases of local inflammation, and in the whole of that nervous centre in cases of fever, is slowly propagated to those cells in which originates the force productive of textural nutrition, and which, becoming preternaturally excited, transmit their morbidly excessive force through nutritive and secretory nerves, and thus, according to the nature of the primarily exciting cause, light up local inflammation in the one case, or general fever in the other; (5) That as, through the medium of the centripetal nerves, the sensory cells in the spinal cord and the vaso-motor cells in the sympathetic ganglia first receive the impulse of the exciting cause, the morbid force which is expended on them becomes, as a general rule, first exhausted; (6) That as the centripetal nerve-cells become thus exhausted, pain gradually subsides, and the peripheral bloodvessels, held firmly contracted until now by the constringing action of the preternaturally energetic vaso-motor nerves, are allowed completely to relax, and thus to convey a superabundance of fuel to the fire originated by the conductors of the nervous force effecting textural nutrition—whether that fire is restricted to some one region of the body (local inflammation) or extends over the whole (general fever)—while the nutritive nerve-centres still continue in excessively vigorous action; and lastly (7), That in those cases in which the pain persists, as "in deep-seated inflammation of the mamma," the morbid force expended on the sensory nerve-cells, instead of becoming exhausted, is constantly renewed by continuous irritation of the sensory nerves, rendered preternaturally sensitive by being within the focus of inflammation, and subjected to pressure or stretching owing to the peculiar character of the structures amid which they ramify.

If, as is generally admitted, pain in the back, chills, and shivers herald the onset of small-pox and other fevers; if pain in some cases of local inflammation is the first and principal symptom; if pain can only be experienced by the agency of nerve-cells in some part of the "true spinal cord"; and if chills and shivers are mainly induced by vaso-motor nerve energy, causing general constriction of the peripheral arteries, the proposition that all fevers and inflammations begin in the nervous system, and are essentially disorders of that system, seems to me incontrovertible; and therefore I adopt it as the fundamental principle by which to explain the pathological phenomena in question. I feel confident, however, that Dr. Radcliffe agrees with me in recognising the truth of this principle; we only differ as to the *state* of the nervous system while those phenomena are observable.

In respect to my second proposition, it must be observed that, even in those cases in which a cause of fever may be fairly supposed to gain access to the system by first coming in imme-

(e) "Dynamics of Nerve and Muscle." By Charles Bland Radcliffe, M.D., F.R.C.P. London, 1871. P. 271, *et seq.*

(f) See "A System of Medicine," edited by Dr. Russell Reynolds.

diate contact with the blood, it is certain that when the sensory nerves throughout the body are bathed with blood which has received a morbid taint, they will become so affected as to produce a profound impression on the sensory centres into which they converge; and therefore that in these cases, as well as in those in which the exciting cause undoubtedly operates primarily at the periphery of the centripetal nerves, we are justified in inferring that that part of the nervous system, the special function of which is the reception of impressions, will be the first to be modified by the agency of the morbid cause in question. Now, if my second proposition be admitted, the fact that pain and "nervous shock" are the forerunners rather than the accompaniments of fever and local inflammation, is at once and easily intelligible, without resorting to the far-fetched hypothesis that "pain of a neuralgic character would seem to be antagonised by an over-active condition of the circulation." Moreover, I repeat my assertion that pain, and especially pain in the back, is annulled by the sedative influence of ice along the spine; but if pain in the back were "antagonised by an over-active condition of the circulation" in the spinal cord, surely the application of ice, which induces an exactly opposite condition, ought, instead of abolishing, to favour the development of pain.

Again, according to the third proposition, the most obvious phenomena of nervous shock—peripheral anæmia—and consequent surface-pallor, while not necessarily denoting a depressed condition of the circulation in the nervous centres, may actually denote and, indeed, originate in an exactly opposite condition. That they do originate in hyperæmia and not in anæmia of the vaso-motor nerve-centres, is demonstrated by Claude Bernard and Brown-Séguard, and is admitted by almost every neuropathologist entitled to form an opinion on the subject, and the demonstration is conclusively confirmed, as it seems to me, by the established fact that those phenomena, like pain, may be abolished by the application of ice along the spine.

In reference to the fourth proposition, I may remark that, as the nutritive nerve-cells are concerned in maintaining that steady equilibrium between the constructive and destructive processes of textural nutrition, which is the essential condition of the continuous life of the organism, it is readily conceivable—and, indeed, to be expected—that they should be less easily and less speedily influenced than are any other constituents of the nervous system by causes operating from without. A splinter in the finger produces pain immediately after its insertion, but a considerable time elapses before the excitement of the sensory nerve-cells, resulting in pain induced by the irritating action of the splinter, is extended to the neighbouring nerve-cells, which are sources of nutritive force, and becomes manifest in that intensified action of textural nutrition we call inflammation, in the part where the splinter is inserted. In like manner, the poisons productive of various diseases—and especially of those constituting the exanthematous group—though producing an immediately perceptible effect on the sensory and vaso-motor nervous system, do not reveal their virulence through the agency of the nutritive and secretory nerves, until several days have elapsed; and it seems to me not improbable that some definite relation will yet be discovered between the length of the period of incubation of each eruptive disease and the force of the poison generative of it, and perhaps it will be found that the greater the force the more quickly it effects those morbid changes in the nutritive processes which manifest themselves in eruption. Moreover, the time which necessarily elapses after the reception of the poison and the full manifestation of its influence by the textural changes which it produces, is prolonged by the temporarily contracting power of the vaso-motor nerve-centres; for, according to Proposition 3, the effect of the poison in those centres is preternaturally vigorous action, and, consequently, such energetic contraction of the peripheral arteries as to produce peripheral anæmia. Now, so long as this condition lasts, the nutritive nerves may function with morbidly intense energy, and yet the evidence of their action may be comparatively slight. But a time soon comes when, according to Propositions 5 and 6, the energy of the sensory and vaso-motor centres is spent: forming as they do the outworks of the associated structures of nervous centres, they are attacked first and yield first. Claude Bernard has demonstrated that when the spinal nerves are severed from the spinal cord, they begin to die at the periphery, and that death slowly and gradually advances from the periphery to the centres. Now, the vaso-motor nerve-centres themselves occupy, in relation to the spinal cord, a peripheral position, and therefore, if arguing from analogy only, I should infer that, in cases of death of the

whole nervous system, those centres die before the spinal cord, and, by a parity of reasoning, I infer that in cases of inflammation and fever their energy is first exhausted. But, confirmatory as this argument is of the propositions in question, it is scarcely needful, seeing that the speedy supervention of what is called the stage of feverish reaction, after a period of chilliness and shivering, is not only inevitable for the reason already explained, but is a fact of common observation. Now when, in the cases under discussion, the energy of the vaso-motor centres becomes exhausted, the peripheral arteries, relaxing, allow a superabundant supply of blood to pass through them, and become the material wherewith the morbidly excited nutritive nerves effect those formative and transformative processes, constituting the most notable phenomena of exanthematous fevers.

If the foregoing interpretation of the facts in question is the correct one—and I am constrained to believe it is—then it is obvious that pain is "antagonised" in no way whatever by "an over-active condition of the circulation." The relation of the phenomena is one of orderly sequence, arising out of the necessary conditions under which the force producing them operates, and is in no sense a consequence of their simultaneous incompatibility. In fact, for the reason stated in Proposition 7, pain and inflammation do very often coexist; and though, as Dr. Radcliffe says, pain is in such cases immediately "relieved or removed by those operative measures which diminish the tension or stretching arising directly or indirectly from the inflammation," the mode of relief does not consist in removing the inflammation, but only the pressure or tension on the sensory nerves, which was protracting their excitement, and, therefore, acting as a continuous cause of the continuous pain.

(To be continued.)

REPORTS OF HOSPITAL PRACTICE

IN

MEDICINE AND SURGERY.

LONDON HOSPITAL.

CASE OF EPILEPTIFORM SEIZURE, BEGINNING IN THE RIGHT HAND.

(Under the care of Dr. HUGHLINGS-JACKSON.)

WITH the report of the following case are remarks, which give briefly Dr. Hughlings-Jackson's views on a class of cases of convulsions, which he believes to be the most important for methodical investigation, in the hope of arriving at more definite conclusions as to the nature of epilepsies in general. These cases he has called (*Lancet*, March 9, 1867; *Medical Times and Gazette*, August 15, 1868) corpus striatum epilepsy, believing the convulsion to be the counterpart of corpus striatum paralysis (the common form of hemiplegia). It is, perhaps, safer to speak of it as convulsion beginning unilaterally. He supposes—at all events, when the spasm begins in the hand—that the disease is in the region of the middle cerebral artery.

A healthy-looking boy, 15 years of age, attended January 30, 1871, for convulsive attacks beginning unilaterally. He has been subject to such fits since July, 1869, and was first seen by Dr. Hughlings-Jackson, December, 1869. The fits began in the hand (the right).

Fits of this class (convulsions beginning unilaterally) do, in most cases, begin in the hand, less frequently in the side of the face or tongue (or both), and rarely in the foot. In other words, the fits more frequently start in those parts on one side of the body which have the more voluntary uses (which have the greater number of *different* ranges and intervals of movement). The same thing is seen in details. When a fit begins in the hand, the index finger and thumb are usually the digits first in spasm; when a fit begins in the face, the side of the cheek is first seized; and when a fit begins in the foot, the great-toe is the part first moved. As implied, there are exceptions. Thus, this boy's fits began in the *outer* fingers of the hand. Indeed, this case is chosen for report because it has several peculiarities, which are not quite in accordance with what *most frequently* occurs, and to which it is desirable to draw attention.

The next thing is to ascertain how the spasm spreads. The boy says "it" first makes the hand "weak"; then spasm attacks the outer fingers, and spreads to the thumb. He

remarks—"If I can manage to keep the hand open I don't go off," but adds, "I can't do it myself, because it comes in the thumb," and tries to show that, although he can bend back the fingers with his left hand, he cannot manage the thumb.

It is well known that fits of this class are often to be stopped by the ligature, or by rubbing the part, or, as in this boy's case, by forcibly overcoming the initial contraction. And such fits may be kept off for a long period, as Brown-Séguard and Buzzard have pointed out, by placing a garter of blister above the point in which the fit begins. The ligature is as successful in averting the fit in cases where there is gross organic disease (*e.g.*, in syphilitic disease of the brain), as in cases where there is no evidence of organic disease. This was said long ago by Brown-Séguard, and Dr. Hughlings-Jackson has seen several cases completed by autopsy, showing the correctness of the observation. (In cases, such as would be usually called idiopathic epilepsy, the patient may shake off the fits by walking about or by stamping. He may remark—"I nearly had a fit, but I got the better of it.")

In this connexion it may be remarked that in some cases of convulsions beginning unilaterally there is, along with the spasm, pain so severe that the patient will ascribe his subsequent insensibility to the pain—no doubt erroneously. The sensation occasionally preceding the spasm ("aura") is probably a skin sensation; the pain with the spasm is, doubtless, from implication of the sensory nerves to the muscles. We seem to have here a sort of caricature of what is supposed to take place in the orderly movements of health. The action of some of the procedures mentioned as of use in stopping the fit, is probably on the sensory nerves of the muscles rather than on the skin nerves—especially in the instances where the fit is stopped, as it frequently can be, by overcoming the initial contractions.

To return to the case—to the further spreading of the spasm when not stopped. If it goes on, "it works" up the arm to the elbow; then to the shoulder; then to the side of the face. As in so many cases of convulsions beginning unilaterally, the attacks are often limited. This boy's fits, he said, frequently cease at the shoulder. In some cases of this class there are for a period only very partial fits, affecting the hand, for instance, or even only one or two fingers (see a case in this journal, January 31, 1863), and afterwards severe convulsions. Indeed, there are many, if not all, degrees of severity in single cases. Thus, the same patient will sometimes have twitching of the hand only, or even movement of one finger; at other times, severe and general convulsions, with profound insensibility and tongue-biting. To continue the case—"If it lasts it goes to the leg." "It has to attack very strong to go to the leg." It is especially important to note the *direction* in which the spasm invades the leg. It begins at the hip, then goes *down* to the knee, and next reaches the foot.

On but one occasion has "it" passed to the other (the left) side of the body. We will call this the "second" side. This is the only case Dr. Hughlings-Jackson knows in which the patient has described an attack of convulsion extending to the second side. The rule is, that patients become insensible long before the second side is reached, and, indeed, before the first side is fully involved. Once more the point of importance is the *direction* of invasion. "It went across the chest" to the left arm, and went *down* the arm. However, the spasm of this limb was slight, and it did not reach the fingers. It will be seen that it attacked the second arm in a direction the reverse of that in which it attacked the first arm. To recapitulate. The sequence of spasm was, in this seizure—*first side*, up the arm, to the face, down the leg; *second side*, down the arm.

As to the sequence of spasm on the first side, there can be no reason to doubt at least the general accuracy of the patient's account, for it is such an account as we often receive from patients. And as to the march of the spasm down the left arm (the arm of the second side), it is to be mentioned that he gave just the same account a year ago (December, 1869). Whilst it is not well to trust to a single observation, and that by the patient, the case may serve to illustrate what has been said as to the importance of noting the exact sequences of spasm in cases of convulsions. We should never neglect the opportunity of carefully watching the march of a paroxysm. By such observations, and by noting the particular parts of the nervous system found diseased after death, we may learn what particular co-ordinations those parts superintend during health—what movements they "contain." For, just as hemiplegia is not to be looked on as loss of power over certain anatomical groups of muscles, but as the loss of a certain number of co-ordinations in which the muscles of the arm and leg serve, so a convulsion is not to be thought of as a spasm of groups of

muscles, but as an abrupt development of certain co-ordinations in which the muscles of the arm, face, and leg serve. When we witness a paroxysm we have to observe (1) the range of the spasm (how far it spreads), and (2) the order in which it spreads. When fits begins in the hand, the spasm spreads up the arm and down the leg; when a fit begins in the foot it spreads up the leg and down the arm. The last observation rests entirely on the accounts patients give, and it must be mentioned that one patient said that after "it" had gone up the leg "it" went up the arm—not down, as most patients tell us who have fits beginning in the foot. It is especially important to note what takes place on the second side. But it must be observed that muscles of both sides of the trunk are involved before the unilateral of the second side are reached, or before they are in strong action. In the boy's case the implication of the thoracic muscles—these are eminently bilateral—seems to have been slight.

Here reference must be made to Broadbent's hypothesis on unilateral and bilateral movements (*see* his original paper, *Medico-Chirurgical Review*, April, 1866.) An account of Broadbent's hypothesis is now easily accessible; it is given in Watson's "Practice of Medicine," vol. i., and as Sir Thomas Watson adopts it, it is useless to say anything here as to its great importance.

In fits of this class the second side is usually less convulsed, and Dr. Hughlings-Jackson believes its parts are convulsed more contemporaneously; but he has had few opportunities of witnessing the convulsion of the second side, and is unable to speak with confidence as to what occurs. As spasms become more contemporaneous there is a nearer and nearer approach to tonic spasm, and Dr. Hughlings-Jackson believes that the further the spasm spreads—in other words, in passing from the voluntary to the automatic movements—the less clonic and the more tonic it becomes.

The boy has loss of use of his right arm for a minute or two after the spasm has ceased. It is well known that after some convulsions beginning unilaterally there is hemiplegia as complete in range as usually follows a clot in the corpus striatum; but the hemiplegia is transitory—it may last minutes, hours, or days. When the spasm is limited the consequent palsy is limited, as in this boy's case. Dr. Hughlings-Jackson has seen a case of absolute paralysis of one arm after a convulsion affecting that limb and the same side of the face, although there was no trace of loss of consciousness. Recovery from the palsy nearly always follows, even when there is organic disease; for the palsy does not depend on the organic disease (not on the destruction it effects), but is probably the result of the excessive discharge upon the nerves and muscles of the region affected—it is the result of the paroxysm itself.

It is to be observed that in some cases of partial convulsion the fit will cease instantly.

In this boy's case there is loss of speech, he says, when "it gets to his head." Trouble of speech more often occurs in those cases where the spasm begins in the right side of the face or tongue, or both. In some cases there is temporary loss or great defect of speech when there is no more spasm than slight twitching of the right cheek. These cases Dr. Hughlings-Jackson has named "epileptic aphasia"—a nomenclature of the same style as "epileptic hemiplegia." Trouble of speech is not often complained of when the fit starts in the hand, even when the spasm reaches the face. Cases are not called epileptic aphasia in which there is no spasm. Temporary loss of speech no doubt occurs from embolism or thrombosis; at all events, it occurs in cases of valvular disease of the heart—rarely, it is true.

The first fit of this series came on the day the boy went to a new situation, and he ascribes its occurrence to excitement; he mentioned that there were a great many boys, and much noise from machinery. Probably the excitement was only the determining cause of the discharge of that *part* of his nervous system which has been diseased at least since July, 1869. That there is a part diseased—that the disease is local—is as certain as it is that the spasm is local. That the same part diseased has been diseased at least since July, 1869, is inferable from the fact that the patient's fits have always started in the same way. Dr. Hughlings-Jackson (*see* London Hospital Reports, vol. i., 1864, and St. Andrews Reports, vol. iii.) thinks that the part diseased in such a case as this is in the region of the left middle cerebral artery. As to the nature of that disease, the *functional* nature of the changes in nerve-tissues is *not* that it is *destroyed*; it is highly unstable, for it discharges occasionally, and, probably, it may be added, that it discharges on slight provocation. There is grey matter, which, by continuous

nutrition, reaches an abnormally high degree of unstable equilibrium. The next point is, by what *pathological* power does this condition of unstable equilibrium result? There is no evidence in this case. The boy has no valvular murmur; he has not had rheumatic or scarlet fever. We may, however, go so far as to infer that in all probability there is not gross cerebral disease—no tumour or other adventitious product. It is safer, however, to say he has had no symptoms of such gross disease; he has not had severe headache, vomiting, and there are no abnormal changes to be seen by the ophthalmoscope. We can only infer, Dr. Hughlings-Jackson believes, that there is a portion of unstable grey matter in the Sylvian region this boy's left cerebral hemisphere, which discharges occasionally. How that instability was caused there is no evidence to show. The patient was treated empirically by bromide of potassium. In cases of this class a longer period of immunity follows treatment than in cases of so-called idiopathic epilepsy.

CHARING-CROSS HOSPITAL.

CANCER BEGINNING IN THE INGUINAL GLANDS, AND EXTENDING UPWARDS ALONG THE LYMPHATICS INTO THE CHEST.

(Under the care of Dr. SILVER.)

W. F., aged 22, a native of Brentford, is a rivetter by trade; his father and mother are both alive and well. There are seven others in the family, and all are healthy. He has always been healthy, sober, and hard-working up to the commencement of the present illness. Two winters ago work was scarce, and so he lived badly. He and his brother, therefore, went to Sunderland to look for work, but could not obtain any; so they had to return, which they did by walking the greater part of the way. After reaching Birmingham he felt a pain in the right groin, and on putting his hand there found a swelling about the size of a walnut. At this time he was footsore, but does not know that the skin of his feet was broken. On reaching home his feet were so much blistered that he had to lay up for six weeks. The feet got better, but the swelling in the groin did not go down. He then resumed work, the swelling still remaining unchanged for about eighteen months; it then began to increase in size, and continued to increase up to the time of his admission into the Hospital.

About six months ago a swelling appeared in his left groin. His attention was drawn to this by a sensation of pain in that region. It, too, increased in size up to about two months ago. He applied to King's College Hospital, and was admitted. There he remained an in-patient for eight weeks. A few days before leaving a swelling appeared in his right leg, behind, from the knee to the ankle. The swelling extended until it affected the whole leg, thigh, and scrotum, but after a week it subsided.

On July 16 he was admitted to this Hospital for the swellings in his groin, and was doing well up to September 25, on which day he went out and got a little wet, which gave him a violent cold. Up to a certain date he used to lie on his right side; he now lies on his left. The time of the alteration is not very clear. After the cold he had a good deal of cough, but did not expectorate much. About a week ago he noticed that his breath was very short.

He now (October 10) has a large irregular indurated swelling in his right groin, in a line with Poupert's ligament, and a smaller one in his left groin. Both legs are swollen and œdematous, the right more so than the left; the scrotum is also infiltrated with fluid. The spleen is enlarged. The left arm is œdematous nearly to the shoulder. The abdomen is much swollen, pits on pressure, is clearly resonant, and is of greater bulk on the left side. The apex-beat of the heart appears to be on the left side of the epigastrium. His respiration is entirely thoracic; the right side of his chest expands much more than the left, but the left is rounder and more full than the other. The right side is loudly resonant in front; the left side is clearly resonant at the apex in front to the level of the third rib, below which there is uniform dulness. Respiration on the right side is puerile; at the left apex it is less audible, yet distinct. In the left axilla respiration is scarcely audible; the voice-sounds tolerably clear. Over the sixth rib, just outside the nipple, there are no heart-sounds audible; breathing barely audible; voice-sounds inaudible.

When this history was taken, the man had newly come under the care of Dr. Silver, having been transferred from the care of Mr. Canton. The man was so weak that a perfect examination could hardly be made. A day or two after he died.

Post-mortem the Day after Death.—The lower extremities were very œdematous, and on opening the abdomen a large quantity of yellow serum escaped. On opening the chest an enormous quantity of sero-purulent fluid escaped from left pleura. The heart was found pushed over to the right side; left lung completely collapsed, but distensible; right lung containing some bloody fluid at its apex; liver larger and paler than usual; spleen very much enlarged, nodular on the surface, and in colour very dark. On removal of the intestines, an enormous mass was found, reaching from the groin to above the level of the diaphragm, enclosing and firmly surrounding the vessels. The vessels, though thus surrounded, were not involved, but only firmly enclosed in the mass. The spleen, which was much enlarged, on section, presented cancerous-looking nodules; and the same kind of growth extended along the thoracic duct, blocking up all the intercostal veins on the left side save two.

Microscopical examination showed the inguinal glands, the abdominal tumour, and the splenic nodules to consist mainly of small, plump, rounded cells, with some trabecular connective tissue, associated with spindle-shaped cells, which were also found in the liver somewhat abundantly. The characters were those of a somewhat rapidly growing cancer.

Remarks.—In bringing this case under the notice of the students, Dr. Silver remarked: There are many points of interest in the above narrative. We have first of all the formation of a glandular tumour as the result of foot-soreness, which, unlike such tumours, remained behind when all the irritation which had produced it had gone. That must be accepted as the beginning of the disease. For a time the glandular mass in the groin kept on getting bigger and bigger, but again, by the testimony of those under whose care the man has long been, it has latterly much decreased. The man, when I first saw him, had a marked and peculiarly pallid hue of countenance, not pure white, but with a yellowish tint as is seen in chlorosis. The tumours in his groins were not painful; and I may as well say that during life the abdominal mass was not detected. The spleen was enlarged to a marked extent. These were the main features of the case: glandular enlargement, splenic enlargement, general pallor, great weakness. How did we try to connect them? Well, in this way. There is a form of disease sometimes known as Hodgkin's disease, from him who first described its post-mortem appearances; this is a disease semi-malignant in character, and characterised by the invasion of various organs with lymph-like elements. It appears to originate in the lymphatic glands, and is also known as lymphadenoma. That would have accounted for the specific symptoms. We could suppose a multiplication of lymphoid elements in the inguinal glands giving rise to increased size and, from tension, pain. We saw the spleen was greatly enlarged, and could suppose the enlargement due to the same cause. The blood was examined, and no undue proportion of white corpuscles was observed, which perhaps somewhat tended to confirm our opinion; and so we concluded that the disease was of this semi-malignant character. But in the other features of the case several points of interest may be noted. It was quite evident that the circulation in the lower extremities was obstructed, for there had long been swelling in them—swelling evidently due to pressure on the femoral veins by the tumours in the groin. These tumours would alike account for the swelling in their subcutaneous connective tissue, and in that of the scrotum; for it was into the connective tissue, and not into any of the connexions of the testicle, the fluid was effused. So, too, as noted, was it with the abdomen; it was the wall of the abdomen which was œdematous, not the peritoneum, which was filled with fluid. The obstruction to the circulation lay, not in the portal, but in the main channels for the return of blood. The quantity of fluid so effused was not large, and it had, in great measure, gravitated to the left side, on which the youth lay habitually, just as it would had it been free within the peritoneum. The origin of this effused fluid did not seem obscure. The superficial abdominal veins at the lower part of the belly return their blood by the saphena and femoral; these were obstructed by the tumours, and so an explanation was easy. Afterwards, when we say "the great abdominal vessels closed and surrounded by a cancerous mass," it was plain that this, too, had to do with the effusion; but at the time the explanation given seemed sufficient. But in the chest, too, there was effusion of fluid, and the effusion was unilateral. How to account for that? In my mind there was a lurking suspicion that the glandular disease had something to do with it—that was the reason why I did not tap; but a sufficient explanation is apparently to be got from the patient's history. He had been out and got wet; he coughed, and he did not spit;

he changed the side on which he used to lie about the same date. All this pointed to subacute pleurisy, with speedy and extensive effusion. So, doubtless, there had been; for, whereas in the other cavities examined the fluid was quite clear, here it was sero-purulent. Nevertheless, here, too, the post-mortem examination revealed other causes of transudation; for on that side the malignant disease had extended along by the thoracic duct, and had obstructed all the intercostal veins save two. Such a condition would readily account for the great accumulation of fluid and the complete collapse of the lung—so complete that it looked like a small spleen, but yet was quite capable of being distended by a blowpipe. Yet, again, there was fluid effused beneath the skin of the hand, forearm, and arm up to a certain level on the left side. How was that to be accounted for? From our point of view, easily enough. Here was a man compelled by the necessity of his case to lie constantly on his left side, the upper portion of his arm pressed closely to his side, and withal with a weak and displaced heart. In these factors we had enough and more than enough to account for the swelling; and when the hand was raised above his head it in great measure disappeared. Thus, in this case we had certain symptoms giving us some idea of the nature of the disease—some diverting our attention from its nature and attracting us to its anatomical site. But the nature of the disease, as revealed by post-mortem examination, was sufficiently interesting; the disease, notwithstanding its peculiar history, was unmistakably cancer—cancer alike affecting the lymphatics and the spleen. Yet in these inguinal tumours we have a history very unlike cancer, of swelling lasting for two years, and then considerably diminishing in size, with no tendency whatever to ulceration. Here, too, was revealed the tendency to spread in the fashion often seen in cancer; the aorta and cava were embedded in a cancerous mass, yet their channels were clear and their walls apparently healthy, though by the lymph-channels the morbid growth had reached upwards into the chest. Finally, the case well shows how anatomical position may give rise to symptoms which have no necessary or even remote connexion with the disease.

Medical Times and Gazette.

SATURDAY, DECEMBER 23, 1871.

A MEDICAL MANIFESTO.

WE publish elsewhere in our pages, this week, a very weighty and important "Medical Declaration respecting Alcohol," which, we are sure, will be most carefully considered by our readers. It has received, already, a very large number of signatures. First among the names subscribed are those of nearly every Medical member of the Royal Households—a list that First President-Elect of the future British Republic, Citizen Dilke, will gloat over. Then come the names of a large number of the most eminent Physicians and Surgeons in London, whether now or formerly on the staffs of

the London Hospitals, or not; and lastly, we find the signatures of several well-known and trusted provincial Medical authorities. Such a document commands the most respectful attention—the more so as it is open to criticism.

We have no idea who originated the movement, or who drew up the Declaration, but we must venture to observe, *pace* the eminent men who have signed it, that it seems to us to be, here and there, not very happily worded. With by far the greater part of it, and with the purpose and object of it, we entirely and most cordially agree. We are "firmly convinced that the great amount of drinking of alcoholic liquors among the working-classes of this country is one of the greatest evils of the day, destroying—more than anything else—the health, happiness, and welfare of those classes;" and we "are also of opinion that many people immensely exaggerate the value of alcohol as an article of diet." We are as far as possible from wishing to lessen the good effect such a paper as the Declaration may do, but we think that many Medical men may object to signing it as it now stands. It is just possible that to some its logic may appear rather feminine, as if it had been drawn up by some one of the lady preachers or writers against intemperance, for it begins—"As it is believed that the inconsiderate prescription of large quantities of alcoholic liquids by Medical men, for their patients, has given rise, in many instances, to the formation of intemperate habits," etc.; and it finishes with—"The undersigned would gladly support any wise legislation which would tend to restrict within proper limits the use of alcoholic beverages, and gradually introduce habits of temperance"—which sounds rather like, "Medical men prescribe alcohol carelessly; therefore, introduce a new Licensing Bill, or adopt a Maine Liquor Law, and gradually shut up the public-houses."

But we do not suppose that this is meant, and a careful perusal of the document would prevent any such error being seriously entertained; so we will pass that by. We think, however, that the first sentence of the Declaration is open to very grave objection. "As it is believed that the inconsiderate prescription of large quantities of alcoholic liquids by Medical men," etc. Believed by whom?—by the large number of eminent men who appear as "the undersigned"? We can hardly think it! It appears to us almost impossible that the Physicians and Surgeons whose names are attached to the Declaration seriously mean to prefer such a very grave indictment against their brethren. Yet the wording of the document may be held to imply that they believe that Medical men are responsible for a large part of the intemperance of the day. We are not prepared to deny that here and there a Medical man may too carelessly recommend a patient to take a little wine for his health's sake, and we fully concur in the opinion that no Medical Practitioner should prescribe alcohol "without a sense of grave responsibility," and that it "should be prescribed with as much care as any powerful drug, and that the directions for its use should be so framed as not to be interpreted as a sanction for excess, or necessarily for the continuance of its use when the occasion is past." But we do not believe that Medical men are, except in comparatively rare instances, guilty of ignoring their responsibilities on this subject; and we believe that where alcohol has been prescribed in large quantities for patients, they almost always hail with joy the permission to lessen the dose, or to altogether leave it off. Out-of-doors drinking and over-the-bar tipping are by far the most common temptations and the greatest evils, and with these Medical Practitioners have nothing to do, except fight against them. But there never yet was a man or woman who indulged in the over-use of stimulants without having a handsome excuse; and "My Medical attendant ordered it," or "I got in the habit when I was so ill, and the Medical men insisted on my taking so much" wine or spirits, forms a very ready and plausible excuse, though we believe it very seldom has any real foundation. The strain and hurry of life in these

days, whether life be one of pleasure or business, or of both, and disappointments of various kinds, are the main causes of whatever of intemperance or excess in the use of alcoholic beverages exists in the upper and middle classes of society; and we confess that we do not believe that this evil obtains to anything like the extent depicted by writers of sensational articles on "drawing-room alcoholism" and the like subjects.

As regards the "working-classes," while their life is one of excessive labour, misery, squalor, and dirt, they will drink. We shall of course gladly welcome any "wise legislation" on any subject whatever, and do our utmost to further it; and we believe that much might and ought to be done to restrict the use of alcoholic drinks, by lessening the number of public-houses and beer-shops, and placing them under better and closer supervision. But very much more good would be obtained by education—not mere secular instruction—and by sanitary measures. As long as the poor are forced or allowed to herd together in overcrowded, ill-ventilated, or non-ventilated dwellings, have little water (and that bad), and adulterated food, so long will they crave for the temporary relief afforded by alcohol, and be irresistibly attracted by the meretricious glitter and splendour, space, and sociability of the public-house. Give them decent house-room, unvitiated air, pure water, and good food—however coarse—and they will much more readily recognise and be taught the duty and advantage of temperance, and the evil of "drinking"; and the public-house will cease to be so attractive.

We hold, of course, that "every Medical Practitioner is bound to exert his utmost influence to inculcate habits of great moderation in the use of alcoholic liquids." We think that the last paragraph of the "Medical Declaration" is rather out of place in a specially Medical document, as it might as well and fittingly be signed by any man or woman, of whatever position or calling; and it appears to us that the first paragraph is so worded as to imply a charge against Medical men which they are very far from deserving. Had it commenced, "As it is popularly believed," etc., or "As it is frequently asserted," etc., we should have had no objection to make, and every Medical man would, we believe, have been ready to give unreserved support to the paper.

COPROLOGIA; OR, TYPHOID IN ITS HOME.

THE term Coprology may be applied to that unsavoury, but very necessary, branch of knowledge which treats of solid animal refuse, and the means of disposing thereof. The basis of it is the fact of Nature's ordination that the undigested parts of the food, and certain coloured and offensive secretions from the alimentary canal, are noxious matters which must be discharged. Then they ought to be allowed to be decomposed into their primitive elements, so as to be rendered not merely innoxious, but useful [in supplying food to vegetables, and through them to animals and to man himself. How lucidly this has been stated by the illustrious Liebig hardly requires to be told, nor how true it is that it conduces to health and wealth to apply animal refuse to its proper place, and how disease and poverty ensue from any other course.

The more untutored tribes of man take no thought of these things, but unload themselves of their burden anywhere. Gipsies have a certain sense of decency, and, vagabond as their life is, always go to the other side of the nearest hedge. In the Highlands of Scotland the people drop these matters at random. There life is reduced to its rudest elements; the people subsist on fish, milk, and scanty crops of oats, and, having no gardens and no wells, get their water-supply from the nearest burn, into which the excrementitious matter is sure to be washed off the rocky soil; hence, if typhoid is introduced, it is sure to spread. Extremes meet; and the most elaborate arrangement of that beastly device, the water-closet,

does but enable the finest lady at a country house to drink her own sewage—as the Highlanders do. So true are the words of Anstey, in the "New Bath Guide"—

"So while little Tabby, etc., etc.
The ladies are drinking it out of the pump."

The first literary notice, historically speaking, represents coprology at its climax of excellence. The Hebrew people, when encamped in the Arabian desert, were ordered by the Mosaic law to go forth out of the camp when they relieved nature, and each man to carry a "paddle" or shovel, so as at once to bury the offensive refuse. Till the earth-closet was introduced, no mode of disposing of refuse so cleanly and efficient had been promulgated.

The Israelites were forbidden to befoul their camp—the dwelling-place of man, under the special care of the Deity. Unhappily for the human race, no commandment has been so systematically violated. There is no animal that does not strive to avoid this kind of defilement. Little birds, as soon as hatched, led by instinct, protrude their tails over the edge of the nest, so that it may not be fouled. Animals which run about as soon as born show no special instinct of this sort, and do not require it. Not so the carnivora, rodents, and others, whose young are born blind and undeveloped, requiring the shelter of the nest. It is manifest that any nest would be unbearable, if flooded with the ordure of a whole litter of young. But see the provision of Nature! The alimentary excreta of young nurselings never have the offensiveness which marks those of adults, and they are devoured by the mother, just as the afterbirth and secundines are. An old cat, purring with maternal ecstasy, may be seen to roll her kittens, one after another, on to their backs, and to lick the lowest part of the abdomen, lapping up all the infant's urine and fæces with infinite relish. And why not? The kitten has but oxidised some of the nutriment which lately flowed through its mother's veins; and perhaps, on its way toward decomposition, it may be as nutritious as some meat extracts, and as nice to the old cat as putrid game, putrid cheese, Chapzugar cheese, brown cod-liver oil, the "ropes" of a woodcock, and the contents of a lobster's gizzard are to the cat's human masters. Anyhow, the cat buries and hides her own excrement if she can, and goes to a distance to do it. She does not store it in a cesspool as civilised man does, just as the negroes bury the dead bodies of their friends under the floor of their hut!

The philosophical student of that part of biology which we have called coprology, will be gratified by many curious notices of it in authors sacred and profane. Stanley, in his very interesting "Lectures on the Jewish Church," tells us that the mystical phrase, to "cover his feet," has reference to a very simple operation of nature. It occurs in the first place in the history of the left-handed man named Ehud (Judges iii., 15), who assassinated the fat Moabitish King Eglon with a long-dagger, which he buried, blade, hilt, and all, in his belly. He gained access to the King in a kind of summer-house, and, having done the deed, made his escape. The servants supposed their master was occupied with the calls of nature, and wondered that he was so long, and "waited till they were ashamed," as it significantly says; then they went in, and found him dead. The other instance is that of King Saul, who turned aside for this purpose (*παροσκευασάσθαι*, LXX.) into a cave, in the recesses of which David and his men were concealed.

In the cities of the East, the inhabitants resort to the flat terraces on the roofs of their houses, where the material is soon dried by the heat of the sun, and often is used for fuel, as narrated in Ezekiel iv., 9. In India the poorer people at this day go out into the fields, where their droppings are greedily devoured by pigs. In many Italian towns the poorer people resort to lanes and byways, where the lank-bellied pigs who are usually led out to feed, with a string round their necks, by an old woman or girl, perform the same office. The bacon

is delicious, and we suppose the entozoa are salted and smoked to death. In the better class of houses in Italy, the arrangements seem to have been the same two thousand years ago as now. At Pompeii, where there was a regular service of water conducted through underground leaden pipes, and a similar system of sewers, there were, as we were informed on the spot, *cloacæ* on the upper floor of the houses, leading down, through a brick shoot constructed in the wall, to the sewer beneath; yet they were refined enough to use the *lasanum*, or close stool, as may be read in Petronius Arbiter's comical account of Trimalchio's supper. Similar shoots exist in the substance of the walls of the magnificent *palazzi* of the Italian cities. The upper aperture or seat is often placed in the queerest situations—in the kitchen near the fireplace, in bedrooms or offices, and often, of course, at the very top storey of the house, which is let in *flats*. A very odious construction exists in Switzerland, where a rough shoot, constructed in the wall, leads to a cesspool just outside the house, which is occasionally emptied, by means of a pump, into a covered cart. A refinement on this practice is the suction of the contents of the cesspool into air-tight metallic vans, exhausted of air. The trapping, or other means of preventing the regress of effluvia, are conspicuous by their absence. Similar rude contrivances existed till quite lately in old houses in the best parts of the West-end of London.

During the middle ages, notices are not unfrequent of the nastiness, not merely of camps, but of towns and castles. In an amusing little book of dialogues for travellers, in Latin, German, French, and Italian, published in 1634, one chapter is devoted to the travel-talk that would be used at inns, and a traveller is represented as saying to the chambermaid—"Ubi est latrina?" The reply is—"Sequere me et tibi viam ostendam; ascendito illuc rectà, invenies ad dextram; quod si eam non videris facile eam olfacies." "Wann ihr's nicht sehet, so werden ihr's wol riechen." The evidence of this quotation shows that the place was upstairs, inside the house, and smelling abominably. Other passages follow which show that the relations of commercial travellers and chambermaids continue to this day as unchanged as the latrines. In ancient castles, where a numerous garrison was confined within very small space, they sometimes used an *oubliette*—a deep trench dug down against the wall of one of the subterranean chambers. Such a place we have seen in the old castle at Dinan and elsewhere. If the castle were surrounded by a moat, a row of perforated seats was established in an overhanging turret; and I have seen notices of the stench and flies bred by this filthy use of the castle ditch, which may be seen in full vigour around the walls of some old French towns—for instance, Vannes, where the filthy projections from the old town walls are in the state they may have been in in the thirteenth century. In one of the accounts of Mary Queen of Scots, quoted by Lingard, mention is made of the annoyance caused to the unhappy captive by the stench from the latrines outside her windows at Fotheringay. In the better classes of country houses in England one or more outdoor temples of *Cloacina* were commonly erected; but instead of being frequently emptied and deodorised, they were left for years. A country squire boasted once that his had not been emptied for thirty years! If no water save the urine were poured into these receptacles, they might, beyond their intrinsic offensiveness, do little harm; when floods of water for water-closets were introduced, they were sure to soak into the wells. It is said that the office of this sort erected by William of Wykeham at New College, Oxford, has never been disturbed; there is a huge vault in the chalk, and that which falls into it dries up harmlessly. It is needless to quote the accounts, such as Smollett gives in his "Humphry Clinker," of the contrivances at Edinburgh in the last century, and of the tub thrown out at night—a practice which still exists in full vigour in some picturesque old French towns.

So far we have tried to show that Religion, Authority, and

Natural Science prescribe some mode of dealing with human refuse, which shall return it at once harmlessly to Mother Earth. But that these laws have been incessantly violated, and the human race habitually poisoned with its own excretions, what a different people we should be!—what griefs and losses we might have avoided! But enough for the present. we must next deal with the more modern form of abomination.

(To be continued.)

THE WEEK.

TOPICS OF THE DAY.

It is with the deepest satisfaction we record that the Prince of Wales has made steady and uninterrupted progress towards health during the past week. Thursday and Friday night were passed tranquilly; sleep was obtained, the suffocative bronchial catarrh and spasm which had given so much anxiety abated, and although the prostration was of course great, yet nourishment was taken, and strength at least was not diminishing. During Friday and Saturday the advantages were maintained. There was quiet sleep on Saturday night; and since then the progress has been satisfactory, although necessarily slow. According to our experience there is no acute disease in which convalescence is sometimes more gradual and protracted than typhoid fever. In many cases this of course depends upon the length of time occupied by the repair of the organic lesions which are the ordinary results of the fever. The separation of sloughs and healing of ulcers, the absorption of effused material in the abdominal and thoracic lymphatic glands, the diminution of splenic enlargement (where it exists), are all processes which require time, and sometimes render convalescence very tedious. But so long as there is no real relapse, no rekindling of the febrile process, and no symptoms pointing to grave abdominal or pulmonary complication, the length of time elapsing before perfect health is regained is not of primary moment. The Prince, we know, has a good constitution. He entered on the fever with a large reserve of strength, which undoubtedly has stood him in good stead; and there is ground for confidently hoping that the days of convalescence may be less in proportion than the duration of the fever.

The groom at Sandringham (Blegg) has died from typhoid fever. He is reported to have been a man of weakly constitution.

We understand that the scheme for a Conjoint Examining Board, drawn up by the Royal Colleges of Physicians and Surgeons, and accepted generally by the Universities, is now under the consideration of the Counsel of the two Colleges. It is greatly to be wished, before the matter goes any further, that the exact position taken by the Society of Apothecaries on the question should be defined. It is certain that no satisfactory Conjoint Board can be obtained without the co-operation of that Society; for so long as the Act of 1815 continues in force, and so long as the Society performs its functions as an Examining Body to the satisfaction of the General Medical Council and the Poor-law Board and general public, candidates for its diploma will present themselves. It will be out of the question to refuse the Licentiates of the Society the right to present themselves for examination for the diploma of any one of the Colleges of Surgeons after the precedent of the last sixty years. The General Medical Council could never assent to such an arrangement after the strong expression it has given to its disapproval of the registration of single qualifications. It should be at once ascertained what are the reasons which prevent the Society of Apothecaries from taking part in the scheme; and, if these are dependent on the construction of the Act of 1815, means should be taken to obtain an alteration of the Act.

ROYAL COLLEGE OF SURGEONS.

THE following is an abstract of the unconfirmed proceedings of the Council on the 14th inst., passing over those portions which have already appeared in the *Medical Times and Gazette*. The report from the Committee on the wording and mode of issuing the several College diplomas was read and adopted, viz.:—“That in the opinion of your Committee each of the several diplomas granted by the College should be issued on the direct authority of the Council, be signed on behalf of the Council by the President, or in his absence by one of the vice-presidents, and bear the College arms; and that the wording of each diploma should be altered accordingly.” The Dental Diploma is to be altered, bearing the College arms, and to be signed by the President. The following resolutions involving slight alterations in the draft scheme for an Examining Board for England, viz.:—“That, in pursuance of the opinion of the Committee of the two Colleges, Clause X. altered as follows be approved—‘That every matriculated student of an English University who shall have completed the curriculum of study required by his University, and shall have passed such an examination. etc.’ That, in pursuance of the opinion of the Committees, the suggestion of the University of London that the nomination of Examiners should take place annually, be adopted, provided that the two Corporations, the Colleges of Physicians and Surgeons, can legally give effect to it.” The President reported that a vacancy would take place in the Court of Examiners on the 2nd proximo, and that a special meeting of the Council would be summoned for filling up the vacancy; whereupon the following letter was read from Mr. Cock:—“My dear President,—Although my virtual retirement from the Court of Examiners took place at the last meeting, when I received such kind expressions of feeling from my colleagues as I can never forget, I believe it right that I should inform you that it is not my intention to be a candidate for the next election.—Yours ever truly, Edward Cock.” Read, a correspondence with the solicitor on the subject of the oath hitherto administered to Members of the Council and of the Court of Examiners, on their accession to office, when the President stated that, in pursuance of the opinion of the solicitor, a declaration in the terms proposed by him would in future be substituted for the oath. Mr. Charles Hawkins brought under the consideration of the Council the question as to the advisability of placing those who pass the examination for the Fellowship in classes according to merit; and, the Council having discussed the question, the subject was allowed to drop. Mr. Gay, in pursuance of his notice, moved that the proportionately large number of rejections at the preliminary examinations for the diplomas of the College was a fact which demanded the serious consideration of the Council, and that a Committee be appointed to consider the subject and report to the Council. On the motion being seconded by Mr. Wilson, an amendment was proposed by Mr. Simon, and seconded by Mr. Erichsen—“That it be a further reference to the Committee appointed on December 9, 1869, ‘to consider and report to the Council on the means offered to the students entering the Medical Profession for passing examinations in general knowledge,’ to consider the causes of the large number of rejections which take place in the preliminary examinations of the College, and to report thereon to the Council.” The amendment was carried, and Mr. Gay appointed a member of the Committee. Mr. Erichsen gave notice of the following motion:—“That, on the occurrence of a vacancy in any Professorship or Lectureship in the College, with the exception of that of Hunterian Orator, due notice be given of such vacancy by advertisement in such journals and at such times as the President shall decide, and that candidates be invited to apply for such vacancy.” Sir James Paget gave notice of the following motion:—“That it is desirable that, before proceeding to any nomination of members for election to the Fellowship under the fifth clause of the Charter of 1852, the Council should determine the conditions under which the election should take

place.” Mr. Charles Hawkins presented one of the extremely rare medallions by Tazzi of John Hunter, and also a bronze Brodie medal.

THE HUNTERIAN MUSEUM.

THIS collection, so rich in specimens of the *Cetacea*—an order upon which Professor Flower has expended so much labour—has lately had another rare and valuable addition made to it through the liberality of Professor Wilson, F.R.S., who purchased and immediately presented a fine specimen of the *Berardius Arnuxii*. In describing this genus, the Conservator of the Museum states it was founded by Duvernoy, upon a skull received at the Museum of Paris in 1846, obtained from an animal stranded in Akaroa Harbour, New Zealand. In the name of *Berardius Arnuxii*, conferred on it by Duvernoy, the captain of the French corvette *Le Rhin* (Berard), and the Surgeon (Arnoux), who jointly presented the specimen, with some others of considerable interest, to the Museum, are commemorated in zoological literature. Only three other specimens of this animal have since been seen, and all on the coasts of New Zealand. One in 1862, embayed in Porisura Harbour, was converted into oil, and can only be conjectured to have been a *Berardius* by its dimensions and a slight description published by Mr. Knox. In January, 1870, another was taken in Worser's Bay, near the entrance to Port Nicholson, and its skull and some bones were preserved for the Wellington Museum; and, lastly, a specimen of this fine animal, which is thirty feet long, and, after *Hyperoodon latifrons*, the largest of the group, ran aground on the beach near New Brighton, Canterbury, in December, 1868, where it fortunately came under the notice of Dr. Julius Haast, F.R.S., the Curator of the Museum at Christ Church. It is the skeleton of this animal which has lately been placed among the fine series of cetaceans in the Museum of the College of Surgeons, thanks to the liberal desire of Dr. Haast that it should be made as available as possible for scientific examination, comparison, and description, and to the generosity of Mr. Wilson, a member of the Council of the College. A detailed and fully illustrated description of this skeleton formed part of a communication to the Zoological Society, and will appear shortly in the *Transactions*, from the able pen of Professor Flower.

HEALTH OF SAILORS AND SOLDIERS.

DR. T. GRAHAM BALFOUR, F.R.S., Deputy Inspector-General of Army Hospitals, and head of the Statistical Branch of the Army Medical Department, read on Tuesday evening, the 19th inst., before the Statistical Society, an able and most interesting paper on the “Comparative Health of Seamen and Soldiers, as shown by the Naval and Military Statistical Reports.” On comparing the infantry regiments in the United Kingdom between 1859 and 1868 with the naval force on the home station during the same period, it appears that the sickness in the navy, as measured by the admissions into Hospital, has been one-fifth, and, by the proportion constantly sick, 1·20 per 1000 of the strength higher than in the army; and the deaths from all causes to have been ·48 per 1000 higher; but the invaliding to have been about 1 per 1000 lower. Excluding accidents and injuries, which are much more frequent in the navy than in the army, the admissions into Hospital of sailors have been one-ninth higher; but the deaths have been ·70, and the invaliding on account of disease 2·28 per 1000 of the strength higher among the soldiers. The difference in the rate of mortality may probably be to a great extent accounted for by the difference of age in the two services, the proportion of boys—at that age when mortality is at its minimum—being 10 per cent. of the force in the navy, and a little above 3 per cent. in the infantry. The excess of admissions in the navy has been chiefly in miasmatic diseases, particularly eruptive fevers, dysentery, and diarrhoea, sore-throat, and erysipelas, diseases of the respiratory and digestive

systems, in boils, abscesses, ulcers, and in accidents; while in the army there has been an excess in ophthalmia, venereal diseases, and the group of unclassified diseases. The influence of diet in the causation among sailors of diseases of the digestive system and of the skin has frequently been observed. On the home station the admissions from dyspepsia in the navy were 37, and in the army 13 per 1000. Colic, also, caused 10 admissions per 1000 in the navy, and 3 in the army. On the home station the navy enjoyed a marked exemption from tubercular diseases; the admissions from consumption were 4, and the deaths 40 per 1000 of the strength lower than in the army. The invaliding for tubercular diseases was also 1 per 1000 lower than in the army. On the Mediterranean station, however, tubercular diseases were rather more prevalent and fatal in the naval than in the military force, and the invaliding for these diseases from the former was more than thrice as high as from the latter. Delirium tremens and epilepsy appear a good deal more prevalent in the navy than in the army. Thirty-five years ago, when public attention was first thoroughly directed to the consideration of the health of the army, and of the means necessary to improve it, the mortality, so far as could be ascertained from the imperfect data, amounted to at least 3 per cent. annually; on the average of five years—1865-69—it was under $1\frac{3}{4}$ per cent. Taking the strength of the army, exclusive of colonial corps, from the army estimates for 1871-72, as 184,000 non-commissioned officers and men, the difference in the mortality represents a saving of above 2300 lives annually—a saving of no small importance, and representing, even at the lowest estimate of the cost of production of a trained soldier, a large sum of money, which would be necessary to replace these men. It must not, however, be supposed that this money-value has been all realised in a reduction of expenditure—many of the improvements referred to have been effected by means of a large outlay; but even after making a very liberal deduction on this account, there will still remain a considerable pecuniary saving as a result of these measures. It should also be remembered that another consequence of this judicious expenditure has been to remove some of those objections to service in the army which rendered it unpopular, increased the difficulty (and consequently the expense) of recruiting, and deterred a better class of men from joining its ranks. In the discussion which followed Dr. Balfour's Paper, Dr. Webster, Dr. Mackay, R.N., Dr. Mouat, Inspector-General Lawson, Mr. Rawlinson, and other members and visitors took part.

RUMOURED CHANGES IN THE BENGAL MEDICAL SERVICE.

For some time past rumours have been circulated, and paragraphs have been going the round of the newspapers, to the effect that the Bengal Medical Service is about to be abolished, the Medical arrangements of the native army handed over to the Inspector of her Majesty's British Forces, a Civil Medical Service organised, and that the members of the present Service are to have the option of electing for one or other department. Quoting from the *Pioneer* of India, we have on late occasions commented on the anticipated change. It appeared to us that the alteration was neither politic nor just, and we echoed the wish of the *Pioneer* that the Government would exercise a wise and liberal treatment under the circumstances, and "render the death of the fine old Service as easy as possible." The *Indian Medical Gazette* disputes the authority of the *Pioneer* for making the statement. The remarks of our Indian contemporary are so just and to the point that we cannot do better than reproduce them in our pages, endorsing the views expressed most heartily. With respect to the "reasons" which are advanced for the change, our contemporary observes—

"They are not very strong and well-founded. The mischievous consequences of promulgating, with an air of authority and certainty, announcements of this kind, can hardly be overrated. Men's mind become unsettled, and the steady, contented performance of duty becomes most difficult, while feelings which

perhaps had better not exist are engendered. We have become aware that the members of the Medical Service have read these newspaper paragraphs with most serious apprehension, and we have received letters regarding them which show that a strong and very general feeling of doubt and anxiety exists. It were well could this feeling be allayed by an announcement of greater authority than that which excited it. All the inquiries which we have been able to make have given no confirmation of the rumours of impending dissolution of the Service, which have been so industriously circulated of late, and we, further, feel assured that Government will never require men to 'elect' for anything whose conditions have not been placed before them in detail, nor ask a certain proportion of the Medical officers of the Indian Medical Service to surrender their commission and the covenant under which they entered the Service, without providing and offering a full and fair equivalent. We shall return to this subject in our next number, but, meantime, would counsel men to disregard these rumours until some stronger earnest of their truth exists than a second-hand newspaper paragraph, which bears improbability on the face of it."

After this protest in the name of a number of the best Medical officers in the Indian army, we trust that the "rumours" and "paragraphs" are without any legitimate foundation. It is impossible to forget that in the Indian Medical Service there have been men who have not only done honour to that Service, but have shed a lustre on Medical science generally. It is hardly necessary for us to refer to such men as Robert Jackson or Ranald Martin. These two men have done as much for Military Surgery in the far East as Larrey did for the soldiers of the Great Napoleon in the most important and successful of his military campaigns. To "shelve" men who tread in the footsteps of these great soldier-Surgeons would be a disgrace to the Indian Government. From the time of Clive to the present moment the prestige of the Indian Medical Service has been sustained with a knowledge of the necessities and duties of that Service with unflinching fortitude, and an ability that has never been surpassed. "The Company" must be fully cognisant of this fact, and it cannot be supposed that they would attempt to ignore it. The history of our Indian empire is pregnant with examples of the services which had been rendered by Indian Doctors to the progress of civilisation in that great empire.

A STIMULUS TO EXERTION.

With a view to extend the practice of vaccination as far as possible, the Newtown Board of Guardians have resolved to appoint the registrars of the various districts to be vaccination inspectors. In order to stimulate them to an efficient performance of their duties, they are "to be allowed one-fourth of the fines inflicted for neglect of orders, for their services."

EDINBURGH ROYAL INFIRMARY.

At the recent election of Superintendent of the Edinburgh Royal Infirmary, out of 146 candidates, the final ballot, by a majority of one, was in favour of Staff Surgeon-Major C. H. Fasson, who is now stationed at Woolwich as Registrar of the Herbert Hospital. Surgeon-Major Fasson has justly earned the reputation of an efficient and zealous officer in the Army Medical Department, and we believe the directors of the Edinburgh Infirmary may be congratulated on having secured his services in the administration and superintendence of that establishment. His election to this important post will, of course, render it necessary for Surgeon-Major Fasson to retire from the Army Medical Service, and this, we understand, he intends to do in February next, on the completion of all his official duties at the Herbert Hospital. We are glad, also, during the present stagnant condition of promotion in the Army Medical Service, to see that the directors of such an important charity as the Edinburgh Infirmary have practically recognised the advantage of having in the person of their Superintendent the combined Professional and military training which the Medical Service of the Army is

Peculiarly adapted to impart. We have no doubt that other similar bodies will be found willing to follow the judicious example of the directors of the Edinburgh Infirmary.

TYPHOID FEVER IN LONDON.

It seems not impossible that we may have something like an epidemic of typhoid fever in London; and this is scarcely to be wondered at, looking at the wretched condition of a large mass of the population, and the little care taken in some districts to remove preventible causes of the disease. The following cases of complicated typhoid fever are recorded in the weekly return issued by the Registrar-General, in addition to those printed last week:—A retired grocer, aged 38 years, died on the 15th inst. from "typhoid fever" ten days, congestion of lungs four days; a housekeeper, aged 53 years, on the 14th, from "typhoid fever" thirteen days, pneumonia four days; a blacksmith, aged 37, on the 11th, from "typhoid fever and bronchitis" thirteen days; the son of a packer, aged 3 years, on the 15th, from "pneumonia and enteric fever"; the daughter of a gentleman, aged 7 years, on the 11th, from "typhoid fever" three weeks, congestion of lungs eight days.

SMALL-POX JOTTINGS.

The Sheffield Town Council have resolved to erect temporary Hospitals, in consequence of the spread of small-pox and typhus fever.—Small-pox has broken out in districts in Fulham not before visited by the epidemic.—Four fatal cases of small-pox have occurred in the last fortnight in Newington.—Small-pox shows great disinclination to leave St. Martin's-in-the-Fields. A fresh case has occurred in Marshall's-court, Bow-street. The Vestry have granted permission to Dr. Skegg, the Medical Officer, to summons owners of property who had taken no steps to comply with the sanitary notices served upon them.—Three deaths occurred last week from small-pox in Poplar Union, and eleven new cases had been brought under notice, and eleven patients were under treatment in North-street Infirmary. Thirty-two persons had been vaccinated in the same period at the public stations.—Small-pox is doing great mischief in Halifax, and there have been many fatal cases.—The disease, which for the past three months has been very prevalent in Belfast, is beginning to decrease, and it is believed the worst is over. The disease, however, is rapidly increasing in Carrickfergus; there are at present fourteen cases in that town.—At Nottingham the small-pox epidemic is still on the increase. There are upwards of 400 small-pox patients in the town, principally in the low-lying and crowded localities, and there are eighty-eight patients in the Workhouse Pest Hospital. The applications for admission to the Small-pox Hospital are so numerous, that the Sanitary Committee will have immediately to build enlarged Hospitals for their reception. The whole of the Post-office *employés* have been revaccinated, as also have the workpeople in several of the large establishments in the town. Objectors to vaccination are being summoned, and a large number of defaulting parents have been brought under the law.—At Wakefield, in the last fortnight, there have been twenty-six fresh cases of small-pox, and the disease is spreading. The Guardians of Wakefield have decided to erect a new infectious Hospital.—The epidemic of small-pox is spreading to an alarming extent in Birmingham; there are twenty-one cases in the workhouse. It is said that most of the patients had been vaccinated. A temporary Hospital is to be erected.—106 deaths from small-pox occurred in the metropolis last week.—In several American cities small-pox is now prevailing as an epidemic.—Dr. Aldis, of St. George's, Hanover-square, reports five cases of small-pox for the week ending the 9th inst., four of which were removed to the Hospital; and six cases for the week ending the 16th inst., four of which were also sent to the Hospital.

THE HEALTH OF BETHNAL-GREEN.

It is marvellous that disease, rife as it is in many of the poverty-stricken and overcrowded neighbourhoods of London, is not more fatal and more prevalent. Mr. Pereira, the Medical Officer of Health for Bethnal-green, reported last week to the Guardians the result of his inspection of the parish. It is scarcely possible to conceive a more frightful state of things, particularly in the wealthiest city of the world. Mr. Pereira says the sights he saw of poverty, filth, disease, and misery completely horrified him. In some of the houses he saw people lying dead in the beds, and others dying. Some of the dwellings were in such a state that he did not believe a scrubbing-brush had ever been used on the floor. In one place he came upon what appeared to be a heap of soot, but on examination he found it was an old counterpane, under which was a woman lying, stark naked, on a hard bed, with a child at her side, whilst the husband, who appeared to be a disreputable fellow, was sitting, smoking his pipe. He had never before the slightest idea that such places of wretchedness were to be found in the parish, and he hoped the Board would use their utmost endeavours to bring about a different state of things.

POISONOUS CONFECTIONERY.

It is remarkable that, as the colouring-matter of confectionery may consist as readily and easily of harmless materials, instead of poisonous, the system of employing dangerous and unwholesome colouring is not extinct. At this season of the year it is particularly necessary to bear this in mind, as effects of a most serious kind may ensue from eating only a small quantity of poison-coloured sweetmeats. A case has just occurred at Glasgow, illustrative of this practice, and deserving of as much publicity as can be given to it. Professor Thorp, of Anderson's University, whilst passing, last week, a pastrycook's shop, observed in the windows a Christmas cake garnished with a very suspicious green-coloured substance. He purchased the cake, and on analysis discovered that the green tint was produced by arsenic. On the following day the Professor's assistant purchased two cakes similarly coloured. The police were informed of the circumstance, and on the shop in question being searched, another cake of the same description was found. The proprietor of the shop admitted that he had painted part of the sugar ornamentation with what is called "emerald green," which he purchased in a drysalter's shop in the city. He was taken into custody pending inquiry.

IMPERFECT INQUEST.

CAVILLERS at the payment of Medical witnesses for making post-mortem examinations and giving evidence, are reducing the coroner's court (in some instances, at least) to a tribunal whose verdicts are of little or no value. On Monday, Mr. Carter, the Coroner for Surrey, held an inquiry in Bermondsey, touching the death of a male child which was found in a railway carriage at the Bricklayer's Arms station. Mr. Powell, the Coroner's officer, said that the deceased was a full-grown child, weighing eight pounds; he had carefully examined the body, and he found its tongue protruding, its nose flattened, and its lips very much discoloured, showing evidently it had been suffocated. A detective said he had been unable at present to get a clue to the guilty person, but asked the Coroner to adjourn the proceedings. The jury, however, in the absence of Medical evidence, returned a verdict of "Found dead in a railway carriage." Now, here was a death occurring under very suspicious circumstances—circumstances which clearly pointed to murder, and yet a verdict is given which amounts simply to the finding of the body! Human life will not be safe if such verdicts are to be returned. It was the emphatic duty of the jury to have known the cause of death, which they might have known had proper Medical testimony been adduced.

FOOT AND MOUTH DISEASE IN CHILDREN.

THERE seems to be little doubt that a malady very similar to the foot and mouth disease in cattle has been prevalent in some parts of England. It is stated in the *Halifax Courier* of last week that the disease has made its appearance amongst the children of Richard Clegg, a plasterer living at Newtown, near Preston. It is asserted that the malady has been propagated by the milk supplied by a neighbouring farm on which the stock has been affected by the foot and mouth disease.

CAUSE AND EFFECT.

THOSE who doubt the bad influence of imperfect drainage and sewerage may take the following fact, amongst others, to show them their mistake. The town of Salford is one of the most unhealthy in the kingdom, and its death-rate is excessively high. What is the cause? The Borough Surveyor, last week, in his report, stated that in his district there are ninety sewers, which contain from six inches to thirty-six inches of deposit.

WHERE WAS THE DOCTOR?

AT the Lambeth Police-court, on Tuesday last, Mr. Buckmaster, connected with the Department of Science at South Kensington Museum, stated to Mr. Chance that a young lady, in a first-class boarding-school in that neighbourhood, had been removed, during illness, to a miserable cottage away from the school; that this cottage was unfit, from sanitary defects, for human habitation, and the paper was rotting off the walls, mildewed and damaged. In this miserable habitation the young patient was kept; the cold from which she suffered turned into congestion of the lungs, and she died last Friday. Mr. Buckmaster said the young lady was from the country, and tenderly brought up, and the terms of payment at the school ranged from sixty to eighty guineas a year. In addition to the wretched state of the cottage, Mr. Buckmaster said the poor girl was put into damp sheets, in a damp bed. This, surely, is a case for inquiry. We may ask, Who, and where, is the Doctor?

RETAINING A MEDICAL MAN IN OBSTETRIC CASES.

IN a former number (November 3) we published, under the title of "Retaining a Doctor," the report of a trial in the Maidstone County Court—*Fitzpatrick v. Hadler*. The Judge said he would reserve his decision on the legal point until the next Court. That decision has since been given; it is as follows:—"That the engagement to attend the defendant's wife during her confinement, but which the plaintiff had been prevented from performing, owing to the defendant engaging another Medical gentleman, to whom he was man-servant, was only a provisional one, and that if Dr. Fitzpatrick had been more profitably engaged at the time and been sent for, he would not have been liable for breach of agreement." The verdict was consequently for the defendant. It need scarcely be said that the Judge was passing no opinion upon the sacredness of the engagement *in foro conscientie*. He simply, after mature consideration, came to the conclusion that the contract could not be enforced by law, evidently, as is to be gathered from his remarks at the first hearing of the case, because "there was no mutual advantage, as was necessary to make a breach of contract—there was nothing mutual." This doctrine is not peculiar to such a case as the present. It affects all contracts or engagements, whether relating to obstetric cases or agreements generally. The law will not recognise a breach of any contract where there has been no legal consideration. The only question in these cases is, whether a promise to attend within a reasonable time after being called upon to do so amounts, in the eye of the law, to a sufficient consideration to support the agreement, though such services were never required, or, rather, were never called for. The Court of Appeal at Westminster

alone can decide. County-court judges may differ, and their decisions are only binding when acquiesced in by the litigants without appeal. As, however, the decision of one county-court judge is not binding on any other judge, the Medical Profession need not be alarmed, as if the judgment of the Maidstone judge were settled and indisputable law; but unfortunately there is no appeal as of right from the decision of a county-court judge unless the debt or damage sought to be recovered is above £20; but by leave of the judge an appeal may be allowed in cases where the claim is for a less amount. It does not appear that Dr. Fitzpatrick has asked this leave, which doubtless would be granted, as the judge can only desire that right should be done.

COD-LIVER OIL SOAP.

A PLAN has been proposed by Dr. Van der Court, of the Hôpital St. Jean, Brussels, of giving cod-liver oil in mass, instead of in the fluid form. He adds to the cod-liver oil carefully pulverised slaked lime, little by little, until a pilular consistence is attained. Of the mass thus made four or five grains or more may be given for a dose after each meal. As a flavouring ingredient, he recommends oil of bitter almonds; that, of course, must be prescribed and used with care. The remedy is most useful in the early stages of consumption, less so in the advanced form, and least of all in the galloping variety of the disease. The more chronic the variety of the disease, the more good this remedy may be expected to do. Sometimes it gives rise to diarrhoea; if so, then the pills are to be left off for a time. The taste of the mass is not disagreeable, and the pills may further be coated in the ordinary way.

THE MANCHINEEL OF SOUTH AMERICA.

THIS plant, which is euphorbiaceous, is reported by the natives to be so poisonous as to give off poisonous effects to those who rest under its shadow. This has been denied on good authority, and was recently put to the test by the well-known botanist, H. Karstens. He gathered some of the juice of the tree in the district of La Guayra, and was presently seized with a burning feeling all over his body, followed by swelling especially of the face and eyes. Next day he could not open his eyes, and their irritation was so great that he had to pass some days in a dark room. On the third day the swelling began to abate, and the cuticle to desquamate, after which he gradually recovered. These effects are similar to those produced by other *Euphorbiae*; but the manchineel (*Hippomane manzanilla*) seems to differ from most in being capable of affecting individuals at some distance. Probably the immediate cause of the irritation is the dried juice, pulverised, and carried by the air.

"THE GARDEN."

THE above is the title of a new periodical conducted by the well-known botanical and horticultural author, Mr. William Robinson. His name will be ample security for the character of the work, for he has already done so much by introducing to our notice so many varieties of beautiful plants—flowers, shrubs, and trees—that we can only be too glad to have the prospect of a continuous rather than an intermittent supply of novelties. To the lovers of gardens and gardening—and their name is legion—this magazine will be most welcome. The first number we have seen contains some admirable hints and some beautiful engravings. We have hints how to plant orchids, how to make and beautify bog-gardens; some notes, to be continued, on the animal pests of gardens; a fine view of the yellow pine of the Yosemite Valley; hints as to indoor gardens; the tomato, and how to use it; with much more we cannot refer to. We heartily commend this magazine to horticulturists, great and small, for all may be benefited by its perusal and study.

MIDDLESEX HOSPITAL.

THE following resolutions have been passed by the Weekly Board and Medical Committee, on the occasion of the lamented death of Dr. Davison:—

“The Medical Committee desires to express its great regret at the death of Dr. John Davidson, late House-Surgeon and Resident Physician's-Assistant, whose intelligence, devotion to duty, high principles, and amiability won the esteem and respect of the whole staff.”

“The Weekly Board desire to record how cordially they unite with the expression of sympathy of the Medical Committee at the death of Dr. John Davidson, and their thorough appreciation of his most excellent character and services.”

PERIODIC RECURRENCE OF PRÆPATELLAR HYGROMA.

IN the *Berliner Klinische Wochenschrift* for November 27 is recorded a very unusual case from the clinic of Friedreich of Heidelberg. The patient was a somewhat delicate woman, aged 36. She came to Professor Friedreich with both knees alike, but with a history of a periodic swelling of the left knee-joint, recurring every twelve days, lasting for a day or two, and then gradually disappearing. The recurrence did not correspond with the catamenial periods, and was accompanied by violent palpitation. The swelling ceased during pregnancy. In Hospital the swelling came on, the pulse rose, and the patient complained of palpitation. The joint was smooth, pale, and not at all tender to the touch, the patient only complaining on violent flexion. Gradually the swelling disappeared, and, for the time, the patient was well. Loewenthal, who reports this case, conjectures, from certain of its features, that it presents an analogy to Graves's disease, and is due to a temporary neurosis.

FROM ABROAD.—M. HUSSON ON THE MILK IN CATTLE PLAGUE—

M. BEAUNIS ON THE WOUNDED ON THE FIELD OF BATTLE.

THE cattle plague (*typhus contagieux*), which prevails now somewhat extensively in France, has given occasion to M. Husson to present a paper to the Académie des Sciences on the ill-consequences which may result from the employment of the milk of the animals suffering under it. It has been pretty clearly proved that neither the flesh nor the milk of such animals will convey the disease, but they both may suffer greatly in their nutritive properties. To enable him to speak decidedly on this last point, M. Husson has analysed milk procured from four cows destined to be slaughtered on account of the disease, from fourteen cows regarded as more or less in a doubtful condition, and from four cows which appeared in no-wise affected. In all three categories the composition of the milk had undergone alteration, containing less butter and sugar of milk in proportion as the cows had suffered from the epidemic influence. As regards its appearance, the milk of the cows supposed to be healthy was normal, while that of the others had a more or less marked reddish-yellow tinge. The flavour of the milk of these cows was disagreeable; but a cat drank fifty grammes of it without suffering any inconvenience. M. Husson concludes from his researches—

“1. When the typhus breaks out in a cow-house, all the beasts therein are subjected, although in different degrees, to the epidemic influence. In fact, in this example, the whole herd died, with the exception of four cows, which never seemed to be ill, although they furnished one of the three specimens of milk analysed. 2. Milk cannot, any more than flesh, transmit the disease to man or to animals that do not belong to the ruminant family. 3. Nevertheless, even during the first stage of the disease, when the yield still continues normal, the milk should not be employed as food for young children, in consequence of the modification that has taken place in its principles. 4. From the commencement of the disease, the combustible elements of the milk in great part disappear, while the azotised elements, on the contrary, are increased in considerable proportions, and are soon found commingled with sanguinolent matters. Frequently there

may be observed, under the microscope, agglutinated globules, either mucous or purulent.”

M. Beaunis, who took an active part in charge of the wounded, first at Strasburg, and then during the calamitous campaign on the Loire, in an interesting account of this last, now publishing in the *Gazette Médicale*, makes the following observation on the question of dealing with the wounded on the field of battle:—

“This leads me to say a few words upon a question that has often been debated, but has as yet not received its solution—I allude to the removal of the wounded from the field of battle. This problem should not be solved by sentiment, but by facts; and at the risk of shocking respectable prejudices, partaken in even yet, at the present day, by many military officers, I shall frankly state my opinion, and explain its foundations. I do not stand forward lightly in this matter, for I have myself witnessed the facts, and have long reflected upon them, and discussed them with officers and with colleagues. The force of circumstances, then, has impelled me to this conviction, that *the wounded should not be removed from the field of battle until after the action has terminated*. Their removal under the fire of the enemy is an useless and dangerous practice, and, more than that, it is impossible.”

In adducing his reasons for this somewhat startling position, M. Beaunis first adverts to the very large number of men who are required for any such attempt, who can only be obtained from the ranks, to the derangement of these, and the encouragement of those who wish to shirk fighting. It is notorious that many more assist in the conveyance of the wounded than are necessary. When two or three men per company are indicated beforehand, or the musicians are so employed, these have been found insufficient, and do not reappear after removing the first wounded. The corps of *Krankenträger*, which it is proposed to copy from the Germans, would require a battalion of 750 vigorous *Brancardiers*, with all their encumbering *matériel*, to be attached to each division, subtracting so many from active service. In the very act of removal, the lives of two valid men, capable of good service, are risked for that of a wounded man, incapable of further service. Leaving the wounded thus is not so harsh a procedure as at first it seems, for it is rare for an engagement to last more than five or six hours; and, if fresh troops prolong the contest, the centre of action becomes displaced. Hæmorrhage is the only source of immediate danger to the life of the wounded. When this takes place from a very large vessel, death occurs before aid can arrive, however prompt; while bleeding from small ones may be arrested spontaneously or by mere compression. For those cases that can only be dealt with by Surgical interference, this, to be effective, either by methodical compression or the ligature, must be immediate—and that is impossible. Although the statistics of the frequency of hæmorrhages are very imperfect, it will be keeping certainly within the truth to say that there are scarcely two or three cases met with among 500 wounded. As to the operations which are termed urgent—such as the extraction of balls, immediate amputations, disarticulations, etc.—there are none of them but can wait a few hours, if not without inconvenience, at least without danger to life.

“Perhaps we should, although very rarely, lose some men who might be saved; but when, without flinching, thousands of existences are sacrificed during a battle, does it not savour somewhat of hypocrisy to make so much noise about arriving at such a result? We must look at war with coolness and with resolution. The cruel truth is this—human life during the combat is as nothing—everything disappears in the face of the supreme necessity of conquering; all that retards victory must be cast aside. It is no longer a human life, but an *impedimentum*. Speak not of humanity. Humanity should consist in not going to war; but, once made, this must be carried to its bitter end. The battle once over, things are entirely changed. Throw now into the field of battle every disposable man, all your Surgeons, all your *infirmiers*, and you will be able in a few hours to furnish all the wounded with succour far more efficacious than the imperfect

and hasty aid given during all the embarrassment of the action. Moreover, the removal of the wounded from the field during the battle is a myth, by which the popular imagination and sensitive hearts are soothed. In fact, it does not exist. Never have I seen an ambulance remove the wounded under the fire of the enemy. Those who say they have done this are imposing on us; or if they have really done it they have committed an act of madness. Ambulances have causes enough of disorganisation, and run dangers enough without creating them needlessly. If from the first battle they had acted thus, not a soul connected with them would now be alive. Still, is there nothing to be done to give these men condemned to death some chance of safety? Perhaps so; but then it must be sought from a different organisation. We may place in the soldier's knapsack, as is done in Germany, a bandage, a compress, and a little charpie, so that if wounded he may be able in some cases to aid himself at first."

MEDICAL DECLARATION RESPECTING ALCOHOL.

As it is believed that the inconsiderate prescription of large quantities of alcoholic liquids by Medical men for their patients has given rise, in many instances, to the formation of intemperate habits, the undersigned, while unable to abandon the use of alcohol in the treatment of certain cases of disease, are yet of opinion that no Medical Practitioner should prescribe it without a sense of grave responsibility. They believe that alcohol, in whatever form, should be prescribed with as much care as any powerful drug, and that the directions for its use should be so framed as not to be interpreted as a sanction for excess, or necessarily for the continuance of its use when the occasion is past.

They are also of opinion that many people immensely exaggerate the value of alcohol as an article of diet; and since no class of men see so much of its ill effects, and possess such power to restrain its abuse, as members of their own Profession, they hold that every Medical Practitioner is bound to exert his utmost influence to inculcate habits of great moderation in the use of alcoholic liquids.

Being also firmly convinced that the great amount of drinking of alcoholic liquors among the working-classes of this country is one of the greatest evils of the day, destroying, more than anything else, the health, happiness, and welfare of those classes, and neutralising, to a large extent, the great industrial prosperity which Providence has placed within the reach of this nation, the undersigned would gladly support any wise legislation which would tend to restrict within proper limits the use of alcoholic beverages, and gradually introduce habits of temperance.

PRELIMINARY EXAMINATIONS.—The examinations in Arts, etc., for the diplomas of Fellowship and Membership of the Royal College of Surgeons, was commenced on Tuesday last, and only brought to a close last night. There were 288 candidates—viz., 68 for the first-named distinction, and 220 for the latter. Owing to the large number of papers to be read, the result cannot be known until the middle of the ensuing month.

GENERAL CORRESPONDENCE.

THE DECLARATION RESPECTING ALCOHOL.

LETTER FROM DR. LIONEL S. BEALE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am very sorry to differ from my friend "F.R.S.," and am aware that the declaration was signed by many in the Profession, for whom all of us entertain the greatest respect. Perhaps I am altogether wrong in obtruding my views upon your notice, and in expressing my disapproval of that declaration, and I am doubtless open to the charge of presumption. Perhaps it would have been better to have signed the document and said nothing; for no one desires to see the healthy working public reduce its consumption of alcohol more than I do. I live almost without alcohol myself, but I do not think people can be made temperate by declarations, and am of opinion that if such machinery could do real good its efficacy would have been proved long ago. The truth is, I felt offended at the assertion made by the gentleman who brought the paper to me to sign, and the suggestion implied in the declaration itself, that there were in the Profession so many who prescribed alcohol *inconsiderately* that those who did not do so were called upon to express in a public document their condemnation of the circumstance. It crossed my mind that, but for the accident of the declaration having been brought to me to sign, I might myself have been put down as an inconsiderate prescriber of alcohol, and a reckless exciter of habits of intemperance. The number of inconsiderate prescribers amongst us ought, indeed, to be very large to justify such a proceeding as that which has been taken. My friend says, "I know personally some such cases, and I presume instances of the kind must have occurred to many." I have not known such cases myself, and I have no reason to presume that the instances are so numerous as to justify me in signing the document. "F.R.S." thinks that "habits of temperance" are to be introduced by wise legislation; others consider that habits of temperance will not in England be enforced by law. I venture to think that habits of temperance may be inculcated in this country to some purpose by personal influence; but I fear that not until the views entertained by temperate persons are thought a little more of than they are at this time, will such change for the better be brought about. Of late years, very little has been done to strengthen the only efficient machinery we have that can be brought to bear upon the erring individual; and if the public did what it could to second the efforts continually being made by men whose services in the cause are less acknowledged than they deserve, it would perhaps gain the end it seems so much to desire. There is hardly a clergyman in the country who does not his whole life long wage war against intemperance. He sees the habit being gradually acquired by the individual man, and does his utmost to avert the catastrophe. Is it not probable—but I hardly dare venture the suggestion—that, if public opinion in the village, town, city, and country would but give its support and approval to his efforts, and work with him in the same direction, the number of drunkards in England would soon be reduced, and the rising generation made healthier and happier than this one and some of its predecessors?

I am, &c.,

LIONEL S. BEALE.

DISTRICT MEDICAL OFFICERS AS OFFICERS OF HEALTH.

LETTER FROM DR. H. W. RUMSEY.

[To the Editor of the Medical Times and Gazette.]

SIR,—Any remarks by Dr. Druitt on the Health Officer question claim respectful consideration. His great personal experience and his acknowledged authority in matters of public Medicine render his recent address on this subject a document of much interest to those who are endeavouring to promote a better system of sanitary organisation. His description of the confusion, incompleteness, and administrative failures which have characterised the Medico-sanitary arrangements of the metropolitan districts is not less true than instructive; and when he declares it to be "the bounden duty of every Medical Officer of Health to make himself acquainted by personal inspection and measurement" with various particulars, which he minutely specifies, concerning "the house-accommodation of all classes" in his district; he would probably admit that

much of this information would be obtained by Health Officers "of the first instance"—that is, by those who would be called, on another system, "Deputy Officers of Health." These, as district Surgeons, would, in fact and in reason, combine curative duties with those of domiciliary inspection and prevention.

Dr. Druitt has also done well to negative the objectionable proposal to separate public Medical duties under the Poor-law from private Medical practice. This project has been, I venture to say, completely disposed of by "A Member of the Joint Committee" in the *British Medical Journal* of November 11, ult. So far, then, we are agreed; and no one has put the case of the District Medical Officers more fairly and reasonably than Dr. Druitt.

It is when he comes to treat of the superior Officers of Health that he appears to be at fault, indecisive, and not always consistent. His notions are apparently limited by his metropolitan sphere of observation. The great majority of the Joint Committee of two great associations appointed to consider this question would, I believe, differ from his conclusions. It is true that, in approaching this part of the subject, he demonstrates the existing necessity for, and affirms the "immense benefit" of, some kind of inspectorial visitation by a superior officer. But when he proposes that the whole of the work, curative and preventive, of the District Medical Officers, or Local Surgeons, as he prefers to call them, should be subject to the "inspection and criticism" of a "superior civil Practitioner," or "civil inspecting Practitioner," he strikes on a rock that will, I believe, sink his vessel of reform.

The District Medical Officers of the provinces certainly do not require, if they would tolerate, an inspecting Practitioner to criticise their curative efforts. They might be thankful for the aid of a pure Officer of Health, in the position of Dr. Trench, at Liverpool, who, being debarred from private practice, can in no sense become their critic or their rival—they might be thankful, I say, for the benefit of an arrangement which, in Dr. Druitt's own words, "would relieve them of the trouble of instituting law proceedings, and of the embarrassment of offending friends and patients"; but such an arrangement need not involve the interposition of another "Practitioner." Indeed, to commit these superior inspecting duties to any Practitioner would be to place him in the same dilemma from which Dr. Druitt wisely desires to "relieve" the district Surgeon.

When, moreover, I read the category of "possible duties" for his "real Medical Officer of Health," I cannot doubt that the engagements of private practice would be, to such an officer, anything but a support and encouragement in his official labours—anything but an aid to his preventive and scientific pursuits—anything but a benefit to the public, who should have a claim to his whole service.

Then as to special fitness for work. That pathology on the one hand, and chemical and physical science on the other, are equally good qualifications for the superior officer, may be granted, without consenting to dispense with either. A thorough knowledge of both would generally result from the "brains" which Dr. Druitt very properly prefers to mere acquirements. No one, however, could obtain the new diploma in State Medicine at Dublin without brains enough to make good use of it.

I am struck with Dr. Druitt's remark on Mr. Simon's suggestion, that the Medical Officer of Health might be advantageously connected with a Hospital, though he were debarred from private practice. Dr. Druitt thinks that the duties of the Hospital Physician or Surgeon to his patients and his pupils, and the regulations of the governors, "might quite as much interfere with urgent sanitary business as might the much more elastic attendance on private patients." No doubt Hospital work may encroach on public sanitary duty. But in this estimate he seems hardly to recollect that the ordinary duties of the superior or inspecting officer, to whom he refers, would not be of an "urgent" kind, and, however arduous, are almost all capable of methodical arrangement; moreover, that the duties of a Hospital Physician are also regulated systematically, and are shared by colleagues; whereas the casual demands on the time and effort of a consulting Practitioner are often remarkably sudden, uncertain, and imperative, and, therefore, far less compatible, even on that ground, with official duty.

Dr. Druitt nowhere seems to acknowledge that the sanitary interests of the public, and the moral independence of the chief officer, are likely to suffer from that domination of personal interests which is inseparable from private practice. On this point the report of the Joint Committee, of which, though a

member, he takes no notice, is sufficiently strong to convince any unprejudiced mind. In the same number of the *Medical Times and Gazette* which contains Dr. Druitt's address, fortunately appears a letter from Dr. Joseph Rogers, who puts this view of the case very forcibly. His objections to curative duties being superadded to those of control and prevention in the higher class of Health Officers, are, to my mind, unanswerable.

I do not believe that anyone who reflects on the circumstances of the assumed precedent, cited by Dr. Druitt, would admit that Sir James Clark's early appointment as Consulting Physician to the parish of St. George's, Hanover-square, "foreshadowed," in any degree, the appointment of a chief officer in legal and preventive Medicine. None of the duties or responsibilities of such an office fell to Dr. Clark. This is just one of those cases which, by being cited inappropriately, obscure the question at issue. The real objections to the combination of private practice with the inspecting office may be evaded, and its dangers may be ignored, by those who have made up their minds not to perceive them; but they have now been made sufficiently manifest, by free inquiry and open discussion, to warn our legislators against any measure of sanitary organisation which does not practically admit those objections, and does not guard the community against those dangers.

December 16.

H. W. RUMSEY, M.D.

AUTHOR v. CRITIC.

LETTER FROM DR. A. S. DONKIN.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have read a review of my recent work "On Diabetes and Bright's Disease" in the *Medical Times and Gazette* of December 16—a review in the highest degree objectionable, inasmuch as it tends, by a suppression and perversion of facts, to mislead the minds of your readers as to the character of my book. By this grave charge I mean that your reviewer attributes to me "inaccuracies and deficiencies" which, on a careful examination, I find I have not committed; but which, on the contrary, only exist in his own imagination, and are in reality, to use the mildest expression, misrepresentations. Surely if I can establish this charge, on the clearest evidence, I have just ground for complaint and for recording my protest against a hostile criticism altogether unwarrantable and unjust.

I shall now proceed to dispose of the whole of the strictures, *seriatim*, of which I complain, and leave your readers to decide the points at issue between us.

In the first place, I am accused of ignorance of the existence of sugar, or a copper-reducing body, in normal urine; but on what grounds this gratuitous assertion is made, I myself am ignorant, inasmuch as I have not given any description or analysis of healthy urine in my book, it not being a treatise on the physiology and chemistry of the urine. I assumed the possession of a knowledge of this subject by my Professional readers, who must be well aware that the presence of sugar in healthy urine is almost inappreciable, even by the most delicate reagents.

Secondly, I am taken to task for not having referred to Fehling's test for urine sugar, which, it is avowed, is "nowadays most frequently employed." To this objection I must reply, that I still adhere to the statement made in my work, that Moore and Trommer's tests are amply sufficient for clinical purposes, though not the most delicate. Is your reviewer aware that Fehling's test is condemned by no less an authority than Professor Vogel, of Halle, as being too complex and difficult for the ordinary use of the Physician? (See *Virchow's Handbuch der Speciellen Pathologie und Therapie*, Band vi. 2, 4, p. 504.)

Thirdly, your reviewer deliberately makes the following statement:—"The two means most commonly used for the quantitative estimation of sugar are fermentation or the polariscope. According to Dr. Donkin, neither of these is in use. He relies on specific gravity alone—surely a most unsatisfactory way of estimating sugar." Now, against this I must protest in the strongest terms, as a misrepresentation of the most unwarrantable description of what I have actually stated on this subject in my work, as will appear from the following passage literally quoted from page 89:—"As already stated, increase in quantity and elevation in density are conditions generally co-existent in the urine of diabetics, so that the degree to which they are developed supplies a very reliable practical guide as to the quantity of sugar voided in any particular case, and an index by which we can safely predicate whether

the amount is small or large; but when it is considered necessary to determine the exact quantity of sugar in any given specimen of urine, we must have recourse to a more definite procedure. For this purpose various methods are employed. One of the simplest and most ingenious is the beautiful apparatus invented by Soliel, and named the polarising saccharimeter, by which the quantity of sugar is accurately measured by the degree of polarisation produced." I must therefore request the reader to blot out this inexcusable misrepresentation on the part of the reviewer.

Fourthly, I am censured for having "merely recorded the experiments of Dr. Sidney Ringer (Mr. is a misprint), as quoted by Dr. Parkes," instead of having instituted investigations of my own, for determining the quantity of urea excreted in the urine in diabetes. Unfortunately this is another misrepresentation on the part of the reviewer; the truth being, that I refer to the experiments of Dr. Parkes and others on this subject, but not to those of Dr. S. Ringer. Those of the latter, quoted by Dr. Parkes, are referred to in my book merely to show the influence of nitrogenous food on the excretion of urea, and not of the disease itself.

Fifthly, I am censured for not having advanced anything new concerning the pathology of diabetes; having submitted instead "the observations of others alone." This statement compels me to believe that the reviewer has not read much of my book; otherwise he could not have entirely ignored my observations on the mal-assimilation of fat in diabetes, which is certainly a pathological question to which I have specially directed the attention of the Profession as a subject of the utmost practical importance, and one entirely new.

Sixthly, I am accused of having referred to a certain contribution by Grohe "in the following cabalistic formula—'Greifswald's Medicinische Beiträge,' B. iii. ii. i." Now, this induces me to ask in what quarter of the scientific world your reviewer has been asleep, that he is ignorant of the University of Greifswald, from which the late Felix Von Niemeyer, as a Professor of the Institution, issued the earliest edition of his now celebrated treatise on Pathology and Therapeutics, and from which, also, Bardeleben, another Professor, first produced his valuable "Handbuch" on Surgery? Surely he cannot be ignorant of the fact that Grohe is a Professor of this University, and that his contribution on diabetes, to which I have referred in my book, is not apocryphal, and that the quotation of it is not "cabalistic."

Such, then, is the complete catalogue of the errors and omissions (and I presume the most flagrant have been selected for exposure by your reviewer) for which I am censured, and on account of which my book is mercilessly condemned as being "poor in quality and insufficient in quantity on anatomy, physiology, pathology, and things in general." But I shall leave it to others to decide from the above defensive observations whether I or his judgment is at fault. Surely, he was morally bound, in justice to my reputation, to have been prepared with reliable and more weighty evidence in support of the opinion he has expressed, and to have shown a more scrupulous regard for accuracy and impartiality in his criticisms.

I am, &c.,

A. S. DONKIN, M.D.

8, Park-terrace, Sunderland, December 18.

WALTER COOPER DENDY.

[To the Editor of the Medical Times and Gazette.]

SIR,—As I am mentioned as one of the executors of the late Walter Cooper Dendy, in the very interesting account of him in your last number, I venture to send you the following remarks:—That account, on the whole, gives, I think, a very true impression of Mr. Dendy, but is not strictly accurate in one or two particulars. "J. F. C." says: "I believe he never gave a private dinner-party to his friends." I myself have repeatedly been present at dinner-parties at his house, and a mutual friend spoke to me only the other day of Walter Dendy's small dinner-parties as among the most agreeable at which he had ever been present, and as perfect in their way. The "Presidential dinner" would not have been what "J. F. C." describes it, if it had been so entirely exceptional as he supposes. Again, the statement that Mr. Dendy "had no amusements out of doors" is not correct. He was fond not only of out-of-door studies, but also of fishing and cricket. He was, moreover, a very considerable traveller, going over a great deal of ground in a short time, and contriving, nevertheless, to bring home many sketches by his own hand. And here I may mention that, apart from travelling, he had very

remarkable geographical knowledge. By the study of maps and descriptions he was able, to a degree I have never known equalled, to realise scenes which he had not personally visited. In talking with him about tours of my own I have frequently been astonished at the accuracy of his conception of places he had never seen—of views from mountains, etc. After the marriage of his brother, some seventeen or eighteen years ago, he gradually became the recluse he was in his last years. "J. F. C." says—"I understand it is the intention of his executors to publish a posthumous volume of his writings." What the executors may do in this respect, I know not; but at present they have not given the subject any consideration. Finally, I am represented as having been unable to "convince myself that Dendy was dead," and as having "positively insisted that he should be examined in his coffin by some Medical gentleman." This is founded on some misapprehension. The facts are simply these:—Finding that his Medical attendant had not seen him since his death, I said I thought he should see him, as a proper thing in every instance. I did indeed notice that Mr. Dendy's forehead was not so cold as might have been expected; but this was easily accounted for. Personally, I had no doubt whatever of his death. I wished him to be seen by his Medical attendant, in accordance with my general rule in such circumstances, when any responsibility rests on me. In my own circle of acquaintance, there have been two cases in which persons have been left for dead by friends and nurses, and have still recovered. In some, if not all, towns in Germany, no interment is allowed to take place without a certificate of death by a Medical officer appointed for the purpose. I think this an excellent regulation. With these trifling exceptions, the notice in your pages of Walter Cooper Dendy is, I believe, as faithful as it is interesting.

I am, &c.,

December 18.

T. S.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, DECEMBER 5.

Mr. HILTON, F.R.C.S., President, in the Chair.

DRS. POWELL and WHIPHAM read a Report on the Specimen of Lung and Kidney submitted to the Society by Mr. Squire. In the lung fibroid and adenoid tissue seemed to be increased around the alveoli. In the kidneys the epithelium was affected, and the Malpighian tufts were amyloid.

Dr. C. T. WILLIAMS reported for Dr. Quain the case of a man sent to Dr. Quain by Mr. Wilks of Salisbury. The patient died of Dilatation of the Aorta, its walls being atheromatous, and the left coronary blocked. There was also fatty degeneration of the corresponding ventricle. The patient was a middle-aged man—a gardener, who worked much in stovehouses. He had latterly lost flesh and colour, and had suffered from dyspnoea. He had some fulness in the neck, and a prominence on the right side of the sternum. He suffered much from angina, and died in a fainting fit.

Dr. CRISP said he had not been able to trace atheroma to such a cause as exposure to a heated atmosphere. In some of the worst cases he had seen there had been no exposure to heat.

Dr. WILLIAMS said he only meant to say that exposure to heat was one cause *inter alia*. He had seen it in stokers, cooks, etc.

Mr. SQUIRE suggested that the heat might involve drink.

Dr. DICKINSON asked if atheromatous disease was more common in hot climates.

Dr. WILLIAMS could not say. He meant that such an atmosphere as that of a conservatory might induce disease.

In reply to the President, he stated that the pain extending down the arm was probably connected with angina.

Mr. HULKE could not understand the *modus operandi* of heat, as atheroma was known to begin from irritation of the arterial walls.

Dr. WILLIAMS also exhibited the Supra-Renal Capsules from a boy of 18, who had shown signs of phthisis. For these he was admitted to the Brompton Hospital, when, after a time, he began to vomit, and his complexion grew darker. Gradually he got weaker, until at last he died. His body was emaciated; his lungs adherent and tubercular, and much pigmented; his supra-renal capsules were enlarged, and they contained soft

cheesy matter, with fibrous material and oil. The lungs were seldom so much pigmented in Addison's disease. The symptoms began six weeks before death.

Mr. A. T. NORTON exhibited a specimen of Epithelioma or Papilloma from the Larynx of a patient who came to St. Mary's Hospital with a white patch below the chordæ vocales. This was relieved, but did not disappear. He was admitted later with great difficulty of breathing. There was a granular ulcer in the right side of the larynx. Nothing was done, and he died in three days. The lymphatic glands were enlarged. The growth seemed to be of the nature of a papilloma.

Mr. I. BROWN asked on what clinical grounds the ulcer was concluded to be malignant, as cancer of the larynx was very rare, except when it spread from other parts. Most growths only assumed malignant characters after repeated removal. There was no appearance here to warrant the epithet.

Mr. NORTON concluded the growth was an epithelioma from its general appearance. It was not syphilitic or warty.

Mr. BROWN said syphilis had nothing to do with warts in the larynx. Syphilitic growths were condylomata in that situation. (Referred to Committee on Morbid Growths.)

Mr. F. CHURCHILL exhibited a specimen of Lipoma simulating Ranula. He said this tumour was removed from under the tongue of an old man, 86 years of age. The specimen is unique so far as the Society is concerned. I have been unable to find in the *Transactions* any records of a lipomatous tumour removed from this situation, and there is no such tumour in the Museum of the College of Surgeons. Mr. Liston refers to the removal of fatty tumours under the tongue in his work on Practical Surgery. Mr. Pollock removed a fatty tumour from below the jaw of a lady 40 years of age, enveloping the mylo-hyoid muscle; but in this case the intrinsic muscles of the tongue do not appear to have been encroached upon by the tumour. In several cases, hardened putty-like masses have been removed from a ranular cyst, as also phosphatic concretions. During the last session of the Society, Mr. Waren Tay exhibited four or five butter-like masses, which he had removed from a ranular cyst, but "under the microscope no definite structure could be detected in them. Entangled in the substance comprising the masses were some cells, and portions of cells looking like *debris* of epithelium." Dr. Meymott Tidy, after a careful chemical analysis, "was disposed to regard the bulk of the deposit as adipose." The history of the case was as follows:—H. T., aged 86, was admitted to the Westminster General Dispensary, under the care of my colleague, Dr. Waite, who treated him for *eczema rubrum* of the leg. After consultation with Dr. Waite as to the nature of the tumour beneath the tongue, supposing it to be a ranula, I suggested that it should be removed in the usual way. He stated that on several occasions fluid had issued out from the tumour, after which it was distinctly smaller. The incisive teeth in the lower jaw were intact, and situated just behind these was a movable (apparently pedunculated) tumour, about the size of a walnut, covered by the smooth glistening mucous membrane of the floor of the mouth. The tumour was also, in part, covered by the sublingual gland; it was soft and yielding, and I was under the impression that I could detect fluctuation. The distended mucous membrane was being chafed by contact with the sharp edge of the teeth during mastication. The old man had noticed the swelling for twenty-two years. It had gradually increased up to the present time. During the past twelve months, however, it had given him pain, in consequence of chafing against the teeth; he much feared that it was a cancer. From its size it had also interfered with mastication, and acted as a serious impediment to his speech. Having removed a portion of the anterior wall of the tumour, I proceeded to turn out the contents, but found, underlying the mucous membrane, a bright glistening mass, resembling a cyst-wall; this was seized with a pair of clutch-forceps and drawn forward, a small portion of it being removed, but still no fluid escaped. I proceeded then to separate the adhesions to the mucous membrane with the spoon end of a director, but the deep connexions were too firm to separate in this way; the finger also failed to enucleate the mass. The tumour was forcibly drawn forward, and these deep attachments cautiously divided with the knife. In this way the tumour, which was lobulated, and enveloping (probably) the genio-hyoglossi muscles, was removed. Exploring the cavity afterwards, I could feel the sharp borders of the vertical muscles, and I was satisfied that the growth had been entirely removed. There was very little hæmorrhage after the operation, and the cavity had completely closed in the course of a week.

Mr. FAIRLIE CLARKE said Mr. Paget referred to a similar

specimen to be found in the museum of Middlesex Hospital. Did the tongue deviate?

Mr. CHURCHILL said No; the tongue was quite straight.

Mr. HULKE said the tumour in Middlesex Hospital was twice as large as this. The time it had lasted did away with the idea of ranula.

Dr. GREEN exhibited a specimen of Interstitial Pneumonia from a man aged 60, who came into Charing-cross Hospital with a broken thigh. He had suffered from chronic bronchitis, and died of an acute attack of that malady. The right lung was adherent; its pleura thickened and soft. There was no consolidation or caseation, but the lower lobe looked like a piece of sponge, and was made up almost entirely of dilated bronchi and fibrous tissue. It was quite soft to the feel. The left lung was like the upper lobe of the right. The kidneys were slightly indurated. In the right lung was a fibro-nuclear growth round the bronchi and bloodvessels. The nuclei were in part fusiform, and the tissue was fibrillated. In some parts the alveoli were little affected. He supposed that the bronchitis had led to dilatation of the bronchi, due to increase of the peribronchial connective tissue, which invaded and obliterated the alveoli in parts. He was inclined to doubt the existence of primary fibroid change. He thought it arose from antecedent pleurisy, pneumonia, or bronchitis.

Dr. WILSON FOX said the case was a very rare one; for simple induration arising in the inter-alveolar substance, without the alveoli being affected, was very rare. He thought Dr. Green's explanation was correct. Primarily, there had been chronic bronchitis, with dilatation and consolidation around, spreading into the alveoli. There was also some catarrhal pneumonia; but the thickening of the septa exceeded its products in amount. There was no phthisis here.

Dr. PAYNE asked what was the condition of the heart, especially on the right side. He did not care to advance views, but he would suggest an explanation—viz., that the soft thickening of the pleura, the induration of the lung, and the dilatation of the bronchi were connected with dilatation of the heart. Stoppage of the due supply of blood was often the starting-point of such changes.

Dr. POWELL said twelve years' bronchitis would render congestion of the base probable, and from that Dr. Green's explanation was clear. He did not well understand dilatation of the bronchi as a primary change. He thought obstruction to the exit of the blood more likely to cause induration than insufficient supply.

Dr. GREEN said the right heart was perhaps slightly dilated, but that was not easily judged of. The absence of pigment at the base of the lung militated against the idea of congestion.

Dr. DICKINSON said he had reported a case where plugging had given rise to hardening.

Dr. CRISP exhibited a model of dilated stomach from an elderly lady who had suffered from pain in the region of the cæcum. She was much troubled with vomiting; there was slight jaundice, and she died exhausted. The greater curvature of the stomach reached the pubes, and the pylorus was near the cæcum. Round the pylorus were some hardened glands. The liver was cirrhotic. He thought the kind of food had a good deal to do with enlargement of the stomach; so, also, had tight-lacing.

Mr. SPENCER WATSON thought living on vegetable food gave rise to gastric enlargement.

Dr. CRISP also showed a specimen of Hip-joint Disease, complicated with Bright's disease, in a boy aged 16. He died of uræmia. The hip disease had probably been induced by a fall.

Dr. DICKINSON thought the kidneys were probably lardaceous. They were referred to him for examination.

Dr. SIMS exhibited a specimen of Malignant Disease of the Liver. The organ was greatly enlarged and smooth. Ascites came on, and vomiting. Death ensued. (Referred to Committee on Morbid Growths.)

CLINICAL SOCIETY OF LONDON.

FRIDAY, DECEMBER 8.

Dr. J. BURDON-SANDERSON, President, in the Chair.

Dr. BROADBENT related a case of Tumour in Left Half of Floor of Fourth Ventricle, with Tumour in Cerebellum. The patient, a child 2 years of age, came under his (Dr. Broadbent's) care amongst the out-patients of St. Mary's Hospital on March 14, 1870. Three weeks previously, the child had begun to have what the mother called "screaming fits," which only came to

an end when it was utterly exhausted. She slept well, ate ravenously, drank much; the bowels were confined; and every morning there was vomiting before any food had been taken. On examination, the left side of the face was found to be paralysed; and the left eye was not closed, either voluntarily or in winking, or when the cornea was touched. There was no marked strabismus; but this eye could not pass the median plane of the orbit outwards. The right hand was clenched and agitated while the child cried, and was continually in motion when it was quiet. The left hand was quiet, or moved naturally. Both legs were continually in motion—the right most. There was little change during the five weeks in which the patient was under observation. The paralysis of the sixth nerve and of the portio dura of the seventh became more marked; the loss of power in the right hand more evident—the rigidity and agitation continuing. The screaming, vomiting, and constipation were little affected by the treatment, which consisted in the application of a leech behind the left ear; and in the administration of an aperient powder—and first, of chloral in ten-grain doses, every four hours; later, of belladonna in full doses. The child died on August 20. A tumour was found to occupy the left half of the floor of the fourth ventricle, involving, as was anticipated, the common nucleus of the sixth and portio dura of the seventh nerves (shown by Stilling and Lockhart Clarke to be situated in the fasciculus teres), and in a less degree the already decussated motor tract from the right half of the body. Another small tumour was found in the left hemisphere of the cerebellum; but as all the symptoms were explained by the tumour in the floor of the fourth ventricle, it had probably not given rise to any characteristic symptoms. Both tumours were gliomatous in structure.

Mr. CARTER asked if there was any ophthalmoscopic examination. He had once seen a paralysis of the portio dura disguised. The child had epiphora of the right eye. His assistant supposed that arose, as usual, from obstruction of the nasal duct, and was about to administer chloroform for the purpose of removing it by catheterism when he noticed that the child cried with one side of the face only. The flow of tears was the only sign of paralysis.

Dr. C. T. WILLIAMS referred to the cerebellar tumour, which he thought would produce some sign.

Dr. BROADBENT said the use of the ophthalmoscope would have been hardly possible, but he would have tried it had he at the time (now a good many years ago) thought of its value. All the symptoms were explained by the tumour on the floor of the fourth ventricle.

Dr. HABERSON narrated two cases of Disease of the Heart. The first instance was that of a young man aged 30, who had been accustomed to great muscular exertion, and in whom the aortic valves were rendered imperfect by continued strain. Hypertrophy and dilatation of the left ventricle ensued; and the physical signs of aortic obstruction and regurgitation were accompanied by urgent dyspnoea and by paroxysms of angina pectoris. The mitral valve at length became so stretched that it ceased to act as a valve, and the indications of pulmonary and abdominal congestion became apparent. At this time a triple sound was audible at the apex of the heart, and continued for several weeks—till, in fact, the right ventricle became accustomed to the additional strain thrown upon it, and beat in unison with the left ventricle. After a time a systolic bruit at the apex replaced the triple sound. The triple sound was explained by the want of synchronous action between the two ventricles. It has been noticed in rupture of the mitral valve, and also in cases of contraction of that valve; and in this instance it occurred for a short period in connexion with an overstrained mitral valve. The patient became slowly exhausted by the increased embarrassment of the heart and by dropsy. The second instance was that of a child, aged 11, in whom severe cardiac disease affecting the mitral valve followed an attack of rheumatism. Three years previously he had the first attack, and had been ill for a fortnight before his admission into Guy's Hospital on February 22, 1871. There was pain in the limbs, and, in the plane of the mitral, a loud systolic bruit, and a less distinct presystolic one, were audible. He improved in health till about the middle of April (12th), when the presystolic bruit became more distinct; and this indication of fresh disease was shortly followed by severe brain symptoms; vomiting and delirium, with hemiplegia on the left side, suddenly supervened; symptoms of great prostration followed, with convulsive movements of the right side, and, when consciousness was regained, he cried out and complained of pain in the head and in the spine. On the third day he began to rally, and in ten days the paralysis began to

lessen, but the hand and arm recovered before the foot and leg. The presystolic bruit also ceased, and the systolic mitral bruit alone remained audible. He left the Hospital relieved on June 24. The presystolic bruit was probably due to deposit upon the mitral and consequent obstruction, and increased deposit led to augmentation of the sound. The cerebral symptoms were traced to embolism; and soon after the onset of these symptoms the presystolic bruit was diminished in intensity, as if the mitral, relieved of a portion of fibrinous deposit, acted more freely. The retrocession of the hemiplegic symptoms was in the inverse order from ordinary hemiplegia from apoplexy—namely, that the arm recovered before the leg and the hand, and the feet before the shoulders and the hips. Very little Medical treatment was permitted in this case, and it illustrated in a remarkable manner the natural subsidence of the symptoms of disease as the circulation of the brain accommodated itself to the temporary obstruction.

Dr. ALTHAUS had recently a case of aortic regurgitation and hypertrophy, of rheumatic origin, under his care. He treated the case with digitalis and iron, and the patient did very well. In another case he was induced to give opium; in three days, anasarca and suppression of urine followed, the legs were punctured, and gangrene and death supervened. He considered the opium the remote cause of the man's death.

Dr. SANDERSON remarked on the interest of the triple apex-sound, and the widened and thinned mitral. Usually, under such circumstances, the mitral was contracted. Had it existed long?

Dr. C. J. B. WILLIAMS had often noted the existence of symptoms like those recorded by Dr. Habershon—viz., the existence of a double systole, so as to produce a triple sound. He had seen that end in mitral regurgitant murmur. He thought it was explained by the mitral valves not tightening at the time the walls contracted. Gradually the sounds became prolonged into a murmur. This supposition was based on the belief that the first sound was due to tightening of the whole mass of the heart, modified by a mitral sound. When there was universal embarrassment of the heart's action, mercury often did good—often most when combined with digitalis. Opium did harm rather than good. Digitalis was of service, doubtless, in increasing the action of the mercury.

Dr. BROADBENT thought there was probably more than one condition leading to reduplication of the first sound. Want of synchronism of the two ventricles, doubtless, did. This was best heard over the septum with the single stethoscope. In cases of disease of the kidney, the right side got the start; in lung disease the left had it. He also thought that mercury did good.

Dr. LANGDON DOWN also considered reduplication to be due to want of synchronism, which, with the use of digitalis, speedily departed.

Mr. LAWSON asked in what position the patient was tapped. Sometimes it was done sitting, and then faintness was almost certain to follow.

Dr. HABERSON, in reply, stated his opinion that, as a rule, opium did harm. He could give no exact date of the stretching of the mitral valves. He thought the cause of the reduplication was sudden tension of the lung and flagging of the right ventricle.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, DECEMBER 12.

Mr. CURLING, F.R.S., President, in the Chair.

A PAPER by Dr. JOHN HARLEY was read

ON THE PATHOLOGY OF SCARLATINA, AND THE RELATION BETWEEN ENTERIC AND SCARLET FEVERS.

In the first portion of the communication the author treats of the morbid anatomy of scarlatina, and gives the details of twenty-eight cases of his own observation. Of these, the greater number died on days ranging consecutively from the third to the fifteenth; the remainder died on the seventeenth, twentieth, twenty-fourth, twenty-ninth, thirty-third, forty-first, and sixty-ninth days. More or less albuminoid and fatty degeneration of the kidneys existed in six of the cases, and these died on the fifteenth, seventeenth, twentieth, twenty-ninth, forty-first, and sixty-ninth days respectively; the kidneys were healthy in the remainder. The pathological changes common (with a few exceptions, depending chiefly

upon the time of the decease of the patient) to all the cases are as follows:—1. *The formation of fibrinous clots in the heart and great vessels during a pyrexial condition at any period of the disease.*—This is the commonest cause of death during the early stage of the disease. It is indicated during life by the reduction, often very sudden, of a full and bounding pulse of 120 to a dribble of 150 or 160 almost imperceptible impulses; and the failure of the heart's action is commonly attended with orthopnea and delirium from obstruction of the pulmonary and cerebral circulation. On opening the body very soon after death, before it has lost a degree of temperature, and while the blood is therefore hot and fluid, the right heart will be found distended partly with dark blood, which coagulates on exposure—and partly, sometimes chiefly, with a large, firm, white, bifid clot, continuous through the auriculo-ventricular opening. Each portion is interlaced with, and firmly adherent to, the tendinous cords and outstanding muscular bands of the cavity in which it lies; and each portion sends a rope-like prolongation into the orifice of the great vessel connected with the cavity in which it is situated—the one entering the ascending cava, and the other the pulmonary artery. These processes frequently occupy half the area of the blood-tubes, and are prolonged in ramifications corresponding to those of the bloodvessels, upwards into the cranial cavity, and laterally into the lungs. On withdrawing these partial casts of the great vessels, they may often be found nine inches long, and to have occupied vessels of the sixth and seventh degree of ramification. 2. *Marked derangement of the hepatic function.*

—The bile was examined in twenty cases. In five only were the characters of the secretion normal, and in these cases death occurred on the third, fourth, twenty-fourth, forty-first, and the sixty-ninth days respectively—days probably in these particular cases too early for the development, and too late for the persistence, of any great derangement. In the remaining fifteen cases the bile was in a deteriorated condition. In two, Cases 10 and 15, the gall-bladder showed decided marks of inflammatory action, the coats being injected, and the mucous membranc rose-coloured. In Case 10 there was a complete absence of bile, the mucous membranc being merely moistened with a few drops of colourless alkaline fluid. In three other cases the bile had a natural greenish-brown colour, but it was greatly deficient, as was that of the remaining ten cases, in solid matters. Thus the specific gravity in none of the thirteen cases exceeded 1014, and the amount of solid matter in 1000 grain measures in no case amounted to more than 36.4 grains, or less than one-third of the normal amount. In one case there were only 11.1 grains of solid matter in 1000 grain measures of the bile. In the majority of the cases the bile was turbid from epithelial debris, but on standing it became clear and transparent, and resembled pale urine. In all the thirteen cases there was a notable deficiency of biliary acids, and in two a complete absence. The colouring matter of the bile was present in every case, and as the fluid trickled over a white surface it usually left a bright gamboge-coloured track. The contents of the intestines agreed with this condition of the bile. If, as rarely happened, the bowel contained solid fæces, it was of a pale ochre or sulphur colour. But the fæcal matters were commonly fluid, grumous, or flocculent, often slimy, and of a pale ochre colour. Such, also, were the characters of the stools before death in many cases. 3. *General inflammation of the lymphatic glands,* usually confined to those of the neck, but occasionally extending to those of the extremities; of the spleen and mesenteric glands; and of the whole of the solitary and agminated glands of the alimentary canal, but commonly affecting only those of the fauces, and of the ileum and colon. The morbid appearances due to this general inflammation of the lymphatic system were remarkably uniform, and they were observed in every case. The tonsils and solitary glandulæ of the tongue, and the external glands of the neck, were perceptibly affected in every case. In several cases large buboes formed in the neck; in three (15, 21, and 22) these were associated with diffuse cellulitis, and purulent infiltration; and in Case 22 the popliteal and axillary glands and their surrounding connective tissue were similarly affected. In these cases the glands themselves were slow to take on suppurative action, and although they were generally much enlarged and purple, comparatively few had softened centres. The spleen was enlarged in twenty-three cases, and in five of these (Nos. 9, 12, 14, 25, and 26) it was increased to nearly twice its ordinary bulk. In two others it was not examined; and in the remaining two cases (10 and 27, in which death occurred on the fifth and sixty-ninth days) it was of the normal size. The mesenteric glands were swollen and inflamed in every case.

In Cases 2, 6, 7, 8, 12, 19, 22, and 24, the mesentery formed a thickened, heavy, lobulated mass, and many of the glands were as large as walnuts or pigeons' eggs. In Case 13 (death on the seventh day) there was only slight swelling of these glands, whereas in Cases 26 and 28, in which death occurred at the forty-first and sixty-ninth day respectively, the enlargement still persisted. Even the small glands in the attached borders of the transverse and descending mesocola were found purple and turgid. The solitary glandulæ of the ileum were in a condition of psorentery—*i.e.*, forming white granular and more or less hard elevations, like a thick sprinkling of large sago-grains, upon the mucous membrane—in fourteen cases. In six other cases, the solitary glandulæ were only partially affected, the swelling was more diffuse, the glandulæ being only moderately raised, but they were always deeply injected, and in some cases had an abraded appearance. In three cases, in which death occurred on the eleventh, seventeenth, and sixty-ninth days of the fever, there was only very slight swelling of a few of these glands; and in four cases, in which death occurred on the fifteenth, twenty-fourth, twenty-ninth, and thirty-third days respectively, the glandulæ were altogether unaffected. The agminated glands of the ileum were more or less swollen and inflamed in every case but one (25), that in which death happened on the thirty-third day. In Case 21 (death on the seventeenth day from suppurating buboes in the neck), there was only very slight swelling. In all the other cases the results of inflammatory action were decided, and in many cases severe. The glands were commonly raised the eighth of an inch above the surrounding mucous membrane, than which they were always more deeply injected. In the greater number of cases the difference was very striking, the mucous membrane being generally pale, and sometimes thin and bare, while the agminated glands were of a vivid red or claret colour. The inflammatory action was usually confined to the glands in the lower third of the ileum, but in three or four cases the whole of the patches from the jejunum downwards were affected. In some of the larger glands isolated foci of inflammatory action were occasionally observed. The interfollicular ridges were often the eighth of an inch wide, giving to the paler glands a spongy appearance; but these ridges were as often vascular, with fine hair-like turgid vessels, and in some cases they were prolonged into folds a quarter of an inch in length (*see* Cases 3, 6, 7, 8, 12, and 15, in which death occurred on the third, fourth, fifth, sixth, and ninth days). In two or three cases an almost bleeding gland had a softened abraded surface. The mucous membrane of the ileum was itself severely inflamed in two or three cases, and was covered by a thick, adherent layer of white opaque mucus. The solitary glandulæ of the large intestine were enlarged and inflamed in eight cases (Nos. 4, 6, 7, 9, 16, 17, 19, and 22). In one of these (9) there was acute desquamation of the mucous membrane of nearly the whole of the bowel. In another case (27), the cæcum was severely congested. In those of the remaining cases in which the large intestine was examined, it was quite healthy. After taking the above described pathological conditions into one general view, it appears that there is an increase of fibrin in the blood during an attack of scarlatina, and that death is likely to occur during the first week from its deposition in the heart and great vessels; that the condition of the biliary function is such as to lead to an outbreak of diarrhœa, if this has not already happened; that a latent enteritis, sometimes general, but commonly only affecting the solitary and agminated glands, exists in a high state of development during the pyrexial stage of scarlatina, and ready to declare itself openly upon very slight provocation; that this intestinal affection is only a part of a general lymphatic inflammation which involves the whole of the lymphatic system, including the mesenteric glands and the spleen, in one common action; and, further, that this condition may persist in some degree, either in the bowel or the mesentery, as late as the sixty-ninth day, and without any outward indication of its presence throughout. From this view one general conclusion is inevitable—*viz.*, that the pathological changes accompanying an ordinary attack of scarlatina include all those of the first stage of enteric fever, and that the transition from one disease to another is but a natural pathological sequence, readily determined by any cause which may increase the intestinal irritation. The proofs of this interchange, or sequence, constitutes the second part of the subject, and contains accounts of the following original observations:—Case 29—Scarlatina. Convalescence on the thirteenth day. Relapse during sojourn in the Hospital, with scarlet rash on the twenty-eighth day; fully developed enteric fever on

the thirty-second day; and convalescence on the fiftieth day. Case 30—Scarlatina. Convalescence on the nineteenth day. Relapse during sojourn in the Hospital on the thirty-first day, followed during the next ten days by fully developed enteric fever; convalescence on the sixty-fourth day. Case 31—Scarlatina. Convalescence on the thirteenth day. Discharged from the Hospital on the twenty-third day. Super-vention of enteric symptoms on the thirty-seventh day. Re-admission in a typhous condition, and suffering from grave enteric fever on the fifty-eighth day; convalescence on the eighty-first day. Case 32—Severe attack of scarlatina. Convalescence on the twenty-seventh day. Slight relapse, with a trace of albumen in the urine, on the thirty-second day. A second relapse on the forty-first day, followed by diarrhœa, with hæmorrhage from the bowel and pneumonia; and death on the fifty-first day. Case 33—Scarlatina. Convalescence on the twentieth day. Discharge from the Hospital on the thirty-first day. Re-admission, with fully developed enteric fever, on the fifty-sixth day; and death on the sixty-fourth day. Extensive ulceration of Peyer's patches. Case 34—Scarlatina. Convalescence on the twelfth day. Relapse during sojourn in the Hospital on the twenty-seventh day. Development of enteric fever on the thirty-second day; and death on the fiftieth day. Extensive ulceration of the solitary and agminated glands. The author next gives a series of cases to illustrate the co-existence of the two diseases; and he concludes as follows:—"The intercurrent or sequence of scarlatina and enteric fever has been frequently noted, and always attributed to accidental coincidence. In my article on 'Enteric Fever' in Reynolds's System of Medicine, I have expressed my convictions on this subject; and so strong were they in favour of the natural sequence of the diseases at the time that work was publishing, that I find I have in the proof-sheet called my contagious variety of enteric fever 'abdominal scarlatina.' I abandoned the term then because it seemed to me that the evidence which I had adduced to show the close relationship implied in it was insufficient to convince those whose opportunities of examining the question in detail were rare, and whose scholastic principles, moreover, would be shocked by such confusion of two diseases which are commonly considered to be specifically distinct. Now, however, that I am enabled to lay before the Society such full and complete evidence as is contained in the preceding observations, I will submit this term to the Profession as a definite description of a disease which the Practitioner will occasionally meet with. Nor will I allow this opportunity to slip me, but, in the interests of truth, will ask my fellow-labourers to go with me one step further, and to discard those transcendental ideas of enteric fever which make of it a disease *per se*, and to open their minds to receive what nature will then soon teach them—*viz.*, that enteric fever and all its attendant phenomena may occasionally become a part of almost any other more general inflammatory condition, specific or simple."

Dr. BROADBENT said that the Society was indebted to Dr. Harley for a very complete description of the pathology of scarlet fever. He could not, however, agree with all the views of the author of the paper. It was quite true that an attack of enteric fever often followed one of scarlet fever; but it must be remembered that the converse was sometimes the case, the two diseases overlapping each other in all directions. Not only did enteric follow scarlet fever, but scarlet fever sometimes followed enteric. He (Dr. Broadbent) had seen instances in which, during an attack of enteric fever, scarlet fever appeared, and ran through its course before the completion of the enteric attack; so that for a time there was a combination of the symptoms of both fevers—sorethroat and intestinal affection, rose-spots and scarlet rash. Their overlapping, and their occasional co-existence, indicated that the diseases were distinct rather than identical. There was no doubt a similarity in the pathological results of the two diseases; but there was this striking difference: that in scarlet fever, unless there were distinct evidence of a new attack, the disease stopped short of ulceration of Peyer's patches; whereas this occurred early in enteric fever. The affection of the lymphatic system in both diseases was no proof of their relationship, further than it showed that they were both blood-diseases.

Dr. SANSOM admitted the elaborateness of Dr. Harley's description of the pathology of scarlet fever; but he thought that much credit was also due to Dr. Fenwick, who had worked at this subject. He agreed with Dr. Broadbent that evidence as to the unity of the diseases was deficient. Another argument against the view of identity was in the difference of the causes; typhoid fever being propagated by emanations,

scarlet fever by contact. It should be remembered that scarlatina raged most in localities where typhoid fever prevailed.

Dr. T. H. GREEN must hesitate considerably before being able to accept Dr. Harley's views. As to the pathological changes in the lymphatic glands, these occurred in other acute inflammatory conditions, especially in children.

Dr. JOHN WEBSTER could not think that scarlet and enteric fevers were identical. He asked whether a child suffering from scarlatina ever communicated enteric fever.

Dr. REGINALD THOMPSON said that there were two points of distinction in the clinical history of the two diseases. First, it sometimes happens that scarlet fever occurs in a choreic patient, and then the chorea becomes mitigated or removed; while, in two cases where he had seen typhoid fever occurring during chorea, the latter disease was not influenced. Secondly, rheumatism often followed scarlet fever, but was not known as a sequence of typhoid.

Dr. CHARLTON BASTIAN said that the facts brought forward by Dr. Harley tended to show the alliance between the pathological conditions of scarlet and of enteric fever. It was known that there was a general resemblance between the pathological conditions in fevers, and that there was a general tendency to affections of the lymphatic system. The evidence brought forward by Dr. Harley suggested the question whether the condition of system induced by scarlet fever might not favour the development of enteric fever. He saw no reason why the two conditions should not be interchangeable. The idea of the so-called specific nature of diseases was derived from the belief in the specific nature of animal and vegetable species; and if there were, as he believed, grounds for doubting the latter, our faith in the former must also be shaken. He rejected the notion of the origin of these diseases from germs, and regarded them as blood-diseases, modified by circumstances in various cases, and bearing a relation to each other much in the same way as certain diseases of the nervous system which are known to be interchangeable.

Mr. SAVORY asked, with regard to the affection of the lymphatic glands, whether all blood-poisons did not chiefly affect the organs concerned in the elaboration of blood. By the term specific, as he understood it, it was meant that the group or class to which it was applied was separated from others by certain well-defined characters. Did cases occur in which it was difficult to say to which group a case belonged? Was there a hybrid between scarlet fever and enteric fever? He also asked whether the two diseases were mutually convertible—i.e., whether one gave rise by infection to the other.

Dr. JOHN HARLEY said that he had noticed cases of inter-currence of the diseases, such has had been described by Dr. Broadbent. He had examined the intestinal and mesenteric glands in typhus fever, and had not found them enlarged to any appreciable extent. The mesenteric glands were no doubt enlarged in the diseases of children. With regard to the relative contagiousness of typhoid and scarlet fevers, he thought that this property had been much overrated in respect to the latter disease. He thought that one of these diseases was capable of producing the other, as he had sometimes seen cases of enteric fever brought from houses in which several of the inmates were at the time suffering from scarlet fever.

OBITUARY.

BERTHOLD SEEMANN, Ph.D., F.C.S.

THIS distinguished naturalist, who was formerly her Majesty's Special Commissioner to the Fiji Islands, died at Nicaragua, on the 10th of October last, at the early age of 47. After a long visit to the Arctic regions as Admiralty Naturalist, Dr. Seemann dared to face, and faced with success, the perils of scientific investigation in the South Sea Islands and Central America, and found time to edit his "Journal of Botany" and his "Flora Vitiensis," which he just lived to complete.

CHARLES COWDELL, M.D., M.B.

CHARLES COWDELL took his M.B. (Univ. Col.) in 1846, and M.D. Lond. in 1852. He died December 15, 1871, in his 57th year. Dr. Cowdell was well known to the Medical scientific world as the originator of the theory of the fungoid origin of cholera, which he published in 1848, in his book entitled "A Disquisition on Pestilential Cholera; being an attempt to explain its Phenomena, Nature, Cause, Prevention, and Treatment, by reference to an extensive Fungous Origin" (published by Samuel Highley), which theory has since been confirmed and acknowledged in the Ninth Report of the Medical Officers of

the Privy Council, p. 515, 1867, in connexion with the account of Professor Hallier's researches as to cholera fungus, and also by letter to the *Times* in 1868 (the exact date and purport of this letter I cannot remember). He also contributed, amongst other things, to the *British Medical Journal*, 1868, "Cases of Traumatic Tetanus Successfully Treated," and "Papers on Epidemic Sorethroat"; and to the same periodical, and the *Medical Times and Gazette*, in 1860, "Cases of Neuralgia successfully treated by Hypodermic Anodyne Injection," which he was one of the first to introduce. For upwards of twenty-two years he filled the post of Physician to the Dorset County Hospital. He was taken ill with an attack of suppressed gout some six weeks since, but did not at first think it serious. His strength, however, failed so fast that Mr. George Curme and Mr. Alfred Emson were called in, and Dr. George Johnson, of London, came down to consult with them. Though at one time he appeared to rally, and his family entertained hopes of his recovery, inflammation of the lungs and jaundice set in, and exhausted his little remaining strength, until, on Friday morning, without a sound or a struggle, he passed away. He was beloved and esteemed by his Medical brethren and fellow-townsmen, both for his Professional skill and his unblemished life of Christian piety. He was interred on Wednesday, the 20th, in the cemetery at Dorchester.—H. C. S.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an extraordinary meeting of the College, on Monday last, the 18th inst., Thomas Bishop, M.D. Aberdeen, 22, Rue de Matignon, Faubourg St. Honoré, Paris, was admitted Fellow; Mr. John Francis Murphy, of Queen's College, Cork, passed his Primary Professional Examination; and the following gentlemen, having conformed to the By-laws and Regulations, and passed the required examination, were granted licences to practise Physic, including therein the practice of Medicine, Surgery, and Midwifery:—

- Bailey, Francis James, M.R.C.S., 51, Grove-street, Liverpool.
- Brabant, Thomas Hughes, M.R.C.S., 34, North Audley-street, W.
- Carr, William Ward, M.B. Lond., Lee-grove, Blackheath.
- Coomber, Frank, M.R.C.S., 51A, Trinity-square, London.
- Davies, Arthur Evelyn, M.R.C.S., Penner House, Newport, Monmouthshire.
- Duke, Douglas William (who passed his examination in Medicine, July, 1871, and has obtained a recognised qualification in Surgery).
- Eardley-Wilmot, Robert, M.R.C.S., King's College Hospital.
- Franklin, George Cooper, M.R.C.S., Victoria-park Hospital, N.E.
- Fraser, John, M.D. Toronto, Strabane, Ontario, Canada.
- Graham, James Elliot, M.D. Toronto, Canada.
- Hemming, John Lamond, M.R.C.S., 10, Southwick-place, Hyde-park.
- Jalland, William Hamerton, M.R.C.S., Guy's Hospital.
- Langridge, George Thomas, M.R.C.S., 71, Myddelton-square, E.C.
- Lees, Frederic Arnold, M.R.C.S., Meanwood, near Leeds.
- Parker, Walter Augustus, M.R.C.S., 55, Cathcart-road, Brompton.
- Rees, Howell, M.R.C.S., Ystalyfera, Swansea.
- Rowland, Edward Roger, M.R.C.S., 1, St. George's-place, S.W.
- Ryley, Henry, L.R.C.P. Edin., Fulbourn, Cambridge.
- Sergeant, Edward, M.R.C.S., St. Thomas's Hospital.
- Todd, William James, M.R.C.S., 4, Gloucester-road, Regent's-park, N.W.
- Younger, Edward George, M.R.C.S., Holly Mount, Blackheath-hill, S.E.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the monthly examinations, held on December 11, 12, and 13, the following gentlemen obtained the Licence to practise Medicine:—

- | | |
|-----------------------------|-------------------------------|
| Budds, William Tracy. | Prendergast, John. |
| De Renzy, Thomas. | Reed, Robert Hamilton. |
| Fleetwood, William John. | Smith, Charles Henry. |
| Heyward, Henry. | Thomas, Edward. |
| Lucas, Edmond Allen. | Wrightson, Edmund Wellington. |
| O'Donnell, Richard William. | |

The Diploma in Midwifery was granted to the following on December 14:—

- | | |
|--------------------------|-----------------------------|
| Budds, William Tracy. | O'Donnell, Richard William. |
| De Renzy, Thomas. | Reed, Robert Hamilton. |
| Fleetwood, William John. | Smith, Charles Henry. |
| Heywood, Henry. | Thomas, Edward. |
| Lucas, Edmond Allen. | White, W. H. |

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, December 14, 1871:—

- Bosworth, John Routledge, Sutton, Surrey.
- Grayson, Francis Dorrell, Henley-on-Thames.
- Harris, John Delpratt, Exeter.
- Hopkins, Frederick Fraser, Henley-in-Arden.
- Millner, Edward, Birmingham.
- Mosley, William Arthur, Nassau, Bahamas.
- Pitt, Isaac, Birmingham.

As an Assistant in Compounding and Dispensing Medicines :
Jones, Morgan, Chipping Sodbury.

The following gentlemen also on the same day passed their first Professional examination :—

Cave, Alfred Ernest, London Hospital.
Eady, George John, King's College.
Gard, William John, Guy's Hospital.
Griffith, Alfred Vavassour, Queen's College, Birmingham.
Joynes, Francis James, King's College.
Parkes, William Edmund, Queen's College, Birmingham.
Vincent, Henry Bixl, St. Bartholomew's Hospital.

APPOINTMENTS.

* * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BANKART, JAMES, F.R.C.S., M.B. Lond.—Surgeon to the Devon and Exeter Hospital, *vice* Philip Chilwell De la Garde, F.R.C.S., deceased.
COLES, GEO. CHAS., M.R.C.S.—Assistant-Surgeon to the Central London Ophthalmic Hospital, Gray's-inn-road, W.C.
LOWE, JOHN, M.B. and C.M. Edin., late Clinical Assistant, West Riding Asylum, Wakefield—Assistant Medical Officer to the Durham County Asylum, Sedgfield, Ferryhill.
SANDWELL, EDWARD, L.R.C.P. Edin., M.R.C.S. Eng.—Medical Officer to St. Andrew's Home for Boys, Soho.
THOM, ALEXANDER, A.M., F.R.C.S.E.—Medical Officer of the Parochial Board of the Parish of Maderty.
YOUNG, ADAM, M.R.C.S., late House-Surgeon [St. Bartholomew's Hospital—House-Physician to the Seamen's Hospital (late *Dreadnought*), Greenwich, S.E.

BIRTHS.

CHAMBERS.—On December 6, at 2A, Sutherland-street, S.W., the wife of Thomas Chambers, M.R.C.P., F.R.C.S.E., of 2, Bolton-row, Mayfair, W., of a son.
DIVER.—On December 11, at Caterham, the wife of Ebenezer Diver, M.D., of a son.
DUDGEON.—On September 23, the wife of Dr. J. Dudgeon, Chinese Hospital, Pekin, of a daughter.
PEARCE.—On December 11, at the Manor House, Brixton-rise, the wife of Channing Pearce, M.B., of a daughter.
WILSON.—On December 12, at 12, Westmoreland-road, Bayswater, the wife of Dr. Charles Cooper Wilson, Surgeon Bengal Army, of a daughter, stillborn.

MARRIAGE.

NASON—CLEMENTI.—On December 14, at Attenoven Church, John Harrison Nason, M.D., of Killumney, to Grace, widow of John Muzio Clementi, Esq., of Bride-park, county Cork, and Waterville, county Kerry.

DEATHS.

ARMSTRONG, JAMES HUNTER, M.R.C.S., late of Gravesend, Kent, at Toronto, Canada, of apoplexy, on December 3.
BROWN, J. C., for upwards of fifty years a Medical Practitioner at Waltham Abbey, on December 15, aged 80.
COWDELL, CHARLES, M.D., Physician to the Dorset County Hospital, at Dorchester, on December 15, aged 56.
FOX, AMY CATHERINE LONG, youngest child of Dr. Edward Long Fox, at Church House, Clifton, on December 17, aged 11 months.
GRIFFIN, ETHEL HARRIET, the youngest and much-loved child of R. W. Wandy Griffin, M.D., at 11, East Park-terrace, Southampton, on December 18, aged 7 years.
HULL, SUSANNA, wife of George Hull, M.D., at 102, Warwick-gardens, Kensington, on December 17, in her 62nd year.
SEEMANN, BERTHOLD, Dr., F.L.S., at the Javali Mine, Nicaragua, on October 10, aged 47.
SKENE, EUPHEMIA, wife of William Skene, M.D.; also, Berthia Neilson, only daughter of the above, at Buckhurst-hill, on December 16.
TINNION, JOHN, M.D., suddenly, at Templehill, Troon, Ayrshire, on December 11, aged 56 years.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

BATTERSEA.—Medical Officer of Health for the Eastern District of this parish. Gentlemen, properly qualified, may send their testimonials to Mr. A. Corsellis, Clerk to the Board of Works, Battersea-rise, on or before December 27.
CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House-Surgeon. Must be a registered Medical Practitioner. Applications and testimonials to the Secretary, Infirmary, Bangor, on or before January 2, 1872.
EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, RATCLIFFE-CROSS, E.—Physician. Must be a Graduate in Medicine of a British University, or a Member of the Royal College of Physicians. Applications and testimonials to the Secretary, on or before December 28. Election at the London Tavern on January 2, 1872, at two o'clock. Attendance required.
EAST SUSSEX, HASTINGS, AND ST. LEONARD'S INFIRMARY.—The appointments of Physician and Assistant-Physician are vacant. The qualifications required are as follows:—Doctor or Bachelor of Medicine of Great Britain or Ireland, or Fellows or Members of the Royal College of Physicians of London, Edinburgh, or Dublin. Applications and testimonials to the Secretary, on or before January 1, 1872.

JERSEY GENERAL DISPENSARY.—Medical Officer. Further particulars of the Rev. P. A. Le Feuvre, Oakwalk, Jersey. The election takes place early in January, and the duties will commence on February 1, 1872.

KING'S COLLEGE, LONDON.—Professorship of Forensic Medicine. Applications, from qualified members of the Medical Profession, to be sent to Mr. J. W. Cunningham, Secretary.

LANCASTER (COUNTY OF) LUNATIC ASYLUM.—Medical Officer. Must be duly qualified and registered. Applications and testimonials to Mr. F. C. Hulton, Clerk to the Committee, on or before January 8, 1872.

LIVERPOOL DISPENSARIES.—Assistant Resident House-Surgeon. Must be duly qualified to practise. Applications and testimonials to the Secretary, on or before December 27. Personal attendance at the Dispensaries Office, Leith Offices, Liverpool, will be required on the following day at two o'clock.

METROPOLITAN FREE HOSPITAL, DEVONSHIRE-SQUARE, CITY, L.C.—Honorary Surgeon. Must be F.R.C.S., or pledged to become such within twelve months. Applications and testimonials to Mr. G. Croxton, Secretary, on or before December 23.

MIDDLESEX COUNTY ASYLUM, HANWELL.—Medical Superintendent of the Female Department. Candidates must possess both Medical and Surgical qualifications. Copies of testimonials to Mr. R. W. Partridge, Clerk to the Visitors, on or before January 6, 1872.

NEWARK HOSPITAL AND DISPENSARY.—Resident Medical Officer and Secretary. Medical and Surgical qualifications required. Applications and testimonials to the Secretary, on or before January 1, 1872. Election on January 9. Attendance of candidates required at twelve o'clock.

NORTH WALES COUNTIES LUNATIC ASYLUM, DENBIGH.—Assistant Medical Officer. Qualifications to practise must be produced. A knowledge of the Welsh language is necessary. Applications and testimonials to Mr. John Robinson, on or before January 10, 1872.

NUNEATON UNION.—Medical Officer and Public Vaccinator for the Nuneaton District. Candidates are required to possess the qualifications prescribed by the Local Government Board. Applications and testimonials to Mr. John Estlin, Clerk, Nuneaton, on or before December 26. Election on the 27th.

SUNDERLAND INFIRMARY.—Junior House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to the Senior House-Surgeon, on or before January 20, 1872.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Belford Union.—Dr. L. G. Broadbent has resigned the Eastern District; area 12,704; population 2869; salary £25 per annum.

Pocklington Union.—Mr. Alfred Jackson has resigned the Second Pocklington District; area 25,555; population 2501; salary £20 per annum.

Poole Union.—Mr. A. P. Hamilton has resigned the Third District; area 7491; population 2050; salary £75 per annum.

Thingoe Union.—The Eighth District is vacant; area 2390; population 585; salary £13 18s. per annum.

APPOINTMENTS.

Blything Union.—Pryce J. L. Morris, L.R.C.P., M.R.C.S. Eng., to the First District. Henry J. Horton, L.R.C.P. Lond., M.R.C.S. Eng., to the Seventh District.

Grantham Union.—George W. Shipman, M.R.C.S. Eng., L.R.C.P. Lond., to the Grantham District.

Market Harborough Union.—Frederick Grant, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A. Lond., to the Workhouse and the Fourth District.

Northleach Union.—Hugh George Webb, L.R.C.S. Ire., L.K. and Q.C.P. Ire., to the First District and the Workhouse.

UNIVERSITY OF DUBLIN. — COMITIA HIEMALIA. —
Baccalauri in Medicinâ: Mauritius Robertus Blunden, Thomas Johannes Browne, Henricus Comyn, Thomas Elliott, Fitzjohn Robertus Irvin, Alexander Macalister, Hamilton MacMullen, Dawson Nesbitt, Harvie Scott, Ricardus Dormer White.
Magistri in Chirurgiâ: Mauritius Robertus Blunden, Henricus Comyn, Jacobus O'Connor, Ricardus Dormer White. *Doctores in Medicinâ*: Robertus Browne, Georgius Fredericus Duffy, Jacobus Marshall Skelton, Gulielmus Henricus Steele.

DR. ALFRED MEADOWS has been elected a Corresponding Member of the Gynæcological Society of Boston.

MR. C. B. COURTENAY has been elected Medical Officer of St. George's-in-the-East, in the place of Dr. Baker, resigned.

DR. REGINALD ALEXANDER, son of Dr. William Alexander, of Halifax, and Dr. P. Nicol, have been elected Honorary Physicians to the Bradford Fever Hospital, which will be open for the reception of patients in a few weeks.

GLASGOW LYING-IN HOSPITAL.—The following gentlemen have been elected officers for the ensuing year:—*Consulting Surgeon*: Dr. George Buchanan, Professor of Anatomy in Anderson's University. *Physicians-Accoucheur*: Dr. J. G. Wilson, Professor of Midwifery in Anderson's University, and Dr. R. D. Tannahill.

THE deaths in Paris last week amounted to 929.

FALL OF A STAIRCASE AT THE GENERAL INFIRMARY, WORCESTER.—Mr. C. E. Hardyman, House-Surgeon, and Mr. C. A. Sheppard, Surgeon, were descending the staircase—a stone one—when it suddenly gave way. We are glad to find that, by their presence of mind, they averted what might have been a very serious casualty, by springing upon the landing a few feet below.

THE Local Board of Scarborough have appointed a committee to investigate the sanitary condition of the town.

DR. MICHAEL, at a meeting of the Medical Officers' Association on Saturday, stated that, in ninety-five cases out of a hundred, the houses of respectable persons were the receptacles of noxious gases, and otherwise defective in a sanitary point of view.

CHOLERA NOTES.—About Dolma Baghtché and Beshik-tash, Constantinople, cholera has broken out, and among the victims are the chief cook and thirteen servers and *marmitans* of the Imperial kitchens. In these kitchens several hundred servants are huddled together, where they live, sleep, cook, and over-eat themselves. The accumulation of filth was inconceivable. The Sultan's Physician, Marco Pasha, remained night and day at the palace for more than a week, to get the place cleansed, sweetened, and disinfected. The disease is now on the decrease, and has lost much of its malignity.—“The cholera,” says a letter from Tabreez, Persia, of the 27th ult., “has now completely disappeared from this town and the immediate neighbourhood, although isolated cases are still heard of in the villages. During its continuance it carried off nearly 12,000 persons in Tabreez alone, where the death-rate at one time reached 420 daily. It is still lingering in Urumiale and the districts of Satmas, but the cases are now happily rare.”—Mr. Pedler reported to the Court of Sewers that the Cholera Committee continued to meet, but, happily for them, the cholera seems to have taken its departure from the Baltic, though it had unfortunately found another way out of Russia. It had found its way to Constantinople, and had extended to Alexandria. The Committee were watching what happened.

THIRTY-SEVENTH ANNUAL REPORT OF THE GLASGOW MATERNITY HOSPITAL.—From the statements contained in this Report we observe that, during the past year, 1011 women participated in the benefits which the institution confers. In 1869-70 the number of the recipients of this charity was exceptionally large, being greater than in any former year. Comparing the year now ended with the one immediately preceding, there is a decrease of 159 in the total number of patients. This diminution, it may be mentioned, has occurred in both the indoor and outdoor departments of the Hospital; in the former there is a falling-off of 24, and in the latter of 135 cases. The Hospital, during the bygone year, has been very free from disease. There was little illness among the patients, and the recoveries were generally rapid and complete. Of the six deaths which occurred in Hospital, only one was occasioned by puerperal fever, whereas, among the outdoor cases, five women were cut off by this disease. In regard to the indoor case, the usual means were at once adopted to arrest and prevent the spread of the fever, and, as the result proved, with perfect success. As in former years, the system adopted for maintaining the Hospital in a salubrious state was, complete segregation, perfect cleanliness, thorough ventilation, daily fumigations with carbolic acid and chloralum, prevention of overcrowding, etc. The experience of this Hospital, for several years past, seems to prove that by the systematic and rigid observance of these measures, puerperal fever may be prevented from becoming epidemic in small Lying-in Hospitals.

PROGRESSION IN A CIRCLE.—Really there is no accounting for the actions of boards of guardians. It has been said that “jurors are not conjurers”; neither are guardians always on their guard. With a singular proclivity to blundering, the Llanfyllin Board of Guardians have cancelled the appointment of the present Inspector of Nuisances, on the ground that the Board had called upon certain parishes to adopt the Sewage Utilisation Act.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

M.D. Cantuar.—The return of the number of Medical degrees granted by the Archbishops of Canterbury from 1840 to 1862, with the names of the persons on whom they were conferred, was made to the House of Commons in May, 1864; the following is a copy:—1840, Robert Hull; 1841, Sir W. Hyde Pearson; 1849, Joseph Laurie; 1850, William Bayes; 1851, Edmund Charles Johnson, Frederick Gilder Julius, and John Green Bishop; 1854, George Canney; 1855, John Hodgson Ramsbotham and Ralph Barnes Grindrod; 1858, Edward Cronin and William Baker; 1861, Edward Westall and John Rayner; and 1862, William Sherwin. The title is now registrable.

An Old Member inquires why the result of the Preliminary Examination in Arts, etc., which has just been concluded at the College of Surgeons, cannot be made known until about a month, comparing, as he states, so unfavourably with the same examination at the Hall. Write to the Secretary on the subject.

H. F. S.—Bishop Hall records a miraculous cure effected on a man by washing in St. Madern's Well, in Cornwall, to which he was three times admonished in a dream. Father Francis gives a particular account of the same case.

Mr. O'Rourke, Belfast.—John Browne, one of the Surgeons to Charles II., published, in 1684, a curious work entitled “Adenochoiradologia; or, an Anatomick-Chirurgial Treatise of Glandules and Strumaeas, or King's Evil Swellings.” Laurentius denies to the Kings of England the power of healing the evil by the touch, and ascribes it only to those of France.

Chirurgian.—You will find the preparation and history of it in the Museum of the College of Surgeons.

W. D. S., M.D.—The Egyptian Æsculapius must not be confounded with that of the Greeks. The mythological veil under which all traces of the history of the Egyptian Medicine are to be found, serves only to demonstrate that the whole is to be looked upon as allegorical, so far as relates to the personages mentioned.

M. S. S. D.—The next examination for the “L.M.” will take place in February. Twenty cases; fee three guineas.

Dr. Macmichael, Penzance.—The leading article on “The Quackery of the Ancients, and its Imitation in Modern Times,” appeared in vol. xiv. of this journal, p. 43. We are assured that the Council of the College will not allow Mr. George Washington Evans to trifle with them in the matter to which we alluded last week. If your patient receives another of his pamphlets, send it at once to Mr. Trimmer, with the post-office envelope, to show the date when sent. On reference to the “Medical Directory,” it appears that the “M.R.C.S.” is his only qualification.

DISPOSAL OF SEWAGE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Are you or your readers acquainted with the names of any towns where the sewage has been emptied into the sea, and where the inhabitants have been obliged to expend large sums of money to divert it away from the sea, on account of the nuisance it caused by being placed there?

Torquay. I am, &c., PAUL Q. KARKEEK.

FLUID MEAT versus MEAT EXTRACT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your impression of December 16 you have done me the favour to insert a communication, to which, instead of *Fluid Meat*, has been prefixed the title of “Meat Extract.”

Not having adopted the name of “meat extract” for any preparation, I would ask you to allow this notice of correction, more especially as *Fluid Meat* has been so designated to mark its close relationship to meat, and distinguish it from extracts, or preparations, which contain only *some* of the constituents of flesh.

140, Leadenhall-street. I am, &c., STEPHEN DARBY.

THE LATE ACTION AGAINST A MEDICAL MAN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow me, through your columns, to acknowledge the following subscriptions on behalf of the testimonial fund now being raised for Dr. D. H. Watson, of Stockton, who, it will be remembered, was honourably acquitted of a charge of unskilful treatment, recently brought against him by a Miss Hutchinson, in the management of a difficult case of inverted uterus. Although getting a verdict and an order for costs against the plaintiff Dr. Watson is still called upon to discharge a very heavy amount, incurred during the conduct of his case, and which, from the inability of the plaintiff to meet the costs which have been incurred, Dr. Watson will have to pay. I have received the following sums:—

	£	s.	d.		£	s.	d.
Dr. Warburton Begbie, Edinburgh	2	2	0	E.H. Hughes, Esq., Stockton	1	1	0
Dr. Wm. Oliver, Stockton	1	1	0	A. Stocks, Esq., Stockton	1	1	0
Dr. Geo. Oliver, Redcar	1	1	0	Dr. Tinniswood, Norton	1	0	0
Dr. B. Meadows, London	1	1	0	A Friend (R. L.), Stockton	1	0	0
A. Davison, Esq., Cramlington	1	1	0	E. Mandall, Esq., Stockton	1	0	0
S.W. Rayne, Esq., Newcastle	1	1	0	Dr. Cuthbertson, Stirling	0	10	6
Dr. G. H. Hume, Newcastle	1	1	0	—Pybus, Esq., Stockton	0	10	0
C. G. Woodd, Esq., Penge, Surrey	1	1	0	W.J. Watson, Esq., Stockton	0	10	0
J. Barugh, Esq., Stockton	1	1	0	Mr. Hudson, Stockton	0	10	6
				Anon., Stockton	0	10	6
				Mr. S. Bowen, Stockton	0	10	0
				Mr. J. Walton, Stockton	0	5	0

Further subscriptions will be thankfully received by Dr. W. Oliver, Stockton-on-Tees; Dr. G. H. Hume, Westgate-street, Newcastle-on-Tyne; or by Yours, &c., GEORGE S. BANHAM, Hon. Sec.

THE GERM THEORY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following item may interest you:—In a book published in China in 1698, entitled “Chang Shêng, or the Art of Procuring Health,” translated by Father Deutrecolles, and inserted in “Du Halde” (vol. ii.), there is the following passage: “Musk, and the blossoms of young oranges, contain imperceptible insects; therefore, do not put your nose to them, lest these small vermin get up to the brain. The air is full of imperceptible eggs (germs) of various small insects, which we suck into the stomach with our breath, but they cannot be hatched there for want of a fit medium; whereas the insects, which lay their little eggs in the mealy cup of flowers, may be drawn up by the nose with a ferment proper to hatch them.” And again, “If in travelling by land you cross mountains burnt up by the sun, though ever so dry, do not drink of spring- or river-water on which the sun shines, for besides that it hath at that time pernicious qualities, it is often full of the spawn of innumerable insects.”

The above contains probably the germ of the present germ theory. I am, &c., J. DUDON.

Pekin, October 7.

Octogenarian.—It is many years since the occurrences to which reference has been made took place, and, looking over some old papers from the curious collection of Mr. Stone, we came across the following "Shakespeare, modernised (travestied)"

[Scene: The Secretary's office in the College of Surgeons—present, Sir William Blizard, in a towering passion, other Members of the Council, Mr. Wilde, solicitor, Messrs: Belfour, Stone, etc.] Noise of fighting and swearing in the theatre, from which rushes Smith, the old Bow-street Officer, bleeding.

The President: What bloody man is that? He can report, as seem'th by his plight, of the revolt—the newest state.

One of the Council: This is brave Smith, who, like a good and hardy Catchpole, fought 'gainst the rebel crew. Hail! honest friend; say to Sir William how stood the broil when thou didst leave it.

Bow-street Officer: Doubtfully it stood; as two spent swimmers that do cling together and choke their art, fierce Magnus Bolus, he from Bedford-square by young and gallows rascals was supported, and fortune on his dammed quarrel smiling, soon placed us on the floor; but all's too weak for brave Ledbitter (well he deserves that name). Disdaining fortune, with his brandished fist, which smoked with bloody execution (like Cribb's dog Billy), carved out his passage till he faced the knave, and ne'er shook hand nor bade farewell to him 'till he unseamed him from the head to heels, and held his galligaskins up in triumph.

President: O valiant Ledbitter! Most worthy officer!

Bow-street Officer: Mark! noble Doctors, mark! No sooner justice had, with warrant arm'd, compelled the younger fry to trust their heels, but the dissecting chap, surveying vantage, with strip'd-up arms and new supplies of Doctors, began a fresh assault.

Sir William Blizard: Dismay'd not this our Captain Ledbitter and gallant Ruthven!

Bow-street Officer: Yes! as vagrauts beadles, or as debtors bailiffs; but I am faint with bleeding—at the nose!

President: As well thy words become thee as thy wounds—they smack of claret both. Go, get him Surgeons. *[Exeunt.]*

The next scene was at Bow-street Police-office, before Sir Richard Birnie, who bound over Mr. Wakley and his friends to keep the peace and be of good behaviour. The refusal to allow the theatre for discussion on any terms to its members has, as our readers know well, since been gracefully conceded by the Council on more than one occasion, and, curiously enough, on the last, to the entire discomfiture of the *Lancet* party. *Sic transit gloria mundi!*

COMMUNICATIONS have been received from—

Dr. POWELL; Mr. J. LOWE; Mr. BANKART; Dr. ALLBUTT; Dr. STRATTON; Mr. J. JONES; MESSRS. BLACKWOOD; Mr. KARKEEK; Dr. J. G. WILSON; Dr. BURROWS; Mr. BANHAM; Dr. J. DUDGEON; Dr. LOCKHART; Dr. J. PATTERSON; Mr. SHERIFF BENNETT; MESSRS. STREET BROS.; Dr. ALDIS; ANEROID; T. S.; Mr. C. F. MOORE; Dr. GOODING; Mr. STEPHEN DARBY; Mr. J. W. TURNER; Dr. JOHN CHAPMAN; Mr. H. S. COWDELL; Dr. McNAB; Mr. T. CHAMBERS; Mr. C. FINNS; Dr. CLIFFORD ALLBUTT; Mr. WOTHERSPOON; Dr. G. BURROWS; Dr. E. LANDWELL; Mr. EDISBURY.

BOOKS RECEIVED—

Berdt Hovell, President of the Hunterian Society—Transactions of the Odontological Society of Great Britain, vol. iv., No. 1—Nicholson's Manual of Zoology, second edition—Bradley and Whitehead's Collated Statistics of English Surgery in Public Charities for 1870—The Utilisation of Sewage, and a Description of the "A B C" Process—Journal of the Scottish Meteorological Society.

PERIODICALS AND NEWSPAPERS RECEIVED—

Croydon Advertiser—Scotsman—Indian Medical Gazette—Pharmaceutical Journal—Chemist and Druggist—North British Daily Mail—North Devon Herald—New York Medical Record.

APPOINTMENTS FOR THE WEEK.

December 23. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

25. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

26. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

27. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

28. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

29. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, December 16, 1871.

BIRTHS.

Births of Boys, 1134; Girls, 1129; Total, 2263.

Average of 10 corresponding weeks, 1861-70, 2057.9.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	1036	1085	2121
Average of the ten years 1861-70	754.8	726.7	1481.5

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 30.23 in. The highest was 30.33 in. on Tuesday morning and the lowest 30.13 in. on Saturday morning.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.

ORIGINAL LECTURES.

LECTURES ON THE
PRINCIPLES OF THE TREATMENT OF
FEVER.

By Dr. LIONEL S. BEALE, F.R.S.,

Fellow of the Royal College of Physicians; Physician to King's College Hospital.

LECTURE I.

(Concluded from page 732.)

IN very severe cases of fever, what we have to apprehend, and that which our greatest efforts should be directed to avert, is *stagnation of the blood in the small vessels, and cessation of the capillary circulation over a considerable part of the body.* To bring about this result, the following circumstances contribute:—

1. Failure of the force of the heart's action.
2. Alteration in the composition of the blood.
3. Growth of the bioplasm of the blood, vessels, and tissues.

I. FAILURE OF HEART'S ACTION.

In many severe attacks of fever the danger to life depends upon the weakness of the heart's action; and of those who succumb to fever, not a few are known to have had a weak heart, and that degree of power as regards the ganglionic nervous system which, although consistent with prolonged, steady, and equable work, is liable to fail if the demand for greatly increased work should arise. The cardiac mechanism may be well adapted for the ordinary requirements of the system in health, but, nevertheless, unable to bear a strain, and quite incompetent to discharge double duty even during a short period of time. There are many who are capable of performing steadily and constantly a moderate amount of labour without suffering, and may perhaps continue to do so, and without being laid up for even a short time, and may even reach in fair health the period of life when the power of active labour ceases, but who would be immediately deranged and in danger of being destroyed, if a double or treble amount of work were suddenly thrown upon them. In all cases of fever it is important that the Physician should endeavour to form an estimate of the heart's healthy power, for by good management we may be able to keep steady the force of the circulation throughout the whole period of the malady. During a critical period it may be necessary to excite the organ to increased action; and at another time it may be desirable to pour in nutrient food instead of stimulants, and thus slowly renovate the strength. There are cases in which, by the failure of the heart to propel the blood with sufficient energy through the capillaries, the patient's life is for a time in great jeopardy. By timely and active measures, we may succeed in exciting the heart to more vigorous action, and thus the patient may be successfully carried through a very dangerous period of the malady. In all cases of fever, it is important to watch very carefully for any indications of decided failure of the heart's action; but, at the same time, it is very necessary not to modify the treatment at every slight change that may be noticed in the force of the heart.

In slight febrile affections, the heart's action is usually sufficient for the work it has to do during the fever. If the feverish condition lasts more than a few days, and the heart contracts feebly, its vigour may often be restored by the administration of small quantities of easily digested food at very short intervals of time. Two or three teaspoonfuls of milk or strong beef-tea every two hours during the night as well as during the day may be given, and a little wine may be ordered if food alone does not have the desired effect. But if, in cases of fever which continue for a fortnight or more, we find the heart's action becoming decidedly weaker, it is necessary to stimulate artificially, at least for a time. A stimulating action is produced by certain remedies which act through the nerves. Stimulating liniments or turpentine externally will sometimes have the effect. Remedies which stimulate the olfactory and respiratory portions of the mucous membrane act in the same way; but the most direct as well as the most efficacious means is by the introduction of stimulants into the stomach; and these also act beneficially in other ways. Ammonia, chloric ether, and various kinds of spirits (when given not too much diluted) produce an immediate though indirect influence upon the force of the heart's contraction. This is proved by the fact

that very soon after a little wine, brandy, or ammonia has been taken when the heart is acting very feebly, as during a partial faint, or from the influence of chloroform inhalation, the vigour of the heart's contractions becomes sensibly increased. The change is often noticed within a few seconds after the stimulant has come into contact with the mucous membrane of the stomach. This action, no doubt, depends upon the influence produced upon the ganglia of the sympathetic transmitted by afferent fibres from the skin (mucous membrane) of the nose, throat, respiratory passages, or stomach, as the case may be. In consequence, the blood is urged with more force through the capillaries of the body generally, and the tendency to death from this cause is postponed, and perhaps averted.

II. ALTERATION IN THE COMPOSITION OF THE BLOOD.

In this place we have to consider how we may prevent the textures and organs of the body being damaged, and life destroyed, by the altered blood circulating in the vessels; and also to inquire whether we can, by judicious interference, promote and accelerate the restoration of the nutrient fluid to its normal state.

It was formerly supposed that the chief thing to be guarded against in the treatment of fever was undue oxidation; but later investigations have proved that fever itself is due directly rather to changes consequent upon insufficient oxidation; and it is, indeed, probable that a febrile state may be engendered by long-continued insufficiency of this most necessary change. It is doubtful if the febrile state could exist in an organism in which the oxidising processes were performed perfectly and at a proper rate. There is good reason to think that if the noxious materials which accumulate in the blood in fevers and extensive internal inflammations could be more fully oxidised, they would soon afterwards be eliminated in the form of urea, carbonic acid, and other excrementitious matters which at last result from the destruction of bioplasm and the oxidation of the products of its death; but while these excrementitious matters, or the imperfectly oxidised materials from which they are immediately produced, continue to accumulate in the blood, the excreting organs cannot eliminate them or alter them fast enough. The latter organs may in many instances be excited artificially to increased action; and it is in this way that many diuretics, sudorifics, and purgatives often afford great relief, and restore the patient to health. But in serious cases, in which the strength is already much exhausted, more especially if the fever has yet a long course to run, there would be danger in pushing too far the use of such remedies. Moreover, the excreting organs cannot excrete some of these unoxidised animal matters. In not a few instances in which the noxious materials have unduly accumulated, it will be found that the secreting organs *cannot be made to act*; as the afferent nerves (see Note on page 731) are in part paralysed, our remedies are powerless. To give excessive doses in such cases would be very unwise, and by so doing we should render the condition worse. Under the circumstances indicated, however, there is danger of the imperfectly oxidised substances accumulating in the blood and in the tissues to such an extent as to place the patient's life in great jeopardy. And the danger is twofold. In the first place, many of the bodies are unstable compounds, and liable to decompose at the temperature of the body. The products of decomposition set free in the blood would very soon destroy the living matter of the blood and tissues, and paralyse and destroy the nerve-fibres and nerve-centres, in which case the patient must die. Secondly, if the compounds which cannot be excreted in the form in which they exist are not to undergo decomposition, they must be quickly taken up and appropriated by living bioplasm of some sort. As the bioplasm of the excreting organs is already surcharged to such an extent as to damage the organs by increase of its bulk, and in other ways, the living matter of the blood, and then that of the tissues of the body, begins to appropriate the excess of pabulum. The white blood-corpuscles increase in size and divide and subdivide, the minute particles of bioplasm grow and increase in number, and the bioplasts of the tissues enlarge, and new centres (nucleoli) make their appearance in them.^(a) But these phenomena cannot occur without the action of the tissues being seriously impaired; and, worse than this, the increase of bioplasm in the blood inevitably leads to impeded capillary circulation, and to stagnation of the fluids in the substance of all the tissues of the body—the result of which, if local, must be destruction to the part of the tissue involved; if general, fatal to the whole organism.

But of the two circumstances just spoken of—the decom-

(a) "Report on the Cattle Plague," 1866.

position of albuminous matters, and the excessive growth of the bioplasm—the latter is by far the least dangerous, for the first is almost necessarily fatal, and rapidly so. But much of the noxious substances which have accumulated may be removed from the circulating fluid by the growth of the bioplasm, and temporarily stored in the form of living matter. Time may be gained for the excreting organs to right themselves, and that most favourable symptom in all cases—free excretion—may occur, in which case the surcharged bioplasm becomes at once reduced in volume, and is ready to appropriate more of the dangerous pabulum. The blood is thus relieved. Its bioplasm again takes up the excess of pabulum in the tissues, whose bioplasm gradually returns to its former volume, and there is every prospect of the normal balance of the nutritive and destructive processes being gradually restored. If, however—as but too frequently happens—the proportion of the noxious matters already formed be very great, the bioplasm continues to increase unduly; and, as has been mentioned, this increase may lead to a fatal result. But still, the state of things established by the undue growth of bioplasm, unlike that resulting from putrefactive decomposition, is not immediately or necessarily fatal; and if by the process life is destroyed, that event is considerably postponed.

III. GROWTH OF BIOPASM.

This, as will have been inferred from the remarks under the last heading, is a very serious change, characteristic of the febrile and inflammatory state, and it is that which most frequently leads to a fatal result, and when recovery takes place not unfrequently causes impaired health or chronic disease. The change was referred to in my "Report on the Cattle Plague" published in 1866, and before that time had been fully described in my lectures at King's College. The alterations are most remarkable, and have been figured by me in numerous illustrations. It is this process of undue growth of bioplasm, which from the first we must endeavour to control by treatment. Although it is some years since I pointed out this most important fact, and laid great stress upon the increase of bioplasm in all fevers and inflammations, it has not, I think, yet attracted much attention. The phenomenon has been discussed by me in several memoirs, and in this place I propose to consider the matter mainly in its practical bearing. Not only shall I be able to show that the increase of bioplasm affords a highly important indication for treatment, but that many different remedies which experience has proved to be of use in febrile and inflammatory diseases are valuable, on account of the influence they exert in checking the growth of bioplasm and preventing the impending destruction of tissue; and although in too many instances the process has proceeded beyond our control, yet even in this case we can often retard the inevitable result.

In bad cases of fever and general inflammation the patient may die, as already indicated, from failure of a congenitally weak heart; but the life of those who have the advantage of a strong and vigorous organ is often destroyed at a later period of the malady by the excessive growth and multiplication of bioplasm in the blood, one consequence of which is plugging of so many capillary vessels of the tissues as to lead to complete suspension of their action, and to damage or destroy their structure. If life be preserved, the structure of the capillaries, nerves, and adjacent textures may be irreparably damaged; and in this way parts of organs of the highest importance to life may be so altered that they can never regain their former healthy condition, in which case the organism will never be so sound, healthy, and vigorous as before.

In the tissues of many cases of death from fever of many different kinds, both in man and animals, I have seen the capillary vessels and small arteries and veins completely obstructed by minute particles of rapidly growing bioplasm, and in not a few instances the minute vessels are dilated in the interval between two constricted points, which leads me to conclude that the bioplasm had actually increased in amount by growth long after the circulation had completely stopped. The walls of the vessels are much altered, and in some instances the bioplasts are five times as large as in the normal state, projecting much into the interior of the vessel, and dividing and subdividing freely—or proliferating, as the saying is.

So far, therefore, from there being increased activity of the circulation (as inferred from the rapidity of the heart's action) associated with the hot feverish state—as used to be supposed—the latter is characterised by restricted capillary circulation and a tendency to complete obstruction of so many of the capillary vessels as to damage tissues and organs and to cause death. Now, it is this tendency to the increase of the bioplasm

that he who treats fever must endeavour to avert; and one thing which contributes in a most important degree to effect this end is the maintenance of the force of the heart's action, as has been already pointed out. By promoting free circulation, so as to keep the whole mass of the blood constantly moving, and mingling, and changing, not only is the growth of its bioplasm impeded, but the bioplasm already formed is exposed to oxidation and other changes, which lead to its disintegration, to be soon followed by the removal of the products of its decay. Whenever the circulation flags, the increase of the bioplasm is favoured, and the first abnormal augmentation takes place in those organs, such as the liver, spleen, and lymphatic glands, in which the circulation is slowest in the normal state, and where the bioplasm is renewed according to the very moderate demands of the system in health. (b) But, besides this advantageous effect, the free action of the circulation renders possible the removal of many noxious materials tending to produce a paralysing or poisonous influence upon the nerves distributed to the capillaries, small arteries, and veins of the skin, urinary organs, and bowels, and the nerve-centres with which they are connected, upon the integrity of which the condition health is absolutely dependent.

Such, then, so far as I have been able to make out, is the interpretation of the phenomena which may lead to the destruction of life if bad cases of fever are left to pursue their natural course. "Nature," it seems to me, manifests neither a conservative nor reparative action during the course of fever, and death may result long before the period arrives when natural repair becomes possible. But, then, can "Nature" be held responsible for the development of the feverish state? The natural history of febrile diseases is pretty well known by this time, and as in many cases we are able to anticipate increase of feverishness, we may place the patient in a more favourable condition to withstand it than "Nature" unaided can achieve, and we may mitigate the force of a blow, although we are powerless to ward it off.

"Expectant Medicine" in severe cases of fever is not justified by the facts known concerning fever, and an expectant attitude will no more save life than it will extinguish fever-poison, effect sanitary improvements, or preserve people in a state of health which will enable them to resist the influence of disease-germs. Expectancy, as a principle, is no more justifiable than is the giving of harmless pilules or coloured water as a practice. In the treatment of real disease, mere passive expectancy means the denial of knowledge, the ignoring of broad facts of observation and experiment, a contempt for the lessons taught by experience, and a disbelief in all that has been handed down to us by those who have observed, and laboured, and thought before we lived.

ORIGINAL COMMUNICATIONS.

HEART DISEASE.

By METCALFE JOHNSON, M.R.C.S., L.A.C.

THE term at the head of this paper bears marks of an indefiniteness which characterises much of the knowledge respecting the pathological states of this organ, and the physiological results which naturally attend any prolonged pathological change, and reminds us of Shakespeare's expression of—

"The heart-ache and the thousand natural shocks
That flesh is heir to."

The popular notions about heart affections are many of them most erroneous, not only in their pathological conditions, but in their physiological relations.

The old language of poesy ascribes to the heart that which we now associate with the brain. Thus we have the "thoughts of the heart," "love from the heart"; and the qualities of fear, boldness, together with all emotions such as end in laughter or tears, are all in the language of figure ascribed erroneously to the heart.

But does the heart ache? As a rule, the greater part of the pain which is referred to the heart is due to some other organ—such as the stomach, or even the large intestine. True, in death from valvular disease, or aortic aneurism, or in rupture of the heart, there is generally an ill-defined pain referred to this region; but this may in such cases as aneurism or rupture

(b) From observations I have made, I think it probable that in acute, severe fevers from ten to twenty times as much bioplasm is produced in a given time as would be formed in the healthy state. Not only is the growth of bioplasm favoured in those morbid states, but destruction of the products of its decay is greatly impeded and retarded.

be referred to pressure upon parts of the body in which sensitive nerves are more nearly and more freely distributed—such as the pleura and the intercostal spaces and muscles.

As a rule, then, we may safely say that heart disease is more or less free from severe pain; for even in the acute stage of rheumatic pericarditis the sense of pain is not sharp, but a dull heavy sense of constriction—very different from the cutting pain of a joint under the same pathological condition.

The pain and uneasiness which are associated with the heart are generally due to some distended condition of stomach or large-intestine, or even in many cases the most acute pain is referable to the lower end of the œsophagus. But, as a rule, the palpitation or irregular action of the heart (even where the natural rhythm of the organ is interfered with) is due, in most cases, rather to functional disorder of the alimentary organs than to the existence of morbid change of structure in the heart or its appendages.

Perhaps there is no disease, on the whole, so appalling to the non-Professional mind; and the verdict of "heart disease," passed ever so kindly, cautiously, and quietly by the blandest of Physicians in the most luxurious of consulting-rooms, is more awe-inspiring than the roughest sentence of death by the harshest judge in the most barren court and before the most brutal of audiences.

It at once conjures up all the horrors of a sudden cessation of life, a summons from the next world without a moment's warning. To the lay mind all the forms of heart disease are centred in one; and, as a rule, the greater part of the fears which are excited in the minds of invalids respecting heart disease are groundless, as the pains, as before remarked, are referable to the stomach, bowels, œsophagus, or, at any rate, to some part of the body under the control of the great sympathetic nerve.

Now, how far this irregular action—this palpitation, this pain, and the sense of præcordial fear—is due to physical causes, such as encroachment on the heart's space, or otherwise, does not seem always clear. In some cases, doubtless, the mere mechanical distension of the greater end of the stomach pressing upon the pericardium (especially if there be any pathological change there) is sufficient to cause not only pain, palpitation, but an intermittent action of the organ, which is very distressing and fear-inspiring. Here one of the privileges of the Physician resulting from accurate diagnosis affords him not only satisfaction to himself but a power of relief to the patient from both pain and fear. But in addition to the simply mechanical obstacle to the heart's regularity, there are causes which act through the sympathetic filaments of the ganglionic system, which, connected on the one hand with the abdominal viscera as their special ruler and regulator, extend their function likewise to the especial stimulus to the heart's action, and, acting as the undigested bit of cheese on a blot of mustard, "which produced the Christmas ghosts" of "Old Scrooge," will oftentimes give rise to the palpitations which excite the fears of heart disease.

The lay opinion respecting the prospect of recovery in heart disease is, as a rule, very despondent, and the fear of sudden death naturally attaches to this opinion. My object in the present remarks is to endeavour not only to throw a light of greater hopefulness upon this lay opinion, but to express an opinion that the Professional despondency is often too great in respect of this affection. From the opportunities I have had of judging in this matter, I am inclined to believe that in many cases the Professional opinion condemns the patient, even while there is hope in treatment. I speak thus upon facts that have come under my observation.

About four or five years ago I was called to a woman, aged 35, suffering from endo- and exo-cardial disease, whose heart's action was a mere flutter. Œdema filled almost every portion of her cellular tissue. She was unable to move, or be moved, from the bed, even for purposes of necessity. I was sent for as a "forlorn hope." Suffice it to say, without giving details of the case, that she is now living, and apparently in good health, and has ever since her recovery been following the arduous duties of what is called a "charwoman." It is now some years since I saw her, but I hear she is well and strong. Of course, it is not to be supposed that the pathological condition is changed for one of perfect health; but the condition of impending death is changed for one in which the functions of life can be performed without pain and suffering. On this occasion, I was informed, in the usual language of such cases, that the previous Doctor had given up hopes of the case, and recommended her to prepare for sudden death. At any rate, no active treatment was being employed

at the time when I was called in, nor were there any signs of such having been the case.

In the case of heart disease, I am disposed to believe that even Professional prognosis is often formed rather on the basis of opinion handed down by the tradition of instructors and the guide of books than by tabulated statistics of actual experience; and my opinion will receive support from facts, that disease of the heart is looked upon by the Profession at large as belonging to that category of diseases of which cancer and consumption stand at the head—cases whose insubordination to ordinary treatment leads us too often to the inaction of despair. In the case of cancer, of course, we have hope in removal; but a fairly started tubercular degeneration, in which lung tissue breaks up, bears with it such a general hopelessness as to induce the greater part of our body to resort simply to palliatives and artificial stimuli.

That this phase of opinion in reference to heart disease is to be discouraged is shown by the following case:—

In January, 1863, B. A. L., aged 12, had been suffering from rheumatism for some time, and at the commencement of my charge of the case, he was seated in a high-backed chair, from which he never moved, night or day, for nearly two months. His legs were filled with anasarca; his abdominal cavity much distended with serum; his breathing very rapid, and distressed by a constant hacking cough; all his food was vomited with great distress; his heart gave audible evidence of extensive endo- and exo-cardial mischief; in fact, his symptoms were of such a nature as to preclude any reasonable chance of recovery. In this state he was repeatedly blistered, and medicines of various kinds exhibited, and in due time his symptoms abated, and he recovered so far that about six months since (more than eight years after his severe illness) I saw him attempting to jump a wall five feet in height. He is now well, and enjoying his life free from anxiety, as any other man. There is, of course, disease remaining, but at present it is of a harmless nature.

Nor should we feel despondent as to the prospect of recovery in great part, even though the case be that of a rheumatic person advanced in years.

Mrs. W., aged 62, had been a sufferer from acute and chronic rheumatism for some years, which on one occasion attacked the meninges of the brain, producing delirium. (This, in my experience, is very rare.) The heart, however, was left with evidences of aortic valve disease. There was also the dyspnoea which appears to arise from pressure on the recurrent laryngeal nerve by aneurismal enlargement. The legs were beginning to show signs of anasarca. The irritability consequent on the speedy expectation of death was manifested to a considerable degree. I therefore prescribed morphia and digitalis to be taken at any time when in pain or dyspnoea. It is now more than four years since she commenced this treatment; and on calling upon her the other day, I was agreeably surprised to find that hardly any murmur, systolic or diastolic, was perceptible. The lady was walking about very comfortably, and, so far as I could see, likely to remain a creaking old woman for many a year to come.

In July, 1871, I was consulted by a lady who had been suffering for many years from heart disease. She has now systolic endocardial murmur with dyspnoea; slight œdema of the legs; heart's action very rapid and irregular, caused at the time of my being consulted by an excessive attack of menorrhagia of some months' standing. After using remedies to arrest the uterine discharge, which yielded in a few days, the region of the heart was freely blistered, and every means used to restore tranquillity. Her symptoms soon became very much less aggravated, and in October her sister wrote me word that Miss — had not been so well for three or four years.

W. T., aged 52, never had rheumatic fever, but has been a very free liver. Complains of dyspnoea, cough, præcordial pain. Can lie flat in bed; no choking in throat; systolic and diastolic bruit; heart's action very rapid—in fact, it sounds like a flutter more than a systematic pulsation. After the use of a blister and some digitalis he was much relieved, and now, after repeating the process—about a fortnight having elapsed—he is almost fit to return to his usual occupation as a stonemason.

From the preceding cases it will be seen

"What drugs, what charms,
What conjuration, and what mighty magic"

have been used. My faith relies mostly on the use of the counter-irritation.

In speaking of remedies, it is so difficult to be certain what evidence is here reliable; for it can hardly be doubted that, if we would believe the testimony of Medical witnesses, evidence

could be brought to show that every drug that exists in the Pharmacopœia is potent to the relief of every evil under the sun. But it might safely be said that should we remove almost any bottle from the shelf for twelve months, yet our mortality-list would be neither longer nor shorter. *Quot homines, tot sententiæ* is true in such a *quæstio vexata* as this. Nevertheless, the testimony of many men has been given in favour of blistering. Now, as to the mode in which the blistering process is brought about, I can speak with confidence of one preparation which has never failed me, and that is a liquid prepared by Messrs. Bullen and Birt, of London. The results of the application of this liquid are not only more certain to be efficacious, but attended with less pain than the old fly-blisters process. Moreover, I am inclined to think that less danger of strangury is experienced when this liquid is used.

Of the use of drugs, one, at least, requires to be spoken of; and the effect of opium in relieving pain must not be passed over.

Of the *modus operandi* of opium, it may be said that apparently this drug acts by producing a numbness or paralysis of the extremities of the ganglionic nerve.

Observation of the effects of the hypodermic injection of morphia will show us the following train of symptoms:—First, in about five or six minutes after the morphia has been injected, a sense of constriction is felt at the pit of the stomach; shortly after, this tightness extends itself to the front of the throat, beneath the pomum Adami. These sensations are shortly followed by relief of the pain in the part affected, and sleep ensues with more or less rapidity. An opinion may here be hazarded (as the sensation is peculiar, and more of a constriction than a pain) that the first feeling at the pit of the stomach is due to the toxic effects having reached the semilunar ganglion, while the sensation in the throat is due to effects upon the cervical ganglia, which, acting on the middle cerebral artery, produce relaxation of the minute arteries, whence ensues "Nature's sweet restorer, balmy sleep."

The *ratio medendi* of counter-irritation is, I think, such as leads us to confirm the old opinion that congestion does not take place in two parts of the body at one and the same time, and that if perforce (as by counter-irritation) the blood be directed to fill the more minute capillaries in the part to which the blister is applied, the blood will be relieved from injecting the capillaries of the part suffering from congestion.

Some years' experience has led me to think that this effect is produced more readily when the parts are in proximity—that is to say, the nearer the counter-irritation is applied to the part undergoing pathological change, the better the chance of success in diverting the congestion.

I am inclined to think I have on more than one occasion seen life lost for want of applying this remedy to the right spot. The efficacy in relieving congestion in the base of either lung posteriorly, by a blister placed over the seat of friction, is astonishing when first made acquainted with it; and I have seen patients suffering from pleurisy or pneumonia, who referred their pain to the front of the chest, blistered over the seat of pain—this is, of course, in the olden days; one would hope it is not so now—and I have afterwards found the crepitation, dulness, and all the other symptoms of disintegrated lung, but not till too late to remedy this defect by counter-irritation over the seat of disease. On these grounds I would insist on the necessity to apply your counter-irritation strictly over the seat of mischief. If the disease be aortic, let the remedy be aortic; if pericardial, to the apex of the heart; if mitral, beneath the axilla, over the seventh or eighth rib.

Trivial as these remarks may seem to be, experience has shown me that they are of importance in that great conflict in which the Medical man is daily found

"Entering the field against the grisly foe."

The hypodermic injection of morphia, always reminds me of Hamlet's question—

"Who would fardels bear
When he himself might his quietus make
With a bare bodkin?"

Lancaster.

ETHER AS A BEVERAGE.—In concluding some observations on the supposed mixing of chloral with beer, the *Chloralum Review* says that the practice of drinking sulphuric ether is on the increase in the North of Ireland, and that one extensive Dublin manufacturer of ether sends the greater part of his production into the far northern counties, particularly Antrim.

DEATH FROM MALARIOUS POISONING.— SUSPECTED STRANGULATED HERNIA.

By J. F. FAYRER, M.D., C.S.I.,

Professor of Surgery, and Senior Surgeon, Medical College Hospital,
Calcutta.

On the morning of August 6, 1871, I was requested by a native Medical officer to see a case of supposed irreducible hernia, with symptoms of strangulation setting in. I found Mr. —, aged 28 years, a healthy, muscular young Englishman, of light complexion, and said to be of most active and temperate habits, suffering from a swelling in the left groin, below Poupart's ligament, which was painful on pressure, and accompanied by general abdominal tenderness. I observed a similar, though smaller, swelling in the other groin; this was much less painful. He was feverish; pulse 104, and moderately firm. His face and neck were covered with a bright red efflorescence; this, I afterwards learned, was usual whenever he was at all unwell. It appears that the day before (the 5th), he had been out greater part of the day, and had fatigued himself much by attending an auction. He also said that, in jumping out of his buggy, he had given himself a strain, to which he ascribes the pain in the groin. He came home at 4 p.m. The day was very damp and sultry—a genuine Calcutta August day. He told his wife that he had a gnawing pain in his stomach, and that he thought it was probably due to fatigue and hunger, and accordingly asked for his dinner. He ate some, but felt no better. Soon after eating he had a sharp rigor—the introduction to all the phenomena of a severe ague fit. The bowels, meanwhile, had acted, and he voided some greenish matter—it was so described; I did not see it. During the thirst, which became excessive, he drank iced water, which was immediately rejected each time; and this continued for some hours during the night. The groin about this time swelled more, and became more painful, the pain extending over the abdomen. It did not appear to have been more severe about the umbilicus than elsewhere. He passed a restless and troubled night; the pain severe, the nausea and vomiting frequent. The fever, which was very severe, abated towards morning. The Babu, suspecting a femoral hernia, asked me to see him. At this time (10 a.m.) sickness had ceased for some hours. The bowels were said to have acted scantily during the night. I examined the swelling in the groin, and sent him off to the Hospital, where he was to be carefully watched, and a report sent to me if any further indications of strangulation made their appearance. I doubted the existence of a hernia, but as the case was obscure, and I could not remain with him, I thought this the best course to adopt. He was depressed and anxious, and suffering great pain in the abdomen and groin.

It appeared that he was rather better and felt easier after reaching the Hospital. Nothing further suggestive of strangulation occurred. At about 2 p.m., symptoms like those of the day before recurred. At about 4 p.m. his breathing, which had been hurried, became more so. Cold sweats covered his body, the pulse became rapid and feeble, and all the indications of collapse rapidly set in. I was sent for, and found him evidently rapidly sinking. He was in intense distress from dyspnoea, and his breathing was painfully gasping and hurried. The face and the lips were dusky and livid; pulse not perceptible at the wrist. Sinapisms were applied. Stimulants and quinine were freely administered, both by the mouth and as enemata. He was perfectly conscious—painfully so, indeed. Slight chloroform inhalation seemed to soothe him; but within half an hour after I saw him he ceased to breathe.

Post-mortem Examination, at 9 a.m. on August 7.—The body was that of a muscular, well-formed man. The abdominal viscera were generally healthy. The spleen and kidneys were quite normal. On the surface of the liver were a few pale patches about the size of a sixpence, but they were quite superficial. There was neither suppuration nor congestion round them; the viscus presented no structural change, and was otherwise healthy. There was no hernia of any kind; the inguinal and femoral rings were perfectly natural. The swellings in the groins, which on investigation I found had been there for some months, probably years (though much smaller than at present), consisted of thickened areolar tissue round a cluster of indurated glands. The intestines were natural; no choleraic fluid was found within them. Thorax: Lungs intensely congested, especially at the back, and containing numerous patches of pulmonary apoplexy throughout their structure; they were œdematous, and the bronchial mucous membranes were deeply congested and

covered with frothy mucus. The heart was normal, and firmly contracted; both sides contained small, firm decolorised clots, extending into the aorta and pulmonary artery; all else was normal.

This was a very interesting as well as a somewhat obscure case. It is an example of the rapidly fatal effect sometimes produced at this season of malarious poisoning—the weather at the time (August) being hot, damp, and replete with malarious influences.

The symptoms were such as not unnaturally, considering the state of the groins, to suggest a strangulated femoral hernia; indeed, so much so, that I was much tempted to cut down on the swelling to remove all doubts. But when I saw him after removal to the Hospital, the collapse was so complete that I did not do so. Death was due to the pulmonary engorgement, accelerated by the formation of fibrinous coagula in the right side of the heart. The overwhelming action of the malarious poison can only account for the rapidly fatal phenomena. The patient was a very healthy and temperate man, his organs were sound, and he had not been ill for months before the day on which this illness commenced. A certain amount of enlargement of the scrotum, combined with hydrocele, together with swelling in the groins, suggest the existence of an elephantoid taint; but in other respects he was free from disease.

Medical Times and Gazette.

SATURDAY, DECEMBER 30, 1871.

ANNUS MEDICUS 1871.

For some time during the autumn her Majesty the Queen suffered very much from debility and general malaise, then from sorethroat, and finally an abscess formed in one arm, and had to be opened. Her Majesty was so weakened by all this, that for many days she was not only unable to leave the house, but was entirely confined to her own apartments. Her illness was not at any time considered at all alarming by her Medical attendants, but the public could not help feeling anxious about an indisposition which was serious enough to interfere greatly with the regularity and activity of her Majesty's habit of life, and were much relieved when, in the beginning of November, it became plainly certain that she was steadily regaining strength, and would shortly be able to bear the fatigue of the journey from Balmoral to Windsor. A statement was widely circulated at one time that her illness was the result of revaccination in the early part of the year, and anti-vaccination agitators so persistently and industriously endeavoured to spread and insist on the truth of the rumour, that at the end of October Sir William Jenner publicly and formally contradicted it, in a letter in which he stated that he "gave the most unqualified contradiction to the report. There is not a shadow

of foundation for it in facts. Her Majesty's recent illness did not commence till many months after the revaccination. There was no connexion, direct or indirect, between the two."

Scarcely had the uneasiness about her Majesty's health been set at rest, when the public were alarmed by an official announcement that H.R.H. the Prince of Wales was suffering an attack of typhoid fever. On October 30 the Prince went to visit Lord Londesborough, at Scarborough, and remained there till November 4. He then returned to Sandringham, celebrated his birthday there on the 9th, and was apparently quite well till the 13th, when, on returning home from shooting, he complained of chilliness, lassitude, and depression; and next morning a whitlow appeared on the forefinger of the right hand. This was promptly cured, but on the 20th the febrile state was greater than the whitlow could be held accountable for, and headache was a predominant symptom. On Tuesday, the 21st, his Royal Highness's Medical attendants, Dr. J. Lowe, of Lynn, and Mr. Oscar Clayton, diagnosed the attack as one of typhoid fever, and Dr. Gull was telegraphed for, and, on his arrival on the 22nd, agreed in the diagnosis and treatment. On the 23rd Sir William Jenner arrived from Scotland, and took charge of the case with Dr. Gull and Dr. Lowe. The attack proved to be a severe one—the symptoms were all strongly pronounced; the functions of the sensorium were greatly disturbed, and at one time the Prince's temperature rose to 105.6°; but there were no complications. His strength continued good, he took nourishment well, and it was known that he had an excellent constitution, fortified by an active out-of-door life; so that the public, though gravely anxious, felt hopeful rather than alarmed as to the result. The bulletin on the morning of December 7 was assuring, as it spoke of the regular decline of the symptoms; but the next day the public were greatly alarmed by the announcement that the previous night had been a "very unquiet" one, and that there was a considerable increase in the febrile symptoms; and from this time till the 14th the Prince's condition was such as to excite the very gravest alarm. One of the most dangerous complications of enteric fever—bronchial irritation, with excessive secretion into the bronchial tubes—had supervened, and this state, which causes severe dyspnoea, was accompanied with most alarming attacks of reflex spasm, and with great prostration. The danger was at times extreme, and for some days the Prince's life hung in the balance. The public anxiety and alarm were intense, and as the 14th approached, and still the bulletins were more and more gloomy, it was impossible not to remember that on the evening of December 14, 1861, the Prince's Father had, while suffering from the same disease, died from sudden intense congestion of the lungs. Most happily, however, the bulletin issued at 1 a.m. on the 14th spoke of less restlessness; that issued at 8 a.m. contained the glad news that the Prince "had slept quietly at intervals during the night," and that there was "some abatement of the gravity of the symptoms." From that date till now the progress of the Prince towards convalescence and recovery has been steady and all but uninterrupted. After such an illness recovery must necessarily be slow, and for a considerable time the utmost care and watchfulness are required. But all has hitherto gone on well; defervescence gradually became complete, strength has gradually and steadily increased, and there has been complete absence of intestinal complications, and of any continuance of pulmonary trouble.

From the 14th the Prince's progress was so satisfactory that before the end of the week her Majesty, and several other members of the Royal family, ventured to leave Sandringham. The departure of Sir William Jenner for a time, and the diminution in the number of the daily bulletins, were also very assuring signs. But, after the strain of the intense anxiety and excitement of the previous days, the public mind naturally remains unusually sensitive, and susceptible of renewed alarm. And this was well and

markedly shown by the uneasiness excited by the bulletin issued at noon on Friday, the 22nd, though it only stated that the Prince had "passed a rather less quiet night," and added that "the general conditions continue as yesterday." After that the daily report was quite satisfactory till the 27th, when it stated that the Prince "had passed the night quietly, but convalescence is retarded by a painful affection above the left hip, attended with some feverishness." This affection is a merely local one, not having any connexion with the hip-joint, or with any of the pelvic viscera, and need not cause any apprehension; and the report of to-day (the 28th) is quite satisfactory. After any prolonged and exhausting illness, and especially after enteric fever, variations in the daily progress to health must be expected; and it is true that for long there remains a possibility that a too great haste to be well, indiscretions in diet or exercise, or some other cause, may light up very grave evils. But we know that the Prince will be constantly watched over and guided with the utmost devotion and the greatest skill and experience; and we may now with most grateful hearts and a happy confidence look to his perfect restoration to health.

Turning now more strictly to our subject—the Medical history of the year—we do not know that the Medical year 1871 can be credited with any great successes or triumphs; but, on the other hand, it has not been marked by any great disappointments or failures. It may perhaps be most fairly considered to have been one of those quiet years which have, happily, no special history. The most striking Professional Medical gains for which the year will be noted will probably be the increased use and more firmly established value of M. Reverdin's discovery of the mode of treating large or indolent ulcers, by means of transplanting small portions of skin on to the granulating surface; and the revival of the external use of cold in the treatment of hyperpyrexia, especially in cases of very great increase of temperature, as in one form of rheumatic pain.

The epidemic of small-pox, to which we alluded in the "Annus Medicus" of 1870, increased in severity and extent through the early part of the present year, till, in one week in February, the deaths from it in London reached the number of 227. Then it slowly, and with oscillations, declined, till, in the third week of October, the deaths from small-pox in the Metropolitan districts numbered only 53, though truly it is sad enough, if not disgraceful, that small-pox should be able to carry off that number of victims in London nearly a century after Jenner's great discovery. And, worse still, the disease is now again on the increase; in the week ending December 9 the deaths from it, in London, were 104, and there is every reason to fear that during the winter our Hospital accommodation for small-pox patients will again be strained to the utmost. Few parts of the country escaped the epidemic, and some of the provincial towns suffered very severely from its ravages. And, indeed, it was more or less rife all over the Continent, in some parts of which it was more generally prevalent, and more fatal even than with us.

At the end of the summer and during the autumn we were threatened with an invasion by cholera, but, happily, the danger gradually passed away for the time. The Privy Council adopted active and fairly prompt measures to prevent the importation of the disease through our seaports, and roused the health authorities to a state of vigilance and preparation which, it is to be hoped, will not be allowed to slumber next year, when the danger of a cholera epidemic will most probably again arise.

Last year we expressed a hope that our legislators would this year be able to devote more time to domestic legislation. The Reform Bill question, the Irish Church and Land Bills, and the Education Bill having been got out of the way, there seemed good reason to expect that, if wars or rumours of wars did not interfere, the Home Secretary might give Parliament some good work to do, and that her Majesty's Ministers might

bring forward some really comprehensive sanitary measures. The way was not stopped, happily, by the Foreign Secretary, the Secretary for War, or the head of the Admiralty, and the Home Secretary did propose great things; but, alas! most of his measures were stillborn, and Government was so absorbed by a Ballot Bill, which did not pass, that very little indeed was done in the way of sanitary legislation. We may, perhaps, however, be thankful to the Ballot Bill for the fact that Government let us alone as a Profession. There was no Government Medical Act Amendment Bill, and two Medical Act Amendment Bills introduced by private members—one, which we may, perhaps, be permitted to call "The *Lancet* Bill," fathered by Dr. Lush, and the other the Bill of the Irish College of Surgeons, taken care of by Dr. Brady—lacking the support of Government, reached the second-reading stage, and were then withdrawn. Another Bill, threatened by the British Medical Association, did not get so far. Mr. W. E. Forster said that he could not pledge the Government to bring in a Bill next year, "but it was their wish and anxiety to do so." Taught by experience, we may be permitted, perhaps, to express our hope and anxiety that Government will let us alone.

It must not be forgotten that the Government did manage to pass three Bills which may be classed as Sanitary. The "Vaccination Amendment Act Bill" made the appointment of Vaccination Officers by guardians of unions or parishes obligatory, instead of permissive only. The Bill, affecting to make vaccination compulsory, as it first left the House of Commons contained a clause inspired probably by the Romish practice of the sale of indulgences, for it granted freedom to continue to disobey the Act with impunity to anyone who paid one penalty of twenty shillings, or two penalties of any amount. Our hereditary legislators, however, struck the clause out, and the Lower House, rather than let the Bill be lost, agreed to the amendment.

The "Act to amend the Metropolitan Water Act, 1852, and to make further provision of the due supply of water to the metropolis, and certain places in the neighbourhood thereof," though a "patch" Bill, was, as originally introduced by Government, strong enough to be likely to prove a really useful measure; but it was so altered and weakened by amendments that very little good can be expected from it, and Lord Halifax informed the House of Lords that "further legislation would be desirable next session to insure a more abundant supply of pure water for the metropolis."

The "Act for constituting a Local Government Board, and vesting therein certain functions of the Secretary of State and Privy Council concerning the public health and local government, together with the powers and duties of the Poor-law Board," is a really large and valuable Act. It may be looked upon as really establishing a Ministry of Health, and is the first result of the valuable report of the Royal Sanitary Commission. The next will, or at least certainly ought to be, the introduction into Parliament by Government, very early next session, of a large and comprehensive sanitary measure, to "consolidate the present fragmentary and very confused sanitary legislation," and providing fully and positively for the organisation of sanitary districts and local health authorities. The intense and universal anxiety excited by the nearly fatal attack of typhoid fever from which the Prince of Wales is hardly yet convalescent, the death of Lord Chesterfield from the same disease, contracted apparently from the same source, and the other circumstances connected with the Prince's illness, have aroused a degree and extent of interest in sanitary science, and the prevention of disease, that will give the Government immense advantage and assistance in legislating on those subjects if they act promptly and without hesitation. They will be inexcusable if, by weakness of purpose, hesitation, or loss of time in the promotion of mere political measures, they let slip such a rare opportunity for

enacting laws that may lead to the annual saving of thousands of lives.

Besides the Royal Sanitary Commission, the Royal Commission on the Contagious Diseases Acts also made their report—a very able and important document, which must necessarily cause next year the introduction of a measure of some sort on the subject by her Majesty's Government. What that measure is likely to be, no one, we should imagine, will venture to predict—unless, indeed, the observation of the effects that have apparently been induced by agitation and clamour, on the delicate nervous organisation of the most prominent and powerful of her Majesty's Ministers, may be thought to warrant the suspicion that the activity and more than forty-women-tongued power of a comparatively small body of agitators may lead Government to propose the total repeal of all the Acts.

Mr. Charley obtained a select committee to consider the best means of putting down baby-farming, and Mr. Dalrymple withdrew his Habitual Drunkards Bill on the promise of a select committee. Both committees may be expected to furnish valuable information and recommendations for much-needed legislation.

The General Medical Council met on July 4, Mr. Quain taking his seat as member for the Royal College of Surgeons, instead of Mr. Caesar Hawkins, and Dr. Gull as member for the Crown, in place of Dr. Rumsey. Of course, everyone was glad to see the Council reinforced by a man of Dr. Gull's ability and experience; but, at the same time, many felt probably some regret that the Crown had not seen fit to nominate in Dr. Rumsey's place some provincial Physician or Surgeon instead of any London Practitioner, however eminent. The proceedings of the Council were fully reported in our pages at the time, and call for but very brief allusion here. The session was short—only six days—and there was unusual reticence and pertinence of speech shown. Dr. Parkes presented an important and very valuable report from the Committee on Professional Education. It noted important improvements made in the system of education and examination by the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries, London, in requiring evidence of practical and clinical study, by the production of proof that each student had filled the offices of dresser and clinical clerk, and by submitting him to the test of practical examinations. It reported, also, that some of the Scottish and Irish bodies had instituted clinical and practical examinations. Some resolutions, founded on the report, were proposed by Dr. Parkes, and were carried in a permissive form—each beginning, that is, with the words, "It is desirable that" such and such a thing be done; and the Council justly and fully acknowledged the readiness and desire the licensing bodies had shown to adopt their suggestions. Considerable time was devoted to the subject of the formation of conjoint examining boards, and to the discussion of a resolution of Dr. Parkes's, proposing to call in the aid of Parliament to enforce their establishment next year if necessary. But the Council declined to suggest any threat of Government interference, and resolved, "That a meeting of the General Medical Council be held early in 1872, to receive the proposals of the bodies for conjoint examinations, and to consider whether any, and what, steps should be taken to carry out the resolutions of the Council in favour of combinations."

For more than two years we have had to bring the subject of the "Unification of Examinations" so repeatedly before our readers, and we have so often had to comment on schemes for the formation of an English Conjoint Examining Board, and to note rumours of the speedy establishment of such a Board, that everyone must be weary of the subject, and must almost despair of the desired object ever being attained. But it does now seem probable that a Conjoint Examining Board for England and Wales, though an imperfect one, will shortly

be established. At the end of 1869 we noted that "most important steps had been taken towards effectively working out, and carrying into practice, the popular idea of one Conjoint Examining Board" for England and Wales. The College of Physicians had appointed a Committee to confer with the Universities and Corporations on the subject, and had prepared a scheme for the composition and regulation of the proposed Board. For a while things looked promising, but before long irreconcilable differences of opinion arose between the College of Physicians and the Society of Apothecaries, and the scheme was dropped; the main cause of its failure being, we believe, the determined refusal by the Committee of the College of Physicians to allow the Society of Apothecaries any share whatever in the appointment of Examiners in Medicine on the new Board. But towards the end of last year the subject was again taken up—the Colleges of Physicians and Surgeons invited the Society of Apothecaries to co-operate with them in concerting "a scheme for the constitution and regulation of a Conjoint Examining Board," and we were able to state that it was believed that "the former difference of opinion between the College of Physicians and the Society had been smoothed away, and there was good ground for expecting that a Conjoint Board would be formed," and that the first meeting of the Committees of the Colleges and of a deputation from the Society of Apothecaries was to take place in the first week of the present year. At that meeting it was unanimously resolved that a Board of Examiners for England and Wales should be appointed by the three Corporations; and a Sub-committee, composed of three representatives from each Corporation, together with the Registrar of the Royal College of Physicians, the Secretary of the Royal College of Surgeons, and the Clerk to the Society of Apothecaries, as assessors, was appointed to draw up a scheme for carrying out the resolution. This Sub-committee worked harmoniously and well, so that early in February a scheme to be submitted to the governing bodies of the three Corporations was agreed on. The Board was to be a conjoint one, the Examiners being appointed by the three Corporations; the Apothecaries' Society sharing with the College of Physicians the nominations of Examiners in Medicine, in Chemistry, Materia Medica, and Botany, and in Forensic Medicine, and with both the Colleges in nominating Examiners in Midwifery; the two Colleges were to nominate Examiners in Anatomy and Physiology; and the College of Surgeons the Examiners in Surgery. Successful candidates were to be entitled to the licence of the Royal College of Physicians, the Membership of the Royal College of Surgeons, and the licence of the Society of Apothecaries, or to any one or two of these diplomas, without other fee or examination, upon undertaking to comply with the by-laws of the respective Corporations. The fee was to be thirty guineas, the exact mode of the division of which was not quite settled, but the Royal College of Surgeons was to receive enough to support its library and the Hunterian Museum. The question of the co-operation of the Universities was left for further consideration. A few days afterwards, on February 20, the scheme was considered by the Fellows of the Royal College of Physicians, and, after considerable discussion, received the full assent of the College. Very shortly after, it came before the Council of the Royal College of Surgeons, and they, by a majority of one, determined to send it back to the Committee for reconsideration, because the scheme practically did not prevent any of the Medical authorities in England from granting registrable diplomas to persons who had not passed the Conjoint Board, which it could not legally do; and because the co-operation of the Universities, in the appointment of examiners or assessors, had not been invited. The Council, however, at their next meeting, refused to confirm this resolution, and afterwards, sitting as a Committee on the scheme, passed a series of resolutions, which, though unpractical or harmless, or weakened by the fact that each was made suggestive only by

the preface "It is desirable," still contained possible elements of discord and mischief. The last and most dangerous of them ran thus: "It is desirable that each of the Examiners in Medicine, Surgery, and Midwifery shall be a graduate in Medicine or Surgery of a British University, holding the highest degree in Medicine or Surgery of his University, or a Fellow or Member of one of the Royal Colleges of Physicians, or a Fellow of the Royal College of Surgeons of the United Kingdom; or that he shall be, or shall have been, a recognised teacher in the subject in which he is appointed to examine." There could be no ground or reason for doubting that the Medical authorities would, for their own credit, appoint the very best men they could obtain, and an attempt thus to limit their choice seemed not a little likely to excite resentment and opposition.

The next step towards the formation of a Conjoint Board was that the Committee of the Council of the College of Surgeons drafted a new scheme, to be submitted to the Committees of the Royal College of Physicians and the Apothecaries' Society. It proposed the representation of the Universities on the Conjoint Board by assessors or examiners, on condition that the Universities should not grant degrees admitting to the Register any who had not passed the Conjoint Board; and it suggested such a pecuniary arrangement as would secure to the College a sufficient income to maintain properly the Hunterian Museum and the College library. All this took us to the beginning of April; then came a pause, during which we had no news about Conjoint Board schemes; but the middle of May brought us a new scheme from the Royal College of Physicians. We cannot, and need not, describe it here—a sketch of its provisions may be read at page 576 of our first volume for the year—but, among other things, it proposed the appointment of a board of examiners by the co-operation of the Universities and Corporations, "it being understood that, liberty being left to the Universities and other licensing bodies to confer, as they may think proper, their honorary distinctions and degrees, each co-operating body will abstain from the exercise of its previous independent privilege of giving admission to the Medical Register"; and it proposed that a "Committee of Examinations" should be appointed by the Universities and the Corporations, which Committee "should determine the number of examiners to be assigned to each subject of examination, should nominate such examiners for appointment by the several Universities and licensing bodies, regulate and superintend all other matters relating to the examinations, and transact such business as might be referred to them by the Universities and licensing bodies, and should report periodically their proceedings"; it proposed, moreover, that there should be two or three Professional examinations for the diploma, and that University graduates in Medicine should be required to pass the final examination only. The scheme seemed a somewhat complex one; it proposed to give the Universities a degree of representation in the Committee of Examinations much out of proportion to their influence over the Profession, and that Committee itself seemed likely to prove a dangerous body unless its action should be so fully and accurately defined as to prevent any risks of its coming into collision with any of the licensing bodies; still, on the whole, the scheme looked a fair one. The Conjoint Board Committee of the Corporations held several meetings to consider it. Before long a rumour was heard of legal difficulties having arisen, and early in July we had to report that the two Colleges had all but agreed on a scheme for the formation of a Conjoint Board, the basis of which was to vest the nomination of examiners in a committee appointed by the four Universities and the two Colleges; but that there seemed to be legal questions relating to the Act of 1815 which stood in the way of the Society of Apothecaries, and that these questions were under the consideration of counsel. A description of this scheme was given to the General Medical Council during their session, and will be found at pages 64,

72, and 79 of our second volume. It has been frequently brought before the governing bodies of the two Colleges and the Universities, and, after being very carefully considered and discussed, has been finally accepted by all those authorities; and it is now under consideration by the standing counsel of the Colleges, in order to make sure that their charters present no legal difficulties to its being practically carried into effect. The solicitors of the Colleges, we believe, do not anticipate that any such difficulties will be discovered; so that we may expect soon to hear that the Conjoint Board is actually in process of formation.

We need not point out that at the best it will be an imperfect and not very satisfactory Board, for the Society of Apothecaries has not found itself able to join in it; and so long as the Act of 1815 continues in force, and conducts its examinations to the satisfaction of the General Medical Council, the Court of Examiners of the Society must hold their weekly meetings, candidates for the Society's licences will present themselves, and cannot, we imagine, be refused, for examination by any of the British Colleges of Surgeons, and their licences will be registrable. We cannot but think that the position of the Society of Apothecaries is very greatly to be regretted. Ever since they, in 1815, undertook the examination and education of the general Practitioners, on the refusal of the Royal College of Physicians to do it, they have performed their work honourably and well, and have ever been foremost in raising the status and education of the Medical Practitioner, and in meeting the wishes and requirements of the General Medical Council. We venture to think that the reasons which have finally prevented the Society from taking part in the formation of the English Conjoint Examining Board should be made known, and further, that if they are solid and good, and really depend on the construction of the Act of 1815, means should as speedily as possible be taken to procure the alteration of that Act.

We need not say much more about the proceedings of the two Royal Colleges during the year. We are glad to record that the College of Physicians has taken measures to increase the value and usefulness of its library as regards recent Medical literature, and has extended to its Licentiates the use of the library and the reading-room, which latter has been re-decorated and, in great part, newly furnished. The daily papers, with quarterly, monthly, and other periodicals, are supplied; and a large number of carefully chosen recent works on Medicine, Surgery, midwifery, and the collateral sciences are placed on the tables, and are changed every three months, or more often, as the Library Committee may think desirable.

The annual election of Fellows into the Council of the College of Surgeons took place on July 6, when there were four vacancies to be filled up, from the retirement, according to the charter, of Messrs. E. Cock, George Busk, and F. Le Gros Clark, who offered themselves for re-election, and of Mr. Lane, who declined being nominated. The other candidates were Messrs. Spencer Wells, G. Critchett, and Barnard Holt; and the choice of the Fellows fell on Messrs. Spencer Wells, Critchett, Le Gros Clark, and Busk. Mr. Cock has just lately retired from the Court of Examiners, of which he had long been a deservedly popular member. Sir William Fergusson, while President of the College, proposed the formation of a museum of surgical instruments and appliances, in connexion with the Hunterian Museum, and his circular letter on the subject will be found at page 52 of our first volume for this year. The idea is a very good and valuable one, and it is to be hoped that the museum will prove a success.

The British Medical Association held its fortieth annual meeting at Plymouth, early in August. The business of the meeting was opened by the presentation of an address of hearty welcome from the Corporation of Plymouth, which was highly appreciated, the President remarking that it was

the first time such an honour had been paid to the Association by any town which had been visited by it. At Newcastle, indeed, the Corporation had welcomed the Association, but not presented it with any address! Perhaps this mode of opening the meeting had something to do, combined with the fine weather, with the spirit of play, rather than work, which more than usually marked the whole period of the meeting. If the precedent is followed, the growing greatness and grandeur of the Association must be more fully shown by its title; the receiving of addresses is one of the marks of a Royal progress, and we may live to record the proceedings of the Royal British Medical Association. The President-elect took for the subject of his address the "History of Plymouth," of which he gave an interesting and comprehensive, though necessarily brief, sketch. The address in Surgery was delivered by Mr. Lister, and was, of course, on his antiseptic system of treatment as applied in Surgery. Dr. George Johnson gave the address in Medicine, choosing for his subject, "Nature and Art in the Cure of Disease." The out-of-doors attractions were so great that the Sections were, we believe, rather thinly attended, but in all of them some good and interesting papers were read, and interesting discussions excited. The report of the Council excited a rather stormy discussion. It stated that the Council had, after an inquiry by a Committee, arrived at the conclusion that there were grave defects in the organisation of the Association, and that the accounts showed a deficit; and they recommended that for the future the General Secretary should be resident in London, and give personal attention to, and be responsible for, the finance and management of the *Journal*. The discussion was warm, but eventually the report was adopted, and its recommendations *in re* Secretary have been carried into effect.

The forty-first annual meeting of the British Association for the Advancement of Science was held in Edinburgh. The opening address of the President—Sir W. Thomson, F.R.S.—was an able production, and dealt with many and various subjects: physical laboratories and observatories, terrestrial magnetism, spectrum analysis, the nature of comets, *cum multis aliis*—but the part which excited most attention, and, may we venture to add, most astonishment, was, as doubtless our readers will remember, that having reference to the origin of life on our planet. The theory propounded being, that when a life-bearing world gets smashed up, by a collision or in some other way, many great and small fragments, carrying seed and living plants and animals, are scattered through space; that it is in the highest degree probable that there are countless seed-bearing meteoric stones moving about through space; that if one such fell on a world hitherto barren, but ready to bear, such world might gradually become clothed with vegetation; and from vegetation all things else might be evolved. And we all know what great events from little causes spring! Many able and interesting papers were read in the sectional meetings from members of our Profession—one of the most valuable and important, perhaps, being "On the Morbid Appearances noticed in the Brains of the Insane," by Dr. J. Batty Tuke and Professor Rutherford. Dr. Carpenter, F.R.S., was elected President of the next meeting, which is to be held at Brighton.

The Social Science Association held its congress in Leeds, and this year the meeting was particularly remarkable for the number of eminent sanitarians who attended in the department of Public Health, and the excellence of the papers read there. Mr. G. W. Hastings, in his inaugural address, delivered to the whole congress, advocated making the country, rather than the parish, the unit of sanitary administration, contending that in such a way only could we obtain the services of persons of sufficient attainments or position for the proper and intelligent discharge of their duties, or to fit them to deal on terms of mutual respect with a central authority.

Nothing special has to be recorded concerning the various

Medical Societies of the metropolis as to their work. The space given in our columns to their proceedings is proof enough of their activity, and it is sufficient here to say that they continue to flourish and do good work. The Medical and Chirurgical Society have "restored" their library, making some improvements and re-arrangements so as to add to its book space and convenience; and a new room, to be used as a reading room, has been added, at the back of the library. The wet weather has so retarded the work of painting and decorating that the new room is not yet fit for use.

The changes in the *personnel* of the Metropolitan Hospitals and Schools were, as usual, noticed in our Students' Number; they have been very numerous and important, and some additional changes have occurred since. Thus, at Charing-cross Hospital Dr. Alexander Silver has become full Physician, succeeding to the vacancy created by the lamented death of Dr. Hyde Salter. At Middlesex Hospital Dr. Greenhow became Physician in place of Dr. Murchison; Mr. Andrew Clark has been appointed Assistant-Surgeon in place of Mr. H. Arnott; and Dr. J. C. Thorowgood lectures on *Materia Medica*, *vice* Dr. Brunton, resigned. Dr. Cayley has succeeded Dr. John Harley as Physician to the London Fever Hospital. Mr. H. G. Howse has been appointed Surgeon to the Evelina Hospital, *vice* Mr. Alfred Willett, resigned. Mr. J. Astley Bloxam has been made Surgeon to the Great Northern Hospital, *vice* Mr. Buxton Shillitoe, resigned.

The new St. Thomas's Hospital, was formally opened by her Majesty on June 21, but patients were not admitted for some weeks afterwards, and we do not know how many available beds the Hospital is considered to number at the present time. The new building cost about half a million sterling, but the treasurer was obliged to appeal to the charitable public for £22,000 to furnish it and make it of any practical use. We do not pretend here to pass any judgment on the cost of the building, or on its excellencies or defects; but certainly numerous complaints have been heard of extravagance of outlay, and of woful deficiencies, defects, and inconveniences of construction and arrangement. The first session of the Medical School in its new buildings was opened by an eloquent and highly interesting address from Mr. Le Gros Clark.

The "Hampstead Hospital Scandal" must be so fresh in the memories of our readers that we need only allude to it. A great amount of public feeling and indignation was excited by various very serious charges brought against the management of the Hospital by three gentlemen who had been Assistant Medical Officers to it, and the Local Government Board very properly ordered a public investigation into the subject by two Special Commissioners, Mr. Henley and Dr. George Buchanan. The charges were brought by the three Medical Officers in a letter published in the *Times*; and the official inquiry was demanded by the Hospital authorities. The inquiry lasted thirty-two days, and an immense amount of conflicting evidence was laid before the Commissioners, whose report thereon has not yet been made public, though it has, we believe, been sent in to the Local Government Board. Whatever the conclusions of the Commissioners may be, two things were, we think, certainly proved—*viz.*, that the existing machinery for meeting and dealing with great epidemics in the metropolis is wofully imperfect and unsatisfactory, and that the present system of Medical management of the Metropolitan Asylums Board's Hospitals, by Resident Medical Officers, without Visiting Physicians, is also unsatisfactory and inefficient.

We have had the pleasure of recording distinctions, honours, and rewards received by various members of the Profession. Dr. Hermann Beigel, who left London to serve his country during the Franco-Prussian war, was rewarded by the Emperor of Germany with the Iron Cross for his services in the field; Deputy Inspector-General Dr. C. H. Gordon, C.B., and Surgeon-Major Wyatt were made Officers, and Dr. Rose Cormack, Chevalier of the Legion of Honour, for their

Medical services during the siege of Paris; and the Société de Secours aux Blessés presented their Cross and Diploma to Sir W. Fergusson, Sir James Paget, and Mr. E. Hart. Mr. Mitchell Henry has entered Parliament as Member for Galway. Dr. Burrows has succeeded Sir James Alderson as President of the Royal College of Physicians; Dr. Parkes has been elected into the Senate of the University of London; and Drs. W. Budd and R. Quain, and Messrs. John Wood and G. W. Callender have received the distinction of the Fellowship of the Royal Society. The Companionship of the Bath has been conferred on Inspector-General of Hospitals J. Paynter, Inspector-General of Hospitals and Fleets Dr. C. A. Anderson, Deputy Inspectors-General of Hospitals R. J. O'Flaherty and Dr. W. C. Macbean, Deputy Inspectors-General of Hospitals and Fleets R. D. Mason and D. L. Morgan, and on Surgeon-Major John Bostock; while Dr. Alexander Armstrong, Director-General of the Medical Department of the Navy, and Dr. David Dumbreck, C.B., have been made Knights of the same distinguished and ancient Order. The whole Profession felt gratified when her Majesty acknowledged the eminence of Mr. Paget and Dr. Robert Christison by conferring on each the social distinction of a baronetcy. No men stand higher in the consideration and esteem of their brethren, or have done more to advance the science and art of Medicine. Dr. John Lowe, of Lynn, has been appointed Medical Attendant to the Prince of Wales's household at Sandringham, and has most amply justified, and indeed repaid the Prince for, his appointment by the devotion and skill he has shown during his Royal Highness's late dangerous illness. Dr. Ballard has been made one of the Medical Inspectors to the Local Government Board, and on retiring from the Medical Officership of Islington had the pleasure of receiving a well-merited testimonial to his very able, long, and indefatigable services from his Medical brethren in that parish. And several other of our brethren have also had the satisfaction of finding their labours publicly acknowledged by the presentation of testimonials and addresses; among them we may mention Mr. E. Cock, Dr. Cordy Burrows, and Professor Halford. The sum collected already towards the Syme testimonial will produce £100 a year; and no doubt the fund which is being collected for commemorating in some permanent way Sir James Paget's valuable services to the School and Hospital of St. Bartholomew, will result in something alike worthy of him and of those interested in the movement.

Death has, as usual, been very busy in our ranks, and we have had to lament the loss of not a few at an age when we might justly have looked for many years more of good and eminent service from them, and they might have expected to be allowed to reap much more fully and for long the reward of their devotion and labour in the work of their Profession. Of such we would here specially mention, with sincere regret, Dr. Hyde Salter, who died at the age of 47; Dr. T. Hawkes Tanner, aged 46; Dr. R. Whitfield Hewlett, aged 32; Dr. James Fawcus (Deputy Inspector of Gaols, Bombay), who died at 38; Count Cyprian C. Wollowicz, M.D., at 31; and Mr. F. W. Richards, M.B., at 29. Many well-known and highly valued men have been taken from us at a later age, indeed, but while still in harness, and looking for many more years of usefulness and success, as Dr. J. Addington Symonds, who died at 63; Dr. J. S. Christian, at 57; Mr. Samuel Solly, at 65; Mr. Langston Parker, at 65; Dr. W. Daniel Moore, at 58; Dr. Charles Cowdell, at 56; Mr. H. S. Illingworth, at 62; Mr. R. Shipman, at 54; and Mr. J. T. Grantham, at 43. Many, happily, whose deaths we have had to record, and of whom we have given obituary notices, lived to a good old age, and some long beyond the three-score and ten years allotted to man by the Psalmist. Dr. R. Filkin had reached the age of 95; Mr. J. Frowd Spencer was 89; Deputy-Inspector of Hospitals Dr. R. Dunn, Mr. Cornelius Butler, Dr. G. F. D. Evans (Shrewsbury), Sir James Murray, M.D., Dr. T. Mayo, Mr.

John Packman, Dr. Waterfield, Dr. James Low Warren, Mr. Samuel Barton (Manchester), and Dr. James Watson (Glasgow) were all more than 80; and Dr. W. Callender Tidy, Sir John Fife, M.D., Dr. M. Nisbet (Cheltenham), Dr. Patrick Anderson, Dr. De Burgh Birch, Dr. J. D. Anderson (Glasgow), Dr. Charles Bloomfield, Dr. J. England (Ipswich), Dr. R. Dundas, Mr. John White, Mr. J. Lionel Beale, Dr. Cursham, Mr. John Savory, Dr. T. Evanson, Dr. Caleb Williams, Mr. Walter Cooper Dendy, and Mr. P. C. De la Garde were all over 70 years of age. While, on the other hand, we have had to mourn the loss of some who were just showing their talents and worth when struck down by diseases caught in the discharge of their duties, as Dr. Joseph Gedge, Chief Medical Officer to Sir S. Baker's White Nile Expedition, at 28; Mr. St. John Wells Lucas, House-Surgeon to the Windsor Royal Infirmary; Dr. Clements, of the Liverpool Workhouse Infirmary; Dr. Hewitt (Dublin), at 25, of typhus; Dr. O. S. Shaw, at 24; and Dr. H. Curran (Dublin), also of typhus; Dr. J. W. Irvine (Liverpool); and Dr. John Davidson, of Middlesex Hospital, of typhoid, at the age of 24.

We cannot leave this sad part of our yearly summary without again speaking of the great regret with which we recorded the death of Felix von Niemeyer. Though only 50 when he died, he had won a world-wide reputation, and stood foremost among the greatest clinical teachers in the German Schools of Medicine. Among ourselves he was held in very high esteem, and his works are widely studied and greatly valued. Among other well-known foreign Medical men of eminence whose death we have this year recorded, we may mention Professor Rossignol, of Brussels; M. Longet, of Paris; and Professor Fred. Holst, of Christiana.

We may now turn to notice shortly our own labours through the year, and the contents of the two volumes we have issued.

We have had the gratification of publishing the valuable "Lectures on Practical Physiology," delivered by Dr. Burdon-Sanderson in the Physiological Laboratory of University College, and Dr. T. Laycock's able and learned "Lectures on the Clinical Observation of Diseases of the Brain and Nervous System;" the admirable and interesting lectures of the Rev. S. Haughton, M.D., "On the Principle of Least Action in Nature, illustrated by Animal Mechanics;" Mr. C. Brooke's "Lectures on Force and Energy;" and Mr. R. Liebreich's "Clinical Lectures on Ophthalmology." We have continued to give Dr. B. W. Richardson's interesting and suggestive "Lectures on Experimental and Practical Medicine," and Dr. W. Moxon's able "Lectures on Analytical Pathology." We have been enabled to give Lectures "On Two Cases of Venereal Disease," and "On acute Abscess," by Mr. C. F. Maunder; on "Optic Neuritis from Intracranial Disease," by Dr. J. Hughlings-Jackson; and on "The Principles of the Treatment of Fever," by Dr. Lionel S. Beale; also, "Clinical Lectures" on "Orchitis from Irritation in the Prostatic Urethra," on "Periostitis of the Temporal Bone," and on "Fracture of the Patella," by Mr. Jonathan Hutchinson; on "Overstrain of the Heart," by Dr. Clifford Allbutt; on "Instances of Successful Treatment of Degenerative Disease of the Kidneys," by Dr. C. Handfield Jones; and on "The Uses and Application of Hodge's Lever Pessary," by Dr. R. Barnes; a "Clinical Review," by Mr. G. W. Callender; and the "Discussion on Purulent Infection at the Paris Academy of Medicine," by Professor Verneuil.

Under the head of "Original Communications" we have given papers on important and interesting subjects from many of the best-known workers and highest authorities of the day. Among these papers we may mention—"Notes on the Pathology of Malignant New Growths," by Mr. Henry Arnott; papers on "Shark-bites in the Hooghley," "Traumatic Aneurism from a Gunshot-wound," "Urethral Fever," "Pyocyanine," "Fatal Injury to the Perineum," and other subjects, by Professor J. Fayrer; on "A Case of Pemphigus,

contracted by Inoculation from an Eruption on the Teats of a Cow," by Dr. E. Ballard; on "Leucocytes and Sarcophytes," by Dr. C. J. B. Williams; on "Entozoa in relation to Public Health, and the Sewage Question," by Dr. Spencer Cobbold; on "The Varieties of Imperfect Speech produced by Brain Disease," and on "Drunkenness as Modified by Race," by Dr. R. Druitt; on "Clinical Observations on Rickets," by Dr. C. Currie Ritchie; on "The Variations in the Prevalence of Venereal Diseases in this Country," and on "Cholera in Ships at Sea," by Inspector-General Lawson; on "The Treatment of Epilepsy," by Mr. Walter Tyrrell; "Surgery in India," by Mr. A. S. G. Jayakar; "Country v. Town Milk," by Mr. John Gamgee; "A Case of Bronchocele," by Dr. Adolph Wahltuch; and on "Urethral Stricture," by Mr. J. D. Hill; "Notes on the Engadine," and on "The Baths of Borneo," by the late Dr. Whitfield Hewlett; Dr. Kraus's "Contributions to the Pathology of the Prostate Gland;" and Mr. J. Sullivan's "Notes on the Yellow Fever as observed at the Havana in 1870," and on "Acute Rheumatism in the Tropics;" papers on "Operations for Vaginal Fistula," by Mr. Lawson Tait; on "Difficulties in the Diagnosis of Cerebral Hæmorrhage and Drunkenness," and on "The Routine Use of the Ophthalmoscope in Cases of Cerebral Disease," by Dr. Hughlings-Jackson; on "Functional Regurgitant Bruit," by Dr. A. Silver; on "The occurrence of Epileptic Attacks of Mania in conjunction with Chorea," by Dr. James Russell; on "Hedonism," "Cerebral and Ganglionic Disorders of Mentation," "Pregnant Sickness," and "The Convolutions of the Frontal Lobe of the Brain," by Mr. Metcalfe Johnson; on "Rheumatism," by Dr. James Ridge; on "Specific Ulcers of the Lower Extremities," by Mr. C. Holt-house; on "Hæmoptysis in Children," by Dr. Vald. Rasmussen; on "The Alice Hospital at Darmstadt," by Dr. C. Mayo; on "Cases of Acute Cerebral Disease," by Dr. W. H. Broadbent; on "The Spectrum Analysis of Bloodstains," by Mr. H. C. Sorby; on "The Several Forms of Phthisis Pulmonalis," by Dr. Douglas Powell; on "Phthisis as a Neurosis," by Dr. Clifford Allbutt; on "A Case of Contractile Phthisis, causing Remarkable Displacement of Organs," by Dr. C. Theodore Williams; and on "Lumbar Colotomy," by Mr. C. F. Maunder; a "Case of Progressive Muscular Atrophy," by C. B. Mesterton, of Upsala; papers on "Puerperal Fevers," by Professor Edward Martin, of Berlin; on "Epidemics of Small-Pox, Scarlet Fever, and Measles in Rotterdam," by Professor A. M. Ballot; on "Extensive Softening of the Brain from Syphilitic Disease," "Sudden Death from Acute Inflammation of the Aorta," and a "Case of Cerebral Rheumatism treated by the Cold Bath," by Dr. Moxon; on a "Case of Myelitis," by Dr. R. W. Tibbets; and on "The Treatment of Pyrexia by a Cooling Pad," by Dr. W. Roberts; besides valuable communications, for which we have to thank Dr. A. E. Sansom, Mr. C. A. Fox, Dr. Jabez Hogg, Mr. J. G. Trench, Dr. T. S. Dowse, Mr. W. N. Hiron, Assistant-Surgeon F. H. Welch, Dr. F. Porter Smith, Assistant-Surgeon G. Waters, Dr. J. Imray, Dr. J. Ward Cousins, Dr. J. Wickham Legg, Mr. Edward Milligen, Surgeon Partridge (of Bombay), Dr. Archer Farr, and other able and valued contributors.

In our "Hospital Reports" we have supplied short but practically ample notes of striking and interesting cases, and such as illustrated the most approved and most novel methods of Medical and Surgical treatment in the metropolitan and provincial Hospitals; and, so far as we were able to spare the necessary space, we have given short reviews and notices of all the best and most important new works, English and foreign, and have recorded the proceedings of the various Medical societies, as showing the progress that is being made in the different departments of Medical science. Our "Topics of the Day" have regularly supplied an instructive and admirable *résumé* of the most talked-of and the most important events of each week, and have, we suspect, been the part of the journal first looked at by most of our readers. Our

pages have also contained abstracts of the lectures delivered at the Royal College of Physicians by Drs. Gee, E. A. Parkes, Guy, and Acland; the Hunterian Oration of Sir William Fergusson; and the Annual Oration delivered to the Medical Society of London, by Dr. Cholmeley; and notices of Dr. Acland's lectures on "Hospitals and Hygiene" to the working-classes; and our "Notes" from at home and abroad have supplied information and "light reading" of an instructive and pleasant kind.

In our Editorial Articles we have criticised, advised, warned, or encouraged whenever the honour and interests of the Profession seemed to call for special comment; and we have also noticed or criticised many of the most prominent theories or vagaries of the day. Thus we have published articles on "Progress! Free Thought! Untrammelled Lives for Women!" on "Female Physic," on "The Medical Education of Women," and on "The Edinburgh Female Medical Students; on "Milk, Town and Country;" on "The Poor-Law Medical Officers, as Assistant-Medical Officers of Health;" on "Army Reorganisation, and the British and Indian Medical Services;" on "State Interference in Medicine;" on "Sanitary Organisation;" and on "The Medical Supervision of Asylums;" on "Unprofessional Advertising;" on "Dr. Mazzoni's Visit to London: Veluti in Speculo;" on "Very Popular Science," "Nec semper Arcum tendit Apollo," and "Confusion Scientific;" on "The Teaching of Psychology in our Schools of Medicine," on "Practical Physiology," on "The General Medical Council," and on "Scientific Work—Pure and Professional;" on "The Future Life of the Medical Student," on "Over-Education or Under-Education—Which?" on "Professor Huxley on Medical Education," on "National Degeneracy," on "The Value of Extract of Meat," on "The Process of Inflammation," "Pus and Pus-Corpuscles," and on "Dr. Burdon-Sanderson on Microzymes." We have traced and commented on the Progress of the Small-pox Epidemic and the Cholera. We have given articles on "Spiritualism," and on "A New Force, popularly so-called; on "Vaccination and Syphilis," on "The Reports of the Royal Commissions," on "The Questions and Theories concerning Town Sewage," on "Coprologia, or Typhoid in its Home," on "The Hampstead Hospital Inquiry," on "The Method of dealing with Intemperance," and on "Sick Transport and Volunteer Aid in War," and "Parisiana."

Our pages have further contained many valuable and highly interesting papers or notices which cannot well be classed under any of the subjects already spoken of. Thus the Franco-Prussian war, and the great events in and around Paris, have supplied us with many articles, as "The History of the First French Volunteer Ambulance," Dr. Cormack's papers on the "Siege of Paris," "The Autumn Tour of a Dresser in 1870," Baron Munday's "Report on the Ambulance de l'Ancien Corps Legislatif," "Work done under the Red Cross," "The French and the Red-Cross Societies" and the Visit of Drs. Ricord and Demarquay to London, "The English Hospital at Metz," and "Physiological Notes from Paris." We have had the pleasure of continuing Mr. J. F. Clarke's "Autobiographical Recollections of the Profession," and of giving some "Reminiscences of an Old Guy's Man." We have published papers on "Direct Representation;" on "Chloral Hydrate," by Dr. B. W. Richardson; on "The Influence of Moisture in the Propagation of Erysipelas;" on "Legislative Measures for preventing Adulteration of Food, Drink, and Drugs," by Dr. Letheby; on "The Sanitary Commission of the Punjab," on "The Contagious Diseases Act in India," on "Fibrinous Coagula in the Right Side of the Heart in connexion with Malaria," on "Scotch Morality," on "The Application of Electricity to Medicine," on "The Effects of Changes of Climate on the Human Body," on "Wunderlich's Medical Thermometry," on "The Physiology of Mind in the Lower Animals," on "The Effects of Compressed Air on the Human

Body," on "Ben Rhydding," on "The Broadmoor Criminal Lunatic Asylum," "The Legal Liability of Persons under Age for necessary Medical Attendance," "The Vaccination Act," "Spurious Tea," and on "The Latest View regarding the Red Blood-Corpuscle." We have noticed Mr. Campbell De Morgan's Address to the Medical Teachers' Association, Dr. Carpenter's lecture on "Deep-sea Explorations in the Mediterranean;" have given "A Summary of Experiments on the Influence of Snake-Poisons," by Dr. J. Fayrer; and Dr. F. A. Hartsen's papers on "Darwinism and Aristocracy, in connexion with some other Questions," and on "Darwinism and Politics," and Professor Steiner's (of Prague) "Clinical Experiences of Chorea."

Altogether, on looking over our volumes for the year, and weighing the results of our labours, we think we are fully justified in feeling assured that, thanks to all who have so ably and heartily helped us, the *Medical Times and Gazette* has continued to merit and repay the favour and consideration which the Profession have so long and so fully given it. And most gratefully acknowledging the confidence placed in us, we heartily wish all our brethren, at home and abroad, a happy, successful, and peaceful New Year.

THE WEEK.

TOPICS OF THE DAY.

MURMURS have been heard in various quarters against the Medical Declaration on the subject of alcohol, whereon we remarked last week. Whilst sympathising entirely with the wish of those who would reduce the consumption of alcoholic drinks in England, we confess that we are not in the least surprised that "the Medical manifesto" has aroused opposition. A loosely worded document, implying a charge little short of criminal—(If carelessness in dealing with the issues of physical and mental life and health be not criminal, what is?)—against the Medical Profession as a whole, and endorsed by many names of eminent Medical men—although some eminent names are distinguished by their absence from the list of signatories—was certain to arouse indignant questioning. One of the most eminent of the remonstrants is Mr. Skey, who wrote to the *Times*, on Tuesday last, a letter, of which the following is an extract:—

"With every inclination to admit the surpassing importance of the subject, I will venture to express my strong impression that had the 'Declaration' been carefully and critically read by all of these gentlemen the list of signatures would have been somewhat abridged.

"May I trespass on your columns by stating as briefly as I can write them my reasons for declining to sign my name to the 'Declaration,' which was sent to me by the President of the Royal College of Physicians for that purpose:—

"1. Who of us has a right to charge any members of our Profession with inconsiderately prescribing for their patients? I object to the 'Declaration' because it is dictatorial, assailing the deliberate judgment of a large body of eminent members of the Profession.

"2. Because the facts on which it is based are very questionable. I have not myself witnessed these 'many instances' referred to of 'intemperate habits engendered by the Medical administration of alcohol,' and I don't believe them.

"3. Because I believe the first two paragraphs will prove inoperative to any useful purpose, so far as alcoholic stimulants are prescribed on principle, and not wantonly ordered to gratify inclination. This alone could justify the term employed in the 'Declaration,' of 'inconsiderately prescribing.'

"May I add one word more? In the month of August last I addressed a letter to the President of the Royal College of Physicians, urging on his attention the desirableness of giving to the Government the sanction and support of our Profession, with a view to check the immoderate and most injurious consumption of alcoholic and intoxicating drinks by the working community of England. Unfortunately, a severe and protracted illness drove the subject from my thoughts, and Dr. Burrows is in possession of my letter only a fortnight ago.

"I shall feel obliged if you will do me the favour to publish this letter. "I am, Sir, your very obedient servant,

"24, Mount-street, Dec. 25.

"F. C. SKEY.

"P.S. It will be inferred that my objections lie only with the first two paragraphs of the 'Declaration.' With the third I am in entire unison, and I will gladly co-operate in any proposal to carry its object into effect."

In answer to Mr. Skey, Dr. Risdon Bennett has addressed the editor of the same paper in defence of the manifesto. He writes:—

"In his letter to the *Times* of this morning, Mr. Skey, in stating his reasons for not signing the 'Medical Declaration respecting Alcohol,' appears to think that those who have done so have unwarrantably charged 'members of our Profession with inconsiderately prescribing for their patients,' and have in a dictatorial spirit assailed 'the deliberate judgment of a large body of eminent members of our Profession.'

"Will you allow me, Sir, as one of the signatories of the declaration in question, and as one who happens to hold a responsible office, which demands the maintenance of the nicest sense of Professional honour and courtesy, to repudiate the imputation which Mr. Skey has cast on those who, like myself, have signed the declaration?

"It is a fact that a widespread belief exists among the more ardent supporters of the temperance movement, whether that belief be well founded or not, that an inconsiderate prescribing of alcohol by the Medical Profession is one of the causes of our crying national disgrace—intemperance. If this be so, it surely behoves the leading members of our Profession, while allowing that they cannot abandon the use of alcohol as a remedial agent; to inculcate habits of caution in prescribing it, whether for strictly remedial or dietetic purposes. This, I believe, is all that was intended to be implied in the two paragraphs to which Mr. Skey objects, and I do not think that any who have signed the document are fairly open to Mr. Skey's censure, while they will, I trust, strengthen the hands of the Government in any efforts they may make to diminish the fearful moral and physical evils of intemperance—evils the magnitude of which no class is more painfully cognizant of or more anxious to suppress than the Medical Profession.

"I have the honour to be, Sir, your obedient servant,

"JAMES RISDON BENNETT, M.D.,

"Senior Censor of the Royal College of Physicians.

"Royal College of Physicians, London, S.W., Dec. 26."

We have already expressed our opinion of the ill-advised character of the manifesto, an opinion which Dr. Risdon Bennett's letter certainly does not remove. Qualified Practitioners of Medicine assuredly do not require to be lectured in the public prints upon the modes of practice they are to pursue, even by "leading members of our Profession."

PRESCRIBING DRUGGISTS.—INQUESTS AND THE RATEPAYERS.

It would appear that a new element has been introduced with respect to the necessity of doing away with drug-sellers prescribing for sickness. According to the report of a late inquest in Bethnal-green, the Deputy-Coroner shrewdly illustrated the cost of ignorant and unqualified Practitioners, not only in regard to life and health, but also with reference to the pockets of the ratepayers. At an inquest held last week, before Mr. Richards, the Deputy-Coroner for Eastern Middlesex, it was shown that a boy aged three years was taken to a "Medical Hall," that he was treated for "hooping-cough," and medicine given him for the cure of that complaint. The day after, however, he was suddenly seized with a "fit of choking," and died in ten minutes. The Medical gentleman who was called in (Dr. Bryant) said that the deceased was a fine healthy boy, and if proper Medical attendance had been forthcoming, he had no doubt, would have been alive now. There was not, in fact, any sign whatever of hooping-cough. Deceased died from croup. The Coroner, in his observations upon the case, made some very sensible remarks. He said:—"The extent to which druggists infringe the provisions of the Medical Act is sometimes frightful, having regard to the fact that the lives of many persons are annually sacrificed through the ignorance of these unqualified Medical Practitioners. The consequence is that, at the last moment, a real

Doctor is called in, and he refuses to certify the result before a coroner's inquiry and the waste of the county money. The want of a public prosecutor is here most manifest; but until this crying evil becomes thoroughly exposed through the medium of the public press, we may look in vain for any proper measures being taken to check the frauds which are daily perpetrated upon the true Medical Profession by men who know as much of the human anatomy as my inkstand." The Coroner's words were fully endorsed by the jury, and a verdict in accordance with the Medical evidence was recorded. We commend the sensible observations of Mr. Richards to all coroners, not one of whom throughout the country has not, unfortunately, experience of cases similar to the one recorded.

ARMY HOSPITAL CORPS.

A COMMITTEE is now considering the new Royal Warrant for the re-organisation of the Army Hospital Corps. The chief feature in the Warrant will be the abolition of the permanent Hospital establishment of the regiments, and the transfer of the men to the corps. If this Warrant gets the signature of the Queen, every regiment in the service will have men attached to it from the Army Hospital Corps, and the regimental Hospitals to a certain degree will become staff Hospitals. Medically, the advantages will no doubt be considerable.

BREACHES OF THE MEDICAL ACT.

CASES of breaches of the letter and spirit of the Medical Act are as "plenty as blackberries." Every case that comes before a legal tribunal shows that the measure, as it at present stands, is most faulty and incomplete, and makes us almost echo the words of O'Connell, that one could "drive a coach-and-six" through it. The last illustration of the powers of the Act would appear to show that it had really some influence over offenders, but inasmuch as "a case" was granted, it has yet to be decided whether the decision of the magistrates at Shrewsbury will be maintained. We confess, looking at the preceding cases, we are not sanguine that it will. The facts referred to are as follows:—Mr. Thomas Andrews was charged last week before the magistrates of Shrewsbury with an infringement of the Medical Act, by falsely assuming the title of "M.D." It was proved that the defendant had for some years been a druggist in the town, and had recently sent out a bill for Professional attendance, had attached "M.D." to his name, and had "M.D." painted on a lamp in front of his door. For the defence, it was shown that the defendant had received a diploma from the "University of Pennsylvania," and Mr. Motteram, a barrister, who appeared for the defence, contended that, even if the College had no power to grant the diploma, if defendant believed that it had the charge must fall to the ground, and he cited cases in support of this view. Mr. George Lever was called into the witness-box, to swear to the authenticity of the diploma, which he did. On being asked to read it—it was in Latin—the witness declined to do so, and subsequently said that the knowledge of Greek and Latin was looked upon as a secondary consideration in the Medical University alluded to. He visited the University, and attended lectures; but he believed diplomas, after an examination by a duly authorised board in this country, were granted. He had no idea, however, what the nature of the examination was. The Bench fined the defendant £20, but granted, on the application of Mr. Motteram, a case for the superior court.

SMALL-POX JOTTINGS.

Two new cases of small-pox were reported in Islington last week, as against three in the previous week. There had been two deaths from this disease, as against one in the week before.—Small-pox continues prevalent in the neighbourhood of Holywell, and in a report made by the Medical Officer

to the local authorities, attention was called to a distressing case at Bagillt, where four of a family slept in the same bed; the father lying all covered with the disease, his wife, son and daughter sleeping with him. The father died, the children sickened, and the mother, who attended upon them, slept on the bare floor in the same room.—The report of the Homerton Asylum last week showed that in the fever side there had been in the fortnight forty-four admissions. In the small-pox Hospital the type of the disease had not improved. During the fortnight there had been seventy-two admissions.—At Stockwell, during the previous thirteen days, there had been seventy-nine fresh cases, and there were only seven vacant beds. The total number admitted to this Hospital had been 2084.—At Hampstead Hospital, during the previous twelve days, 160 fresh cases had been received, leaving 298 under treatment. During the previous twelve days, forty convalescents had been received from Stockwell, making an apparent increase in the Hampstead Hospital district returns. The detailed report showed that during the year 4984 vaccinated persons, and 1170 unvaccinated, in all 6154, had been treated in the Hospital.—Small-pox continues to spread alarmingly at Birmingham. All the beds set aside at the Queen's Hospital for small-pox patients are full, and within two or three hundred yards of the Hospital there are between forty and fifty persons suffering from the disease. In all parts of the town but at Spring-hill and in the immediate neighbourhood it is spreading rapidly.—At Norwich, the last week's returns showed a total of thirty-five cases, as against twenty-one in the previous week, of small-pox. The Marchioness of Lothian has presented an iron small-pox Hospital to the town.—Dr. Lankester reports from St. James's, Westminster, that there are still some cases of small-pox in the parish, and during the year there had been 232 cases of small-pox and thirty-three deaths.—Five deaths are reported last week from small-pox in Poplar, and thirteen new cases. In the week thirty persons were vaccinated at the public stations. There were fourteen small-pox patients under treatment in the North-street Infirmary, Poplar.—Dr. Dudfield reports two deaths from small-pox last week at Kensington, and there were also two fresh cases in the workhouse reported by the Vaccination Officer.—Mr. C. F. J. Lord, Medical Officer of Health for Hampstead, in his annual report, just printed, says:—"After excluding such new population as come into the parish through the Small-pox Hospital, St. Peter's Home, and the North London Consumption Hospital, 'hard hit by death,' the mortality has little exceeded fourteen per 1000. Cases of infanticide, or 'dropped children,' and accidents by drowning—though these are only a dozen—have been also excluded from the calculation. So low a death-rate is momentous when viewed by the side of the idle outcry of danger to the health of Hampstead through the Small-pox Hospital and through the unfounded alarm of the parish losing its high standing as the *mons salubris* of the metropolis."—Small-pox had diminished in Hackney to ten during the fortnight ending on Saturday last, against fourteen in the preceding fortnight, but there had been a far larger mortality in the Small-pox Hospitals, amongst the patients from other districts, than usual.—Dr. Aldis, St. George's, Hanover-square, reports one case of small-pox (vaccinated) in the in-wards, and the death of a woman, aged 38 (vaccinated), in the out-wards, for the week ending December 23.

SMALL-POX AND REVACCINATION IN DUBLIN.

DUBLIN is suffering from small-pox, which, in some cases, has already assumed the same severity of type that has characterised the present epidemic in its march through many parts of England, of continental Europe, as well as of Asia, etc. A period of actual exemption from small-pox, brief though it was, deceived some of our countrymen on this side of the water, leading them, unfortunately, to think they had become in their island home protected, under all circumstances, from

the loathsome and oftentimes fatal malady now in our midst. Certain Professional men in Dublin even still look on revaccination with but slight favour, wilfully shutting their eyes to what has been passing around them in the world at large; consequently, so far as the influence of these gentlemen has extended, the public have not adopted the valuable protection afforded by revaccination. One of the journals in this city has in at least one issue of its columns, as we have heard, taken up the cause of the anti-vaccinators so far as to endeavour to decry revaccination.

THE PROPOSED CONJOINT MEDICAL EXAMINATION BOARD IN IRELAND.

THE formation of an Irish Medical Examining Board has attracted a good deal of attention of late in Dublin. Several meetings of the deputed members of the several licensing bodies have recently taken place, and it may be said that the general tone of feeling was favourable, and promises that the movement is likely to become popular, and to end in the formation of one portal for entrance to the Profession in this country. Where many interests are involved, it necessarily happens that a considerable diversity of opinion on different points may exist. It appears to be generally understood that no exception will be taken to the participation in the examining body by all the present Licensing Corporations and Universities in Ireland. This is as it should be, and bids fair to insure a thoroughly fair and practical examination for the future candidates. It is, however, unfortunate that some difficulty threatened from an effort on the part of the Universities to exempt their men from undergoing the three earlier examinations, as they demanded that such candidates for practice should be only required to pass the final or fourth examination. For ourselves, we shall not, we trust, be considered as desiring to underrate the value of a University course of education, for we most highly approve of it. At the same time, we think that the other examining bodies should hesitate before allowing University students the sole right to be exempted from the first three examinations, as we consider that such a measure would in some degree, at least, frustrate the object of a Conjoint Board; which, if constituted, as now agreed upon here, of practical and able Examiners in Physic, Surgery, Midwifery, and Pharmacy, as well as in all the elementary branches of the science of Medicine, would insure a very competent and impartial tribunal, whose decisions would justly command the approval and respect of all persons competent to judge of such an important matter.

PROFESSOR HUXLEY AT THE LONDON INSTITUTION.—SEVENTH AND EIGHTH LECTURES.—CONCLUSION.

PROFESSOR HUXLEY commenced his seventh lecture by referring to the localisation of psychoses. By an active operation of the mind the amount and definiteness of localisation vary in the different senses, being *general* in smell, taste, and hearing, but *definite* in touch, pain, and warmth. He then gave a sketch of the secondary psychoses derived from the various sensations. Thus, from smell we can form the idea of *succession* and *similarity*, but not of *contemporaneity*; co-existent smells at least cannot be referred to distinct places. The ideas of *co-existence* and *locality* from taste, pain, and touch are very definite. From touch are also derived new ideas not to be obtained from the other two sensations above named—namely, *distance*, *form*, and *motion*. Two points of the skin touched at the same time will originate the idea of distance; if three or four points be touched we become aware of the idea of form; and if we were deprived of all the other senses, a succession of points touching the skin would enable us to form an idea of motion. The same idea might be originated by the sensations of heat and cold, and perhaps of pain.

All the sensations which he had been hitherto considering were referable to the surface of the body and no farther; but

the next class, or the *visual* sensations, are always referred *outwards* from the body. The sensation of light, according to physical philosophers, results from the influence produced on the sensitive expansion of the filaments of the optic nerve, by the vibrations of that extremely delicate and subtle atmospheric fluid known as "æther." Actual contact with a heated substance is not necessary for the production of the sensation of warmth; so, likewise, actual contact with a luminous body is not essential to the production of the sensation of light. But the falling of light upon the naked optic nerve itself will produce no sensation. An intermediary apparatus is necessary, and this is supplied by the retina, in the arrangement of the various layers into which, in consequence of recent progress in anatomical knowledge, it is now generally divided. These Professor Huxley demonstrated by a diagram representing a vertical section of the retina. He showed how the ordinary fibres of the optic nerve radiate among the various layers, and at the outermost margin of the retina come into relation with the "rods and cones" forming Jacob's membrane. He explained the analogy between these "rods and cones" and the "spindle-shaped filaments" which form the intermediary apparatus in the organ of smell, and stated that there is reason to believe that there is a connexion between each ultimate fibrilla of the optic nerve and one of these innumerable rod-like and cone-shaped processes. In the organ of smell a similar arrangement is observed, with this difference, that the spindle-shaped bodies come to the surface of the olfactory mucous membrane, while in the eye the ultimate rods and cones are protected from contact with the air. This, however, is merely a difference of detail rather than of principle. If the eye be traced through the series of living beings, it will be found to differ chiefly in the complexity of the superadded apparatus, and at last, in the worms, it will be found to be a simple transparent cell connected with a nerve-filament; and in the eyes of insects are observed numerous facets, under each of which "rods and cones" are directly connected with the optic nerve.

Professor Huxley next described the result on this minute and delicate nervous apparatus of the impingement of a single ray of light of less diameter than one of these rods—such a ray as might be supposed to come from the immense distance of one of the fixed stars. By its action on the nervous "rod" the nerve-change necessary for the production of sensation is originated and transmitted through the optic nerve to the brain, and the sensation of light in a specified direction outside the body is at once produced.

Many have been the attempts to explain this idea of "outness" peculiar to the sense of sight. None of them has ever appeared tenable or satisfactory to Professor Huxley, and, in the present state of our knowledge, it must be considered simply to be a primitive faculty of the sense of sight. It exists even in the dazzling coruscations well known to school-boys under the name of "fireworks," which are produced by a blow on the eye. Pressure with the finger on the inner and lower parts of the closed eye produces the appearance of a ring of light with a dark centre, in a direction outwards and upwards, and entirely outside the body. Professor Huxley explained this as the result probably of the pressure conveyed through the fluid contents of the eyeball to a point in the retina opposite to that at which the finger is applied. Where the pressure is strongest on the sensitive apparatus, it obliterates for the time the action of the nervous "rods"; but on the rods immediately surrounding this particular spot it exerts an irritating effect; causing in them a nerve-change similar to that produced by a ray of light, and the sensation of a luminous ring is produced, while the centre remains dark, in consequence of the inactive condition of the "rods" on which the pressure is strongest.

From the incidence of two rays on the retina we could form the ideas of *co-existence* and *distance*. Three or more rays would communicate to us a knowledge of superficial *form*, and from

a succession of rays we could appreciate *motion*. These ideas, he had shown, could also be originated by the tactile sense; but at the same time Berkeley's paradox is correct—that there is something totally different between the ideas of distance, form, motion, as communicated to our minds by tactile and by visual sensation. In Locke's "Essay on the Understanding" appears a problem, proposed to Locke by Mr. Molyneux, as follows:—Suppose a person born blind to have attained a knowledge of "form" by touch only, and then suppose the power of vision to have been in some way established, could that person recognise by sight the objects with which he had become familiar by touch? Locke replied in the negative, confirming Molyneux's opinion. Such, also, would be the reply of Professor Huxley. How, then, speaking of a round object, do we imply *feeling* round to the touch and *seeming* round to the sight at the same time? This is to be accounted for only by the intense and long-continued association of ideas from our earliest infancy. So, also, are the visual deceptions of paintings to be accounted for. Solidity has two meanings—first, simply *geometric*, for which at least two surfaces in different directions are essential, and of which sight is capable of communicating the idea; there is next *material* solidity, of which sight can give no notion. The unaided touch, also, cannot originate the idea of material solidity. Touch alone communicates merely an idea of surface; and, in order to get the idea of solidity, we must combine motion with the tactile sense; and then, from the muscular sense, through the association of ideas, we become aware of the varying degrees of material solidity presented by external objects.

In his eighth and concluding lecture, Professor Huxley continued the subject of the laws of vision. He explained how it is that, in accordance with the law by which the cause of a luminous sensation is referred outwards, in the direction of a line perpendicular to the retina at the point on which a ray of light falls, we see objects in their true positions instead of upside down, as is the image of the external object on the retina. It might also, he observed, be asked, as we have no knowledge of what occurs inside the eye—that is, no consciousness of the image on the retina being upside down—why should we see the external object in that position? He next noticed the influence of refraction through a prism in changing the apparent positions of objects. Sight only gives us the *direction* of an object, the exact *position* in that direction being communicated by collateral phenomena through the association of ideas, muscular sense, etc. The difficulty of defining the exact position with one eye closed is well known, and may be exemplified by the attempt to snuff a candle under such circumstances. It may be asked why with two eyes do we see only one object? This is in consequence of perfect coinciding or overlapping of the picture referred outwards from each eye with that from the other eye at the point where the axes of vision converge on the object. We believe that we see the object at the point of convergence of the optic axes, and this is the only explanation which Professor Huxley could give of the power of defining the exact position of an object with two eyes. Professor Huxley next described the action of the stereoscope, on the principle of the overlapping of the pictures formed in each eye. He illustrated this subject by many diagrams roughly drawn on the black-board; but it would be impossible, without similar drawings, to follow him through his remarks.

He noticed at considerable length the aërial or spectral images which may be caused by squinting strongly while gazing at any object. The image in each eye coincides with that in the other at the point at which the axes of the squinting eyes cross, a little in front of the real object; and by squinting very strongly, the impression may for some time be maintained, and the image will follow us as we retreat, and vanish—as all ghosts do—on our approaching it closely.

During the short period which remained, Professor Huxley

explained, as far as it was possible to do so, the internal structures of the ear. Sound is not referred outwards or localised, as sight and touch are. We cannot from it form any distinct idea of locality; but we can appreciate the character, intensity, and diversity of sounds in immense variety.

Professor Huxley, in concluding the course, remarked that at its commencement he had told them he never could adhere to a programme. They would now admit that this statement had been verified. He had to omit all notice of locomotion, voice, and speech. His object, however, would have been attained, if he should have succeeded in impressing upon his hearers that in such studies there are two distinct lines of inquiry, the mechanical and the mental. Mechanism cannot explain mental operations; there is however, a connexion between the two. There are two gross blunders against which he would warn them—First, that neuroses and psychoses are *not* connected; second, that it is possible to explain the development of psychoses as a necessary result of antecedent neuroses. The two sets of phenomena differ entirely in *quality*; nevertheless, in some way or other, psychoses *are* secondary on neuroses.

We feel that our notes give such an imperfect outline of Professor Huxley's lectures, that we trust the whole series may shortly be published in an extended form. We consider the fact of immense audiences attending during the winter weeks, to hear Professor Huxley's expositions on metaphysical and physiological subjects, a highly significant indication of the value attached by the public to information on such points, and of the appreciation in which the learned Professor is held by a very large class of educated people. As a sign of educational progress, and, at the same time, of the existence of an educational want, the popularity of such a course of lectures should exert a marked influence on the course and nature of the instruction of the rising generation.

FROM ABROAD.—HYDRARTHROSIS OF THE KNEE IN FRACTURE OF THE FEMUR—OIL BATHS AND SILICATE BANDAGES IN THE TREATMENT OF WOUNDS.

ON the occasion of a communication presented by M. Gayet to the Lyons Society of Medicine, "On Hydrarthrosis of the Knee in Fractures of the Femur," M. Ollier observed that he had long observed this circumstance, but did not consider it as peculiar to the knee-joint. Indeed, in the articles "Ankyloses" and "Arthrite," in the "Dictionnaire des Sciences Médicales," now publishing, he has shown that such swellings may affect various joints, the amount of effusion being proportionate to that of the irritation produced by the fracture. Ordinarily, it is serous in its nature, but it may become purulent, notwithstanding its distance from the seat of fracture, when this is the seat of violent inflammation. M. Ollier refers these effusions to the propagation of irritation through the osseous tissue, and has described them under the name of *arthrites par propagation*, or *secondaires*. What led him to take this view of their nature was that he had observed them to be produced experimentally in other traumatic lesions of the bones, which could only operate by transmitted irritation, as after breaking up and evacuating the medulla through perforations made in the bones. He is unable, therefore, to agree with M. Gayet's view, that these effusions are a consequence of obstacles to the return-circulation in the vessels of the medulla. The irritation transmitted through the vascular tissues of the bone gives rise to an increase of the normal secretion of the synovial membrane, and the same thing is observed in some forms of coxalgia. M. Ollier does not consider that the effusion in the knee is here connected with the synovitis of the hip-joint, but with the juxta-epiphysary osteitis of the upper part of the femur, which, in consequence of the relation of the diaphysis with the articulation, soon becomes confounded with the true coxalgia. The propagation of the irritation through the femur seems also, to him, to furnish

the most general explanation of the persistent pains in the knee observed in coxalgia. With M. Gayet, M. Ollier believes that, in some exceptional cases, hydrarthrosis of the knee may assist in completing the diagnosis of fracture of the femur. But this is only an example of what is met with, more or less, in all joints which form the limits of a fractured bone, being more easily recognisable in the knee in consequence of the extent and superficial position of its synovial membrane. M. Ollier has observed it distinctly also in the elbow and wrist after fracture of the ulna, and in the instep after fracture of the shaft of the tibia. If femero-tibial hydrarthrosis is less frequent after fractures of the tibia than after those of the femur, this is because the vessels of the synovial membrane and of the articular soft parts have more numerous anastomoses with those of the femur than with those of the tibia. M. Ollier regards the proposition of removing the effused fluid by means of an aspirator as useless, inasmuch as it is generally absorbed in the course of a few days. In removing it we should transfer a serous into a dry arthritis—that is, we should facilitate the production of ankylosis, or at all events, the stiffness of the joint, which will take place as long as the synovial membrane is distended with fluid.

M. Delore observed that he had often met with this hydrarthrosis of the knee in fracture of the femur, but he does not believe that it should be employed as a sign of such fracture, as it may be produced by a simultaneous contusion or sprain. He cannot admit the theory of transmitted osseous irritation, as it may supervene very rapidly after the fracture. M. Gayet explains the hydrarthrosis by an obstacle to the medullary circulation only; but it would seem more reasonable to admit an impediment in the circulation in the whole substance of the limb, induced by the extra-osseous effusion of blood which takes place in all fractures. M. Delore also refers to the phlyctenæ which are sometimes produced, containing either blood, or more or less coloured serosity, and which, he believes, are due to the same cause as the hydrarthrosis. He is certain that the hydrarthrosis is very seldom dependent upon arthritis, and that very rarely can the pain in the knee, observed in coxalgia, be attributed to arthritis. Very often we are able to squeeze the knee without giving rise to any pain, while this immediately appears if we apply pressure at the hip. Moreover, these pains are found not only in the knee but also in the leg, or even in the foot. In his opinion they are sympathetic. M. Ollier added, in explanation, that these effusions are to be distinguished according to the period when they occur. Those which are produced immediately, or rapidly, are due to distension or spraining of the knee, which accompanies most fractures; while those which come on more slowly are the products of propagated irritation. The former result from laceration of the capsule and synovial membrane, more or less blood being always added to the effusion; the latter, which are simply the result of propagated irritation, consist of a more or less transparent serosity, as in any other case of serous arthritis.

In an article in the last number of the *Gazette Hebdomadaire* M. Viennois gives an interesting account of the "Isolating Dressing of Wounds" as pursued by M. Ollier of Lyons. He observes that among the various modes of effecting this manner of dressing of late years, that of Lister has excited most attention; but his is so long and complicated that the omission of some detail may easily prevent its succeeding. For this reason M. Ollier has, during the last two years, treated wounds by means of *oil-baths*; and, where these could not be applied, by keeping the wound and the limb surrounded by dressings constantly soaked in oil—in fact, a continuous oily irrigation. For the continuous water-baths employed by Langenbeck, Valette, and others, M. Ollier believes that oil constitutes a preferable material, as, being lighter than the fluid products

of the wound, all putrefied or putrescent matters sink through it to the bottom of the vessel. They no longer sink remain in contact with the wound, and by traversing a carbolised layer of the oil become disinfected and innocuous during their passage. However abundant such products are, they are removed from the wound by means of the oil, which also forms an efficient protection against the access of the air to the wound. Moreover, the oil is not like water—absorbable by the wound—and thus isolates it without furnishing it with any septic elements. It is sufficiently transparent to render it unnecessary to remove the limb from the bath in order to watch the progress of the wound. The oil may be rendered antiseptic by adding about 50 per cent. of phenic acid. After trying various forms of apparatus, M. Ollier now uses zinc vessels approaching in shape to the limbs which are to be immersed in them during the period of treatment. For amputations of the arm or leg, he employs a yet simpler plan, taking a pig's bladder of sufficient capacity to embrace the stump, and, having filled it with oil, fixing it above the knee or above the shoulder, as the case may be. The stump is thus kept in a continuous bath of oil, which furnishes it with a soft cushion, and may require renewal every three or four days, according to whether the adjustment becomes disturbed or not. When the bath cannot be applied, a layer first of charpie and then of wadding is wound round the limb, and thoroughly saturated with oil, which is also kept frequently, or even continuously, applied.

Although, from this mode of dressing, M. Ollier has derived excellent results, he has, nevertheless, given a full trial to M. Alphonse Guérin's wadding dressing somewhat modified, which is cheaper, and requires less minute attention. The modification consists in adding a silicated bandage over the cotton, in order to prevent motion of the wounded region, this being a powerful antiphlogistic means. He also soaks the first layers of cotton that are applied with carbolised oil, especially when the condition of the tissues causes it to be feared that there may be partial mortification and abundant putrescent secretions. And as, by imbibition of the oil, the cotton loses some of its elasticity, he places over it thick layers of dry cotton, sometimes alternating these with carbolised cotton. The whole is enclosed in the silicated bandage, which is from time to time varnished over with silicate. M. A. Guérin makes no attempt at securing union by the first intention, but M. Ollier frequently effects this by the combination of the cotton and silicate. Of course, this is not attempted when the condition of the wound precludes it, as in secondary amputations, practised amidst more or less infiltrated tissues which are inevitably destined to suppurate. But when amputation has been performed in healthy tissues, and on young subjects, and especially when minor amputations or disarticulations are practised, or when the removal of tissues leaves a wound favourable to union, the attempt should be made. It would certainly not be prudent to count upon complete immediate union after amputations of the leg or the thigh in large Hospitals; but in those of the forearm, supra-malleolar of the leg, the fingers, etc., such union may be often obtained. In all cases a safety-valve is left by introducing into the wound a drain or small tent.

M. Viennois refers to numerous cases in which the practice has succeeded in M. Ollier's hands during several years, and in his own in the late war.

RECRUITAL OF THE FRENCH ARMY.—France cannot at most furnish more than 300,000 per annum who have attained their 20th year; and of this number 48 per cent. at the very least have to be deducted for exemptions for infirmities, defect of stature, and various other causes. The army can, therefore, receive only 156,000 new soldiers annually, and, if these are kept at service for three years for military instruction, the active army would amount to 468,000 men, whence are to be deducted the percentage for deaths and dismissals for various causes.—*Gazette Hebdomadaire*, Dec. 13.

REVIEWS.

The Physicians' and Surgeons' Visiting List, Diary, Almanac, and Book of Engagements for 1872; upon a plan furnished to the publishers by FRANCIS SEYMOUR HADEN, Esq. Twenty-sixth year. London: John Smith and Co., 52, Long-acre.

PUNCTUALITY, attention to the right thing at the right time, and all those methods of conducting affairs which are called "business habits," include the practice of making memoranda of daily transactions. But to make memoranda habitually, it is necessary to have some system which shall be simple, involve no expenditure of time, and be intelligible at a glance. These are the qualities which characterise "Smith's Visiting List," of which a long series is in our private desk, and an edition for the coming year lies before us. It enables the Practitioner to make a summary of his day's work with the smallest possible expense of time and trouble, and is suitable for every grade of the Profession, from the lordly specialist who lolls in his barouche to the humblest suburban general Practitioner who performs his useful and ill-paid drudgery on foot. The new edition contains a table of doses of various Medicines, selected from Squire's "Companion to the Pharmacopœia," and a page of Post-office information. In other respects it does not deviate from the convenient form, size, and contents of former years.

PROVINCIAL CORRESPONDENCE.

SCOTLAND.

EDINBURGH, December 26.

SMALL-POX has now assumed the proportions of an epidemic in our midst. The number of cases is rapidly on the increase, and the area of infection is gradually enlarging. It is difficult to estimate the number of cases in the town, but a pretty good idea may be formed from the numbers under treatment at Watson's Hospital and the Royal Infirmary. Into the former building, since it was opened a fortnight ago, about 140 cases have been admitted. In the Royal Infirmary there are upwards of thirty cases under treatment. In addition to these there are a number of cases in private practice.

The number of deaths from this cause was twenty last week, against twenty-one the week before. Considering the large number of cases, this is a comparatively small mortality. It is gratifying to learn that the type appears to be milder than in previous severe epidemics of the disease, and that it has not attacked anyone who has been revaccinated. In almost all the severe cases there has been evidence either of imperfect vaccination or of no vaccination at all.

The disease is spreading rapidly over the towns and villages of Scotland, and we hear of it successively in Dundee, Perth, and Aberdeen, not to speak of numerous smaller towns and villages.

The female Medical question is again to the front. Blasts and counter-blasts in the daily newspapers have for some days past indicated the coming struggle. An important decision by the University Court is looked for to-day, and a battle royal is expected on Monday at the meeting of the contributors to the Royal Infirmary.

On Thursday last, the University Court met for the purpose of hearing an appeal by Professors Masson, Bennett, and Calderwood against the following resolution of the Senatus Academicus:—

"The Senatus Academicus represent to the University Court the propriety of rescinding their regulations with reference to the admission of women to Medical education in the University, but without prejudice to the rights and interests of those ladies who have already entered upon a course of study, and without prejudice to the rights of Professors to give separate instruction to ladies in such classes as the University Court may from time to time think fit and approve."

The majority of the senators were represented by Professors Muirhead, Turner, and Lister. After hearing the question argued at considerable length on both sides, the Court adjourned consideration of the appeal till a future day.

It has been satisfactory to observe that, during the last six months, a good deal of attention has been directed to the legal phases of the question.

The Committee for Securing a Complete Medical Education to Women in Edinburgh have obtained a further opinion from the Lord Advocate and Sheriff Fraser in reply to the following question:—Whether, in the first constitution or charter of the

University, or in any of the subsequent statutes, there is anything which limits the benefits of the University to male students.

The learned Counsel give a summary of the charter of erection and confirmation of the "College of Edinburgh" by King James VI., dated April 14, 1582, by which "he delegated to, or conferred upon, the Magistrates and Town Council the character of patron and founder of this new seminary of education. The powers of superintendence and control thus conferred upon the Magistrates and Council remained with them till the Act of 1858 was passed, by which the more important powers were transferred to the University Court."

An Act of Parliament, passed in 1621, "which may be considered as the charter of erection of the University," confirmed the powers of the Magistrates and Council to superintend, control, and regulate all matters concerning the internal government of the University.

The Lord Advocate and Sheriff Fraser are "of opinion that, in virtue of the powers they thus possessed, the Magistrates and Town Council could at any time, during their 266 years of University rule, have done what the University Court did in 1869—grant permission to women to be educated at the University."

At the same time they admit that all the regulations which they did pass "proceed on the footing that only male students attended the University; many of them were inapplicable to females, and we cannot," they say, "find any trace of its being contemplated by the patrons that females might be students. And we do not find any evidence of a female having attended the University. Therefore," they continue, "while we are of opinion that the Magistrates and Council had the power to pass a regulation authorising the attendance of women at the University, and to compel the Professors to teach them, yet, as they never passed any such regulation, no women could have insisted upon admission to University education as a legal right prior to 1869. The University Court, by Sec. 12 (2), are now vested with all the powers of internal management and regulation formerly possessed by the Magistrates and Council; they have done what the latter never did, although they lawfully might. They have, by their resolution of November, 1869, given to women the right to demand, equally with male students, admission to the University."

It is thus sufficiently clear that the University Court was not in any way bound to admit the right of females to become students, and it is equally clear that they bear the whole responsibility of the present confused state of the question. If so august a body as the University Court has taken a leap in the dark, and has landed itself in the mire, the most dignified thing it can do surely is not to continue to stand up to the middle or go right over head and ears in the mud, but, guided by the light of law and of the great bulk of public opinion, to retrace their steps at once to better and safer ground.

December 27.

The University Court met yesterday to consider the appeal by Professor Masson, etc., against the resolution of the Senatus Academicus. No decision was arrived at, and the Court is to meet again on Tuesday next for the purpose of disposing of the question.

OBITUARY.

ROBERT ST. JOHN MAYNE.

It is with deep regret we announce the death of this highly esteemed and much respected young Surgeon, which took place on the morning of December 16, at his residence in Rutland-square, Dublin. A few days previously Mr. Mayne was attacked by small-pox, and his illness shortly assumed a very grave character, an uncontrollable hæmorrhagic tendency rapidly becoming developed. It was in the wards of the Meath Hospital, of which institution Mr. Mayne was elected a Surgeon less than two years ago, that he, in the discharge of his duty, became exposed to the contagion of the disease which caused his death. Though he was but 28 years of age, he had already secured the confidence of his colleagues; the respect of his pupils, both at Hospital and in the Carmichael School of Medicine, to which also he was attached as a Lecturer on Anatomy; and the esteem and affection of a widespread circle of friends. In a word, he bade fair, had he been spared, to enjoy a like popularity with his father, the late Dr. Robert Mayne, who fell a victim to typhus fever not many years since. It is not often that such a numerous party of Professional friends and pupils grant themselves the melancholy

satisfaction of accompanying to their last resting-place the earthly remains of one cut down in the spring-time of life, as that which assembled some days ago to do honour to the memory of Robert St. John Mayne. Mr. Mayne was L.K. & Q.C.P. Ire., and L.R.C.S. Ire.

JOHN CHARLES HUNTER,

Of Wilton-place, Belgrave-square, London, was born on August 20, 1799, and died at his residence on December 19 instant, where he had been for above forty years in practice. During the early part of that period he held, among other appointments, that of Inspector of Vaccinators to the National Vaccine Institution, and for some time was resident Medical attendant to the Earl Dudley. He died of a painful and lingering illness, due to emphysema of the lungs and heart disease. He became M.R.C.S. Eng. and L.S.A. in 1821, also L.R.C.P. Lond. in 1863. He was author of the sixty-third volume of the "Family Library." To Sir Thomas Watson, Sir D. Gibb, Drs. Pitman, Harcourt, and other Medical men, are due the best thanks of the family and friends of the deceased, for their great kindness and attention to him.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, December 21, 1871:—

Beardsley, Arthur Arnold, Grange, Lancashire.
Chilcot, James, Southsea.
Cowley, John Selwyn, Upton-on-Severn.
Griffiths, William Edwin, Kensington.
Lungley, Frank, Lewes, Sussex.
Parkes, William Edmund, Handsworth.
Richards, John Edward, Ruabon, North Wales.
Sayer, Charles Wathen, Sutton, Somerset.
Searle, George Clement, Tewkesbury.
Sergeant, Edward, Leeds.
Sharpe, George Metcalfe, Hunslet, Leeds.
Wallis, Edward Darby, Bodmin, Cornwall.
Wilkinson, Joseph Cradock, Spalding.
Willis, George, Soham, Cambridge.

As Assistants in Compounding and Dispensing Medicines—

Anthony, David, Cardiff.
Bannerman, Charles Alexander, Preston.
Hensby, Robert Place, Mildenhall.
Perks, Samuel Woodhouse, Hitchin.

The following gentlemen also on the same day passed their first Professional examination:—

Atkins, Francis Thomas, Guy's Hospital.
Barrow, Frederick, King's College.
Bromley, John Maddan, University College.
Bryan, Clement Frederick, Guy's Hospital.
Crouch, Ernest John, Charing-cross Hospital.
Keer, George Edwardes, Guy's Hospital.
Nash, William Gunner, Guy's Hospital.
O'Brien, James Octavius, Guy's Hospital.
Page, Herbert Markant, Birmingham Hospital.
Saer, David Protheroe, St. Mary's Hospital.
Tayler, Herbert Price, Guy's Hospital.

APPOINTMENTS.

* * * The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new appointments that take place.

BLOXAM, J. ASTLEY, F.R.C.S.E.—Surgeon to the Great Northern Hospital.
DAVIES, D. A., M.R.C.S., etc.—Resident Clinical Assistant to the Hospital for Consumption and Diseases of the Chest, Brompton, *vice* Dr. Swan, whose period of office has expired.
HARVEY, HENRY, M.B. Edin., L.R.C.S.E.—Senior House-Surgeon to the Southern Hospital, Liverpool, *vice* Dr. William Little, resigned.
HUMPHREYS, J. H., M.R.C.S. and L.S.A., late Assistant-Physician to the Middlesex Hospital—House-Surgeon to the Royal Surrey County Hospital.
INGLIS, ANDREW, M.D., F.R.C.S. Edin., Professor of Midwifery at the Aberdeen University—To the Aberdeen Dispensary, *vice* Mr. Robert Smith, Surgeon, deceased.
LEWIS, LEWIS, L.R.C.P. Lond., M.R.C.S.E.—Resident Medical Officer to St. Pancras and Northern Dispensary.
ROCHE, E. B., M.R.C.S.—Surgical Registrar to King's College Hospital.
RODGER, JAMES, M.B., C.M., M.A.—To the Aberdeen Dispensary, *vice* Dr. Angus Fraser, resigned in consequence of his appointment to the Infirmary.
WALKER, T. SHADFORD, Surgeon to the Liverpool Eye and Ear Infirmary—Lecturer on Ophthalmic Medicine and Surgery at the Liverpool Royal Infirmary School of Medicine.

MILITARY APPOINTMENTS.

38TH FOOT.—Staff Surgeon Charles Henry Browne to be Surgeon, *vice* Watkin Sandon Whylock, M.D., appointed to the Staff.

48TH FOOT.—Staff Surgeon-Major Francis Holton, M.B., to be Surgeon, *vice* William Robert Burkitt, appointed to the Staff. Staff Assistant-Surgeon James Maybury Beamish, M.D., to be Assistant-Surgeon, *vice* John Gordon Grant, appointed to the Staff.

80TH FOOT.—Staff Surgeon David Chambers McFall to be Surgeon, *vice* Ralph Robert Scott, appointed to the Staff.

MEDICAL DEPARTMENT.—Surgeon-Major Arthur Rudge, from the Royal Artillery, to be Staff Surgeon-Major, *vice* Staff Surgeon John Harrison Robothan, appointed to the 63rd Foot; Surgeon Watkin Sandon Whylock, M.D., from the 38th Foot, to be Staff Surgeon, *vice* Charles Henry Browne, appointed to the 38th Foot; Surgeon Ralph Robert Scott, from the 80th Foot, to be Staff Surgeon, *vice* David Chambers McFall, appointed to the 80th Foot; Surgeon William Robert Burkitt, from the 48th Foot, to be Staff Surgeon, *vice* Staff Surgeon-Major Francis Holton, M.B., appointed to the 48th Foot; Staff Assistant-Surgeon David Chambers McFall to be Staff Surgeon, *vice* Staff Surgeon-Major Robert Thomas Buckle, M.D., placed upon half-pay; Assistant-Surgeon John Gordon Grant, from the 48th Foot, to be Staff Assistant-Surgeon, *vice* James Maybury Beamish, M.D., appointed to the 48th Foot; Apothecary to the Forces John McIntosh has been permitted to retire upon half-pay.

BIRTHS.

BUZZARD.—On December 20, at 56, Grosvenor-street, the wife of Thomas Buzzard, M.D., of a son.

CLOVER.—On December 23, at 3, Cavendish-place, Cavendish-square, the wife of J. T. Clover, F.R.C.S., of a son.

DALTON.—On December 19, at Llandudno, the wife of Thomas Dalton, M.D., of twins.

JEPSON.—On December 26, at the residence of her father, W. S. Burton, Esq., Inner-circle, Regent's-park, the wife of Octavius Jepson, M.D., Stone, Dartford, of a daughter, prematurely.

MACNAB.—On December 23, at Bury St. Edmunds, the wife of Robert Macnab, M.D., F.R.C.S. Edin., of a daughter.

ROBERTS.—On December 22, at Avenue House, Peckham-rye, the wife of J. C. Roberts, M.D., of a son.

VERNON.—On December 26, at 44A, Wimpole-street, Cavendish-square, the wife of Bowater John Vernon, F.R.C.S., prematurely, of a son.

WATSON.—On December 24, at 7, Henrietta-street, Cavendish-square, the wife of W. Spencer Watson, F.R.C.S., of a daughter.

MARRIAGE.

BRABAZON—PIERPPOINT.—On December 19, at the parish church, Warrington, William Philip Brabazon, M.D., of Lymm, to Eleanor, elder daughter of Benjamin Pierpoint, Esq., of St. Austin's, Warrington, J.P.

DEATHS.

ARMSTRONG, ALFRED, M.D., of Lower Norwood, of diphtheria, on December 18.

CLAY, THOMAS FREDERICK, L.R.C.P., M.R.C.S., L.S.A., at his residence, Stratford, Essex, on Christmas-day, aged 62.

GRACE, HENRY MILLS, Surgeon, at his residence, Dorvend, Bristol, after a brief illness, of inflammation of the lungs, on December 23, aged 63.

HALE, MARY EUGENIA, the beloved child of Robert Douglas Hale, M.D., at 16, Queen Anne-street, Cavendish-square, on December 19, aged 18.

HECKFORD, NATHANIEL, M.R.C.S., M.D., founder of the East London Hospital for Children, Ratcliff-cross, after a lingering illness, at Ratcliff, on December 14.

HOFMANN, JAMES, eldest son of Professor Hofmann, of Berlin, at Berlin, of diphtheria, on December 17, aged 22.

HUNTER, JOHN CHARLES, L.R.C.P. Lond., M.R.C.S. Eng., and L.S.A., at his residence, 30, Wilton-place, Belgrave-square, S.W., after a long illness, on December 19, aged 72.

MADDOX, AMELIA, wife of R. L. Maddox, M.D., at Woolstone, Southampton, Hants, on December 26.

MILLER, PATRICK, M.D., at The Grove, Exeter, on December 24, in his 90th year.

OAK, CATHERINE MARY, relict of Thomas Oak, M.D. Lond., at her residence, Blackheath-park, on Christmas-day, aged 82.

RICHARDSON, EDWARD, M.D., late of New-road, Commercial-road, St. Hastings, of pneumonia, on December 16, in his 48th year.

TRAILL, MARY, the wife of William Traill, M.D., at 78, Grosvenor-road, Highbury, on December 24.

VERNON, EMMELINE AGNES, the dearly loved wife of Bowater John Vernon, F.R.C.S., at 44A, Wimpole-street, Cavendish-square, on December 26, aged 22.

WILLMOTT, THOMAS, M.R.C.S., late of Chester-street, Belgrave-square, at Penrith, Australia, on October 15, aged 55.

VACANCIES.

In the following list the nature of the office vacant, the qualifications required in the Candidate, the person to whom application should be made, and the day of election (as far as known) are stated in succession.

ABRIDGE UNION.—Medical Officer for the Eleventh District. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. A. Watson Miller, Clerk, on or before January 8, 1872. Election the following day.

CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House-Surgeon. Must be a registered Medical Practitioner. Applications and testimonials to the Secretary, Infirmary, Bangor, on or before January 2, 1872.

EAST SUSSEX, HASTINGS, AND ST. LEONARD'S INFIRMARY.—The appointments of Physician and Assistant-Physician are vacant. The qualifications required are as follows:—Doctor or Bachelor of Medicine of Great Britain or Ireland, or Fellows or Members of the Royal College of Physicians of London, Edinburgh, or Dublin. Applications and testimonials to the Secretary, on or before January 1, 1872.

HOLLOWAY AND NORTH ISLINGTON DISPENSARY.—Qualified Assistant to the Resident Medical Officers. Applications and testimonials to the Treasurer, at the Dispensary, Palmer-place, Holloway, N., on or before December 30.

JERSEY GENERAL DISPENSARY.—Medical Officer. Further particulars of the Rev. P. A. Le Feuvre, Oakwalk, Jersey. The election takes place early in January, and the duties will commence on February 1, 1872.

LANCASTER (COUNTY OF) LUNATIC ASYLUM.—Medical Officer. Must be duly qualified and registered. Applications and testimonials to Mr. F. C. Hulton, Clerk to the Committee, on or before January 8, 1872.

MIDDLESEX HOSPITAL.—Resident Obstetric Assistant. Must possess at least one legal qualification. Further particulars of the Secretary, to whom applications are to be sent, on or before December 30.

MIDDLESEX HOSPITAL.—Resident Physician's Assistant. Candidates must be legally qualified to practise. Applications and testimonials to the Secretary, on or before 11 o'clock a.m., on Saturday, December 30.

MIDDLESEX COUNTY ASYLUM, HANWELL.—Medical Superintendent of the Female Department. Candidates must possess both Medical and Surgical qualifications. Copies of testimonials to Mr. R. W. Partridge, Clerk to the Visitors, on or before January 6, 1872.

NEWARK HOSPITAL AND DISPENSARY.—Resident Medical Officer and Secretary. Medical and Surgical qualifications required. Applications and testimonials to the Secretary, on or before January 1, 1872. Election on January 9. Attendance of candidates required at twelve o'clock.

NORTH WALES COUNTIES LUNATIC ASYLUM, DENBIGH.—Assistant Medical Officer. Qualifications to practise must be produced. A knowledge of the Welsh language is necessary. Applications and testimonials to Mr. John Robinson, on or before January 10, 1872.

ROCHDALE INFIRMARY AND DISPENSARY.—Medical Officer, who must possess a qualification to practise, and be unmarried. Applications and testimonials to Mr. Lee, Secretary, Lord-street, Rochdale, on or before January 4, 1872.

ROYAL CORNWALL INFIRMARY.—House-Surgeon, Secretary, and Dispenser. Must be a Member of the College of Surgeons of London, Dublin, Edinburgh, or Glasgow; or a Licentiate of the Society of Apothecaries. Applications and testimonials to the Treasurer, Mr. R. Tweedy, Truro, on or before January 20, 1872.

STOCKWELL FEVER HOSPITAL.—Resident Medical Superintendent. Medical and Surgical qualifications required. Forms for applications may be obtained of the Clerk to the Board of the Metropolitan Asylum District, 37, Norfolk-street, Strand, on or before January 1, 1872.

SUDBURY UNION.—Medical Officer for the First District. Candidates must possess the qualifications prescribed by the General Orders of the Local Government Board. Applications and testimonials to Mr. Henry C. Canham, Clerk, on or before January 4, 1872. Election the same day.

SUNDERLAND INFIRMARY.—Junior House-Surgeon. Medical and Surgical qualifications required. Applications and testimonials to the Senior House-Surgeon, on or before January 20, 1872.

UNION AND PAROCHIAL MEDICAL SERVICE.

* * The area of each district is stated in acres. The population is computed according to the census of 1861.

RESIGNATIONS.

Sudbury Union.—The First District is vacant; area 12,651; population 3195; salary £55 per annum.

APPOINTMENTS.

Greenwich Union.—Charles Albany Wade, M.R.C.S.E., L.R.C.P. Edin. to the Greenwich Central District.

Honiton Union.—Frederick A. O'Meara, L.R.C.S. Edin., L.R.C.P. Edin., L.H.A. Dub., to the Eighth District.

Keighley Union.—James Crocker, M.R.C.S., L.S.A., to the Bingley District.

ROYAL MICROSCOPICAL SOCIETY.—The next meeting of the Society will be held on Wednesday, January 3, at eight o'clock precisely, when the following papers will be read:—"Fossils of the Coal Measures," by Dr. Carruthers, F.R.S.; and "Fermentation and its Results," by Mr. James Bell.

THE next competitive examination of candidates for Assistant-Surgeons in the Royal Navy will be held in February next.

It is stated that Mr. Stansfeld has in hand a Bill for Amending and Consolidating the various Public Health Acts, and that the measure will be introduced next Session.

THE Liverpool Health Committee at their last monthly meeting resolved to defer the appointment of a public analyst *sine die*.

THE Hackney District Board of Works last week decided to increase Dr. Tripe's (their Medical Officer) salary from £350 to £450 a year. Dr. Tripe's services fully justify the extra remuneration awarded to him.

WE regret to announce the death from a stroke of paralysis of Dr. Blythe, Professor of Chemistry in Queen's College, Cork.

THE University of Zurich numbers at present 310 students, of whom 168 are Medical.

SIEGE OF STRASBURG.—M. Poncet, one of the Medical Officers, supplies the following list of losses on the part of the military engaged:—There were 270 of the garrison killed, 177 died from their wounds in the ambulances, 268 from their wounds in the Hospitals, and 146 from internal disease—total, 861 deaths. Thus, there were but 715 deaths from wounds, which is but a small proportion, considering that the siege lasted forty-five days. Of course, many civilians were killed and wounded also by the shots directed upon the town itself.—*Gaz. des Hôp.*, Dec. 16.

SEVERAL bad cases of typhoid fever are reported from Denbigh. Wells, into which the surface drainage is permitted to percolate, are said by Medical Practitioners to be the origin of the outbreak.

ACADÉMIE DE MÉDECINE DE PARIS.—M. Barth has been elected President, and M. Depaul Vice-President, for the ensuing year. M. Jules Bécларd has been re-elected Annual Secretary, and M. Dubois (d'Amiens) retains his post of Perpetual Secretary. This latter gentleman has been absent, both from the Academy and from Paris, during the last two years in consequence of an attack of cerebral hæmorrhage, which has been followed by hemiplegia. His general health continues pretty good, and his intellectual powers are scarcely impaired, although he has considerable difficulty of speech.—*Union Méd.*, December 21.

DEATH OF DR. HELLER.—Dr. Johann Florian Heller died, after a short illness, on November 21. He was 58 years of age, and had for some years past suffered from disease of the heart. He was Director of the Pathologico-Chemical Institute, and teacher of Pathological Chemistry in the Vienna University, besides having extensive employment as a Government expert. The progress of pathological chemistry has been greatly forwarded by his efforts; he was, indeed, the first who placed this branch of Medical science in its proper position in Austria, and his work in this direction has obtained general recognition both at home and abroad. Clinical examination of the urine has obtained its present important position, both in Hospitals and in private practice, in great part through his exertions. Latterly he has been so much employed in official duties as to be unable to publish any work, but he has continued to inspire younger inquirers with some of his own energy. His well known periodical, "*Archiv f. Pathol.-Chemie und Mikroskopie*," was continued during ten years.—*Wiener Méd. Zeit.*, Nov. 26.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

Mr. C. H. W. Parkinson (Wimborne).—The cases are of grave importance, and shall be noticed fully next week.

W. C. S., Cheltenham.—The National Vaccine Establishment was formed by the Government in 1808. Sydenham, in his "Methodus Curandi Febres, etc.," published for the first time in 1666, wrote a chapter small-pox. It is said that Sydenham doubted the contagious nature small-pox. Huxham's "Treatise on Fever" appeared in 1750.

What next?—A Lincoln newspaper, of considerable circulation and reputation, contains the following startling announcement. We congratulate Dr. O'Neill on the "exclusive" honour conferred upon him.

"On the 12th inst., Dr. O'Neill, of Lincoln, had the honour conferred upon him of being elected a Fellow of the Royal Medical and Chirurgical Society of London. Dr. O'Neill is the only Physician in the county on whom this distinction has been conferred. The Royal Medical and Chirurgical Society obtained a charter from William IV., and is instituted for the cultivation and promotion of Medicine and Surgery, and the branches of science connected therewith; and its Fellows are the *élite* of the Medical Profession of the three kingdoms, and of the Continent."

Medicus writes:—"I enclose an advertisement for the Editor. It may be a matter of doubt which is most injured—the individual, or the Profession to which he belongs."

SPECIAL NOTICE.—Medical and Surgical Consultations gratis every Friday from two to three o'clock.—W. Jacobs has great pleasure in announcing that Dr. H. Bourguignon, Belfort House, Horsell, M.D. Paris, L.R.C.P. Lond., Laureate of the Institute of France, Knight of the Legion of Honour, Member of several Medical Societies, Author of several works on the Nervous System, Skin Diseases, &c., will attend at the Medical Hall, High-street, Woking Station, every Friday, from two to three o'clock, and give Medical and Surgical consultations gratis."

Burglar.—The Commissioner of Police of the metropolis has circulated a paper cautioning householders against the most common modes by which thieves effect their entrance into dwelling-houses. The plates of the ordinary window-fastenings should be made to overlap each other, and every sash should have a self-acting stop at each side. Entrance is often effected through the front door, by means of skeleton keys, and we may observe that a pound is never better spent than in a good genuine "Bramah" front-door lock—bearing in mind that most of the locks sold as "Bramahs" are sham, and that any key will open any one of them. Medical men are particularly liable to deceptions by persons professing to come as patients. A contrivance to hinder these gentry from getting out—or, at all events, from getting out without touching a spring, which rings a bell—would put a check on the rascals. There is another kind of robber whom Dupuytren used to circumvent by means of a bell. When a patient who ought to pay left his consulting-room without bestowing the customary honorarium, he touched a particular bell, whereupon the porter, before opening the front door, said—"I believe Monsieur has forgotten his fee," and thus forced the would-be *bilker* to be honest.

Paris.—A paper by Professor Gubler, of Paris, on the "Therapeutic Uses of Cod-liver Oil," will, we hope, appear in an early number.

Pills of Chloral, Chlorate of Potass, Sulphur, etc.—Will the sender of these favour us with his address?

* Miller's bunion-spring, mentioned in our issue of November 25, is to be had at 29, Leicester-square, W.C.

Llan.—"You pay your money, and you take your choice." We believe that the articles of higher quality may be obtained of that firm by anyone who selects them and pays the price, and that they will equal the average sold by other firms. On the other hand, the lower qualities must, as a matter of physical necessity, be subject to greater variation, and must be at the risk of the buyer.

Ty.—Podophyllin gripes more than some purgatives; but not more than senna and scammony, if administered in efficient dose, and alone. It is one of the earliest feats of Medicine to combine various purgatives, so that, like glasses of different qualities in one lens, each shall correct the aberrations of the others, and it is equally an old plan to "obtund their acrimony" with aromatics and anodynes. Doubtless, also, much depends on the solubility of a purgative, for it is conceivable that, without the most minute sub-division, any purgative shall gripe. No one has yet explained why aloes is so much more potent when given in substance than in solution. As for action on the liver, scammony, colocynth, and senna all bring down dark greenish-yellow motions. The smallness of the dose is the charm of podophyllin. As an anti-syphilitic, we know it not.

COMMUNICATIONS have been received from—

Dr. YOUNG; Mr. SPENCER SMITH; Mr. J. H. EDWARDES; Mr. F. WHITBURN; Mr. E. B. ROCHE; Dr. BRAKENRIDGE; Dr. PLAYFAIR; Mr. C. HUNTER; Mr. W. W. REEVES; Mr. C. H. W. PARKINSON; Dr. JAGO; Dr. MACNAB; Mr. W. THOMSON; Dr. LIONEL S. BEALE; Dr. CLIFFORD ALBUTT; Dr. J. R. HARDIE; Dr. BEVERLEY; Dr. ALDIS; Mr. RAINEY; Mr. T. S. WALKER; Mr. AUDLAND; Mr. L. LEWIS; Dr. WILMOT; Dr. PORTER SMITH

BOOKS RECEIVED—

Nouveau Dictionnaire de Médecine et de Chirurgie—Can Chloroform be Used to Facilitate Robbery? By Dr. S. Rogers (New York)—Sir Henry Holland's Recollections of Past Life—McCurry on the Duty of Medical Men in relation to the Temperance Movement—Bennett on Intra-thoracic Growths—Chemists' and Druggists' Diary, 1872.

PERIODICALS AND NEWSPAPERS RECEIVED—

Pharmaceutical Journal—The Salopian—Lincoln Journal—Melbourne Argus—Medical Temperance Journal, January.

APPOINTMENTS FOR THE WEEK.

December 30. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; King's, 2 p.m.; Charing-cross, 2 p.m.; Royal Free, 2 p.m.; Hospital for Women, 9½ a.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m. ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, LL.D., F.R.S., "Ice, Water, Vapour, and Air." (Lecture II.)

January 1, 1872. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; St. Peter's Hospital for Stone, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

2. Tuesday.

Operations at Guy's, 1½ p.m.; Westminster, 2 p.m.; National Orthopædic, Great Portland-street, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m. ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, LL.D., F.R.S., "Ice, Water, Vapour, and Air." (Lecture III.)

PATHOLOGICAL SOCIETY, 8 p.m. Annual Meeting, Election of Officers, etc. The following Specimens will be exhibited:—Mr. Sibley (for Mr. Blakewell), "Photograph, from a case of Leprosy." Dr. Dickinson (for Mr. Bradley, of Manchester), "Deformity of Pharynx." Mr. Hulke (for Mr. Hickman), "Pea in Lachrymal Canal." Dr. Galton, "Perforations of Bowel in Typhoid." Mr. Arthur Norton, "Malignant Growth of Femur." Dr. Kelly, "Ulcer of Bronchus opening into Pulmonary Artery." Dr. Clifford Allbutt, "Sections of Medulla in Hydrophobia; Syphilitic Disease of Encephalic Arterioles." Dr. Leared, "Renal Calculi of Cystic Oxide." Mr. Lawson, "Sequel of a case of Blood-cyst."

3. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1½ p.m.; Middlesex, 1 p.m.; London, 2 p.m.; St. Bartholomew's, 1½ p.m.; Great Northern, 2 p.m.; St. Thomas's, 2 p.m.; Samaritan, 2.30 p.m.; King's College Hospital (by Mr. Wood), 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.

4. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; Royal Orthopædic, 2 p.m.; West London, 2 p.m.; University College Hospital, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m. ROYAL INSTITUTION, 3 p.m. Prof. Tyndall, LL.D., F.R.S., "Ice, Water, Vapour, and Air." (Lecture IV.)

5. Friday.

Operations at Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

VITAL STATISTICS OF LONDON.

Week ending Saturday, December 23, 1871.

BIRTHS.

Births of Boys, 1106; Girls, 1058; Total, 2164.
Average of 10 corresponding weeks, 1861-70, 2023'5.

DEATHS.

	Males.	Females.	Total.
Deaths during the week	960	983	1943
Average of the ten years 1861-70	723'2	706'9	1430'1
Average corrected to increased population	1573
Deaths of people aged 90 and upwards

DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

	Popula- tion, 1871.	Small-pox.	Measles.	Scarlet Fever.	Diphtheria.	Whooping- cough.	Typhus.	Enteric (or Typhoid) Fever.	Simple continued Fever.	Diarrhoea.

in United Kingd'm	7204001	33'8	5041	4367	55'5	24'0	40'8	4'88	0'67	1'70	

At the Royal Observatory, Greenwich, the mean reading of the barometer in the week was 29'81 in. The highest was 30'22 in. at the beginning of the week, and the lowest 29'59 in. on Thursday evening.

* The figures in this column are the unrevised numbers enumerated in April last, raised to the middle of the year by adding 1-40th of the rate of increase which prevailed between 1861 and 1871. As the population of Dublin and its suburbs showed a decline between the Censuses of 1861 and 1871, the enumerated number in April last has been inserted for that city, the population being assumed to be now stationary.
