VOL. I, No. 1

APRIL 6, 1901

\$4.00 PER ANNUM

For the Cause of Independent and Professional Journalism.—Less than three months ago a circular letter was sent out to test professional opinion and desire as to the establishment of a weekly journal which should be owned and controlled by the medical profession, and conducted in its interests regardless of societies, institutions, factions, or commercial influences. The enthusiastic responses received demonstrate the general resolve that there is henceforth to be absolute professional control of our journals and literature. Medical editors must be responsible to the profession and not to the publisher or capitalist.

The *American-Medicine Publishing Company* was incorporated on February 1, and the stock was offered in small amounts to members of the profession. By March 1, the allotted 600 Founders' Shares, at \$50.00 each, had been subscribed for, and sufficient of the preferred and common stock had been sold to warrant the resolution to establish AMERICAN MEDICINE. An editorial staff, a large corps of collaborators, and a sound and well equipped business department were soon organized. Later, reputable business firms answered solicitations for advertisements in the same spirit of good will. Less than one-third of American physicians have been asked to aid us, and yet the support received and promised justifies the pride of the founders of AMERICAN MEDICINE in the great success of their undertaking, unprecedented in the history of medical journalism. Prospectus, list of founders, stockholders and subscribers will appear elsewhere in this issue.

A Word of Acknowledgment and of gratitude is due those who have so nobly encouraged us during the last three months in our aim to add one to the number of professionally owned journals. It has been impossible to reply fittingly to the thousands of helpful letters sent, and we trust that this recognition and thanks may not be the only way of showing our appreciation. Those many letters said in different ways that the cause of independent medical journalism was a sacred one, and they commanded no waste of words, but the doing of the deed, the realization of the desire. The heartiness with which the proposal was greeted by editorial colleagues shows the unanimity and unselfishness characteristic of professional literary workers. Publishers and business men, by their good will, have made clear their appreciation of the fact that good medicine is in the long run good business, because, as everywhere, so here, "Hon-

esty is the best policy." All this should aid in quickening the resolve in each of us to unite our great guild for the realization of the ideals which all have at heart, through the stimulation of a more perfect *esprit de corps*, and a more unflinching devotion to the common good.

The Endowment of an Independent Medical Journal is today the greatest need and the most imperative duty of the American medical profession. No one who has not had long and direct experience as an editor can imagine the professional evils that flow directly and indirectly from the publishing and financial control of editorial action. They cannot be brought before the public eye and sentiment aroused to rid ourselves of them until a journal shall be established the editor of which shall be free from a thousand existing forms of intimidation and subservience. This freedom can be secured only by endowment. Every physician who has an opportunity should never fail to call to the attention of philanthropists and capitalists the fact that far more than hospitals, libraries, or any other educational or curative institution, the primal and fundamental condition of medical reform and progress lies in the endowment of a great independent medical journal.

Smallpox and Death.—The last report issued by the U. S. Marine Hospital Service shows that from December 28, 1900, to February 8, 1901, there were 4,359 cases of smallpox in the United States, with 55 deaths; the figures for the corresponding period of the previous year were 2,026 and 67 respectively. This shows quite a difference in the death-rate—one of the lowest of any extended epidemic. Doubtless this is due to a general vaccination which has been in progress for some months. It is quite probable that if vaccination and revaccination were systematically done annually this disease would in time become extinct. This has been demonstrated in many localities where the only occurrence of smallpox was due to importation from without.

Quack Legislation has been undertaken by several quack legislatures, but that of the Wisconsin lawmakers as regards the gold-cure treatment of impecunious inebriates has proved to be a gold-disease. The counties were permitted to pay the bills for this "treatment," and at

once, of course, the number of the diseased and of the treaters began to increase at an alarming rate, one county alone furnishing 133 patients. The Supreme Court held that the law was not a legitimate exercise of police power and the tax not for proper objects of charity. Now, *Who will pay the piper?*—becomes a humorous question. A police judge in Toledo has just held that drunkenness is a disease. If so, of course, the community must cure it in the impecunious. But, we would add, the community is scientifically bound to discover the etiology of this "disease" as much or more than is any physician. The logical conclusion is clear: those who produce and spread the "disease" are the true criminals. Proceed, then, O sapient legislators and judges, to punish the disease makers, and thus to prevent the evil. Licensing the whiskey-seller and authorizing the "disease" he produces at the expense of the public, then taxing the public to cure the pathologic consequences, is a proceeding worthy of quacks—legislative, judicial, or medical.

The Early Diagnosis of Typhoid Fever by Means of Blood-Cultures.—Of late active efforts have been made by many investigators to discover some more accurate means of early diagnosis of typhoid fever than have been at our disposal in the past. The most important of these new methods are: the Widal reaction, and the examination of the blood from rose spots and the examination of the stools for typhoid bacilli. The typhoid bacilli have also been found in the urine in a sufficient number of cases to make the bacteriological examination an important aid. Until quite recently, however, typhoid bacilli have been found in the blood in only a few isolated cases of typhoid septicemia and the examination of the blood for bacilli in ordinary uncomplicated cases has not been considered a means of diagnosis of any special importance. In a most thorough paper concerning the clinical value of the various methods of bacteriological investigation in typhoid fever, Scholz and Krause (*Zeitschr. f. klin. Med.*, Bd. 41, H. 5 & 6) have dismissed the subject in a single short paragraph with the statement that the diagnosis of typhoid fever by blood-cultures is impractical and that the bacilli are found in the general circulation only in rare cases. Encouraged by the successful results of several observers who have obtained the typhoid bacillus from rose spots, Dr. Rufus I. Cole has recently undertaken the routine diagnosis of typhoid fever by blood-cultures. His results were reported at the Johns Hopkins Medical Society on February 4. Dr. Cole has thus far made cultures in 15 cases of typhoid fever at from the sixth to the twenty-seventh day of the disease and he has obtained a positive result in 11 cases. In all of these cases the Widal reaction was present, but in 5 the bacilli were found in the blood before a positive Widal reaction was obtained. In 2 cases the diagnosis of the trouble was quite obscure until blood-cultures had been made. Cultures from the urine were made in 10 of the cases with a positive result in 5. In employing this method of diagnosis Dr. Cole emphasizes the necessity for using large amounts of blood and of diluting freely in bouillon. From 8 to 10 cubic centimeters of blood were used, this amount being divided between 6 flasks, each flask containing 150 cc. of bouillon.

Care in technic is also very important. These investigations were undertaken without any previous knowledge that similar work was being done by German investigators. Schottmüller (*Deutsche med. Wochenschrift*, August 9, 1900) in a preliminary paper mentions having obtained the bacillus in 40 out of 50 cases in which he made blood-cultures. Auerbach and Unger have also undertaken a similar series of investigation. In the *Deutsche medicinische Wochenschrift* for December 6, 1900, they report positive results in 7 out of 10 cases. They also used fluid media and large dilutions.

These encouraging results from 4 independent observers make it seem quite probable that in this method we have a new and important addition to our means of early diagnosis. All of these methods of certain diagnosis require skill in bacteriologic technic and patient careful work, but in the future medical men must not be satisfied with probable diagnoses in obscure cases so long as exact means of positive diagnoses are at hand. The fact that positive results were obtained by Dr. Cole in 5 cases before a positive Widal reaction was obtained seems to indicate that this method may be more valuable than the Widal reaction, which thus far has been considered the most important means of early diagnosis.

Journalistic Seasickness might well be the designation of a peculiar hysteric affection that is almost entirely confined to medical men. The old adage, "Physician cure thyself," also does not seem in this instance to apply. There is a strange fondness among us for starting a medical journal without taking the trouble to own it, without the business ability to manage it, and after it is set agoing we exhibit a most astonishing apathy concerning its conduct or fate. Soon it takes a header, gets wretchedly crippled, dies, or—does far worse. Then arise croaks of I-told-you-so, followed by a sort of epidemic of acute and periodically recurrent nausea. It is not the vomiting of pregnancy, however. In some cases this symptom lasts during the rest of life, with complete literary anorexia and anemia. Pathologically it is interesting, and, if disease is ever so, amusing; but a wise physician is in no doubt either as to etiology or treatment. The germ of foolish selfishness has not been isolated, and careful prophylaxis is the only treatment. To a strong man failure teaches the lesson, not of renunciation, but how to succeed, and to a good man not of disgust and pessimism, but of greater devotion to the right. If the very alphabetic conditions of journalistic success have not been complied with the proper object of disgust is oneself, and not the profession. The profession is "all right."

Heredity and Human Progress.—No reasonable person can question the influence of heredity, whether in the production of social progress or degeneracy. At the present there are many complacent individuals who are inclined to take the optimistic view and believe that the world is progressing toward an earthly paradise. In a recent book entitled "Heredity and Human Progress," Dr. W. Duncan McKim takes exception to this view. From personal observation of the present condition of things he contends that the world is degenerating because

of bad and weakly people who are surviving under conditions of misplaced philanthropy and sentimentality. Crime is increasing and becoming worse and more dangerous in its varied forms. The hereditary legacy of the past is heaping up burdens of insanity, disease, vice, and crime which society will not long be able to bear. We are keeping alive by artificial means people whom merciful nature would have killed off in earlier times and our present methods are entirely inadequate to deal with these troublesome problems.

The writer of all this is a physician who from his professional life has a chance to know more of the diseased and shady side of life than most men and he is evidently a close and careful observer. It cannot be doubted that modern city life with its unhygienic, underfed slum population must inevitably produce some such horrors as Dr. McKim outlines but his remedy for this state of affairs is hardly likely to be thought of, much less adopted. He suggests killing off by the most painless means science can suggest the weakest and most vicious part of the degenerate population. The tendency to degeneracy must be stopped and can only be stopped, McKim believes, by inflicting death on those whose burden of sin, lust and insanity cannot be borne by the healthy moral section of mankind.

Dr. McKim is right in his estimate of the danger from the degenerate classes, but it is practically impossible in the first place to draw an exact line between them and the higher classes of society. His statement with regard to keeping alive the unfit is in part true, but it cannot be questioned that even at the present many of the best and finest both intellectually and physically are taken off by the infectious diseases such as diphtheria, typhoid fever, and tuberculosis. No one would think of going back to the conditions of the Middle Ages and allowing smallpox and the plague to run their course without attempt at checking them by the methods of modern preventive medicine in order that the unfit might be weeded out, for it is certain that equally many of the fit would be taken. A remedy better fitted for those classes who are unquestionably hopelessly depraved, criminal and idiotic is that which has been several times suggested of late, namely, the unsexing of these classes and thus preventing them from producing others of their kind.

Illegitimacy in Porto Rico.—According to the latest official report issued by the Superior Board of Health of Porto Rico, the illegitimate living births almost equal those of the legitimate living births, the former being 633 for the month, and the latter 845. The still births numbered 107, and the total deaths were 4,001, or a rate of 53.3 per thousand population. Of these 1,294 were under 5 years of age. There were only 29 deaths from typhoid, 16 from pneumonia, and 133 from tuberculosis. The marriages numbered 259. Previous monthly reports showed a greater death rate, and in some months the number of illegitimate births exceeded the legitimate, indicating a peculiar condition of affairs. The population of the island is given as 953,947.

The Conservative Treatment of Bubo.—In the past large incisions and thorough cureting or the entire

extirpation of the affected glands have been commonly advocated in the treatment of bubo resulting from chancre. In one of the lectures given under the direction of the Royal Bureau of Instruction, at Berlin, Krulle (*Berliner klin. Wochenschrift*, November 12, 1900), condemns such radical measures for the treatment of ordinary cases, and expresses his belief that in many cases such treatment gives rise to permanent edema or elephantiasis. He advises the application of hot compresses after it is evident that suppuration is inevitable, and as soon as the suppurative process is well established he advises opening the abscess by a small incision, squeezing out pus, washing with distilled water and the injection of a 1% solution of silver nitrate. If several glands have broken down, each should be opened independently. Every two or three days the dressing should be changed, the secretion squeezed out and silver nitrate solution injected until the secretion becomes serous. Such treatment does not usually make it necessary for the patient to give up his occupation; it avoids the necessity for extensive operation under anesthesia and leaves a scar which is hardly visible.

This suggestion as to a more conservative method of treatment will, we believe, meet the approval of experienced men who have carefully observed the results of excisions and other radical operations in the treatment of bubo. The healing is certainly not hastened by such radical treatment. On the contrary, the extensive incisions if closed nearly always break down, leaving a large granulating surface which requires a long time for complete healing. The less extensive operation gives a better result without the necessity for the patient's giving up work, taking ether, or a prolonged stay in the hospital.

The Sequels of Gonorrhoea and their Significance in Surgery.—During the past year a series of lectures on syphilis and gonorrhoea have been held in Berlin under the Direction of the Royal Bureau of Public Instruction. For the most part these papers are of unusual merit and are worthy of the careful reading of those interested in this subject. One of the best of these papers, by Professor Franz König, with the above title, appeared in the *Berliner klinische Wochenschrift*, November 19, 1900, p. 1078. He notes with astonishment the slow progress which has been made in the knowledge of gonorrhoea, although this disease was well known long before the time of Hippocrates. Not until the specific organism was discovered by Neisser in 1879, was it understood that this infection may become general and that the gonococcus may be found in every organ and in every body cavity and may even lead to death.

He divides the sequels of gonorrhoea into three classes; the local affections in the neighborhood of the urethra, such as periurethral abscesses, strictures, etc. The ascending processes affecting the oviducts and ovaries, or the prostate and testicles, the bladder, ureters and kidneys. The blood infections, which give rise to severe acute gonococcus pyemia or the less severe forms affecting the heart, the pleura and the joints. In the limits of his paper he found it impossible to discuss these numerous forms of infection, but to indicate their practical significance he considered only some of the severe infections of the kid-

ney and of the joints. He mentions two extremely severe cases of pyonephrosis, one of them requiring nephrectomy and nearly leading to the death of the patient.

The gonorrhoeal joint affections are even more frequent and important. He discusses the symptoms, diagnosis, and treatment at some length. To indicate the frequency and severity of these affections he mentions that during the past five years 18 cases of severe gonorrhoeal infection of the hip have come under his notice. One of these patients died from a double pyelitis which existed at the same time. Of the remaining 17 patients only 6 were discharged entirely cured. In all the others there was more or less limitation of motion and in 4 there was permanent shortening. These very severe cases of joint and kidney affections are not usually recognized, as they are easily mistaken for tuberculous processes.

The fact that so many severe cases of gonorrhoeal hip disease occurred in the practice of one trustworthy observer makes it evident how important is this form of infection. Probably no infectious disease is much more common or may be followed by more serious results. Yet the gravity of gonorrhoeal infection has long been overlooked and underrated by most practitioners. It is still common to hear such matters passed off in a light way by men of experience as not more serious than a hard cold. This must be to some extent the result of neglect to keep thoroughly posted as to the results of careful investigations since the discovery of the gonococcus. No doubt it will always be impossible to get rid of this disease entirely, but if it were generally known how serious may be the consequences, the number of infections would no doubt be much less. The education of the public in this respect is chiefly in the hands of the medical profession. Have we been doing our duty in this respect? The establishment, as in Berlin, of a series of lectures by prominent men in all of our large cities, would certainly not be without great influence in the right direction.

The Humors of Christian Science have been exemplified in the hearing of the recent Brush will case in New York. The strange thing about the minds of these people is that they are entirely unconscious of this humorous element. It is a striking psychologic anomaly that the laws of the objective world can be so completely ignored as to result in belief that broken clocks can be made to go, moulting birds to cease shedding their feathers, and drooping rubber plants to flourish, by the application to them of the principles of Christian Science. To save the situation, a witness testified that the plant was watered by one of little faith at the same time that it was being "held in thought" by the healer. Mrs. Eddy herself has been forced to have recourse to the dentist for an aching molar, and in the family of a famous "healer" there are two chronic sufferers from what we call disease. Mrs. Eddy has become at last so far mindful of worldly ways as to advise her followers to indulge the silly believers in pathology by obedience to the law as to the notification of infectious diseases. There is a gleam of possible sanity in this pitying permission to us deluded mortals, that yields some comfort and hope.

The Medical Society of the State of New York has increased its membership so that there shall be five delegates instead of one from each assembly district. The object of the change is to bring the County Societies into closer and more vital relations with the parent body. As heretofore, the members serve for three years, attending two meetings of the Society at Albany, when they become eligible as permanent members. The County Society dues remain unchanged, i. e., \$5.00 to the State Society from each assembly district. The most noteworthy feature of the changes instituted is the establishment of the semiannual meeting for scientific purposes only, to be held this year in New York City early in October. Under the able presidency of Dr. Elsner an excellent meeting is expected. Prior to this time there has been but the annual meeting at Albany, and owing to the great accumulation of business matters a large portion of the allotted time has been absorbed by them. The less "business" a scientific society has, the more time it has for science. The quicker it gets through with this business the more clearly it exhibits its own unity and professional temper. It is true that the advancement of scientific medicine and the upholding of the standard of medical education, by concerted action is most important, and requires not a little time and attention, but our chief work lies in medicine itself and not in medical sociology.

Primary Tuberculosis of the Vagina is of such rare occurrence that the report and conclusions by Jorfida of Padua (*Journal of Tuberculosis*, Vol. III), are of unusual interest and suggest many points for earnest consideration. Ordinarily, tuberculous lesions of the vagina and vulva are secondary to infections higher up in the genital tract, and do not occur primarily; however, the reports of cases by Demme, Da Paoli and others, indicate the possibility of such infections. Demme has described cases in infants, in which the lesions were seated at the ostium vagina; and the primary character of the lesion was proved by the fact that these cases underwent radical cure. Schenk has described a case of primary tuberculosis of the clitoris which extended incidentally into the urethra. The patient, a child of 4, was cured by resection of the urethra and some of the anterior vaginal wall. Tuberculosis of the genital organs naturally suggests the responsibility of the physician in regard to the marriage of tuberculous individuals. If marriage takes place the tuberculous wife runs the greater risk because of the prejudicial effects of pregnancy, parturition and lactation upon the course of the disease. If the husband is the unfortunate victim then the case, reported by Murrell, of tuberculosis acquired by a woman previously healthy and without tuberculous family history, from her husband who had died of that disease, is very suggestive. The susceptibility of the female seems greater than the male, if we may judge correctly from the statistics of Weber, who followed up the fate of 68 tuberculous individuals who had married healthy men or women. Of the 29 sound males who married consumptive females only a few became tuberculous; but of 39 healthy women who married consumptive men no less than 18 became infected and the disease appeared to run its course with unusual rapidity.

Marriage in Cases of Tuberculosis must, in view of such direful consequences, be most earnestly deprecated when either individual is infected, however beautiful and sentimental may be the argument that a married consumptive gets better care and nursing than one unmarried. Another powerful argument against marriage is the inherent right of every child to be well born, physically as well as morally, and not be doomed to come into life poisoned by tuberculous toxins imbibed from the tissues of the parents, and to be the host of myriads of tubercle bacilli transmitted through its umbilical vessels. On the other hand, the drain of pregnancy and parturition exhausts the vitality of the woman so seriously that her death is frequently hastened many months, and a pulmonary disease that might have been arrested, becomes incurable. In fact, so pernicious is the influence of tuberculosis upon the course of pregnancy and upon the fetus, that Martin has agitated the question of the feasibility and expediency of interrupting pregnancy in a tuberculous woman; and Maragliano and Bossi have occupied themselves with the same subject. The following conclusions are of interest: (1) Pregnancy and parturition, by reason of the lost blood and impoverished energy, have a pernicious effect upon tuberculosis; (2) tuberculosis has a disturbing action on the course of pregnancy and upon the fetus; (3) if the fetus survives, another tuberculous unit is added to society; (4) intervention should be by the most rapid and least laborious method. Krause's method of terminating pregnancy is advised when urgency is not required, while in the opposite case the Bossi method is employed.

The chief reasons why the tuberculous should not marry are these facts: that 30% of the cadavers of the tuberculous show urogenital lesions (Posner); that gonorrhoeal epididymitis has a special tendency to become tuberculous; that such an enormous percentage of the wives of tuberculous men develop that disease; and that the offspring of such parents so often present anomalies of weight, growth and nutrition, if not decided congenital disease. Hence, without usurping the innate right of individuals to decide such questions for themselves, it is plainly the duty of the physician to explain the dangers of matrimony under such conditions, and to urge single life upon those unfortunates contemplating marriage.

One Cause of Lower Mortality Rate in Chicago over that in some of the older cities may be that the population of Chicago is to a considerable extent composed of persons who have come there from different parts of our own country and from many foreign countries. The tendency to emigrate gives evidence of unusual enterprise which is usually accompanied by a good physique. Again, the emigrants are mostly in their prime, and they come to the city after the weaklings have been weeded out by the diseases of childhood. While these causes are undoubtedly of considerable importance, the Department of Health of the City of Chicago and all in any way connected with its management are to be heartily congratulated on the excellent showing in the face of many difficulties which are always present in the rapid building up of a metropolis.

The improvement has been great, but neither the medical profession nor the public can afford to rest contented. There can be no question but that the mortality rates are capable of still greater reduction. The means of bringing about this improvement are largely in the hands of the members of the medical profession and are indicated in Dr. Reynold's summary. The public needs further education in regard to sanitary matters and the medical profession needs to make more united efforts to bring about reforms in municipal legislation which will still further improve the efficiency of medical inspection of schools, the examination of the food, the bacterial diagnosis of disease and the improvement of water supply.

A New Use for an Old Remedy.—Dr. F. C. Gram, Registrar of the Buffalo Health Department, has observed that vaccination exerts an influence on grip not hitherto noticed by medical writers. The health-authorities of that city have just concluded a general vaccination, the work being done at a time when the city was in the throes of one of the fiercest epidemics of grip which it has had for years. Dr. Gram noticed that simultaneously with the manifestations of vaccination the grip disappeared. He then experimented on himself, as well as on others, in whom grip had been diagnosed, and in each case the disease was aborted, leaving the patient without any of those annoying and persistent sequels, which are sometimes worse than the disease itself.

The Scientific Use of Hospitals.—Clinical teaching as a regular part of medical education is of comparatively recent introduction in the majority of medical colleges both here and abroad. The use of the facilities offered in the wards of large hospitals for the instruction of students is now more generally appreciated, but only in comparatively few of the very best hospitals is this material utilized to the very best advantage. In a recent paper in the *Nineteenth Century and After*, January, 1901, Sir Michael Foster presents some valuable ideas in this connection. He calls attention to the misdirected talk which we hear against hospitals being used for purposes of experiment. He insists that every touch of the surgeon, every counsel of the physician is more or less of an experiment. For neither the physician or surgeon can be absolutely sure of the result of his act. While on the other hand, he is prepared to make use of the knowledge afforded by the result. Were such experiments conducted not for the welfare of the patient, but simply for the advancement of knowledge, there would be justification for the attitude just mentioned. The analysis of the phenomena presented at the bedside and in the post-mortem room is not so complete and especially not so systematic as it might be and ought to be. Some patients of course complain of being needlessly worried, but it is only a comparatively short time since complaints were made of even the use of the clinical thermometer. The days when a test-tube, a spirit-lamp and an imperfect microscope supplied all the equipment needed for clinical study have long since passed. Every hospital should be provided with clinical laboratories thoroughly equipped with all the needed appliances of science where the most careful investigation of every feature of cases in any way

imperfectly understood should be made. The duties of the head of every scientific laboratory and of his chief assistants, Foster believes, should be three-fold: To teach beginners what is known; to carry on personal research into the unknown and to train those who are no longer beginners the way of inquiring after the truth. The output of such laboratories properly conducted consists on the one hand in the healing of the sick and on the other in the increase of knowledge, the two being indissolubly joined together.

While Sir Michael Foster very favorably mentions the hospitals and clinical laboratories of the United States in his article, there is every reason why we should not rest satisfied with what we have. It is only in comparatively few of our very best institutions that adequate clinical laboratories are to be found. While the objection which he mentions that patients do not like to be experimented upon may be considered a reason for not establishing laboratories and carrying out research, as a matter of fact, entrance is more eagerly sought to the wards of such hospitals as do possess these most advanced scientific facilities than to any other hospitals. At present there are thousands of students both graduate and postgraduate who need instruction of the kind which such well equipped laboratories are prepared to furnish and every effort should be made by those who have influence to promote this good work in every way possible.

A National Department of Health.—Is it possible that at last we have the beginning of such an organization? Every physician and every patriot must fervently hope it is true. In the last hours of Congress one of the items of the Sundry Civil Appropriation Bill passed read as follows:

"For building for laboratory, marine hospital service: For the erection of the necessary buildings and quarters for a laboratory for the investigation of infectious and contagious diseases, and matters pertaining to the public health, under the direction of the surgeon general, \$35,000; and the Secretary of the Navy is authorized to transfer to the Secretary of the Treasury, for use as a site for said laboratory, 5 acres of the reservation now occupied by the Naval Museum of Hygiene."

This enactment, giving the Marine Hospital Service the functions of a National Health Department, really only makes permanent and enlarges the scope of the work long carried on by Surgeon General Wyman. It is strange how tardily civilization and science realize the primal duty of preventing disease and of caring for the public health. We congratulate Dr. Wyman and hope that he may secure many more and much larger appropriations in the future.

The Need of Independent Medical Journals, judging from a number of the opinions we have met, does not yet seem to be clearly defined in many minds. In our American multiplicity of journals we are in danger of losing faith and of despairing of the realization of any ideal. Thus comes a confusion as to the true function of journalism, and a drifting with the tide. In a vague way we know that great circulation does not make a great journal, nor does the large number of pages. Some like to grumble at the advertisement pages, but none of the grumblers would pay twice or thrice the usual sub-

scription prices in order to have his journal without them. It is a cheap and stupid virtue to get the advertiser to pay a large part of the expense of publishing medical journals and then abuse both him and the publisher for the subscriber's parsimony. Critics are plentiful who pounce down upon the poor editor if he makes a single error in accepting or publishing a bad thing, but many do not recognize the good things, and none thanks him for the unknown heroism of rejecting a hundred temptations. The editor who refuses a bribe of thousands of dollars does not tell of it, and is not thanked, of course, but the sin of the one who accepts, if perchance he is even suspected, is soon excused and forgotten. Many like to see unprofessional conduct rebuked, but are careful not to hold up the hands of the one who does the rebuking, and if misfortune befall him, they will pity him for "always getting into trouble," etc., and will virtuously pass by on the other side.

The Touchstone of Professional Spirit is furnished by some occasions in medical evolution, so that as men range themselves upon an ethical question they may be known ever after as upholders or not of the sacred torch of professional life, which, as has been said, flashes from lifted hand to hand along the generations. It is comparatively easy to recognize the arrant knave and quack, but a large number of men are neither good nor bad, not generous nor mean, until some occasion arises that forces them to disclose and to act in accord with the dormant nature. Then suddenly the world sees the hypocrite where he belongs and one knows at last who are friends and who are enemies. Such is the blessing concealed in professional revolutions and the crises of medical evolutions.

Subscribers to Medical Journals

Should be grateful for:—

1. Heavy paper, of good quality and color.
2. New type, chosen with regard to its effect upon the eyes and mind of the reader.
3. Good proofreading.
4. Good presswork.
5. Mailing in envelopes, unfolded.

Should vote against:—

1. Thin, sleazy, dirty paper.
2. Old and battered, inartistic type, ruinous to eyes and disposition.
3. Typographic blunders upon every page.
4. Bad printing, with poor ink.
5. One-fourth of a cent a copy saved by folding and crumpling in poor wrappers.

In brief,

For a liberal publisher who values his subscribers' rights and good-will more than a few thousand dollars, and for a printer who has an artist's pride in his work.

In brief,

A publisher who governs all details of his work by the sole motive of money-making, and a printer like-minded.

BOOK REVIEWS

A Manual of Personal Hygiene.—Edited by Walter L. Pyle, A.M., M.D. Illustrated. Cloth. Pp. 344. Price \$1.50 net. Philadelphia. W. B. Saunders & Company. 1900.

This is the first work in its field, in which the many advantages arising from the collaboration of specialists have been secured; the wisdom of the method employed is obvious when the character of the subject is considered. The object of this manual is "to set forth plainly the best means of developing and maintaining physical and mental vigor;" and it is difficult to see how the object could have been more nearly attained than has been done in this excellent work. Each chapter, prepared as it is, by a specialist, gives evidence of a familiarity with the subject and shows an easy method of treatment which it would have been impossible to expect from any single writer. We have read this book from beginning to end, with profit and delight, and have turned the last page with regret; but, with the conviction that here at last is the book so long sought by the physician and teacher; a book thoroughly sensible while strictly scientific, and so simple in its phraseology as to be easily understood; in short, a book to be recommended to young or old of either sex. The presentation of the special anatomy and physiology which precedes the discussion of the hygiene of the part involved, is accurate and adequate and much clearer than that usually found in popular works on physiology; while the subjoined exposition of "proper living upon a physiologic basis" affords authoritative advice of the highest value.

The chapters on the hygiene of the skin and its appendages, and on the hygiene of the brain and nervous system, are particularly interesting and satisfactory, though in the latter we wish that Dr. Courtenay had, in his list of out-of-door fads adapted to counteract the toxins generated by cerebral over-activity, included a stronger plea for nature studies, botany, zoology, mineralogy and geology; and that he should lend the influence of his pen to cheek, rather than to encourage, the use of the gun. Relaxation and health secured by the slaughter of bird and beast is gained at too great a cost, and the modern method of hunting with the camera in place of the gun is highly commendable. In the matter of illustration the book is not quite all that could be wished, and in future editions we hope to see more and better illustrations, together with additional chapters covering the hygiene of the reproductive system, and a special discussion of the best means for assuring that most important factor in well being—being well born.

Die Faeces des Menschen im normalen und krankhaften Zustande mit besonderer Berücksichtigung der klinischen Untersuchungsmethoden. (Human Faeces in Normal and Diseased Conditions with Especial Reference to Clinical Methods of Investigation.) By Professor Ad. Schmidt and Dr. J. Strasburger, Privatdozenten in the University of Bonn. Part I, pp. 96. Six lithographic plates. August Hirschwald, Berlin, 1901.

This, the first part of a work on coprology, designed to satisfy alike the demands of investigators and practitioners, deals with the macroscopic and microscopic appearances of human feces in health and in disease in a detailed and praiseworthy manner. The subject matter is very well arranged, the concise diagnostic remarks at the end of each chapter being especially commendable. The plates are excellent. If the good features of the first part be maintained, as they doubtless will be, in the second part, the work should certainly stimulate interest in a field of clinical research that unfortunately has been too much neglected.

The Medical Examination for Life Insurance and Its Associated Clinical Methods, with Chapter on the Insurance of Substandard Lives and Accident Insurance, by Charles Lyman Greene, M.D., Clinical Professor of Medicine and Physical Diagnosis in the University of Minnesota. Ninety-nine illustrations. Philadelphia, P. Blakiston's Son & Co. 1900.

In a handbook of 526 pages the author has written an admirable volume which we have no hesitation in saying is by far the best and most exhaustive work that has so far appeared on the

subject of medical examination for life insurance. In his preface he explains the fact that several medical colleges have introduced a special course of lectures on this topic at the request of many life insurance companies, which is undoubtedly a step in the right direction. Dr. Greene has had the advantage of having had his manuscript read by several of the most prominent medical directors and clinicians in this country who have made many valuable suggestions which have been incorporated in the book. The opening chapter is an interesting historical account of the early development of life insurance, which at first was of a purely speculative character, its statistics being based on those of the gaming table. Even in these days, the author tells us, the persistence of the solicitor was remarkable, and he aptly quotes the verse which might well apply to our own time:

"By fire and life insurance next
I'm intercepted, pestered, vexed
Almost beyond endurance.
And though the schemes appear unsound
Their advocates are seldom found
Deficient in assurance."

He gives a succinct account of the various problems that confront the medical examiner in his daily work, and offers many valuable suggestions, evidently the result of extended practical experience, as to the personal qualifications required for a successful examiner; his duty to the applicant; to the company he represents and to himself. The details of the examination blank are carefully considered, and every point in which the examiner may experience a doubt is so well explained that even the merest tyro, after studying this chapter, would have no difficulty in presenting an accurate medical report of any risk. In our opinion, Dr. Greene has pointed out what is undoubtedly a great source of annoyance and expense to all life-insurance companies and is a standing reproach to the medical profession in general. We allude to the carelessness of the average medical examiner in recording his observations on the application blank. Frequently it happens because questions are left unanswered or important facts are omitted, upon which the medical directors at the home office may base their opinions, that a delay occurs in issuing the policy to the applicant, who, in the interval, may have changed his mind or may have been approached successfully by the agent of a rival company. An analytic review of the conventional questions on the medical blank forms one of the most valuable chapters in the work. Nothing has been overlooked, especially in regard to the influence on the risk of weight and height, heredity, environment, family history, previous illness, occupation, and the use and abuse of alcoholic and other stimulants. As might have been expected from the author's recognized ability as a clinician, the chapter on the physical examination of the applicant shows much original work. We are heartily in accord with the author's plea for thoroughness, especially in the examination of the chest. He very properly insists that the applicant—if a male—should in every instance be stripped to the waist, and points out the absurdity of examinations for insurance which are made through starched clothing or heavy garments. Such examinations have no possible value as to the exact state of the applicant's heart and lungs. The author disarms criticism when he states that he had made no attempt to treat the subject exhaustively but to give in a concise form such information as will enable the examiner to act promptly and efficiently in all cases. We think, however, that the differential tests between serumalbumin and nuclealbumin might have been included in the text, especially as some of the leading companies now require their examiners to apply them in all cases. The chapter on the insurance of substandard lives (which has hitherto been confined to the English and Scottish offices) is of interest in view of the fact that some of the largest companies in the country now write this class of risks, when a few years since they would not consider them on any plan. Dr. Greene treats this part of his subject from the standpoint of the medical director, rather than from that of the medical examiner, and gives a number of statistical tables bearing on the factors which may influence the expectancy of these substandard lives. He also illustrates with the assistance of actuarial tables the methods by which the various companies seek to protect themselves

from loss in accepting this class of extra hazardous risks. In a footnote on page 315 the author sums up the subject by quoting Dr. Glover Lyons, of London, who has pointed out the fact that medical men deal in generalities only, and it must always require actuarial computation to fix the probable duration of life. Attempts to defraud life insurance companies are presented interestingly and details of many celebrated and historical cases are given. The volume closes with a special chapter on accident insurance, written by Dr. J. B. Lewis, of Hartford, Conn., a recognized authority on this subject, who presents useful hints for those who are liable to be called upon to testify in court on these "Manufactured Cases" of alleged railroad or street car injury. We have nothing but praise for the general arrangement of the volume. The marginal notes are admirable and serve to impress on the reader's mind the salient points of the text. A very complete table of contents and index are valuable features of the work which, as a specimen of book making, reflects much credit on the author and his publishers.

The American Year-Book of Medicine and Surgery for 1901. Edited by GEO. M. GOULD. A yearly Digest of Scientific Progress and Authoritative Opinion in all branches of Medicine and Surgery, drawn from journals, monographs, and text-books, of the leading American and foreign authors and investigators. Arranged with critical editorial comments, by eminent American specialists. In 2 volumes—Vol. I, including *General Medicine*, Octavo, 681 pages, illustrated; Vol. II, *General Surgery*, Octavo, 610 pages, illustrated. Philadelphia and London: W. B. Saunders & Co., 1901. Per volume: Cloth, \$3.00 net; Half Morocco, \$3.75 net.

The issue of the Year-Book for 1900 in 2 volumes received such general approval from the profession that the same plan has been continued. This arrangement has a two-fold advantage. To the physician who uses the entire book, it offers an increased amount of matter in the most convenient form for easy consultation, and without any increase in price; while specialists and others who want either the medical or the surgical section alone, secure the complete consideration of their branch at a nominal sum, without the necessity of purchasing considerable material for which they have no special use. The volumes for the current year have been as carefully revised, and present as complete a review of the world's medical literature as have those in the past, the whole series constituting a most valuable reference-library for the busy practitioner.

Parkes' Practical Hygiene. Sixth Edition (Hygiene and Public Health). By LOUIS PARKES, M.D., D.P.H., (London University); Lecturer on Public Health at St. George's Hospital Medical School, etc.; and HENRY KENWOOD, M.B., D.P.H., F.C.S., Assistant Professor of Public Health, University College, etc. London: H. K. Lewis. Philadelphia: P. Blakiston's Son & Co.

The administration of health affairs is usually in the hands of laymen, and the authors of the sixth edition of this work have succeeded in their endeavor to furnish a practical book. That portion of public health work which it is necessary to perform in chemical or bacteriologic laboratories has been omitted, one of the evidences of common sense present throughout the entire volume; another, is the absence of unnecessary technical terms. The work is divided into 12 chapters, and the subjects treated are of vital importance to the individual or community. Chapter II on the collection, removal and disposal of excretal and other refuse, and Chapter IX on communicable diseases and their prevention, each occupy over 100 pages and are unusually complete and satisfactory. The closing chapters, on statistics and sanitary law and administration, are the least important portions of the work from our American view-point, being based almost entirely upon the conditions existing in England and naturally having much local coloring.

Diseases of Children. Taylor and Wells. P. Blakiston's Son & Co., Philadelphia. Second edition. 1901. Pp. 850.

The second edition of "A Manual of Diseases of Children," by John Madison Taylor, A.M., M.D., and Wm. H. Wells, M.D., is offered in January, 1901, 2 years after the first edition. The book is now much larger than before both in size and subject matter, being about the customary dimensions of a text book on medical subjects. The very full table of contents

shows that it covers the ground ordinarily attempted by books of that class. The work is of joint authorship; the one a medical teacher who, judged by his title, shows that he is familiar with neurology, a valuable modern qualification. The other is an obstetrician, of wide experience as a teacher in his line which includes the important branch of the care of infants and their feeding. The partnership is an eminently suitable one and the product is creditable in all respects, bearing the stamp of research and a practical familiarity with modern clinical needs. The authors claim to have thoroughly rewritten their book and to have added much new matter. A comparison with the first edition shows that some of the chapters are now shorter and clearer, notably the one on diphtheria, which in the first was rather verbose. Others are amplified somewhat and a number of short articles are inserted where the need appeared, filling out the chapters symmetrically. The arrangement of the subjects is practical rather than strictly scientific, notably in the chapter on Diseases of the Skin, where the alphabetical order is observed. This precedent is followed by most text-books on medicine and will be found satisfactory until the advances in nomenclature and etiologic arrangements can be offered in an acceptable form. The phraseology is clear and pleasing; the orthography is good, and the subject matter fairly balanced in the amount of space allotted to each. The views expressed are modern and temperate; the teaching is sound and conservative. Altogether it will fill a prominent place as a students' text-book on this important subject. The presswork throughout is of the first order and the paper unusually handsome. An excellent and full index is added.

Saunders' Medical Hand Atlases: Atlas and Epitome of Gynecology. By Dr. O. Schaffer, of Heidelberg. From the Second Revised and Enlarged German Edition. Edited by Richard C. Norris, A.M., M.D., Gynecologist to the Methodist Episcopal and Philadelphia Hospitals. With 207 colored figures on 90 plates, 65 text illustrations, and 272 pages of text. Price, \$3.50 net. Philadelphia: W. B. Saunders & Co., 1900.

This is one of the best of Saunders' Medical Hand Atlases. As stated in the editor's preface, "The value of this Atlas to the medical student and to the general practitioner will be found not only in the concise explanatory text, but especially in the illustrations." The value of any work on gynecology depends to a large extent upon the illustrations. The illustrations in this Atlas are exact reproductions of the fresh specimen, which convey at once a clear idea of the true condition of affairs, impressing the subject matter more fully upon the reader. The large experience of Dr. Norris as a clinician and teacher, pre-eminently fits him for editing a work of this kind. To Dr. W. H. Thomas is due credit for the translation. In addition to the scope of the work there is a therapeutic table giving the indications, actions and dosage of the various drugs, of value in gynecic practice. Owing to the well-prepared index, reference can be quickly made to any part of the text. The clear and concise manner in which it is written, the method of grouping, and the systematic manner of describing the various diseases, all tend to commend this work to the student and the practitioner. In the articles on treatment, the latest and improved methods only are given, little stress being laid on the operative procedures, the object being to describe the nonoperative methods which are of value.

A Text-Book of Histology: including Microscopic Technique. By A. A. Bohm, M.D., and W. von Davidoff, M.D., of the Anatomical Institute of Munich. Translated by Herbert H. Cushing, M.D., of Philadelphia. Edited with extensive additions to both text and illustrations by G. Carl Huber, M.D., Junior Professor of Anatomy and Director of the Histological Laboratory, University of Michigan. Octavo, 501 pages with 351 illustrations. Cloth, \$3.50 net. Philadelphia and London: W. B. Saunders & Co., 1900.

In these days of extensive pathological research a substantial, yes even a profound, knowledge of histology is presupposed. To keep pace therefore with demands of pathology the histologist must push forward the limits of his field both fast and far. Painstaking, full and extensive as our American text-books on this subject may be and though translations of foreign authors be many, yet none of them fully measure up to the

book before us. It is recognized as the highest authority in Germany. To it have been added, by Dr. Huber, both his own contributions in this field and those of various other American investigators. The work is also planned according to the needs of American schools and students. The division on technic is clear and lucid, never prolix. Each method advocated is clearly set forth. The diagrammatic figures add materially to the teaching value of the book. A careful selection of methods is apparent. No attempt is made to include all methods ever used whether antiquated or not. There might be room for difference of opinion regarding the omission of some agents from this department. For example, creosote is not mentioned among the clearing fluids recommended. Wisdom is shown in confining the subject of injection methods to a mere summary. A very prominent feature of the book is the extensive treatment accorded the subject of general histology. This is certainly to be commended. One hundred and sixteen pages are devoted to this section. The circulating mediums are classed as a fifth division of primary tissues. The connective tissues also are classified in a different manner than usual. The subject of nervous tissues presents the greatest advance in this department. It includes all the recent work of the editor in conjunction with DeWitt. The remaining 290 pages are devoted to special histology. The subject of blood and lymph is most carefully treated. The treatment of lymphoid tissue is deserving of high commendation. In this connection also the work of Mall on the spleen is incorporated as being one of the most notable advances in the field of histology. The cuts, illustrating the finer supporting structure of many organs, the liver for example, are exceedingly satisfactory. They tell their story as no words ever can. Those illustrating the respiratory tract are a distinct advance over any found in our usual text-books. A radical departure is noticed in the classification of the several portions of the uriniferous tubule. The former complicated nomenclature is ignored and the tube is divided into only 5 segments. The greater simplicity will appeal to all beginners. Heidenham's theory of urinary secretion is given the preference over all others. The work of Flint upon the suprarenal gland is drawn upon very fully in the treatment of that subject. The histology of both the male and female genital tracts is thoroughly treated. The treatment of the central nervous system is well in advance of anything to be found in any other histology of today. Each section throughout the work is followed by its appropriate technic. The illustrations are unusually good and add immensely to the book's value. Dr. Cushing's excellent rendition of the German text has enabled the editor to fully utilize the author's work. A faithful English version of the German foundation with the addition of our American researches and an American presentation of facts have produced a book on histology which surpasses anything of its kind now in print. The publisher's name is sufficient guarantee of the materials and workmanship employed in its production.

The Technic of Surgical Gynecology. By Augustin H. Goelet, M.D., Professor of Gynecology in the New York School of Clinical Medicine, etc., etc. Published by the International Journal of Surgery Company, Medical Publishers, 100 William street, New York. Pp. 340.

The purpose of this little volume, as indicated by its author, is to describe with sufficient fulness and clearness of detail the more common gynecologic operations, and it is devoted exclusively to operative technic, preparation for operations and after-care of the patient. No attention is paid to the indications or diagnosis of conditions present. The frequency with which the specialist meets cases in which infection has occurred at the hands of unclean or unskilled operators, or in which unjustifiable manipulations or contraindicated procedures have been employed, amply warrants such a volume as this; and we can commend it to the busy practitioner and young gynecologist as a safe volume to follow. The chapter on preparation of the patient for gynecologic operation is especially valuable. If patients were more systematically and thoroughly studied prior to operation, fewer postoperative sequels and complications would undoubtedly occur. The text is amply illustrated by the introduction of 142 figures and diagrams, which add to the value of the book.

A Text-book of the Practice of Medicine. By James M. Anders, M.D., Ph.D., LL.D., Professor of the Practice of Medicine and of Clinical Medicine in the Medico-Chirurgical College, Philadelphia; Attending Physician to the Medico-Chirurgical and Samaritan Hospitals, Philadelphia, etc. Fourth revised edition. W. B. Saunders & Co., publishers. 1900.

This text-book has been deservedly popular with the profession, and has rapidly passed through 4 editions, a fifth, we understand, being in course of preparation. The treatment of the subject matter is concise and at the same time lucid and comprehensive, especial attention being paid to the etiology, pathology and differential diagnosis of diseases. The therapy is up to date and so arranged as to give the busy practitioner the needed data in the fewest words. The problem as to how much bacteriology should be included in a standard text-book of the practice of medicine seems to have been very happily solved by Professor Anders, his treatment of this much mooted subject being modern and thorough without being too copious. The book contains 56 diagnostic tables, a feature which will be greatly appreciated by the student as well as the practitioner. The illustrations are, on the whole, good—some of them excellent, especially those of the malarial parasites and of the diseases of the blood. Comparatively few formulas are given, but those present show careful selection. Taken as a whole, the work is excellent and certainly deserves a place on every physician's desk. For purposes of ready reference and comprehensive study it has no superior.

An American Text Book of Physiology, by Henry P. Bowditch, M.D.; Henry H. Donaldson, Ph.D.; W. H. Howell, Ph.D., M.D.; Frederick S. Lee, Ph.D.; Warren P. Lombard, M.D.; Graham Lusk, Ph.D., F.R.S.; W. T. Porter, M.D.; Edward T. Reichart, M.D.; Henry Sewall, Ph.D., M.D. Edited by William H. Howell, Ph.D., M.D., Professor of Physiology in the Johns Hopkins University, Baltimore, Md. Second edition, revised. Two vols., illustrated. Pp. 598 and 533. Philadelphia and London. W. B. Saunders & Co. 1901.

That a text-book on Physiology, emanating from the leading investigators and teachers of the chief medical schools of America, has proved a success is not surprising, and the appearance of a new edition gives evidence of the appreciation of a book which is the most authoritative and up to date work on the subject. The present edition appears in 2 volumes, an improvement over the bulky single volume of the first edition. The revision has been complete and the discussion of the central nervous system has been enriched by distinctly new matter. Numerous new figures and a considerably enlarged index add to the usefulness of the work.

The plan of placing the great divisions of the subject in the hands of recognized authorities in these departments of physiologic research has resulted in a uniformity of excellence as rare as it is satisfactory. Just enough attention is given to the historic development of physiologic theory and discovery to enable the student to grasp the tremendous progress that is being made by means of modern experimental methods. The myriad ascertained facts which have led to accepted theories are so arranged and presented as to lead naturally to true generalizations, and there is little danger of a student of this work being carried away by the various fads of the day. The discussion of the broader applications of the facts of reproduction, of heredity, and of sex is comprehensive and lucid; and gives the reader a clear idea of the latest views on the subject. The bibliographic references scattered through the work not only serve as guides to the more important recent monographs, but they add authority to the text and are helpful to the student in directing him to original sources.

X-Rays Without Electricity.—It was announced this week at a sitting of the Paris Academy of Science that M. Curie, a chemist, had separated a new gas from radium. This gas is intensely phosphorescent and will glow for months in the dark. It was also announced that M. Naudon, a scientist, had found means of producing x-rays without electricity by exposing a metal plate to the rays of the violet end of the spectrum.

AMERICAN NEWS AND NOTES

GENERAL.

Not a Case of Yellow Fever in Havana is said to exist at the present time.

The Lane Lectures for 1901 will be delivered by Mr. Malcolm Morris, of London, England, about the first of September.

Leprosy in the Philippines.—It is estimated that there are in the Philippine Islands 20,000 cases of leprosy. Attempts at isolation and segregation are made on each island, and steps have been taken towards the selection of one island for a leper colony to which the lepers on all the islands may be sent.

To Discuss Sea-sickness.—Rumor says that sea-sickness is to have a journal for its discussion. Any one knowing a cure or alleviation, or contribution of value is invited to contribute to this journal. A prize of \$20,000 is reported as offered for a specific. The idea of a special journal devoted to this subject originated, as might be surmised, with a Parisian.

Improvement in Cuba.—Very important results have been secured from the attention given to sanitary improvement in Cuba. A superficial view of the change since American occupancy will detect this. The death rate has fallen from 82.32 in 1898 to 19.32 in 1901. Congress demands that this work shall be continued when the island becomes independent.

Disease Spread by School Slates.—The spread of disease has been attributed to the use of the slate and pencil in schools. Boiling in a solution of sodium carbonate has been done to prevent this. The disinfection of books is more difficult, though of more importance. For this purpose the Washington Lyons apparatus is used. Lead pencils should not be used during an outbreak of contagious disease nor should any papers be carried home by the children.

Rinderpest is reported to exist in the Philippine Islands and the Secretary of War in pursuance of recommendations from Secretary Wilson has taken necessary action to prevent its introduction into the Hawaiian Islands and the United States by animals brought on government transports and has provided that special precautions shall be taken on the Pacific coast to prevent the landing of susceptible animals without their being turned over to the Department of Agriculture for quarantine, under the supervision of the Bureau of Animal Industry.

Obituary.—DENIS D. GAHERTY of Carillon, Quebec, March 24, aged 44.—EDWARD B. LIGHTHILL, of Newark, N. J., March 25.—AUGUSTUS HOELTGE of Cincinnati, March 26.—HENRY K. YEAKLEY at Fort Terry, Plum Island, March 27, aged 30.—HENRY WORTHINGTON of Los Angeles, Cal., March 12, aged 49.—WILLIAM F. CHANNING of Boston, March 19, aged 81.—JAMES W. H. LOVEJOY of Washington, D. C., March 18, aged 76.—WILLIAM FLEET LUCKETT of Washington, March 30, aged 63.—JAMES TAYLOR KREPPS of Pittsburg, March 31, aged 55.—CITIZEN SURGEON HALL of the Department of Northern Luzon, Philippines, of osteomyelitis.

The New Army Ration prepared under the direction of General Weston, chief commissary, has been approved. The principal change is in the increase of the sugar ration, being 20 pounds to each 100 rations, instead of 15 pounds, as heretofore. The vinegar component, which was 8-25 of a gill, is changed by allowing half of that amount in cucumber pickles when desired. In the fruit component 1 2-5 ounces of jam is allowed for the field ration in place of 1 3-5 ounces of dried or evaporated fruit, which is the allowance for the garrison ration. A change is made in the travel ration by allowing the canned tomatoes to be served on the first day instead of the fourth, as heretofore.

Smallpox exists in endemic form, 23 cases reported, at Thurber Junction, Texas, an eating station on the line of the Texas and Pacific Railway, and it is said to have caused great havoc among the Indians on the North Fork of the Yellow River about 15 miles from Medford. The bodies of 15 Indians were recently discovered in the snow near the camp. Cases are reported in Wisconsin from Waukesha, Manitowoc, Brillion, Kewanee, Green Bay and Merrill. The chief census commissioners throughout the Dominion of Canada have been instructed to order the vaccination of all the enumerators under them as it is believed that a mild form of the disease, "walking smallpox," prevails in different parts of that country.

Plague at Cape Town and Manila.—An increase in the number of plague cases in Manila is reported by the Marine-Hospital service for the week ended February 9. The Board

of Health has divided the city into districts, each district being inspected daily. There is also a further increase in the number of cases at Cape Town. It is claimed that the infection of Cape Town was carried by diseased rats and an active crusade is being waged against the rodents.

The bubonic plague is assuming a graver aspect. The number of European victims is increasing. Malays offer considerable opposition to the removal of plague patients, and also of the bodies of those who have died of the disease. The Government has informed these people that if this continues, the Malay community will be isolated outside the city.

NEW ENGLAND STATES.

Dr. A. P. Grinnell, of Burlington, Vt., has brought suit against Edward Weston for causing the arrest of himself and wife, damages being put at \$50,000.

Scared to Death.—Myran A. Olmstead, of South Norwalk, who was bitten by a dog on January 25, died on March 26. Fear of hydrophobia, intensified by the talk of his companions in the factory where he worked, is supposed to have been the cause of his death.

The Robinson School is the name for a new school, the establishment of which is proposed in a bill now before the Massachusetts Legislature and to which boys from 15 to 18 years of age may be sent when convicted of crime. The single aim of this school would be to make these boys into good citizens by treating them not as prisoners, but as pupils and combining a varied course of instruction with thorough manual training. The plan is approved by the Massachusetts Prison Association, by experts in penology, and by judges and chiefs of police.

NEW YORK.

Hypnotism.—The bill before the Assembly Public Health Committee to require the licensing of persons practising and advertising to teach hypnotism, mesmerism and suggestive therapeutics obtained a hearing, but was not acted upon.

The Cause of Cancer.—It is reported that Professor H. R. Gaylord, of the University of Buffalo, who has been conducting researches in the New York State Pathological Laboratory during the last 2 years, has discovered the cause of cancer, but no public statement has yet been made.

Cleanliness in School.—School teachers in Brooklyn complain that the school-rooms are not washed often enough. Sweeping and dusting as usually done is not sufficient as any marching exercise stirs up a great deal of dust endangering health and causing conjunctivitis.

Osteopathy, according to a bill before the Assembly, may be practised in New York by those who pass a satisfactory examination by the State Board of Regents in academic subjects, and who have received a license to practise from the said board. No osteopath, however, shall be allowed to prescribe medicines or drugs in treatment of diseases, or be allowed to use operative surgery, or treat contagious or infectious diseases.

Scarlet Fever in New York.—Scarlet fever has been quite prevalent in and about New York City. The strictness of sanitary requirements in the city secures a fuller report of cases, and consequent appearance of greater prevalence of the disease. The mortality is much below that of last year. English authorities agree that its recurrence may be expected every 6 years. Its impartial distribution among rich and poor, children and adults is noteworthy.

Doctors not Appreciated.—Mr. J. Luther Pierson of Wall-halla was in court a few days ago charged with having allowed his 2-years-old daughter to die without having the care of a physician. He was sentenced to jail but told the judge that his wife was very ill. When again arraigned, he told the court that he had become the father of a boy baby and that mother and child were doing well, no physician having been in attendance. The judge held him in the sum of \$1,000 to answer to the indictment. Pierson declared his determination to submit to any hardship rather than employ a doctor. His wife shares his views in the matter.

New Light on the Housing Problems.—The report of the New York Tenement House Commission is noteworthy for the thoroughness and practical character of its recommendations. The aim of the commission is to encourage commercial building of tenement houses conforming to the proper standards of sanitation and comfort. It lays special stress on housing reform through private enterprise. They refuse to recommend any legislative restrictions which would place too heavy a burden on the builder. It strongly recommends that a city tenement house department be created and charged with the sole duty of supervising dwellings.

Plan to Legalize Christian Scientists.—Assemblyman Bell, of Albany, has amended his Christian Scientist bill, and now has hopes of passing the measure. Under this bill Christian Scientists will be prohibited from practice in surgical and contagious or infectious disease cases. He thinks that this restriction will remove the opposition of the medical profession. Members of the New York County Medical Society and other physicians are much interested. Although there has been no meeting of physicians to discuss the matter, it is generally understood that they will maintain their original stand. The fight over the bill has developed the fact that the Christian Scientists have one of the most compact political organizations in the State.

Prosecution of Spitters in New York City is being undertaken more seriously than usual by some of the magistrates, and by President Sexton of the Board of Health. No less than 25 arrests have been made recently. Mr. Sexton has assigned 70 of the 100 policemen detailed for tenement house and other sanitary work to the special duty of riding about town on surface and elevated railways and arresting violators of the anti-spitting section of the sanitary code. The persons arrested are to be dealt with in the regular way in the police courts, and the officers will also report from time to time the general results of their work and observations to Dr. Roberts, the sanitary superintendent. The street railroad companies, wherever they have not already done so, are required to change the signs prohibiting expectoration in the cars so that they also name the penalty for violating the law, which is a fine of \$500. Half a year ago very few of the signs contained more than the bare statement that "spitting on the floor of this car is prohibited, by order of the Board of Health."

PHILADELPHIA.

Orator of Academy of Surgery.—DR. JOSEPH M. SPELL-188Y has been appointed orator of the Philadelphia Academy of Surgery for the year 1902.

Dr. Horatio C. Wood has been compelled by strain of overwork to give up temporarily his practice and lectures at the University of Pennsylvania.

Vaccination.—The Supreme Court of Pennsylvania has rendered a decision that school authorities may exclude from the schools those who refuse or neglect to be vaccinated.

Overheard in a Street Car.—"How is your mother?" "Oh, poor mother has been having a very serious time. She had gastrology; it went to her brain and broke out in a dreadful carbuncle on the nose. The poor dear was unconscious for nearly six weeks."

Pediatric Society.—Dr. L. Emmett Holt, of New York, will address the Pediatric Society at the meeting of April 9. Following the meeting a reception and dinner will be held at the Aldine Hotel.

Presentation of Dr. Keen's Portrait.—An oil painting of Professor W. W. Keen was formally presented to the Jefferson Medical College Thursday evening, April 4. The painting is a testimonial to Professor Keen from the students and alumni of the college and the hospital staff. Dr. J. Chalmers Da Costa delivered the address of presentation and Hon. William Potter accepted the gift on behalf of the trustees.

A Foreign Fellowship to the value of \$500 has been established by the Alumnae Association of the Woman's Medical College of Pennsylvania to be offered for the year 1901-1902 to all alumna of the college. Any candidate for this fellowship should apply to a member of this committee for the terms under which this fellowship will be granted; Dr. Bertha Lewis, chairman; Dr. R. Fleisher, secretary, Dr. Anna E. Broomall, Dr. Rachel Williams, Dr. Jane L. Hiersom, committee.

Pure Water Supply engages the attention of the New Jersey Women's Federation of Clubs, and it urges the State Legislature to enact such laws as are essential for the preservation of the forests. The value of the forest land of the State is estimated at \$41,299,199. Joseph Wharton, the largest owner in the pine belt in the southern part of the State, has preserved about 50,000 acres which contain ponds and lakes of sufficient capacity, he says, to supply the city of Philadelphia with pure water.

Pathological Society.—At the regular meeting held March 28, Dr. William G. Spiller read a paper on **Cerebellar Lesions without Cerebellar Symptoms**. Cases including tumors, cysts, sclerosis, etc., were reported. A conclusion drawn was that tumors and abscesses of the cerebellum are not proper causes from which to judge the functions of that organ, as pressure on other parts may cause symptoms not due to the cerebellar lesions. Dr. D. L. Edsall reported a case of **Malignant Endocarditis**. The diagnosis could not be made definitely until cutaneous and visceral lesions developed 5 or 6 days before death. A point emphasized was that in examining the blood for bacteria large quantities should be used. In the case

reported, a few drops of blood on agar gave no results, while 3 cc. in a tube of bouillon developed a culture of streptococci. Dr. M. B. Hartzell exhibited a pigmented epithelioma or **Alveolar Melanotic Sarcoma** and also a specimen showing marked degeneration of the epithelium in the skin bordering a chronic ulcer. Dr. W. B. Eaton read a paper on the **Histogenesis of Myomas**. A study of small spherical tumors has shown in several cases a genetic relation between the musculature of vessels and the tumor. The inclusion theory is believed to explain only a few cases.

Vital Statistics of Philadelphia for the week ended March 30, 1901:

	Cases.	Deaths.
Total mortality		532
Inflammation of appendix 3, bladder 3, brain 15, bronchi 17, kidneys 22, heart 3, liver 1, lungs 78, pericardium 1, peritoneum 7, pleura 1, stomach and bowels 21, Brain—diseases of 3, abscess 1, softening 3, congestion 4, tumor 1		172
Heart—diseases of 42, fatty degeneration 1, neuralgia 2		12
Asthma		45
Lungs—diseases of 5, edema 3, tuberculosis of 74		4
Inanition 17, debility 5, teething 4		82
Influenza		26

Academy of Surgery.—At the meeting of April 1, Dr. JOHN A. WYETH, of New York, read the paper of the evening on **Amputation at the Hip-joint for Sarcoma; its tendency to recurrence**. Dr. Wyeth characterized sarcoma as the most malignant of tumors. This is true of all three varieties—round, spindle, and giant cell. Statistics of 267 cases of hipjoint amputation were given. Of these 131 were for sarcoma with an operation mortality of 6%. Satisfactory histories of 83 cases that survived operation were obtained. Of these 51 cases recurred. The location of the tumor or its relation to bone or soft parts has little to do with the safety of the patient. Dr. Wyeth then detailed his personal experience, dealing especially with the question of pyogenic or streptococic infection of the patient. One of these cases in particular was a woman with a very large fungating recurrent growth. An attack of erysipelas was induced, and the patient is now entirely healthy after a period of 16 years. In another case of sarcoma of the jaw pyogenic infection was allowed after operation, and serum from the blebs of a case of erysipelas was also used. The latter produced no infection. A virulent culture of the streptococcus of Fehleisen was then used, this producing erysipelas. The patient has been entirely well since. Dr. Wyeth's conclusions are that the streptococcus infections have an inhibitory effect on sarcomas, and that they should be used to prevent or cure recurrences. Infection should be produced at intervals of not longer than 6 months and be continued for at least 6 years. Dr. W. W. KEEN reported 4 cases of **amputation of the upper and 2 of the lower extremity**. All of them died sooner or later from recurrence. He would operate on all cases as recurrence is very often internal and is not so offensive and painful as the original growth. No operation in continuity is allowable and no case should be operated upon if the hemoglobin is below 50%. Dr. W. B. COLEY, of New York, reported 6 cases of **amputation at the hipjoint**. In 1 no after-history was obtained, there was recurrence in 4, and the last, operated on in August, 1900, has no recurrence yet. All cases should be operated upon in spite of the discouraging statistics. The toxin treatment should be instituted after all operations for sarcoma.

The patient should be allowed to recover from the operation and then receive a systematic treatment of a month or 2 at a time with short intervals for 1 to 2 years. The toxin treatment does not cure all cases or a large proportion of cases, but it does cure some. At least 4 cases of round cell sarcoma have been cured by it. Dr. WYERER stated that safety to the patient lies in early recognition of the disease and in early and wide removal of the growth. As to the question of immediate or secondary infection, the immediate may be dangerous in anemic persons. In robust individuals, as most cases who have sarcoma are, he would insist on immediate infection after operation. The subject was further discussed by Drs. Bloodgood and Young, of Baltimore, and Drs. Flexner, Harte, Deaver, Massey, Rodman and Willard.

The **Duhring Dermatological Society** has recently been formed with the following membership: Drs. L. A. Duhring, Arthur Van Harlingen, H. W. Stelwagon, J. V. Shoemaker, M. B. Hartzell, J. F. Schamberg, E. S. Gans, C. N. Davis, E. W. Stout, I. M. Koch and J. F. Wallis. Meetings are held on the third Tuesday of each month at the various centrally located hospitals. No papers are read, but cases of rare interest are exhibited and discussed. Dr. H. W. Stelwagon is chairman of the society and Dr. Jay F. Schamberg, secretary. Following are the proceedings for March 15:

Dr. MILTON B. HARTZELL presented (1) a case for diagnosis. The patient, a woman, 40 years of age, for the past 4 years has had a measles-like eruption over the entire cutaneous surface, except the face and scalp. The eruption is ill-defined, slightly scaly, dusky-red in color, and "blotchy" rather than diffuse. In winter the itching is slight, but in summer quite severe. The patient's general health is excellent. (2) **Epidermolysis Bullosa**. H. F., a boy of 7, poorly developed, has suffered from a bullous affection almost continuously since he was 3 weeks old. The bullae occur upon the hands (palmar and dorsal surfaces), the extensor surfaces of the forearms, the elbows, the ears, over the sacrum, the knees, the anterior surface of the legs, the backs of the feet, and occasionally upon the tongue and the inner surface of the lips. The nails of the thumbs, index and middle fingers have been lost. The bullae are frequently hemorrhagic. The skin of the hands and legs, where the lesions have been most frequent, is decidedly atrophic. The mother states that "whenever he bumps himself blisters appear." No other member of the family has suffered from a similar affection. At present there are several hazel-nut-sized hemorrhagic blebs upon the hands, and crusts upon the elbows and knees.

Dr. H. W. STELWAGON presented: (1) **A Case for Diagnosis**. Patient is a farmer, aged 45, in good health. First noticed in 1891 a pea or dime-sized elevation on back in lower dorsal region toward right side. This gradually enlarged and a few new elevations appeared nearby and became merged in the original spot. There were no subjective symptoms. Three years ago (1898) the area began to extend more rapidly and became infiltrated and somewhat hard, and later it began to become more or less irregular on the surface, furrowed and lumpy. The parts have felt stiff and painful in the process of bending over. At the present time there is an area of irregularly rounded shape, about 6 to 8 inches in diameter, with rounded ridged elevations and depressions, the ridges and furrows tending to radiate towards the center. Here and there over the surface and near the peripheral portion are several small, rounded papulo-pustular looking elevations, surmounting an elevated ridge which are suggestive of former openings. There is no pus, however; there has never been any discharge nor open wound or lesion. The color of the whole area is a sluggish purplish red or violaceous, with a lighter colored center. The part feels brawny and infiltrated and thickened deep in the tissues, but there is no agglutination with the ribs beneath, the whole mass being movable. There is no evidence of ulceration outlying this area. Higher up are 2 elevations purplish red in color, suggesting roughly the beginning nodes of erythema nodosum. The general appearances are suggestive of an actinomycosis, but there are no openings and no discharge, although here and there is a suggestion of possible former liquid infiltration. A section of tissue examined showed merely inflammatory changes. There is no syphilitic history. Actinomycosis, syphilis, blastomycetic dermatitis and morphea were all considered. (2) **A Case of Dermatitis**. Patient is a woman aged 34, with a pendulous skin of right elbow region. It began to form 13 years previously, and the tissues had gradually become loose in folds, finally becoming pendulous. The region involved, extending several inches above and below the joint, was covered with a thickened, dark-colored skin, upon which were apparent 50 to 100 scattered slightly projecting sebaceous gland outlets, filled with small comedo-like plugs which could be easily squeezed out. The disease spread by an advanced pigmented skin. (3) **Ulcerating Scrofuloderm**. Colored girl aged 17, with large number of old cicatrices, and several scrofulo-gummatous and suppurating glands about the lower jaw and neck, extending from the ear and involving the whole submaxillary and neck region from one side to the other. The condition began when the patient was 4 years old. Family history tuberculous. (4) **Case of Actinomycosis**. A farmer, aged 35, exhibited at a previous meeting, with actinomycosis of the chin region and lip, of 3 years' duration. Patient is gradually recovering under large doses of iodids. There are still open sinuses;

as yet it has not been possible to demonstrate the fungus. Dr. JAY F. SCHAMBERG presented (1) **A Case for diagnosis**.—A woman, aged 35, has for 6 months been suffering from lentil to pea-sized nodules upon the hands, and at times upon the feet and ears. The lesions begin as firm, deep-seated, painful, pinkish-red tubercles, which in the course of one to several weeks break down and form necrotic pustules. The patient has never suffered from frost-bite. Her general health is good, and there is no family history of tuberculosis. The members were inclined to regard the case as belonging to the group of poorly understood eruptions occurring in the "chilblain regions," and possibly scrofulous in character. (2) **Delayed Hereditary syphilis** (*syphilis hereditaire tardive* of Fournier). The patient, a girl of 15, presented upon both legs just above the ankle, a number (2 upon one leg and 3 upon the other) of half-dollar sized ulcerations. The ulcers discharged a profuse mucopurulent exudate. But slight infiltration and little or no pain present. The mother states that the patient has never previously had any eruption upon the skin, nor any manifestation elsewhere which might be construed to be syphilitic in character. The mother, however, has had 4 miscarriages. Under the use of 5 grains of potassium iodid and 1-24 grain of biniodid of mercury the ulcerations had become much less deep and one had almost entirely healed. The diagnosis lay between an ulcerating scrofuloderm and hereditary syphilis. The latter disease was tentatively diagnosed, and from the success of the treatment instituted it would appear that the affection was a delayed hereditary syphiloderm.

SOUTHERN STATES.

Dr. J. B. McCAN, a well known physician of Richmond, Va., who has attained eminent success during the active years of his professional life, has retired.

Increased Use of Absinthe.—Physicians in New Orleans find the use of absinthe increasing and means are being considered to reduce the consumption if possible.

A Smallpox Epidemic in West Virginia has become so alarming at Weston that the presiding judge of the Circuit Court has decided to postpone the sessions until the next term.

Washington Water Supply.—Preparations for providing a filtration plant are proceeding as rapidly as the circumstances will permit though no definite plan can be approved until a site has been obtained by the government, and this has not yet been done.

Quarantine Proclamation.—Governor Sayers, of Texas, has issued his annual gulf coast and border quarantine proclamation against all vessels and persons coming from districts infected with yellow fever, bubonic plague, cholera or other contagious diseases. This quarantine went into effect April 1, and continues indefinitely.

Sanitary Improvement.—One of the last acts of the Maryland Legislature at its extra session was to devote \$12,000,000 for sewerage in Baltimore. The bill was not favored by the politicians because of the influence which the expenditure of so much money would give to the Mayor, but the public necessity was strong enough to demand the measure.

A Mistaken Case of a "Bullet in the Brain".—A man recently died in Washington, D. C., who was supposed to have carried a bullet in his brain since 1857. Autopsy showed instead that the bullet must have fallen out of the single opening in the skull at the time of the accident. A piece of the fractured cranial bone 1 by ½ inch was, however, found imbedded and encysted in the cortex, and this showed traces of the lead bullet.

Physicians' Orphans' Home.—With the view of founding such an institution an organization has been effected, and building sites for its location have been considered in Asheville, N. C.; Louisville, Ky.; Colorado Springs, Colorado; Canton, Ohio, and Lookout Mountain, Tenn., but Bristol, Tenn., and Virginia, has been settled upon as the one most suitable, and an option secured on property there. To put the orphanage in operation, \$35,000 remains to be raised.

Consumptive Convicts in Texas.—Texas has an isolated farm for those convicts suffering from tuberculosis, where they receive treatment practically similar to that followed in sanatoriums and have a highly nutritious diet including stimulants. Cleanliness and the observance of sanitary measures are imperative. When able to leave their beds they are obliged to be in the open air, and they sleep in a spacious stockade. The employment is entirely in market-gardening and no one is required to work beyond his strength. This farm has returned to the State in 2 years a net profit of about \$2,500 and it is said many men who went there scarcely able to feed themselves and apparently in the last stages of tuberculosis are now quite well.

The Alabama Legislature has recently ordered a similar segregation of consumptive convicts.

The Johns Hopkins Hospital Medical Society.—At the meeting of March 18th Dr. MACCALLUM reported a curious

form of peritoneal tuberculosis. He referred to a form of tuberculosis occurring in cattle in which large nodules are formed both in the peritoneum and the pleura. These nodules are conglomerated tubercles covered by a fibrous capsule and embedded in a new formed tissue of proliferated connective tissue cells. They increase to such an extent at times that they become pedunculated from their very weight and hang suspended from the peritoneum in the peritoneal cavity. Dr. MacCallum exhibited a number of pathologic specimens from various animals and stated that such a condition is extremely rare in human beings, in fact, he had only found 1 case recorded, by an Italian in 1867. An elderly woman died at the Hopkins Hospital some time ago with symptoms of pulmonary tuberculosis. At the autopsy in addition to the pulmonary lesions tuberculous nodules were found in the spleen and liver and there was a tuberculous meningitis. The peritoneal surface itself was quite smooth but there were numerous nodules hanging from it into the peritoneal cavity. Many of the nodules had very long pedicles, and in some instances when the nodules were picked up it was possible to cause the fluid contents to flow back down the pedicle into the peritoneal tissue and even into another pedunculated nodule. Some of them had been cut off from their blood-supply until they had a strangulated appearance, and in 1 instance the pedicle had become detached and the nodule floated free in the cavity. Microscopically the nodules were found to have the character of caseous tubercles. Toward the center of the nodules the cells were necrotic and in this zone numerous tubercle bacilli could be found. In discussion Dr. WELCH referred to the long controversy that has existed concerning the resemblance of this condition so common in animals to human tuberculosis. Virchow believed that they were distinct diseases, but the prevailing opinion has been that some relationship exists and this has been strengthened by experiments which have shown them to be mutually interinoculative. Dr. Welch also referred to Theobald Smith's work on the differences between the bacilli of animal and human tuberculosis. In regard to the formation of the pedunculated nodules, he accepted Dr. MacCallum's explanation as true in part, but would suggest the possibility of another explanation for some of them. There is a circumscribed peritonitis in which a vascularized membrane forms on the peritoneum quite analogous to the membrane in hemorrhagic pachymeningitis. The tuberculous nodules could form in such an adventitious membrane and it would offer a better explanation for the appearance of some of them; for instance, where a very small nodule has quite a long pedicle it can hardly be supposed that it was formed by its own weight when associated with it were numerous very much larger nodules with short pedicles or none at all.

Dr. KNOX exhibited a specimen of *Lipomyoma of the Uterus*. He remarked that lipoma, while common in many parts of the body, are very rare in the uterus and the combination seen in this case was unusual. The patient was a woman, aged 62, the mother of 13 children, and with a good family and personal history. The first symptoms of any trouble occurred 9 years ago, when she had a slight serosanguinolent discharge which lasted for a few weeks but was not accompanied by pain. After an interval of 7 or 8 years the discharge recurred, disappeared within a brief period and then again reappeared a few weeks before admission to the hospital. On examination Dr. Kelly found a large mass occupying the pelvis and extending half way up to the umbilicus. An operation was performed, the tumor removed and the patient made a slow but uninterrupted recovery and is in good health today. For some time after the operation there was nothing in the case to suggest anything but an ordinary myomatous uterus, but when the specimen was examined on making sections, it was found that the whole surface was traversed by numerous whitish bands dividing the tumor into lobules, and on scraping the surface minute globules of fat could be pressed out, which is never the case in ordinary myomas. There were no areas of marked softening anywhere in the tumor. On microscopic examination, the mass of the tumor was found to be made up of large fat cells, enclosed in a network of firm tissues composed largely of a fibrous tissue with oval and spindle cells and a considerable amount of granular intercellular particles. The tumor was homogeneous throughout. In discussion Dr. CULLEN remarked that although they had been making a systematic examination of all cases of myomas and had examined now something over 600 specimens they had never seen but the one of this character. In only one other case was anything resembling it found, and in that instance there were only 7 or 8 small areas that looked like the tissue found throughout this whole tumor.

Dr. CHARLES L. LEONARD, of Philadelphia, read a paper on *The Advances Made in Medical and Surgical Diagnosis by the Roentgen Method*, and followed this by a very interesting stereopticon exhibition of slides, showing skiagraphs of bone lesions and of kidney calculi.

WESTERN STATES.

New Filtration-Plant for Louisville.—Louisville, Ky., will profit greatly from its new filtration-plant, in that it will have fine water for drinking and bleaching purposes.

Minnesota Legislation.—A bill recently passed by the Minnesota legislative body makes it a misdemeanor punish-

able by a fine of \$50 for any person in Minnesota to smoke a cigaret.

Smallpox in Iowa.—On March 27, Mayor Hartenbower, of Des Moines, issued a proclamation requesting that all public schools, theaters and churches and other places of public assembly be closed on account of the prevalence of smallpox.

A Large Hospital Supported by Assessments is proposed in Cleveland, Ohio, by Health Officer George F. Leick. The wage-earners are to be asked to contribute 40 cents a month, which, it is calculated, would yield \$360,000 a year. After the first year, the assessments would be 20 cents a month. The buildings are to cost \$350,000. The plan is simply an insurance against neglect and poor treatment during sickness.

The rapid disappearance of the forests in the vicinity of Lake Geneva, Wisconsin, has become a subject of serious consideration by the property owners of that section. James Jensen, in the *Forester*, says that in order to improve and cultivate the ground, the owners clear away the undergrowth and natural grasses. These act as a blanket to keep the roots of the trees warm and also hold the moisture necessary to nourish them. Thus, in the mistaken effort to improve the land is found the reason for the decline of the forest, with the consequent influence on meteorologic conditions and public health.

Vaccination.—In the mandamus proceedings brought by Joseph P. Tracy, of Ravenswood, whose 3 children were forbidden to attend school because they had not been vaccinated, Judge Dunne, of the Circuit Court of Illinois, rendered a decision that the school authorities have no right to exclude children from the public schools who have not been vaccinated unless there is evidence that the disease is so prevalent as to render rigid precautions necessary. Later after listening to evidence of the prevalence of smallpox in and around Chicago, Judge Dunne ruled that the emergency existed which justified the insistency of the authorities to have the children vaccinated.

Unsuitable Marriages.—The Minnesota State Senate has passed Senator Chilton's bill forbidding the marriage of insane, epileptic and idiotic persons, and requiring that all applications for marriage licenses shall be accompanied by a medical certificate. By an amendment, which was adopted, the marriage of any feeble-minded person more than 45 years old is permitted; by the original reading of the bill this permission was only granted to women. Local statisticians had noticed an increase in the number of imbeciles and otherwise mentally weak persons in the State, and many such cases were found to be hereditary. This marriage law is proposed as a preventive of propagation by such. The law imposes a fine on the male contracting party who is proved unfit, and also upon the person who celebrates such ceremony. The present weakness of such a law is the ease with which persons desirous of evading such restrictions can gratify their wishes in another State. For this reason the enactment must, however wise it may be, in a measure fail.

Rocky Mountain Industrial Sanatorium.—An organization of physicians and other professional men and women has recently been incorporated in Denver for the establishment of an industrial refuge for tuberculous patients of slender means, who go to mountainous states in the hope that the altitude will effect a cure, but who almost invariably succumb to the unsanitary conditions forced upon them by their poverty. This organization aims to be national in its scope and it will endeavor, through auxiliary societies, to reach these patients before they leave their homes in other States. This plan embraces the erection of a sanatorium about 20 miles from Denver, to be carried on as an industrial colony and they hope to raise the large amount of money needed by the "Cottage Endowment plan." The Young Women's Sanatorium Auxiliary has been organized and a branch will be established in every city and town throughout the United States to cooperate with the Board of Directors in securing money for the endowment of the cottages, and for library, furnishing, etc. By utilizing the labor of the patients it is believed the work of the institution will be performed, the sanatorium provisioned, and remunerative work be conducted. The incorporators of the Rocky Mountain Sanatorium are William H. Gabbert, Associate Justice of the Colorado Supreme Court; Charles Hartzell, attorney; A. Mansfield Holmes, M.D.

CANADA.

Pauper Inebriates.—The Ontario Government has now under consideration a bill drafted by the Public Health Committee of the Ontario Medical Association conjointly with a committee of the Prisoners' Aid Association, providing for the economic remedial and reformatory treatment of pauper inebriates, and proposes to deal with it as a habit which must be broken up, a disease which must be cured or a mania which must be controlled. The financial burden is to be borne conjointly by the government, by the benevolent public, by the municipalities and by the drunkard.

FOREIGN NEWS AND NOTES

GENERAL NEWS.

The Plague in Africa and India.—The plague is increasing in India. In Bengal during the week ending February 23, 4,066 persons died of plague.

Scientific Expeditions.—For the purpose of continuing his research on malaria, Prof. Koch has organized a series of expeditions to the German protectorates and other tropical regions. He will direct the work from Berlin.

Hypnotism.—The Hungarian Government has issued a mandate against the practice of hypnotism, except by physicians and under special permission. The fact that a number of offenders have escaped punishment lately on the plea that their crimes were due to hypnotic influence, has led to this measure.

Obituary.—DR. JOHN DUGAN, Consulting Surgeon to the British Legation at Peking, and Professor of Anatomy and Physiology at the Imperial College in Peking.—SURGEON-GENERAL GORE, C.B., M.D., late A.M.S.—DR. BENJAMIN BARLOW, F.R.C.S., Vice-president of the British Medical Association, March 7, aged 87.

The Sleep Center.—Observations recently made by English experimenters tend to support the view of the existence somewhere between the medulla and the brain of a center which regulates the phenomena of sleep and awakening. The idea is expressed that a certain amount of accumulated carbonic acid gas, following fatigue, acting on this center produces sleep, while an excess excites it and produces wakefulness.

Italian Red Cross Antimalarial Campaign.—During 1900 an antimalarial campaign was conducted by the Red Cross Society, in the Roman Campagna. Medicines, food, and medical comforts were provided at various stations with great economic advantage both to the people, and to the hospitals to which otherwise they should have been sent. The number of persons treated was 4,513, of whom 3,751 were suffering from malaria.

Action of Chloroform on the blood.—MM. Lambert and Garnier have shown by recent experiments that the reducing power of defibrinated blood is greatly increased by passing chloroform vapor through it. From the fact that any variation in the composition or reaction of the blood necessarily modifies the nutrition of the nerve centers, the above conclusion may explain the disagreeable, and sometimes dangerous symptoms which occasionally follow the administration of chloroform.

Alcoholism from a Medico-legal Standpoint.—In some observations made by Mr. Justice Wells to the grand jury at the Durham Winter Assizes, England, he states that after nearly 70 years on the bench he is convinced that drink and gambling are the cause of the vast majority of the crimes of violence and dishonesty. He believes that such criminals require medical treatment in a reformatory rather than imprisonment. He thinks that many cases of paroxysmal inebriety have inherited mental instability.

Sea Hospital for French Fishermen.—Under the auspices of the *Societe des Oeuvres de Mer*, a steamer has been constructed with special adaptations for medical and surgical work among the fleet of French ships engaged in cod-fishing. This is to replace the sailing vessel *Saint Pierre* which left St. Malo April 1, last year, and though dependent on sails for progression, in 6 months completed 5 cruises, embracing the whole of the fishing ground and established communication with 301 fishing boats, when all slight cases of sickness or injury among the crew were attended on board their own craft; the more severe cases, 88 in number, were transhipped into the *Saint Pierre* for treatment. It also delivered 7,261 letters among the fishermen and conveyed home to their families and friends 4,020 in return and during her cruises rescued 10 sailors adrift in 4 dories.

GREAT BRITAIN.

Cremation in Great Britain.—A bill to permit the establishing of local crematories for human remains has passed the House of Lords and is now before the Commons.

Kissing the Bible.—By the existence of the Oaths Act of 1888 whereby the oath may be administered to witnesses in the English court without their having to "kiss the book" a dangerous practice is dispensed with. It is to be regretted that all courts have not yet adopted the "Scotch fashion." It has been stated that the two Testaments in the City of London Court are kissed by 30,000 persons annually.

Port Sanitary Laws.—At a meeting of the port sanitary authorities of Liverpool, England, two unanimous opinions regarding the plague were discussed. First, its early recognition, for which a bacteriologic laboratory should be provided. Second, that they endeavor to secure more power regarding the discharge of the cargo of infected vessels. And that as rats are considered the greatest danger of importation special attention be given to their destruction.

CORRESPONDENCE

ANATOMY IN RELATION TO ART.

BY

W. W. KEEN, M.D.,
of Philadelphia.

To the Editor of AMERICAN MEDICINE:—The contributions of Americans in the higher realms of anatomy have not been very frequent. In Artistic Anatomy I recall but a single serious attempt, the very successful and beautiful atlas by Dr. William Rimmer of the Boston Museum of Art. I am very glad to notice another contribution in this field by Dr. George McClellan.* It augurs well for the development of art in this country that so handsome a contribution to its literature should be made by one who has been now for 12 years constantly teaching anatomy to the students at the Pennsylvania Academy of the Fine Arts. Dr. McClellan, like Sir Charles Bell, is not only an anatomist, but an artist as well, as has already been shown in his beautiful "Regional Anatomy," and we are very glad to welcome him in this new field of art.

Anatomy for the artist is of limited scope. It cares nothing for the viscera unless they influence the surface form. It takes little note of deep muscles which do not modify form, though they may produce important motions. On the other hand, the small muscles of the face or the large gluteal muscles and the muscles of the back are of the utmost importance to the artist. In some cases the ordinary functions of muscles are for the artist very frequently reversed. For example, the muscles of the leg and foot, for the ordinary anatomist originate from the leg and are inserted into the foot. For the artist this is most frequently reversed, since their function is to steady the entire body and retain it in the erect posture, in which case the origin is from the foot and the insertion on the leg. The nasal bones for the artist far outweigh the femurs, and the influence of the position of the arms and of gravity on the level and the shape of the female breast require his most careful observation.

Dr. McClellan's text is very satisfactory. He uses simple terms, which to the artist are much more comprehensible than the more scientific terms of medicine. His style is concise, sometimes almost too much so. I could have wished that he had pointed out the reason for the change in the mid-point of the body, which he correctly states before 2 years of age is above the navel, is lowered to the navel at 2 years of age and progressively falls further and farther below that point after 2 years. The reason for it, of course, is the very slight development of the lower extremities in the infant and the much greater development in the adult, especially at the lower end of the femur where the growth from birth to adult stature is 7.3 times, while the growth of the entire body is only about 3.37 times. A similar relation governs the proportions between the face and the cranium. In infancy the face is extremely small, but enlarges very much as the teeth develop.

One criticism that might be made is that it would have aided the artist in contrasting the male and female forms much better had Plates 1 and 3, which now present the front and profile form of the male in one plate and the female in the other, contained a front view of the two sexes in one and a profile view of the two sexes in the other. This would have drawn attention to what the plates really do show very well, the marked difference in profile not only of the female chest, owing to the great development of the breasts, but also to the female abdomen, which is so much fuller in its lower segment than that of the male.

One very ingenious method of teaching anatomy not only to art students, but also to medical students and so employed for 16 years by Dr. McClellan is shown in Plate 81. The nude model is clothed in a complete set of tights on which are painted the principal superficial muscles; the varying action of

*Anatomy in Its Relation to Art, by George McClellan, M.D. Illustrated by 388 original drawings and photographs made by the author and expressly ordered for this work. Published by the author and printed for him at the press of Alfred M. Slocum Company, Philadelphia, 1900. Square quarto, pp. 142.

these muscles in different positions show admirably on this apparently dissected, yet living, model.

The whole book is a most creditable one to its author (who is also his own publisher), to the Academy of the Fine Arts, and to American artistic literature. It deserves to be widely known.

MOLLUSCUM FIBROSUM.

BY

GEO. L. WILKINS, M.D.,

of Baltimore.

To the Editor of AMERICAN MEDICINE:—The following interesting case came under my observation at the Baltimore city jail, February 6, 1901.

Charles D., colored, very dark, well developed, fair intelligence, aged 33, born at Avondale, Ohio. First noticed the growth

about 1 year ago. No evidence of an inherited tendency, traumatism, history of syphilis, eruptive diseases, acne or pustular affections. The total number of growths is 210, and they are most numerous and perfect in their development on the back, mainly in the scapular regions. They vary in size from $\frac{1}{4}$ to 3 inches in diameter. They present a great variety in form and shape: linear, oval, cylindrical, dome-shaped, sessile and pedunculated. On the front part of the chest there are 5 or 6 elongated growths, and on the left shoulder they appear as a long broken line. In these regions they are strongly suggestive of keloid. They are largest and most distinctive in their character on the back and shoulders. In this region many are pedunculated, some coalesce and several on superficial examination slightly resemble the markings of psoriasis. To the touch some are soft, while others are firm and fibrous in their character. The skin covering the tumors was either loose or stretched. There was no pain on pressing the growths, nor was there any disturbance of the general health.

Keloid is peculiarly prone to return after operative treatment, while on the other hand fibroma molluscum may be successfully treated by removal of the growths. Accordingly this patient was sent to City Hospital for operation, and subsequently went to Johns Hopkins Hospital.

SECONDARY SUTURE OF RESECTED ULNAR NERVE, SEVENTEEN MONTHS STANDING. IMMEDIATE RESTORATION OF FUNCTION.

BY

ERNEST LAPLACE, M.D.,

of Philadelphia.

Professor of Surgery, Medico-Chirurgical College.

To the Editor of AMERICAN MEDICINE:—The following case is of more than usual interest and I desire to bring it to the attention of your readers:

On May 10, 1899, G. K., aged 16 years, fell on an axe severing the ulnar nerve at the right elbow, causing complete ulnar paralysis. Local treatment healed the wound, but nothing was

done to repair the nerve. The usual ulnar atrophy followed. On December 7, 1900, 17 months after the injury, the boy was operated upon at the Medico-Chirurgical Hospital. The lower part of the ulnar nerve was found imbedded in a fibrous mass. The upper extremity was difficult to recognize, but a dissection from above led to a neuroma about $\frac{3}{4}$ of an inch long and $\frac{1}{4}$ of an inch wide. The neuroma was resected, also about $\frac{1}{2}$ an inch of impaired nerve tissue from the lower extremity. The two extremities of the nerve were brought together by gentle and steady stretching, lasting fully 2 minutes. When the proper length was reached, 10 finest silk sutures were placed about the neurilemma, bringing the resected ends in perfect apposition. The arm was dressed in the extended position.

The hand being wrapped in an antiseptic towel during the operation, I did not observe what effect might have resulted then and there, but the next morning I was surprised to find perfect motion in the little finger, while before the operation there was complete paralysis. As no healing could yet have taken place, I concluded that the restoration of motion must have been immediate owing to the perfect approximation which allowed nerve force to pass through. Sensation was also restored, but at certain points the impression received was referred to certain other portions of the affected area. This was no doubt due to the educated sensory fibers not having in every part met their former continuous fibers above. Some, however, had met their former severed ends, and these responded accurately to their educated sense. The patient was exhibited to the County Medical Association on December 12, the fourth day after the operation, and demonstrated perfect motion and complete sensation, though not always referring the sensation to the exact spot where the impression was received.

The important points in this unique case therefore are:

1. Resection of $\frac{1}{2}$ inches of the ulnar nerve with neuroma 17 months after injury.
2. Perfect apposition of nerve ends by steady stretching and the application of 10 sutures around the neurilemma.
3. Immediate restoration of motion and sensation.

A DEVICE FOR PARAFFIN IMBEDDING.

BY

D. H. GALLOWAY, M.D.,

of Chicago.

To the Editor of AMERICAN MEDICINE:—For 2 or 3 years I have been using what I think is a very convenient device for imbedding blocks of tissue in paraffin. It is a printer's composing-stick, 6 inches long and 2 $\frac{1}{2}$ inches wide. It has an adjustable slide fastened by a thumb set-screw; this slide is set at a dis-

Printer's stick for paraffin imbedding

tance of 4 inches from one end which gives a space 4 inches long by 2 $\frac{1}{2}$ inches wide. This space is divided across by 6 nonpareil slugs $1\frac{1}{2}$ inches long. These are separated by 6 quods $\frac{1}{8}$ of an inch wide placed at the back of the stick. Lengthwise across the other end of these slugs is placed another slug 4 inches long; this divides the space into 6 small spaces or boxes $\frac{1}{8}$ of an inch wide, $\frac{3}{4}$ of an inch deep and about $1\frac{1}{2}$ inches long. In these spaces 6 separate blocks of tissue may be imbedded at once, the quods being numbered on the end so that the tissues may be identified. Of course if only 1 or 2 blocks are to be imbedded, only that number of compartments need be set up. When the tissue is ready for imbedding, a small amount of melted paraffin is poured into the compartment, the tissue properly arranged therein and the compartment completely filled with paraffin. The stick is then placed on a cake of ice or in a shallow dish containing cold water. The metal conducts the heat away so rapidly that the paraffin is hard in a very few moments. This

is far more convenient than the old method of paper boxes which most of us were taught to use. It will readily suggest itself to every one that the size of these compartments may be modified to suit the work in hand; but the size I have given has been the most convenient for my work. The accompanying drawing illustrates the device as I have described it.

DEATH FROM ANESTHETICS.

BY

F. C. GRAM, M.D.

Registrar Buffalo (N. Y.) Board of Health.

To the Editor of AMERICAN MEDICINE:—I am frequently requested to furnish mortality statistics regarding a particular causation of death, in which the inquirer happens to be interested, and in so doing I have made certain observations which I consider of interest to the medical profession.

My attention has just been directed to a statement that "the number of deaths under ether anesthesia is estimated at 1 in 75,000; under chloroform 1 in 11,000." Another authority places these figures at 80,000 and 16,000 respectively. From facts in my possession I believe I am justified in saying that these figures are inaccurate, unreliable and misleading. I have no knowledge as to their origin, but surmise that they are based on hospital experience.

During my service as Registrar of Vital Statistics for the Buffalo Health Department I have recorded over 40,000 deaths. Out of this number only 3 are certified as due to anesthetics. One is recorded as following "anesthesia administered for operation," and 2 from "uremia following anesthesia."

I have personal knowledge of more than 4 times that many deaths under anesthesia during the same period, but they were certified as due to other causes. It is not my purpose here to discuss cause and effect, but simply accuracy. Few physicians or dentists are willing to go on record as having lost a patient under anesthesia, and the death is therefore credited to heart disease, nephritis, shock and other causes, which certainly are a factor, but which would not have become such at that time without anesthesia.

So long as these conditions exist it is absolutely impossible to obtain reliable statistics on this subject.

CLIMATE AND DISEASE.

By W. H. BURR, M.D.,
of Wilmington, Del.

"Some hae meat and canna eat,
And some wad eat but want it.
We hae meat and we can eat
And so the Lord be thankit."

To the Editor of AMERICAN MEDICINE:—If it is true as some writer has said that "climate is fate," is it not incumbent upon the medical profession to devote a little more time to the scientific aspect of climatology in its relations to diseased conditions, and endeavor through a careful and judicial treatment of the subject to remove as far as possible the elements of chance and place the whole subject upon a scientific basis.

Volumes have been written upon climatology and climate (unfortunately much of the material has been contributed by or drawn from railroad folders and real estate speculators) but it is only in recent years that the haphazard method of prescribing climate formerly in vogue is happily disappearing with other medical fakes and bogies. It has been customary in past years to prescribe climate as one would castor oil to be taken at bed-time (or some portion of the day without regard to the time of the day), then wait for results. All kinds of promises have been made the unfortunates who wait upon our wisdom, even so far as to assure them of bodily regeneration equal to that spiritual regeneration, promised by the Divine Prophet of all of us.

In a paper published recently by Dr. Van Meter, of Denver, the subject of climate is fairly considered, although the position taken by the author regarding the ultimate outcome of tubercu-

losis, even under the most favorable environments, seems to me to be more radical and hopeless than facts warrant. When a physician states that 85% of all patients afflicted with tuberculosis sooner or later die as result of that disease, whatever the environment may be, I think the position taken is more dogmatic than true.

If statistical figures are relied upon to prove the assertion, then I can only repeat the old saying that nothing is more misleading than statistical figures, and as the doctor complains that the city of Denver has already been injured by misleading mortuary statistics regarding tuberculosis, it seems strange that he should fall into the same error. It may be true that 85% of all cases of tuberculosis die as direct result of that disease, but in compiling figures to show result of climatic treatment of tuberculous persons, the number only of those who seek climatic change should be taken. Then if you eliminate from this number those who have had injudicious advice in regard to climate, I think it would surprise the profession to know how many cases are cured. I do not say *arrested* but *cured*, for I do not believe that we can deny a cure in the case of a tuberculous person any more than to any other condition of disease. * * * Every one knows that "death from *old age*" is generally a misnomer, and that we all carry the seeds of some diseased condition with us which will eventually terminate in death unless we shall, as seems improbable, all accept the dietum of the Christian (?) Scientist "that there is no such thing as matter," and why one should concede arrest in 1 case and cure in another is beyond my comprehension.

I spent 3 months in Colorado last summer and met scores of persons who to all intents and purposes were cured of tuberculosis. Some of them recovered under circumstances and environments that would be considered unlikely or unfavorable. I met persons in the high towns 10,000 feet above sea-level of whom I was assured that they had been brought in on stretchers, and they were apparently hale and hearty. Others had had the same experience in the lower towns. I saw men who came into Colorado with an immediately previous history of violent pulmonary hemorrhages and who were doing the hardest kind of mental and physical labor, were hale and hearty, and the fathers of healthy families. If tuberculosis like syphilis and some other contagious diseases did not wear itself out, under favorable circumstances and environments we should expect the whole human race would annihilated within a reasonably short space of time.

REMOVAL OF POWDER-STAINS.

By J. NEELY RHOADS,
of Philadelphia.

To the Editor of AMERICAN MEDICINE:—Last summer an Italian woman came to me to have me remove powder-stains from her face. A boy a week or 10 days previously had thrown a giant shooting cracker into her face, badly and permanently blacking it. In the meantime, she had applied to a hospital and had been subjected to several long, painful treatments in futile attempts at picking the powder out of her skin. On her visit to me I, also, attempted to pick out the individual grains, but it was so tedious, and the patient objected so much on account of the pain that I began to look around me for some other way. A chemist friend suggested the use of hydrogen dioxide. I applied it at once, full strength; and gave the patient a bottleful to use at home. She came back in 2 days with the powder-stains all removed. I have been waiting for another case, but as more than 6 months have now passed without my seeing the second one I send this account to you for publication.

Smallpox.—Smallpox is reported from Clarksville, Tenn., Des Moines, Iowa, New York, Jersey City and Nashville. In Clarksville the situation is more difficult on account of the ignorant opposition to preventive measures on the part of the negroes. The same difficulty is experienced among the Italian patients of Jersey City. In San Juan, Porto Rico, and in the City of Ponce, there are some cases of a mild type. In Porto Rico the Anshantees do not regard a Board of Health and places of quarantine as necessities. A spread of the disease is not feared.

ORIGINAL ARTICLES

THE MEDICAL ASPECTS OF CARCINOMA OF THE BREAST, WITH A NOTE ON THE SPONTANEOUS DISAPPEARANCE OF SECONDARY GROWTHS.

BY

WILLIAM OSLER, M.D.,
of Baltimore, Md.

Professor of Medicine, Johns Hopkins University.

The consulting physician sees mammary cancer at two stages of its progress. Dreading the surgeon, and hoping against hope, a number of women prefer to come to him at the first detection of a tumor. But these form a small fraction of the cases. A large majority are the unhappy victims of the internal metastases after operation. For some years I have been interested in this class of cases, and have collected material bearing upon the question of these late, more strictly medical, manifestations of the disease.

Recurrence may occur in the bones and other parts at an indefinite period after the detection or removal of the primary growth. In a case which I saw with Dr. Agnew, fully 18 years had elapsed since the discovery of the breast tumor. S. W. Gross¹ reported an instance in a patient who had had atrophic scirrhus of the breast for 17½ years. Shields quotes a case of Dickinson's, in which secondary paraplegia occurred in a woman who had had an atrophic scirrhus of the breast for 14 years.

On the other hand generalization may occur with extraordinary rapidity. Case XIII in Nunn's Monograph on Cancer was a young woman, aged 27, seen in April with cancer of the left breast, which she had noticed for several months. In June she had ptosis of the left eyelid, and subsequently had paraplegia. He quotes a still more acute case. "The patient, under the care of Mr. Pearce Gould, was aged 29; had borne 4 children; after suckling the last one about 8 months symptoms of mischief commenced in the left breast and the axillary glands participated. The patient died within 4 weeks of her admission into the hospital, having a temperature of 101.8, and somewhat higher toward the end. The post-mortem showed infiltration of the left breast and a similar condition of the right breast, effusion into the left pleural cavity, the lumbar vertebrae were invaded, both suprarenals were cancerous."

The cases may be arranged into those with *cerebrospinal*, *thoracic* and *abdominal* manifestations.

I.—CEREBROSPINAL MANIFESTATIONS.

The tendency of secondary carcinoma to involve the bones, especially those of the spine, makes the complications of this group very frequent. Of 858 cases of cancer of the breast collected by Hahn (Freiburg Dissertation, 1887), 35 had metastases in the bones, 21 of these in the vertebral column, 11 in the extremities, 1 in the skull. Taking the post-mortem statistics collected by the same writer, of 554 cases, 82 had metastases in the bones.

Borner (Berlin Dissertation, 1886, Ueber Metastasen nach Mammacarcinom in der Wirbelsaule) has dealt very fully with the question of recurrence in the spine. He

quotes the interesting remark of Billroth, that cancer of the vertebral column is seen particularly in patients with the atrophic form of scirrhus, which is sometimes so trifling that patients come first under the care of the physician. He gives the statistics of the Vienna Pathological Institute, in which in 366 cases of carcinoma of the breast in 72,000 necropsies, 9 had metastases in the vertebral column.

(a) *Cerebral*. The bones of the skull are not often affected. Broca reports a case with generalized cancer of these parts secondary to scirrhus of the breast. There was facial paralysis.

Secondary cancer of the brain is rare, but a few cases are referred to in the literature.² The only instance which has come under my notice is the following:

CASE I.—Symptoms of brain tumor; old sclerotic scirrhus of the breast.

November 12, 1886, I saw with Dr. Agnew, Mrs. X., aged about 75, who had had for several months headache of great severity, and occasional attacks of vomiting. She was a small woman, moderately emaciated, but looked fairly well in the face. Within a week or 10 days she had become drowsy, and her condition was evidently alarming. There was no paralysis. She had a double optic neuritis, which, with the intense character of the headache, the vomiting and the drowsiness, were suggestive of brain tumor. Dr. Agnew then mentioned that 18 years before she had consulted him for a scirrhus of the left breast. He had not advised operation, and it had gradually become shrunken. On examination there was an old, puckered, cicatricial scirrhus, with an extreme grade of retraction of the nipple. The patient gradually became more drowsy and died in coma.

(b) *Spinal*. In many ways this is perhaps the most important of all the groups. Anyone who has had to do with the post-mortem room in a large general hospital has seen many instances of secondary involvement of the bones of the spine with compression of the nerve-roots, or compression of the cord itself. Cruveilhier describes and illustrates the condition, and to him we owe the name *paraplegia dolorosa*. Charcot in 1866 described a painful paraplegia in certain cases of cancer, and he has given a very clear account of the condition in one of his lectures.³ The main characteristics are pains of great intensity, usually about the sides and down the legs, or, if the secondary masses are situated higher, they may be in the arms. There are areas or zones of anesthesia, sometimes the so-called *anaesthesia dolorosa*; or shingles may break out. One feature of the pain, too, is very characteristic; the patient may get into a comfortable position and remain so for an hour or more; then the slightest movement of the spine gives exquisite torment. The crises of pain which these poor victims suffer are simply atrocious. There may be the most extreme feature of pressure on the nerve roots without any paraplegia. In some instances, indeed, the nerves may be involved by enlarged glands in the pelvis. When pressure on the cord begins in addition to the disturbances of sensation and the pain, there are often painful spasms of the muscles, in which the legs are drawn up, sometimes very forcibly. Ultimately there may be complete paraplegia with involve-

²Walsham, Cases of carcinoma with secondary growths in the brain, *Lancet*, 1890, II. Wilson, Case of scirrhus of the brain secondary to that of the breast, *Lancet*, 1892, I, 464. Gery, Tumor of the brain, etc., after 2 operations on the breast, *Bull. Soc. anat. de Par.*, 1892, xvii.

³Oeuvres Complètes, Tome II, p. 116.

¹Transactions of the Pathological Society, Phila., 1880.

ment of the bladder and rectum. A very remarkable fact is that in certain of these cases the spinal symptoms may disappear, and a patient from a desperate condition of paraplegia dolorosa may recover sufficiently to be able to walk about, as in Cases V and VI.

Charcot insists that in any case of painful paraplegia, particularly in a woman, one should look carefully for atrophic, indolent scirrhus of the breast, and gives a case of cervicobrachial neuralgia almost identical with Case IV of my series.

Mr. T. W. Nunn, in his monograph on Cancer (1899) states that the access of the spinal mischief is very insidious; that the pains may begin in the region of the neck and extend to the branches of the brachial plexus; one or more fingers being specially neuralgic. He says they are quite dissimilar to the neuralgia arising from implication of the intercostohumeral nerves in the scar. In many cases the patients complain of rheumatic pains in different parts, or the pains may be regarded as neuralgia, or even the symptoms may be thought to be due to hysteria. I have seen a number of cases within the past eight years, the more notable of which I here give in abstract.

CASE II.—I saw at the Hot Springs with Dr. Chapin, Mrs. Z., aged about 53 (?), who had had a scirrhus of the breast removed some months previously. For several months she had had sharp pains in the legs, with increasing disability. At the time of my visit she had agonizing pains in the lower abdomen and down the legs. No secondary masses could be felt. Gradually the picture became that of an extreme paraplegia dolorosa. I did not see her again, but heard of her death some months later.

CASE III.—The next case I saw was with Dr. Ellis, at Elkton, Md. The patient had had a breast cancer removed a year or so before, and I was asked to see her for a condition of agonizing pain in the side and down the legs. I rarely have seen any one who appeared to suffer more excruciating pain than this poor woman. She had gradual loss of power in the legs, evidently with pressure signs, as they were drawn up frequently, and the severe shooting pains down the backs of the legs and around the flanks. She died paraplegic some months later.

This is the usual type of the disease and the cases are only too common. The other cases in this group present more unusual features.

CASE IV.—*Cervical nerve-root pains; cancer of breast.*

On October 28, 1895, I saw with Dr. Pole, Mrs. C., aged about 52 or 53, who had been complaining for 5 or 6 months of severe pains in the region of the neck. They began about June, and were thought at first to be neuralgic and rheumatic, and she went to the Hot Springs. They had never ceased, though they got better at times. She had lost a good deal in weight. The pains were almost entirely confined to the neck. They shot sometimes up the jaws and up behind the ears, but not down the arms. She had no weakness of the arms, no weakness of the legs.

The patient looked well, and was fairly well nourished, though she had lost considerably in weight. There was nothing specially noticeable about her as she rested quietly in bed; in which position she had no pain. So soon as she attempted to move the head forward, as in taking anything to eat or drink, she felt the pain at once in the back of her neck. She had the greatest difficulty in getting out of bed. She had to turn on her side, get up with the help of her arms and knees, and held the neck very stiffly. She stood up and walked about quite well, but in sitting in a chair she had much more pain in the neck than in the recumbent posture. She could move the head from side to side without much pain, though not to the full extent. She could push the head backward to a slight extent, but to bend the head forward gave her at once a great deal of pain.

The head and neck were carried quite stiffly. The examination of the neck behind was negative, with the exception of pain on deep pressure upon the fourth spine. The bodies of the vertebrae examined from the pharynx were quite smooth.

It was impossible to get her to contract actively either sternocleidomastoid. There were no sensory changes; no spots of hyperesthesia. The pains did not extend down the arms. The grasp of the hands was good; no impairment of the motor power in the legs. She walked well and readily. The knee jerks were decidedly increased. She complained occasionally of pains in the side; they were not regular girdle pains.

I confess I have been a good deal puzzled by this case. She gave a very clear, matter-of-fact statement; the examination of the neck was almost negative, yet the whole appearance of the patient and the attitude, particularly the way she got out of bed and back into bed, was strongly suggestive of something more than cervicobrachial neuralgia. When she returned to bed I proceeded to examine the side, and took the opportunity to feel the breasts when I found the left one enlarged, firm, nodular, and evidently the seat of scirrhus. The nipple was not retracted; the skin over it was smooth, and the whole gland seemed to be affected. This at once threw a totally different light upon the case, and though she had no foci of evident metastases, yet the loss of weight, the existence of the tumor in the breast, and the nerve root symptoms seemed sufficient to make it quite clear that she was the subject of secondary growth in the vertebrae of the neck.

During the next month the patient gradually failed; the pains above described continued; she had a great deal of difficulty and pain in swallowing; she died December 2.

Charcot reports an almost identical case of a woman who had suffered for some months with a cervicobrachial neuralgia, which had resisted all treatment. He says, "Struck by the special characters presented by the pain, and calling to mind some of the facts which I had seen at the Saltpetriere, I asked if there was not a lesion of the breast. The reply was negative, but I insisted on examining for myself, when I found, to the great astonishment of the patient, that one of the breasts was retracted, with an atrophic scirrhus."

CASE V.—*Tumor in right breast noticed January, 1897; operation November, 1897, scirrhus; good health for a year; in September, 1898, pains in the back and down the legs; recurrence in the right eye; gradual increase of the pains in the legs; orthopnea; emaciation; recurrence in the left breast; tumor mass on sternum; effusion in right pleura. After remaining for months in a desperate condition, gradual improvement; disappearance of tumor on sternum; improvement in vision of the right eye; throughout 1900 persistence of pains to slight extent, but general improvement.*

Miss X., aged 31, consulted me October 6, 1897 for a lump and pain in the right breast, which had been first noticed in January. She had had a fall from her bicycle in November, and to it the trouble was attributed. In a few weeks she entered the Johns Hopkins Hospital, where Dr. Halsted did a most extensive radical operation. The glands in the axilla were much involved; to one of them the axillary vein was adherent, and part of it had to be excised. The case is No. 7,043 in the surgical histories of the hospital. The histological diagnosis was scirrhus. The patient improved, and returned to her home in a few weeks.

On September 24, 1898 she returned complaining of difficulty

of vision in the right eye and pains in the back and down the legs. She looked well, but I was naturally apprehensive about the condition, and, as she and her mother were on their way to Philadelphia to visit the father, who was under the care of Dr. de Schweinitz, I asked them to let Dr. de Schweinitz examine the eyes carefully. The following day he reported to me that there was a tumor in the right eye. He had not been told about the operation, and of course when informed he recognized the condition at once as a secondary carcinoma. There was no local recurrence in the ear.

Winter of 1898-99. I saw the patient again on November 31. She had shooting pains about the sides, cough, and pains in the legs. There was no pain in the right eye, the vision in which had become progressively worse. About Christmas she became confined to her bed, and the pains were so severe that she had to take morphia. She passed the winter in great distress, the condition becoming steadily aggravated. I saw her twice, and in May her condition seemed really desperate. She had become very thin; there were constant orthopnea, and paroxysms of very severe pain at night, so that the morphia had to be increased to 2 grains at a dose. The emaciation was extreme. The pains were chiefly down the legs and around the sides. There was no local recurrence, but a lump had appeared in the left breast. There was tenderness about the fourth and fifth dorsal spines. About the junction of the manubrium with the gladiolus there was a distinct tumor, which was very tender, and which looked like a new growth in the bone. There was an extensive pleural effusion on the right side.

I left for England shortly afterwards, and, of course, did not expect to find her alive on my return. She gradually improved through the summer, the dyspnea lessened, the pains became less intense, and toward October she began to get up and move about.

Winter of 1899-00. She had on the whole a gaining winter. The pains were less intense, and the morphia was reduced to about a grain 3 times a day. She improved in color, gained in weight, and was able to walk about the house and about the grounds. A remarkable change had taken place in her back. There was a distinct prominence about the fourth and fifth dorsal spines, the back was stiff, and she had a marked stoop. The kneejerks were a little exaggerated. The pains down the legs, which were formerly so excruciating, had almost entirely disappeared. The tumor on the sternum had disappeared. There were no local recurrences. The tumor in the left breast had not increased in size. The most remarkable thing was the progressive improvement in the vision of the right eye, which had been almost entirely lost. She could now recognize faces and even see large type.

During October of 1900 I saw this patient twice. She had improved in every way. She was able to do very much more. She drove a mile and a half to the station to meet me, and drove me to the station on my return. She was still very thin, but her appetite is fairly good, her color is good, she walks stiffly, but gets about with much more comfort than formerly.

I saw her again on December 9, 1900. She had had a little more pain, particularly in the right leg, the sight had not been so good, and on the whole she had been failing somewhat, though she was still able to be up and about, and her appetite was fairly good. There was no local recurrence, and there was no increase in the tumor in the left breast.

[TO BE CONTINUED.]

The Cure of Suppurative Cerebrospinal Meningitis.—Netter (*Annales de Med. et Chirurg. Infantiles*, July 1, 1900) reports 6 cases of cerebrospinal fever in which lumbar puncture gave purulent fluid containing the diplococcus meningitidis. A complete cure resulted in 5 of the cases, in 1 case the patient was left with ankylosis of 2 joints and labyrinthine disease. The author attributes his success to 3 factors: (1) The use of warm baths (100° to 104° F.) lasting 20 to 30 minutes, and given every 2 or 3 hours, day and night; (2) lumbar puncture repeated several times in the course of the disease; and (3) the systematic administration of normal salt-solution subcutaneously when the patient could not take sufficient nourishment by the mouth.

THE MORTALITY OF OPERATION FOR OBSTRUCTIVE JAUNDICE.

BY

JOHN B. DEEVER, M.D.,

of Philadelphia.

The following is the classification of causes of obstructive jaundice by Murchison (Osler)—(1) by foreign bodies within the ducts, as gallstones and parasites; (2) by inflammatory tumefaction of the duodenum or of the lining membrane of the duct; (3) by stricture or obliteration of the duct; (4) by tumors closing the orifice of the duct or growing into its interior; (5) by pressure of the duct from without, as by tumors of the liver itself, of the stomach, pancreas, kidney, or omentum; (6) by pressure of enlarged glands in the fissure of the liver, more rarely by abdominal aneurysm, fecal accumulation or the pregnant uterus; (7) to these may be added lowering of the blood pressure in the liver, so that the tension in the smaller bile ducts is greater than in the bloodvessels. In this class very probably may be placed cases resulting from mental shock or depressing emotions.

Of the above causes of obstructive jaundice I have only met those relating to calculous obstruction of the hepatic, hepatic and common or of the cystic ducts, where the stone was located at the junction of the cystic and hepatic ducts with obstruction of the latter; stricture and angulation of the common duct caused by adhesions which were making either pressure or traction; pressure on the common duct from carcinoma of the head of the pancreas, either alone or in connection with cancer of the duodenum. A condition to which my attention has been drawn upon more than one occasion is the association of attacks of jaundice with very movable kidney, and I have been inclined to attribute this in part at least to traction upon the peritoneum and consequent angulation of the common duct.

The causes of death in the cases which I have lost were consecutive and secondary hemorrhage, exhaustion and cholemia. I have, with one exception, been fortunate enough to have had autopsies in these cases and thus have been able to rule out peritonitis as a cause of death.

Mayo Robson¹ reports 22 deaths following operation for the relief of obstructive jaundice. Of these, 7 patients died as the result of hemorrhage either consecutive or secondary; 5 of exhaustion; 4 of shock; 3 of heart failure (1 of these cases was complicated by nephritis); 1 of an abscess between the liver and diaphragm which was not discovered at the operation; 2 of peritonitis; in 1 of these last a small hole was torn in the colou by the breaking up of dense adhesions, and in the other a ligature which had been used to tie off the cystic duct in amputation of the gallbladder slipped, and caused extravasation and peritonitis. It would seem, therefore, that his experience coincides with my own and that peritonitis is not a common factor in the mortality. It is a question with me if most of the cases which are fatal because of exhaustion or heart failure are not in reality cases of cholemia. Shock cannot be separated from hemorrhage as a cause of death, for it is the loss of blood either at operation or following it that causes the shock.

¹ Disease of the Gall Bladder and Bile Ducts, 2d Edition, 1900.

From the present status of surgical interference for obstructive jaundice it should not have the mortality credited to it from either of the causes mentioned, as I will try to show later on. Neither consecutive nor secondary hemorrhage should occur, and particularly consecutive hemorrhage. The latter is due, purely and simply, to the blood changes consequent upon the prolonged jaundice. The exact changes which take place in the blood I believe have not been definitely determined. It is probable, however, that there is some chemical change which inhibits the fibrin-forming element and thus prevents rapid coagulation. The ordinary blood counts indicating anemia, hemoglobinemia, leukocytosis, etc., do not account for the tendency to hemorrhage in obstructive jaundice. The effects of the bile salts on the bloodvessels must also be taken into account. There seems to be a relaxation of the arteries which interferes with their proper contraction, thus encouraging free bleeding.

I have encountered but 2 cases of secondary hemorrhage and in each of these there was a period of consecutive bleeding preceding the onset of secondary hemorrhage which was controlled only after the wound had been packed with gauze. In both of these cases the gauze packing introduced to control the consecutive bleeding was removed on the seventh day, the removal being effected without difficulty and with practically no pain. In one case, 3 days after the removal of the gauze, secondary bleeding occurred costing the patient her life. The same may be said of the second case, except that it was only by the most heroic efforts that her life was saved. Intravenous saline transfusion given by my house surgeon, Dr. Moore, upon 2 different occasions, full doses of opium, absolute rest of the stomach, nutritious enemas, etc., were the means to which we can ascribe her recovery.

I have seen but 1 death from consecutive hemorrhage alone. This patient died within 24 hours following the operation. The control of primary hemorrhage by means of the ligature is certain. I have never been unfortunate enough to wound the portal vein or any large vessel. To guard against consecutive bleeding calcium chlorid in doses of 30 grains for 3 or 4 days before, as well as after operation, as recommended by Robson, I believe good practice; yet, I am sorry to confess, I have not been able, in my comparatively limited experience, to attribute much good to it. A wider experience and greater familiarity with its use may perhaps convince me of its utility and benefits. Suprarenal extract has lately taken a place as a hemostatic and in one of the cases herein reported it was tried with seeming success.

Obstructive jaundice due to gallstones is usually due to obstruction of the common or hepatic ducts. It may, however, and in fact frequently does, occur when the gallstones are confined to the cystic duct or gallbladder. Here the obstruction to the flow of bile is due to the associated cholangitis. This is a rather favorable condition of affairs for operation, as the removal of the gallstones from the cystic duct or gallbladder will be followed by a rapid subsidence of the inflammatory swelling of the common duct. Reidel² says that two-fifths of the cases of jaundice in cholelithiasis arise in this way.

Drainage plays an important part in the above result; this is probably accounted for by the fact that the valve-like action of the reduplication of the mucous membrane lining the cystic duct is overcome by the obstruction to the flow of bile and the slow regurgitation becomes a steady flow of bile into the gallbladder and the drainage provides for the escape of the excess.

There is a class of cases in which the inflammation in and about the gallbladder is so intense that the surrounding tissues and organs become gangrenous and the patient succumbs to the exhausting effects of local and constitutional sepsis. The following case is an illustration:

C. P., aged 53, for several years prior to the present attack has had "bilious attacks" without jaundice or pain. The present attack began 5 weeks before admission to German Hospital, December 4, 1900. He had pain in the region of the gallbladder, radiating to the shoulder; he was tender over the gallbladder, but was not jaundiced. He continued his occupation for 2 weeks. Three weeks prior to admission the pain and tenderness became more aggravated and jaundice made its appearance for the first time. The jaundice had gradually increased until the present; the bowels were constipated; the gallbladder enlarged, and upon deep pressure tenderness could be demonstrated.

OPERATION.—The gallbladder was enlarged and tied to the liver by dense adhesions. It contained many large stones, pus and bile, and its walls were ulcerated and friable. The common and cystic ducts presented the same condition as the gallbladder, and contained many stones; there was 1 stone in the hepatic duct. The stones were all removed and the cavity packed with gauze and drained. On the sixth day the gauze packing was removed liberating a considerable amount of pus; the tissue about region of the gallbladder was necrosed and a large pus cavity led down behind the liver. The patient died of exhaustion due to local and constitutional sepsis. The necropsy disclosed localized fibrous peritonitis; no involvement of general peritoneum.

A careful study of the causes of the mortality of obstructive jaundice leads us naturally to the consideration of the best methods to adopt to combat the disease. Shall we treat them as medical cases with the prospect of surgical help if medical measures fail, or shall we treat them as purely surgical cases? And if the latter, how and when? If we take the 6 causes for obstructive jaundice we can see that 2, namely, inflammatory tumefaction of the duodenum or bile ducts and changes in blood pressure, produce purely medical cases; while in the others, the indications are distinctly and positively surgical.

The most common of all causes, and more common than all the others put together, is obstruction from gallstones. Parasites are so rare that they may be passed by with the mention, although the indication is distinctly surgical when they do occur. Every case of cholelithiasis that I have operated upon has given a history of repeated attacks treated medically, yet they have not been cured of the disease nor freed from its dangers. Each succeeding attack is accompanied by local and systemic changes which detract from a favorable surgical prognosis. We have seen that the most common cause of death is hemorrhage caused by changes in the blood; the next most common is exhaustion, or what we believe to be cholemia, and third most common, shock, which is a result of hemorrhage; and that these 3 causes are undoubtedly enhanced by delay or long continuance of the pathologic factors of the disease.

PHELPS' OPERATION FOR CLUBFOOT WITH A REPORT OF 1,650 OPERATIONS.*

BY

A. M. PHELPS, A.M., M.D.,
of New York City.

In 1878 I performed my first operation of open incision upon a relapsed clubfoot. It was a case which had been operated upon by various surgeons and subsequently treated, and also by myself, by subcutaneous tenotomy, and the mother requested me to straighten the feet or amputate. When I proceeded with the open incision method, I was astonished to find that I had corrected the deformity perfectly without cutting bone.

Fig. 1.

I read a paper before the Eighth International Congress which met in Copenhagen in 1884, reporting there 36 cases operated upon by myself and other sur-

geons. Subsequently I published in the *Post-Graduate Medical Journal* a report of 538 cases from that clinic. Since the first operation in 1878 I have operated on 1650 cases. In my first series of 538 cases I performed osteotomies in 17. In the last 1100 I have never resorted to osteotomy but have amputated 4 times. Over 100 of them occurred in adults varying in age from 20 to 60 years. The introduction of subcutaneous tenotomy by Stromeyer in 1835-8 was an innovation, and one of the steps in the operative treatment of clubfoot. The operation of cuneiform resection by Davy of London, and the resection of astragalus by Lund of Manchester, marked another period in the operative treatment.

I find the mortality from bone operation amounts to from 3% to 5%. Davy's operation gives a mortality

Figs. 2, 3 and 4.

of 3.5% while that of Lund gives a mortality even greater. The mortality in 1650 by open incision, 17 of which were attended with bone operations, was nil, and I have yet to find the history of a single case in which mortality was recorded.

I have urged upon the profession in America the importance of performing the operation for the following reason:

1. There is no mortality attending it.
2. Any foot at any age can be straightened.
3. The results from the operation are as good or better

Fig. 5.

than from any bone operation or mechanical treatment whatever.

The important arguments against bone operation are:

1. The resection of the tarsus means the shortening of the foot just in proportion to the amount of deformity.
2. The removal of any bone results in a shortening of the foot.
3. The removal of the astragalus, results in the shortening of the entire limb from $\frac{3}{4}$ to $1\frac{1}{2}$ inches, depending entirely upon the age of the patient.

In the series of 538 cases, I find that the relapses amounted to 6%. Those relapses were entirely due to negligence upon the part of the patient or parent.

The idea of performing tenotomy or any operation, leaving the foot in a deformed position, and afterward straightening it by mechanical methods, has been entirely abandoned in America. The application of clubfoot shoes and other mechanical devices for straightening clubfoot, requiring months and years of careful work, have also been discarded. We now believe in America that these feet should be immediately attacked and placed in a supercorrected position utilizing the weight of the body to prevent relapse, and good results are obtained in a few weeks.

The question arises as to the time to perform the operation. I beg to state that if every case of clubfoot could be treated at birth by manipulation and fixation, not more than 1 case in 10 would require any operation. But unfortunately, these cases come into our hands months after

the child is born, and nothing short of an operation, or years of treatment by mechanical appliances would be of any avail. Therefore we have come to this conclusion in America. If the foot remains deformed at the fourth month after birth, manual manipulation is employed for a short time varying from a few days to a few weeks, when it should be immediately operated upon if the mechanical treatment fails. And the plan which we follow is this; in the order which I enumerate:

*Paper read before the British Medical Association, August, 1900.

1. Manual manipulation and fixation.
2. Subcutaneous tenotomy.
3. Open incision.
4. Linear osteotomy through the neck of the astragalus.
5. Cuneiform resection from the body of the os calcis.
6. Pirogoff's amputation.

So, understanding this law which we now follow, we can readily observe that open incision stands between

Fig. 6.

subcutaneous tenotomy and osteotomy. Osteotomy should never be performed as a primary operation, and should always be secondary to open incision.

The normal foot is in a plastic condition up to birth, and it is not until the fourth year that the bones of the tarsus become ossified. For this reason, the earlier the treatment of clubfoot is begun the better. I would say, as soon as the placenta is delivered, and you have assured your

self that the mother is in no danger of postpartum hemorrhage, begin the treatment.

This consists in subjecting the foot to such manipulation with the hand as will restore the foot as nearly as possible to the normal position. The next step is to apply a number of strips of adhesive plaster in such a way as to draw the foot around towards the normal position, and hold it there. If the adhesive plaster causes irritation of the skin, first apply a roller bandage, then the adhesive plaster, and finish this simple effective dressing by another roller bandage. This is a beautiful

Fig. 7.

to the knee. The manipulation and the application of this simple dressing is continued at short intervals. If the deformity has not been overcome by the time the infant is 3 or 4 months old, it is then an imperative duty in the vast majority of cases to operate.

How shall the operation be done? My rule is to tenotomize, beginning with subcutaneous tenotomy of the tendo-achillis to bring the heel down. As the parts are put on the stretch, cut every part offering resistance.

Where the skin is short, cut it, and likewise the other tissues, and do not stay the hand until you have succeeded in putting the foot into a supercorrected position. If we stop short of this, we will produce what was formerly known as "relapsing clubfoot"—a condition which is solely due to not overcorrecting the foot, and hence allowing the weight of the body to

Fig. 8.

operate in such a manner as to cause the deformity to recur. If, however, the foot is supercorrected, the weight of the body will tend to increase the supercorrection, and therefore there will be no relapses.

Inward twist of the tibia requires osteoclasis. How much better is such orthopedic work than the old plan

Fig. 9.

of "interrupted traction"—a method in which the foot was subjected to traction 8 or 10 times every day for many years! The best orthopedic appliance ever devised is the human hand.

At the time of publishing my first paper, in 1881,

Fig. 10.

on the operation of open incision in clubfoot, and in a subsequent paper read before the Eighth International Congress, Copenhagen, in 1884, my observations were not extensive enough to enable me to speak with any

degree of authority on the subject. My convictions as to the advisability of the method, however, were strong, and upon theoretic grounds, sustained by a limited number of cases, with results, I advised the operation. Mature experience now enables me to correct, or I might say more clearly define, many points which at that time could not be made perfectly clear. I argued then for the operation. Now I desire to present a method

by any other method, are we justified in performing a primary osteotomy or resection of the astragalus? Clearly not, for the results after primary bone operations are no better. Failures are common and the mortality is about 5% whereas, in operations on soft parts there is no mortality.

And then, are we justified in treating a case by instrumental means for years, when a moment's work with the tenotome or knife would shorten the period of treatment to as many weeks, with a result equally as good? Certainly not, if the patient will consent to an operation. The tinkering and fooling with clubfoot with traction machines, covering over long periods of torture reckoned by years, with all its failures, brought orthopedics of the past into disrepute. The surgeon and patient became disgusted, and out of the chaos and wreck we saw methods devised which shortened the period of treatment, and cured cases which chagrined the orthopedist. These methods of mechanics,

Fig. 11.

which should govern all operative procedures in club foot, giving to the operation its proper place in surgery. The difficulties which the profession have encountered have been the varied methods and operations which, from time to time, have been urged as the cure for all cases; and, only after a personal application of the method or operation urged, has the operator discovered that his ship of anticipation has been wrecked upon the rock of experience. Primary osteotomy, astragalus resection, cuneiform tarsectomy, open incision, and prolonged and interrupted traction with intricate machinery, have all run the gauntlet of observation, and the roadside everywhere is strewn with lamentable failures.

Why should this be so? Simply that method, based upon some pathologic fact and data of experience, has been ignored.

I do not at this time care to discuss the etiology and pathology of talipes varoequinus. Permit me to say, however, that in all the pathological specimens which I have examined, the distortion of the soft part has been out of all proportion to the deformity of bone; and many specimens of severe deformity which I have in my collection show but slight bone-deformity, and that is confined chiefly to the neck of the astragalus, while in other specimens the os calcis is also deformed. These distortions, added to a great dislocation of the small bones of the tarsus, with changes in their articular surfaces, and frequently an inward twist of the tibia, constitute the bone-deformity of talipes varoequinus in a very large per cent of cases occurring in children. Now, if these observations are correct, and we can with perfect safety to foot and life extensively divide soft parts, and secure useful feet in a short time, or as good results as can be obtained

when carried to extremes, as we have all been obliged to witness, degrade the orthopedic surgeon to the level of the chiropodist or mere instrument maker, and one step farther carries him, with all his good intentions, within the vale of empiricism. Again, on the other hand, the surgeon becomes impatient with his cases and devises an operation. It proves serviceable in many cases, fails in others, until he finds himself

Fig. 12.

blindly following his operation and not a principle, mutilating feet unnecessarily, and finally, in disgust, he abandons his pet operation.

A remedy for all this is a method, and nearly every operation ever devised will find its legitimate place in surgery.

The method which I propose to govern the management of clubfoot, requiring operative work, is this:

1. Exclude all cases which, by manipulation or force, can immediately or in a reasonable length of time, say a few weeks, be cured; then the following rule should be followed:

2. Cut the contracted parts as they first offer resistance, cutting in the order of those parts which first contracted when the deformity was produced, beginning with the tendo-achillis open.

3. The shortened inner side of the foot and short skin indicates the operation.

The operator will then proceed, after strong manipulation or force is applied with a clubfoot machine or with the hands (see Figs. 11 and 12), to divide subcutaneously, first the tendo-achillis. If the skin is not short, subcutaneous tenotomy in the sole of the foot will usually suffice. If the skin is short, an open incision one-fourth the distance across the foot should be made, beginning directly in front of the inner malleolus, and carrying down to the inner side of the astragalus (see Fig. 6). Through this incision the following tissues can be cut, if they offer strong resistance, in the order given: (a) Tenotomy of tibialis posticus (see Fig. 3); (b) division of abductor pollicis (see Fig. 4); (c) division of plantar fascia through the wound; (d) division of flexor brevis muscle; (e) division of long flexors; (f) division of deltoid ligament, all its branches (see Fig. 7); (g) peroneus longus—posterior ligament.

4. Linear osteotomy through the neck of the astragalus (see Fig. 8).

5. Resection of a wedged piece of bone from the body of the os calcis, the point meeting the linear osteotomy through the neck of the astragalus. The foot will now swing to a straight position (Fig. 8).

This method of osteotomy is a correction of my former paper, in which the cuneiform section was taken from the cuboid bone.

AN OBSCURE CASE OF HYSTERIA WITH ASSOCIATED RIGHT MYDRIASIS AND AMBLYOPIA AND LEFT MYOSIS.

BY

H. A. HARE, M.D.,
of Philadelphia.

Professor of Therapeutics in the Jefferson Medical College; Physician to the Jefferson College Hospital.

There are no cases which are more apt to puzzle the physician than those which present hysterical symptoms closely aping true organic disease, particularly if the ordinary signs of hysteria are absent and there is a history of injury which has been sufficiently severe in type to be capable of resulting in the changes from normal apparently present. I desire to report the following case because it was of this variety and also because it presented certain symptoms of a hysterical character not commonly met even in those who present this most varied clinical picture. There was nothing about the patient to suggest hysteria in the sense of the hysterical facies and manner; she seemed to suffer genuine pain and presented a

history which while it teems with hysterical signs as one looks back at it, seemed even more full of traumatism and organic disease as the history was gathered from herself and her friends. There can be no doubt that it is one of those cases so well described as hysteria superimposed on traumatism.

The patient is a white woman of 33 years, referred to me by my friend Dr. B. B. Levingood; a native of Pennsylvania, unmarried, with living healthy parents and 2 brothers and 1 sister, all of whom are in good health save that 1 brother has writer's cramp. She menstruated first at 11 years of age; then caught cold and did not menstruate again till 14. She had the usual diseases of childhood—measles, whooping cough, diphtheria (twice) and scarlet fever (at 15 years). She did not recover from the effects of the scarlet fever for 2 months, during which time she was confined to bed. She went out into snow while the eruption was on her. During that time she had much pain in right side and lower axillary region and in the lumbar region. After this period of 2 months she got out of bed, but has not been entirely well since, having had attacks at irregular intervals—about 2 weeks or more—of pain located as above noted, and this pain has been at times most severe and excruciating, causing her to become "black in the face." This pain radiated downward from the left renal area toward the hypogastrium. The attacks varied in length and intensity and were controlled somewhat by morphin, which was given hypodermatically 3 to 8 times per day for many weeks. The attacks came on very suddenly and without warning, and were always on the left side. After these paroxysms, stones, white, and usually about the size of grains of buckwheat, were usually found in stools. On one occasion a stone the size of a cherry was found. During a period of 5 days preceding discovery of this stone the patient was unable to move arms, legs or body, and vision and hearing were imperfect, though she was not in great pain, this being probably an hysterical state. After this her general health was poor for some time, and she had a bad attack of inflammatory rheumatism, being in bed 6 weeks. She gradually recovered from this attack but the pains in the left loin, which for a time were relieved, returned, the attacks of paroxysmal pain began again, and she was in bed for 9 months, during which time she had no menstrual periods but vomited blood at menstrual periods, which in her case was always 6 weeks. During the 5 succeeding years she had several attacks of inflammatory rheumatism, pneumonia of left lung, malarial fever, 2 attacks of intermittent fever with regular chills (tertian), also "falling of womb," from which she suffered intensely for a long while, and which was treated and corrected.

Eleven years ago while writing she found her sight deficient and discovered that one eye was entirely blind. Oculists, she says, told her she had "paralysis of the optic nerve." For the past 4 years the pupil of the left eye has been tightly contracted but the vision in that eye is better than before. The right pupil is widely dilated, giving so odd an appearance that she is in the habit of dropping eserine into that eye each day to make it myotic.

After the period of 5 years above referred to she was comparatively well for 2 years and able to be on the go nearly all the time. On April 15, 1896, she fell violently over a loose plank in a board-walk, and received a twist at the waist, after which there was a lump about the size of a lemon in her left side (not definitely located) and ecchymosis from the knee to the axilla. She was very sick and weak for a half hour, but then resumed household duties for 3 weeks. She then had an attack of bloody purging preceded by nausea and vomiting, after which the lump disappeared. Soon after soft bodies were found in her stools which a doctor pronounced gallstones, and which were very numerous. During 24 hours she "fainted 27 times" although not in great pain. She had paroxysmal attacks of pain at intervals since till July last, when she had the last one. Two years ago menstruation stopped and has not occurred since, but she has passed "bloody corruption" through bowels, and has hematuria. The hematuria first recurred at regular intervals of 6 weeks but since then irregularly. During this time she has had intense cramps in lower abdomen, the left hip and

thigh. An examination of her urine showed no blood macroscopically, but red blood-cells under the microscope on two occasions.

She has been examined under ether for genital trouble but does not know result. At another time when not under ether she was told that both ovaries were diseased and the uterus flexed. Since July she has had repeated swelling of abdomen and limbs, especially lower limbs, lasting 1 to 3 days.

When the patient came under my care December 2, 1900, she had been in bed nearly all the time since the previous July, and was suffering with severe pain in the back and left flank. The patient stated that her digestion was very good. She gives a history, however, of having had fearful attacks of vomiting in which she ejected green, yellow and black material. Her bowels were constipated when she was first seen but she had had much diarrhea.

An examination of her blood showed hemoglobin, 52%; red cells, 2,190,000; leukocytes, 9,400.

A physical examination of her right side showed that it was impossible for her to completely extend her left leg, the knee always remaining slightly flexed, and any attempt at straightening it caused elevation of the pelvis and severe pain. She could not bear any weight on the left leg and could not stand, unless supported by a nurse on either side upon whom she threw nearly all her weight, because standing on the right leg hurt her lumbar spine. At the level of the left kidney there was distinct bulging and slight fluctuation with exquisite tenderness. An eminent surgeon saw her with me and declined operation, as he did not think that there was any local trouble which could be removed by operative measures. His diagnosis was that she had had syphilis with parasymphilitic lesions which neither operation or mercury would benefit. This view seemed to him confirmed by numerous scars on the forearms and legs, which later proved to be due to hypodermic injections. A few days later another surgeon saw her with me, and the result of his examination was the following notes: There is present an abnormal fulness in the left loin where there is great tenderness. The spine is tender in the lumbar region, and there is both superficial and deep tenderness in the swollen region. The tenderness extends anteriorly in front of the iliac crest, and pain is caused by flexion of the left thigh upon the abdomen. The hip joint is not involved; neither are the vertebrae.

There was at this time constant pain with paroxysmal exacerbations, which caused her to double up and bury her head in the pillow. A skiagraph was taken with no result. She was quieted only by morphia in very large doses.

The history of a fall followed later by the discharge of pus and blood from the rectum on two occasions when the pain was particularly severe, led us to suspect a perirenal abscess which had ruptured into the colon, and this seemed the more likely by reason of the frequent appearance of blood in the urine. The other possibility considered was a kidney stone.

On December 17, lumbar nephrotomy was performed. The kidney was brought out into the wound and incised but no pus or stone was found, and a probe was passed readily into ureter. The kidney was bound down by moderate adhesions. The incision was closed with tube drainage. The erector spina muscle was severed to the extent of 2 inches during operation, and later sutured with catgut. The patient reacted well but suffered a good deal of pain, for some days requiring morphin for relief and a capsule of antipyrin and chloretone. There was for a number of days considerable blood in the urine.

On January 5, she began to complain of a headache, especially around the left eye, and nausea. She stated that as this was her only good eye she was alarmed at the loss of vision, and that there was a halo about objects. I therefore asked Dr. de Schweinitz to see her with me, and he kindly made an examination which showed that

the pain was not connected with any organic change in the eye.

Dr. Spiller then saw the case with me, and the result of our examination was as follows: Her power of smell was slightly impaired equilaterally, and the power of taste in the tongue was also markedly impaired, but there was no hemianesthesia of the conjunctiva of the arms and body. The temperature-sense in the upper and lower extremities was normal and the kneejerks were exaggerated with a tendency to repetition. The Babinski reflex was bizarre in character and was followed by an imperfect clonus of many muscles of the lower limb.

Because of the continued inability to use the left limb without great pain in the pelvis, thigh and psoas, and iliacus muscles, Dr. Hearn carefully examined her at my request but notwithstanding the fact that she seemed to suffer excruciating pain when the leg was moved, nothing pathologic was to be found. In order to make the case perfectly clear and exclude the possibility of an organic lesion in the pelvic organs, Dr. George E. Shoemaker examined the patient with entirely negative results.

[TO BE CONTINUED.]

CARCINOMA OF PYLORUS.

SECONDARY TO ROUND ULCER; PERFORATION; RESECTION OF PYLORUS; RECOVERY.

BY

FRANK BILLINGS, M.D.,
of Chicago, Ill.

Zeuker believes that most cases of cancer of the stomach originate from an ulcer base. Lebert states that 9% of cancers of the stomach grow from an antecedent ulcer or ulcer scar. Rosenheim places the percentage at 6. Hemmeter¹ quotes Kollmann's² 14 cases, in which ulcer preceded cancer, and adds that up to the present time 14 other cases have been reported. Ulcer of the stomach or evidences of the previous existence of ulcer is so commonly found in the dead house³ that it is not improbable that Zeuker is correct in the statement quoted above. The following case presents many interesting points:

A. T., male, aged 28, married, a shoe laster, German-American, came to me for examination on May 21, 1900. A paternal uncle died of "tumor" of the abdomen. Otherwise the family history was negative. He has used alcoholic drinks moderately, usually drinking beer, and has smoked daily, in moderation. He denies syphilis, but had an attack of gonorrhoea several years ago, from which a perfect recovery was made. He has never been very ill until the present trouble began, but had the ordinary diseases of childhood. He has worked hard as a shoe laster for several years, and has taken all sorts of food, usually, however, a plain mixed substantial diet of meats, bread, potato, etc.

For three years he suffered from attacks of indigestion characterized by epigastric fulness, sense of weight, bloating of abdomen, eructations of gas and constipation. The attacks became more frequent, and finally there was some pain in the epigastrium after a full meal and the stomach region became tender to the touch, and the pressure of the clothing over the epigastrium was painful. In November, 1899, vomiting occurred about once a week until February, 1900, when the attacks of

¹ Dis. of the Stomach, p. 560.

² Berlin Klin. Wochenschr., 1891, 5 and 6.

³ Welch 5%.

emesis became more frequent, and he vomited at least once a day. The vomiting usually occurred at night, and consisted of a large amount of watery, dark colored, acid fluid. The vomitus usually contained particles of food, and he often recognized food which had been ingested so long as 48 hours before.

The pain became more severe with the advent of vomiting, and it was frequently severe before the vomiting, and often was relieved by emptying the stomach. No fresh blood has been noticed, but a coffee-ground like material has been vomited. The bowels have been constipated, and at times the stools have been black and offensive. Recently pain in the epigastrium has been almost continuous, and has been aggravated by taking food. The appetite is failing. He has lost steadily in weight from 156 pounds maximum 3 years ago to 142 pounds in November, 1899, to 126 pounds at the present time. He has continued at work until November in spite of the loss of flesh and strength and the inability to take and retain adequate nourishment.

Examination showed a large frame and emaciated body. The skin had a dirty, muddy, and pale hue. The tongue large, indented, flabby and coated with a whitish fur. Teeth well preserved, breath offensive.

The chest was negative to examination and there were no

MUCOUS SURFACE OF PYLORIC MASS

- (a) Seat and bottom of round ulcer.
 (b) Perforation.
 (c) Portion removed for microscopic examination.

glandular enlargements. The radial pulse was small, with low-tension and beat 68 per minute. The temperature was 98.8° F. The abdomen was moderately round, not tympanitic, and the abdominal muscles thin and flaccid. The greater curvature of the stomach could be easily seen and peristaltic waves could be elicited in the stomach wall and seen to pass from left to right. A mass, tender and passively movable could be felt in the epigastrium, extending to the right costal border in the usual position of the pylorus. Stomach splashing was very marked.

Examination of the rectum was negative in result. The sigmoid appeared full and resistant.

A stomach tube was easily inserted and the gastric contents were expressed. The patient had taken a glass of milk 2½ hours before coming to the office.

The gastric contents showed:

A darkish fluid with a rancid odor.

Free HCl. 0.146.

Total acidity: 0.430.

Lactic acid: a trace present.

Microscopically: granules of starch (no starch taken for 20 hours, fat drops and blood pigment (i. e.: hematin crystals).

Exactly 2,000 cc. of water was put into the stomach and all

of it was withdrawn. This amount of water did not measure the full capacity of the stomach, because it was evident at the time that a good deal more water could have been added without causing pain, but the possible risk of producing some harm made us desist.

The urine (single specimen) gave a specific gravity of 1.023, was alkaline, turbid, and contained no albumin, no sugar, no blood and no casts.

The blood-examination gave: Hemoglobin 56 %; red cells, 3,200,000; white cells, 11,400.

A diagnosis of pyloric stenosis from gastric ulcer was made.

On May 22, one day later, the stomach was washed once more after a test meal. The findings were practically the same as those recorded above.

The patient was sent to the Presbyterian Hospital for observation and treatment. He was placed in bed. Nutrient enemata of peptonized milk and egg were given every 4 hours. A colonic flushing with normal salt solution was used once a day. The rectum was made tolerant by the use, twice a day, of a suppository containing a half grain of opium. The patient was allowed occasional sips of hot water, but nothing else was taken into the stomach.

From the time of admission to the hospital on May 24 to 12 o'clock noon on May 28, the patient was comfortable and happy. The epigastric pain entirely disappeared. There was no nausea and no vomiting. The temperature remained normal. The pulse was relatively slow, soft and small.

At noon, May 28, the patient complained to the nurse of a moderately severe epigastric pain. The house physician, Dr. Russell, could not detect any alteration in pulse or temperature. An hour later, however, the temperature in the rectum was 97.6°, the pulse 85, the extremities moderately cold and sweating, the epigastrium more tender, but there was no spasm of the abdominal muscles.

I saw the patient at this time and ordered an eighth of a grain of morphin hypodermically. Hot applications were made to the extremities and an ice coil was applied to the epigastrium.

The morphin gave relief and the patient remained quiet and undisturbed until 8 p.m. when Dr. Russell noted the temperature was rising to 102° F., the pulse to 100, small and rather tense, and that the abdominal muscles were rigid. The liver dulness in the mammary line was obliterated. I visited the patient and found the condition noted. Dr. Arthur Dean Bevan was called and a diagnosis of perforation of the stomach was concurred in.

The patient was rapidly prepared for operation, and at 12 o'clock midnight, 12 hours after the first symptoms, Dr. Bevan made an abdominal section.

A tumor-like mass occupied the pylorus. A perforation had occurred in the anterior aspect of the pylorus. The lymphatic glands about the pylorus, duodenum and hepatic vessels were much enlarged. The walls of the perforation, comprising the tumor mass, were friable, and closure of the perforation was not deemed possible. The large mass at the pylorus and the presence of many enlarged glands made the diagnosis of carcinoma probable. A curative operation did not appear possible. Therefore Dr. Bevan performed a rapid resection of the pylorus in a most skilful manner.

A mass about 3 inches long was removed. The duodenal and gastric stumps were closed and then a gastroenterostomy was performed with a Murphy button.

The photograph of the mass excised gives a good idea of the size of the perforation and of the carcinomatous infiltration. It shows the partially healed round ulcer of characteristic form and shape. A microscopic examination revealed histologically a typical scirrhous carcinoma.

The patient made a phenomenal and uninterrupted recovery from the operation, and by July 1 was able to leave the hospital. The appetite was good, digestion excellent, and there was a steady gain in strength and weight.

The improvement continued until December, 1900. Since then he complains of indigestion, of epigastric fullness and pain after food and of failing appetite. The weight and strength are decreasing. Nodules can be felt in the liver and there is every evidence of carcinomatous involvement of other abdominal organs.

The interesting points to be noted in the case are:

1. The age of the patient—28 years.
2. The presence of much HCl in the stomach contents 2 hours after a small amount of milk was taken. HCl is present often in carcinoma of the stomach secondary to ulcer, but not usually in the amount present in this case.
3. Perforation of the stomach with an opening the size of an ordinary lead pencil, caused but little discomfort and only slight constitutional disturbance for 8 hours.
4. Recovery after a formidable operation made hastily at night.

PUERPERAL SEPSIS: ITS PREVENTION AND METHODS OF TREATMENT.

BY

E. E. MONTGOMERY, M.D.,
of Philadelphia.

Professor of Gynecology, Jefferson Medical College; Gynecologist to Jefferson Medical College Hospital; Gynecologist and President of Medical Staff, St. Joseph's Hospital, etc.

That medicine is a progressive science is abundantly demonstrated by a comparison of our present position upon this subject with the views held but a little more than a quarter of a century since. Then the exquisitely written work of Fordyce Barker upon puerperal diseases was a recognized authority, and this substantially asserts there is a special disorder peculiar to puerperal women appropriately named *puerperal fever*, the symptoms of which are essential, and not the consequence of local lesions, a disease as distinct as typhus fever, typhoid fever or relapsing fever.

In the spring of 1875, as an Interne of the Philadelphia Hospital, I completed my term in the surgical wards where a number of cases of erysipelas were under my care and assumed charge of the obstetrical wards. My advent was followed by the usual spring epidemic of puerperal fever. Some five years later while serving as visiting obstetrician to the same wards, in searching for the cause of another sporadic epidemic of this disease, it was found that the drainage of the entire department terminated in a cellar well and not in a sewer. The well had become filled and the sewage was overflowing the cellar. In the light of our present knowledge, it is surprising that under the conditions of that day any cases should have escaped without a fatal visitation.

The now recognized similarity of this so-called disease with surgical fever or sepsis, was already dawning upon the medical horizon. Simpson and Holmes had both asserted its contagious character and the former had compared the changes upon the surface of the uterus with those which frequently took place upon the stump of the amputated limb. Hervieux and Schroeder had already denied the existence of puerperal disease as a distinct entity and the former ascribed its existence to a peculiar

miasm which is similar to that which engenders erysipelas, hospital gangrene, etc., in camps, while the latter ascribed it to poisoning from septic material from the genital organs. Today every tyro in the profession recognizes sepsis as the cause of the hydra-headed manifestation formerly designated as puerperal fever, and the majority of the laity is so well acquainted with its origin as to render miserable the life of the physician in whose practice the disease occurs.

Naturally, under the old regime midwifery hospitals were hot-beds of pestilence, and the mortality in all such institutions was excessive. Thus, Hervieux quotes 247 cases of puerperal peritonitis in one hospital. The recognition of microorganisms as the productive factor and the acceptance of surgical asepsis and antisepsis in the treatment of parturient women has so revolutionized results that from being a place to be avoided the modern obstetric hospital presents cases of sepsis less frequently than is found in general practice. The existence of sepsis in a well regulated lying-in hospital is now very rare and it is invariably accepted as evidence that some one has blundered. Such results demonstrate that the disease is avoidable. Our city mortality lists, and the frequent necessity for operation upon women for pelvic lesions directly traceable to puerperal diseases, demonstrate that many of our general practitioners are not thoroughly alert to the possible development of this disease and its subsequent serious consequences.

I do not purpose to enter upon the consideration of the pathology of puerperal sepsis, nor to any extent upon the discussion of its symptoms, but a very superficial observation of its manifestations and serious results even when the patient survives, renders it evident that the most important feature in its treatment is prevention. One would suppose the knowledge that the disease is preventable would invariably lead to the employment of the measures which ensure against its development, but to accomplish such practice requires much additional education of the profession as well as of the masses.

This education is rendered difficult because the danger is so intangible as to be unrecognized until its manifestations are present. The difference in vulnerability of a number of individuals is so variable that possibly only a few are susceptible to the infection or unable readily to eliminate it when invasion has occurred. The measures to insure against its occurrence require painstaking preparation upon the part of the physician, nurse and patient.

It requires such recognition of and belief in the possibility of infection as will keep the physician constantly on the alert to avoid carrying disease himself or to prevent the patient or her attendants from serving as avenues for the spread of contagion. I am quite aware that to carry out the suggestions I shall make for the avoidance of sepsis will impose a grievous burden upon him who practices obstetrics, but will not the assurance of work well done, the freedom from avoidable disease and death in his clientele more than compensate him?

The admission that sepsis in the puerperal woman is similar to that which occurs in wounds otherwise produced renders it evident that the more closely we can apply surgical measures to obstetrics the more gratifying will be the results.

1. It becomes evident that the event must be anticipated and preparations made to secure, if possible, a clean room and a clean bed. The clothing, bedding, and napkins should be as nearly surgically sterile as attainable. The old practice of employing the clothing awaiting the laundry about the patient should be discarded. When possible the bowels should have been swept out by a purgative and the lower bowel emptied by an enema. The external parts should have been thoroughly washed with soap and hot water. When there is any reason to suspect previous infectious disease the vagina should be scrubbed with a solution of tincture of green soap ℥ij, creolin ℥ij, to water 0ij, and afterward mopped with alcohol or a solution of formalin. A pad wet with sublimate solution should be kept over the vulva.

2. The physician and nurse should wash their hands and arms with hot water and soap, using the nail brush freely and carefully cleansing the nails. The fingers should then be scrubbed with gauze wet with a solution of sublimate in alcohol (1-500); a basin of sublimate solution (aq. 1-2,000) should be alongside the bed, and in this the hands should be immersed before every examination or manipulation. When the physician has recently been in attendance upon cases of septic or other infection he should change his clothing and in addition to the employment of the methods of cleansing designated, should wear rubber gloves.

3. The diagnosis of the size and roominess of the pelvis should have been secured at a preliminary examination prior to the occurrence of the labor, and the position and presentation of the fetus recognized by external and internal palpation so that digital examination during the course of labor is done only to observe its progress, and then always with the precautions advised.

4. The labor should be conducted in such a manner as to secure the least possible injury. Instrumental interference is desirable when delay renders it evident the patient is unable to complete the work unaided. Long pressure of an impacted head in causing contusion and loss of tissue vitality is more baneful than timely interference.

5. Labor should be terminated by the entire removal of placenta and secundines. Contraction of the uterus must be secured to avoid the retention of clots. When instrumental delivery has occurred, or it has been necessary to exercise manual investigation of the uterine cavity following delivery, the uterus should be irrigated with a quart of formalin solution (1-1500). If this solution is employed at a temperature of 110° to 115°F. it serves as a hemostatic and promotes contraction of the organ. The vagina and vulva should be carefully examined for injuries and lacerations, which should be immediately repaired with chromicised catgut suture. Occasionally it may be necessary to insert sutures in the cervix to control bleeding when large vessels have been torn. It is usually admitted that the condition of the cervix is not favorable for the primary repair of its lacerations.

6. In the after treatment the nurse must be impressed with the importance of the most rigid personal antisepsis. She should not be permitted to proceed to the use of the catheter or apply local measures without care-

ful cleansing of the hands. It was my misfortune a few years ago to see in consultation several cases of sepsis which had followed in the wake of a single nurse.

Among the poorer classes the attendant frequently has the household duties to manage as well as the care of the patient, and when she proceeds from the handling of uncooked meat to the manipulation of the patient without special precautions the infrequent occurrence of sepsis is only explainable upon the recognized greater immunity of such patients to the infection.

Not every woman who has an elevation of temperature following labor is necessarily septic, for the parturient state does not render her immune to the ordinary ills of mankind, but its existence should require close observation and careful investigation as to its cause. Blood-examination should be resorted to, to exclude typhoid fever and malarial conditions.

It should not be forgotten that septic infection may enter through a fissure of the nipple as well as by the genital canal. Sepsis may be simulated by putrid intoxication resulting from the decomposition of retained clots or secundines. This condition is recognized by digital examination and the removal of the offending material.

When careful examination excludes other causes and digital exploration reveals an empty uterus, the presence of high temperature justifies the suspicion of sepsis.

TREATMENT.—When we admit that the Protean manifestations of this disease are due to the influence of microorganisms, it becomes evident that the treatment should consist in the employment of such measures as will, first, promote the resistance of the individual to their baneful effect, and second, will aid in their elimination. In our present knowledge it is advisable to institute measures directed simultaneously to the attainment of both these objects. The intestinal canal should be swept out and kept open by saline purgation, the nutrition sustained by readily digested food, the temperature moderated by sponging, cold packs, and the local application of ice-bags.

Heart depressants, as the coal-tar preparations, to reduce temperature, should be employed with the greatest caution, and their use should not be prolonged. The tendency is to rapid asthenia, and the flagging powers should be sustained by strychnin, digitalin and atropin, preferably given hypodermically. This tendency may also be combated by the alcoholic preparations, but not so early nor in so large doses as usually administered.

Upon the efficacy of the employment of the antistreptococcic serum there is much diversity of opinion. Much difficulty necessarily exists in determining the particular organism responsible for the infection, and it can readily be recognized that the serum would not be efficacious in affording relief against other forms of bacteria.

In my own experience when the associated erysipelatous manifestations render it evident that the streptococcus was the probable microorganism to be combated, the serum has been exceedingly beneficial. In its employment, care should be exercised to secure fresh serum. This seems to me an explanation for the failure and even adverse results of the Marmorek serum in this country.

The quantity of serum to be employed, and the frequency of its administration will depend upon the

virulence of the attack; 10 cc. to 30 cc. can be given twice daily as the conditions demand.

OPERATIVE PROCEDURES.—The operative procedures may be palliative, or radical.

The procedure most frequently employed is that of curetment. While the use of the curet is indicated in cases of sapremia or putrid intoxication, its employment when the uterus is empty as in cases of sepsis, must be considered of doubtful propriety. The microorganisms have already passed beyond the structures which would be removed by the instrument. In all cases, however, I believe irrigation of the uterus with hot normal salt solution, or formalin solution, will be advantageous in disinfecting and removing decomposing detritus which would otherwise add to the elevation of temperature and increase the labor of elimination through its absorption.

Of the radical procedures, hysterectomy is most frequently advised, but the mere existence of sepsis does not indicate hysterectomy. While it is true that the uterus is most frequently the avenue through which infection enters, its removal can only be considered advisable when the organ is the seat of localized accumulations which serve as secondary foci for the spread of the disease. The infection may enter through lesions of the vulva and vagina, involving the bloodvessels, lymphatics, and cellular tissue, without the uterus being diseased. Some years ago, I was in consultation with three other physicians over a woman who had undergone an extensive laceration of the pelvic floor as well as of the cervix. Hysterectomy had been advised. Examination led me to believe that the febrile symptoms were induced by the retention of decomposing accumulations caused by perineal sutures. Their removal and frequent irrigation of the surface resulted in subsidence of the symptoms and the recovery of the patient.

Not infrequently the infection passes through the uterine cavity to the tube or an ovary, while the uterus escapes with but slight involvement if any.

In 1892 I operated upon a woman in this city who had been confined 2 weeks before, from whom the left tube and ovary were removed for a pus-collection. This patient has since given birth to a child. A patient of Dr. McCormick, of Williamsport, developed a high temperature which subsided following curetment and uterine irrigation. Three weeks later a persistent return of the high temperature in the absence of any recognizable cause led to an incision of the abdomen for exploration. No disease of the uterus was recognizable, no adhesions were found, but the left ovary was the size of an unhulled walnut and was covered upon one side by a flake of greenish exudate. After its removal the ovary was found to contain a half-ounce of greenish yellow pus. The patient had an uninterrupted convalescence.

While, by citing these cases I wish to demonstrate that hysterectomy is not the operation *per se*, I by no means desire to disparage its importance in selected cases.

When by the persistent enlargement of the organ, marked tenderness over its surface, and the maintenance of septic symptoms it is evident the uterus is the seat of disease, it should be removed even though the condition of the patient may seem desperate.

Dr. D. P. Rettew, of Coatesville, asked me to see a woman in the city hospital who had been confined 4 weeks previously. A prominent gynecologist a week before had declined operation. Although she had a temperature of 104° and a pulse of over 120, I felt that an operative procedure afforded her the only hope. A pus-collection occupied the left tube and side of the uterus. Hysterectomy was done. In endeavoring to remove a mass of exudate over the bladder the latter organ was ruptured, allowing a pint of urine to escape. The cavity was irrigated and gauze packed over the bladder opening, the tissues being too friable for sutures. A catheter was retained for 10 days and the patient recovered.

The treatment of sepsis may be summarized as follows:

1. Prevention by the exercise of the most careful asepsis and antisepsis.
2. The accurate study of each puerperal case to recognize the cause of high temperature and eliminate other factors than sepsis.
3. The maintenance of the vital forces and the promotion of elimination by the administration of diet and remedies to meet indications.
4. The employment of serum injections when streptococcal infection can be recognized or justifiably inferred.
5. Resort to operative procedures must be governed by the local manifestations. Curetment is rarely justifiable in pure sepsis. Peritonitis or localized cellular inflammation in the pelvis should indicate vaginal incision and drainage. Hysterectomy is indicated whenever the uterus can be recognized as the seat of localized collections. When the ovary or tube only is involved, it should be removed. The recognition of a pus-collection should indicate its evacuation or the extirpation of the organ in which it is situated.
6. The continuance of symptoms of sepsis when local manifestations are not recognized will justify incision to determine the presence of secondary sources of infection.

ON THE ANATOMY OF THE RENAL VESSELS AND PELVIS OF THE KIDNEY IN RELATION TO DIGITAL EXPLORATION OF THAT ORGAN IN THE OPERATION OF NEPHROTOMY.*

BY

WILLIAM KEILLER, F.R.C.S., Ed.,
of Galveston, Texas.

Professor of Anatomy, Medical Department, University of Texas.

It is the custom of the surgeon in operating for renal calculus, should he fail to feel a stone in the extrarenal portion of the pelvis of the kidney, to puncture the organ with a needle in the hope of striking the stone. Should he not by this means find the stone, he does not hesitate to make an incision into the convex border and to explore the whole pelvis and infundibula with his finger. It is, at first thought, astonishing that in pursuing this bold course, he meets only venous hemorrhage, which, though profuse, is easily controlled; and that the kidney may be explored, a stone or several of them

*Read by Abstract before the Society of American Anatomists, December, 1899, and before the Texas State Med. Assn., April, 1900.

extracted, the organ stitched up with catgut and that no after-hemorrhage or leaking of urine take place. On the other hand, I have seen the kidney cut into on the dorsal surface with disastrous results.

As an anatomist I had difficulty in understanding how this could be done, for the examination of the kidney by the ordinary method of dividing it vertically into

Fig. 1. Diagrammatic cross section of the kidney. A. Line of safety in opening kidney. B. Calyx. C. Infundibula. D. Fat of the renal sinus continuous with the perirenal fat. E. Renal artery dividing outside the renal sinus. F. Ureter. G. Renal vein. H. Renal vein, dividing within the renal sinus.

halves did not clear up the difficulty. This year a method of dissecting the vessels and ureter out of the kidney substance suggested itself to me, which made such unlooked for revelations that I venture to lay the dissection before my professional brethren as adding something to our anatomic knowledge, and putting a hitherto empiric operation upon a sound anatomic basis.

The subjects in my dissecting-room are first preserved by being injected slowly with 10 gallons of a fluid containing 2.5% formalin, 2.5% carbolic acid and 10% glycerin. Such subjects keep indefinitely with very little care, are pleasant to dissect, and demonstrate many points in visceral anatomy hitherto very imperfectly understood by students supplied with bodies preserved by other methods. At any time after 1 week has elapsed from the date of the preservative injection the arteries are filled with a hot mass of gelatin and lead chromate, which sets when cold and is permanently solidified by the action of the formalin, and which is so perfect that in many cases the finest arterial anastomoses are made perfectly evident. In successful cases the kidneys are beautifully injected, sometimes even with capillary minuteness. It occurred to me to pick away the renal substance from the vessels with my forceps and thus trace the arteries into the interior of the organ, and

the pursuit of this method brings out a series of anatomic facts which I have not seen sufficiently described.

Examination of a number of kidneys shows that while at even a short distance from the renal pelvis the renal vein lies in front of the artery, and the artery in front of the ureter, so that these structures lie in the order of vein, artery, ureter, from before backwards, yet at a variable distance from the pelvis, usually about an inch (see Fig. 1), the artery divides into a dorsal and a ventral trunk. These pass respectively to the dorsal and ventral side of the renal pelvis, and the vein, at first ventral to the trunk of the artery, lies dorsal to its ventral branch, that is between the artery and the pelvis (Fig. 1.). In addition to these, a branch of the artery usually passes to either end of the organ, and one or the other of these, usually the lower, is frequently a separate artery, given off from the aorta some distance below the renal. The lower branch is so often independent as to be called the inferior renal.

The vein does not divide as soon as the artery; but close to or within the hilum gives off 2 or more great trunks in a vertical not a horizontal plane. These first great venous trunks lie wholly in front of (ventral to) the pelvis and infundibula, thus differing very markedly from the arteries which, as I have said, assume at once a ventral and dorsal (anterior and posterior) relation to the pelvis (Fig. 1.).

If now the kidney substance be carefully picked away from the vessels, the arteries will be found to maintain

Fig. 2. Diagram of the vessels of the kidney after the renal parenchyma has been dissected away, and they and the pelvis have been separated into 3 leaves, as described in the text. A. Leaf of dorsal vessels. B. Middle leaf of the infundibula and pelvis. C. Renal artery. D. Renal vein. E. Leaf of ventral vessels turned aside. F. Ureter.

throughout the whole kidney substance a ventral and dorsal relation respectively to the pelvis and infundibula, so that when the dissection is finished the kidney can be split up as it were into 3 leaves, a ventral leaf consisting of vessels, a dorsal leaf consisting of vessels, and between these a leaf composed of pelvis and infundibula (Fig. 2).

Between these leaves, and uniting them somewhat loosely, is fat-laden areolar tissue. The veins at first all lie between the ventral arteries and the pelvis (Fig. 1), and from these large trunks, each as large as the superficial radial or median vein at the wrist, join the arteries which supply the dorsal segment of the organ, some of these

crossing proximal to the main divisions of the pelvis some distal to the division of the pelvis into infundibula that is crossing between the infundibula or even between the calyces. As is well known the renal arteries are terminal; that is there is no anastomosis between the branches, hence no anastomosis takes place between the arteries which lie dorsal to, and those which lie ventral to the pelvis and infundibula. This arrangement explains why a surgeon can make an incision into the convex border of the kidney and with his finger split it up almost from end to end without causing any marked

arterial hemorrhage. It will be seen, however, that several large veins will be cut or torn across, hence the free venous bleeding. But the pressure in the inferior vena cava being almost nil, such hemorrhage is easily controlled by pressure and suturing.

On the other hand, a short vertical cut on the dorsal flat surface of the kidney will sever one or more large arterial trunks. Should an incision be necessary on the dorsal surface, it should radiate toward the hilum, and not approach too near the hilum lest one of the larger vertical trunks of the artery be injured. It is noteworthy that more particular examination of the renal vessel shows that the artery in addition to its dorsal and ventral branch gives off what we may describe as a suprapelvic and an infrapelvic branch to the upper and lower ends of the organ respectively, and this renders resection of either end, or even wedged-shaped resection of the middle of the kidney, say for a tumor, a feasible operation. This has been done experimentally on dogs by Bradford, the remaining part functioning satisfactorily. I think it could be most safely done by cutting through the renal substance with a strong catgut ligature. Such a ligature would cut through the parenchyma but compress the vessels. This method has been used in removing segments of the liver.

While on the subject of the renal vessels I desire to call attention to the frequent occurrence and occasional large size of an inferior renal artery. It may arise from the aorta over an inch lower down than the renal, and be as large as the ulnar artery at the wrist. It should certainly be looked for in a nephrectomy and if found, ligated separately. No vein accompanies it. While I have not any exact data to go upon I should judge that a well marked inferior renal artery occurs in at least 10% of all cases. The renal artery may also be replaced by a third, fourth, or fifth vessel, arising anywhere between

its normal origin on a level with the first lumbar vertebra and the internal iliac.

Let us now glance at the pelvis and infundibulum. In his incomparable anatomic notes in his "Manual of Operative Surgery," Mr. Treves says that the "calyces are too narrow to admit of the introduction of a finger for exploration." Yet surgeons lead one to believe that it is possible to explore the interior of the infundibula and pelvis by incision through the convex border. On examination of specimens as to shape and actual size of the radicals of the ureter, you will notice that the more branched specimens are the more usual types (Figs. 3, 4, 5). It will also be seen at once that no finger can be introduced through the normal infundibula into the pelvis of the kidney. At the hilum the capsule of the kidney is folded round the parenchyma and thus bounds a large sinus about 1 inch in depth and 2 inches long. Here the capsule lining the sinus is pierced by the branches of the renal vessels and blends with them and the calyces. The infundibula and larger vessels are here imbedded in fat. A finger introduced through a cut in the convex border will probably enter one calyx, split to a variable extent the corresponding infundibulum and thus enter the renal sinus, and may palpate the outside of the remaining calyces, the infundibula, and the pelvis, and thus detect a stone, which may be then removed by cutting into the containing infundibulum. It must be very rarely possible to pass a probe from such an exploratory incision into the ureter. Any attempt to do so will only thrust the probe into the perirenal connective tissue. It

Fig. 3.—Pelvis, infundibula, and calyces of the kidney, actual size

Fig. 4.—Pelvis, infundibula, and calyces of kidney, actual size

Fig. 5.—Pelvis, infundibula, and calyces of kidney, actual size

must be remembered that a pathologically dilated pelvis may nevertheless be easily entered by the incision under consideration.

Before closing let me glance at the technic of renal exploration for calculus. Having got the kidney well into the usual dorsal wound and steadied there with 2

fingers of the left hand on its anterior surface, the whole surface of the organ should be palpated, then the pelvis may be examined by introducing a finger along the pelvis into the renal sinus, remembering that a large artery lies in your way. Failing to find a stone there and remembering that the more expanded infundibula are on the upper and lower ends of the organ, these ends and finally the center may be explored with a needle. Should a stone be found, an incision along the convex border will be the safer route to it, unless it be very near the surface when an incision radiating towards the hilum may be preferable. Failing to find a stone by puncture, a vertical incision 1 inch long and $\frac{3}{4}$ of an inch deep should be made into the convex border of the kidney, the finger introduced and pushed gently on. It will then lie in the connective tissue of the renal sinus and may be dorsal or ventral to the pelvis. The middle, lower and upper infundibula should be examined in the order named, avoiding as much as possible splitting the ends of the organ, as at either end there is a good deal of interlacing of large vessels. The withdrawal of the exploring finger will be followed by free venous hemorrhage, readily controlled by pressure of the supporting fingers and subsequently by deeply buried catgut sutures through the parenchyma. As considerable damage will be done to at least one infundibulum, the lumbar wound should be packed, as urine may leak out, and an enormous amount of hemorrhage may be completely concealed should the wound be closed.

A RARE FORM OF EXTRAUTERINE PREGNANCY.

BY

BRICE W. GOLDSBOROUGH, M.D.,

Chief of Staff of the Cambridge Hospital, Cambridge, Md.,

AND

THOMAS S. CULLEN, M.B. (TOR.),

Associate Professor of Gynecology in the Johns Hopkins University.

On February 28, 1901, Dr. Goldsborough was called in by Dr. I. N. Tannar of Vienna, Maryland, to see what the doctor supposed to be a case of obscure pregnancy. The patient had 1 child 9 years ago. In April, 1900, she missed her period and since then presented the usual signs of pregnancy; nausea, enlarged breasts, increase in size of the abdominal girth. In August, while lifting some boxes, something suddenly gave way in her left side. This occasioned severe pain and she had to remain in bed until November 1. About the middle of September there was a bloody uterine discharge, and accompanying it was considerable pain and nausea. Subsequently, she had several similar discharges which may have been menstrual periods. During the month of November she was able to be out of bed, but had to return in December. Throughout the entire illness she has had a good appetite, has been fairly well nourished. When seen her temperature was 101.5°; her pulse 140. Immediate removal to the Cambridge Hospital was advised, and on the following day she was driven 23 miles.

On examining the patient under anesthesia the abdomen is seen to be very prominent. There is, however, no bulging in the flanks. The umbilicus is converted into a tumor fully 5 cm. long by 3 cm. broad (Fig. 1). The skin over this appears to be much thinned out and at one point has given way. From this abraded area a chocolate colored fluid is escaping. This is exceedingly offensive. Around the umbilicus the tissue is markedly indurated and pits on pressure. On vaginal examination the cervix is found to be intact, but it is impossible to

outline the uterus. Nothing can be detected laterally. After cleansing the abdomen as far as possible, an incision was made just below the sternum and continued down almost to the pubes. The abdominal cavity proper was not exposed; that is to say, none of the abdominal contents came into view. Filling the cavity was a large quantity of chocolate-colored fluid; a fetus between 6 and 7 months and a large placenta. The placenta was attached low down in the pelvis, was exceedingly friable, but came away without producing any hemorrhage. The walls of the sac were about 4 mm. in thickness and excessively friable. They reminded one very much of granulation-tissue. It is impossible to determine where the pregnancy took place, as the pelvic organs were entirely walled out. It is probable, however, that the uterus ruptured and that the fetus with its membranes intact escaped into the abdominal cavity. The fetal membranes have then become attached to the abdominal wall and to the surrounding structures. After removing the fetus and the placenta, this large sac which extended almost from the sternum to the pubes and laterally filled the entire anterior portion of

Fig. 1.—The drawing of course is somewhat diagrammatic. It represents a longitudinal section of the body. The fetus with the fetal membranes are lying immediately beneath the abdominal wall and are attached anteriorly to the peritoneum almost from the sternum to the pubes. (B.) At the umbilicus the fetal sac bulges into the hernial opening and at the most prominent point this hernial sac has given way, allowing the fluid to escape externally. At A the numerous granulations have formed on the inner surface of the sac. The fetus is well preserved, appears to be about 6 months old and shows slight maceration on the face, on the arms and legs. The site of the placenta is roughly outlined by the dotted lines. The cervix is seen to be normal but on account of the marked distortion, the presence of the abdominal tumor and the oedema it was impossible to outline the uterus or appendages, hence their relation is left hazy. The bladder and rectum are in their normal positions. As will be seen from the drawing a median incision in the abdominal wall would open directly into the sac and in no way involve the general peritoneal cavity.

the abdomen was thoroughly washed out with salt solution and loosely packed with iodoform gauze. The upper half of the incision was closed, the lower half left open to insure thorough drainage. At the time of operation the patient's pulse was 140. The operation occasioned no shock. The anesthetic was given by Dr. John Mace, and assisting the operator were Drs. Brice Goldsborough and Guy Steele.

Following the operation the temperature ranged from normal to 101.5° for the first 4 days, since which time it has shown no elevation. The pulse was weak and irregular for 6 days, but since then has regained its normal tone. The pack was removed on the seventh day with the escape of moderate amount of discharge. A light gauze drain was then inserted. On March 13 the

abdomen was perfectly flat and all evidence of edema had disappeared. On removing the drain there was a slight discharge. On bimannual examination it was now possible to outline the uterus to some extent. The organ was about the size of a 2 months' pregnancy and situated directly behind the pubes. It was slightly movable.

Pathological Report (Gynecological Pathological Number 4,744). The specimen consists of a foetus with its accompanying placenta. The foetus when folded upon itself is 17 cm. in length. The distance from the occiput to the heel is 29 cm. The child is well formed, shows no external abnormality and is a female. There is a moderate quantity of hair but the skin has to a great extent macerated and the pigmented layer is readily peeled off. The umbilical cord appears to be about 8 cm. in length. It shows nothing of interest. The placenta is approximately 16 x 10 x 5 cm. It is very friable. In some places it presents the usual appearance, in others, especially in the depth, the tissue is somewhat homogeneous, is hemorrhagic and suggests breaking down.

Histological examination of sections from various parts of the placenta show that it consists almost entirely of necrotic tissue and canalized fibrin. The contours of the villi are everywhere visible but the nuclei of the epithelial cells as well as those of the stroma of the villi have entirely disappeared. The central portions of numerous villi are partially filled with calcareous plaques. At 1 point are a moderate number of disintegrated polymorphonuclear leukocytes. Otherwise the entire tissue is devoid of nuclei.

This complete necrosis of the placenta accounts for the ease with which it was peeled off and also for the absence of hemorrhage during its removal.

THE EARLY DIAGNOSIS OF INSANITY.*

By

CARLOS F. MACDONALD, A.M., M.D.
of New York City.

Professor of Mental Diseases and Medical Jurisprudence of the University and Bellevue Hospital Medical College, New York; Ex-President of the New York State Commission in Lunacy.

The fact that in a vast majority of cases of insanity the responsibility of recognizing its existence in the first instance devolves upon the family physician, renders the importance of the subject indicated by the title of this paper to the general practitioner at once apparent and furnishes a justification, if one were needed, for its presentation to this society. Moreover, the importance of the subject is amply attested by the fact that insanity is a disease which invades all classes of society and from which no one can claim exemption; that in effect it is more serious and far-reaching and involves a wider range of interests, whether as regards the welfare and happiness of individuals, of families or of communities, than any other malady known to mankind. To the individual it involves during its existence a loss of man's highest attribute, reason, and in a large majority of cases a loss of that priceless boon, personal liberty; it also involves a disturbance or destruction of his social and business relations, a loss of control of his property and affairs, and, if

the disease happens to take an unhappy form, great mental anguish and distress, amounting in many cases to "a living death" which may endure for many years, and finally death itself. To the family it frequently involves great anxiety and distress and in many instances personal danger; also a removal of the loved one from the family circle to the care of strangers with its attendant expense and possible loss of source of income, if the victim happens to be the head of the family; and finally, it involves the stigma which unfortunately and wrongfully still attaches to families known to be tainted with mental disease. To the community it involves the safety of life and property and an enormous expenditure of public funds for provision for the care and treatment of the dependent insane—the State of New York today having in round numbers 22,000 insane persons in custody, with an outlay of \$20,000,000 for hospital plants and equipments, and an annual expenditure of \$5,000,000 for the care and treatment of their inmates.

It has been well said that there is no disease which on its first invasion of the family circle creates a profounder sense of distress and helplessness than that of insanity; nor is there one which is more likely to be mismanaged in the initial stage, the friends of its victim being unable usually to comprehend its importance or even to realize its presence; or realizing it, they are at a loss to know what course to pursue, and in their stress and anxiety they naturally turn to the family physician for advice and assistance. Then too, a considerable proportion of cases, especially among the wealthier classes, have to be treated at home for a time, particularly in the early and most important stage of the disease as regards its curability, while a certain number of cases may properly and safely be treated at home throughout the disease, provided they are in competent medical hands.

It may be said, in passing, that the study of insanity presents nothing that is new or incomprehensible; that its phenomena on the mental side consist largely of modifications of the natural characteristics or tendencies of the individual, whether in the direction of perversion, exaggeration or diminution of those qualities, these modifications being merely the outward expression or symptom complex of diseased conditions, functional or organic, of the brain—conditions which are due, directly or indirectly, to moral or physical causes.

In other words, insanity is a disease or disturbance of the intellectual areas of the brain which is marked by derangement, partial or complete, of the mental faculties; a derangement which manifests itself by a prolonged departure from the methods of thinking, feeling and acting which were usual to the individual when in a state of mental health. From this it will be seen that there is no common standard of sanity departure from which constitutes insanity, as otherwise all mankind would be more or less insane, inasmuch as no two individuals think and feel and act precisely alike. Hence no man is insane because he is different mentally from other men. On the contrary, every individual has his own standard of sanity which may differ widely from that of every other person, and it is only when he differs from himself, when he is departed from his normal mental state, or is in a state of mental alibi, so to speak,

*Read before the Medical Society of the State of New York, at Albany, N. Y., January 29, 1901.

or when, in common parlance, he is "out of his mind," that he may be regarded as insane.

Thus it appears that insanity is a relative condition, a comparative state; and that the standard of comparison in each instance is to be found within the individual himself. Hence, as before remarked, a man is insane only when he differs from himself, and in order to declare him so we must exclude all other men from consideration and compare the condition in which we find him at the time of the examination, as indicated by his conduct, manner and speech, as well as by his physical state—especially as regards the performance of his bodily functions, including the state of the circulation, the tongue, skin, pupils, appetite, the state of the bowels, the condition of sleep, motor symptoms, etc., with his normal mental status as determined by his heredity, his birth, his mental development, disposition and temperament, affections, education, moral sentiments, habits and environment, in order to determine wherein and to what extent he is departed therefrom. For instance, an individual of so-called excitable temperament may exhibit, from trivial causes, mental exaltation or the opposite, mental depression, which up to a certain degree would be clearly within the range of physiologic mentality; whereas, similar manifestations from similar or even widely different causes, on the part of another whose organization, temperament and mental habit are of a different order might very properly stamp him as insane. That is to say, two individuals may exhibit precisely similar mental symptoms and one be of sound mind while the other would be a pronounced lunatic.

Such being the case, it becomes of the utmost importance in the diagnosis of insanity, especially in obscure or doubtful cases, to institute a careful comparison of the individual with himself. It is only when the physiologic limits are passed and the man enters into a psychopathic state that he may be regarded as insane. Nor is it always possible to say just where health ends and disease begins, so gradually, in most cases, does the one state merge into the other. Insanity, like most other diseases, does not suddenly enter the system at one door while health departs at the other; and while in rare instances the disease may make a rapid onset, usually its approach is gradual and the prodromal stage, which is aptly termed the stage of alteration, in contradistinction to the later stage of aberration, may cover a period of weeks or months or even years before the so-called established stage, that is, the stage of actual aberration, is reached.

The significant diagnostic factor to be sought for in the early stage of the disease is evidence of the prolonged departure to which reference has been made, that is, a change in the mental characteristics of the individual. In fact, any prolonged change in the mental or moral tone of an individual should at once excite suspicion of approaching insanity, especially if he descended from insane or neurotic stock. The watchful eye of affection is usually quick to discern a deviation from bodily health in a member of the family circle, long perhaps before the occurrence of serious or structural disease, but when foreshadowings of disease begin to appear upon the mental horizon how frequently it occurs that friends and rela-

tives, either through ignorance of their true significance, or through consciousness of an inherited taint and dread of the odium which attaches wrongfully thereto, close their eyes to mental vagaries, absentmindedness, eccentricities of conduct and other functional disturbances, mental and physical, which usually mark the approach of mental disease and which should have aroused their anxiety. The histories of many of the chronic insane in custody today would reveal the sad fact that in the beginning of their malady these prodromes, these danger signals, were unheeded and the disease allowed to proceed unchecked until it had reached a state of hopeless chronicity.

Prominent among the premonitory symptoms of insanity are disturbances of the bodily functions, morbid emotional manifestations and alterations in the mental characteristics of the individual. Somatic functional disturbances express themselves in various ways, such as *pavor nocturnus*, insomnia, headache, tinnitus, vertigo, clammy extremities and other vasomotor disturbances, anorexia, indigestion, constipation, etc. It should be said in passing that while these phenomena, especially insomnia and constipation, are frequently observed in the prodromal stage, they may one or all occur in persons who never become insane; hence, they are not to be regarded as pathognomonic, nor singly, perhaps, even diagnostic, of mental disease.

If the tendency is to mental exaltation, or mania, the emotional changes usually take the form of unnatural buoyancy, loquacity, undue levity and morbidly quickened mental operations, the patient frequently appearing to be unnaturally bright. If the tendency is to mental depression, or melancholia, there are gloomy forebodings, morbid introspection, hyperconscientiousness, senseless self-condemnation, a morbid aversion to friends, morbid suspiciousness, irritability and frequently a vague sense of impending evil of some kind. Marked alterations of character are seldom wanting in this stage of the disease. Thus, for instance, the devout person may become profane, the refined, immodest and disregardful of the proprieties and decencies of life; the staid individual, capricious and vacillating; the social, unsocial; the good-tempered, irascible; the industrious, indolent; the temperate, intemperate; the cheerful, sullen and morose, and the levelheaded, conservative business man embarks in senseless enterprises. These symptoms, being in striking contrast to the individual's normal mental status, are indicative of a departure therefrom, and when observed they should always excite suspicion of impending insanity; and while they may vary as regards number, order of occurrence and intensity, their presence is always significant as danger signals, especially when they occur in persons who are predisposed to mental disease by reason of inheritance, neurotic diathesis, previous attacks of insanity, head injury, alcoholism, drug addiction, syphilis, mental shock, prolonged mental strain and worry, general ill health, etc.

It should be borne in mind that insanity is rarely due to a single cause, whether predisposing or exciting. If careful investigation to discover the etiologic factors be made, it will be found in most cases, when reliable data are obtainable, there exists a combination of causes, all

of which are conducive, directly or indirectly, to cerebral malnutrition, which after all is the immediate exciting cause of all insanities. In other words, any disease or condition which impairs the bodily nutrition or alters unfavorably the quality or quantity of the blood-supply, or which seriously disturbs the normal reflex excitability of the nervous system, is capable of becoming either a predisposing or exciting cause of insanity, especially when it occurs in an individual having a psychotic taint, whether inherited or acquired. This would include in the etiologic category all forms of disease, whether local or general, acute or chronic, and all manner of functional disorders; and inasmuch as the etiologic importance of any of these conditions depends upon their potency in producing malnutrition of the brain, it becomes important to fix in mind at the outset the fundamental fact that insanity of whatever type is directly due to functional or structural derangement of the cortical substance of the brain.

Hence in estimating the relative importance of any class of causes, whether predisposing or exciting, we must take into account the part they play in rendering the brain unstable through its denutrition, and thus preparing it for a mental breakdown. In other words, the functional integrity of the mental faculties depends entirely on the healthful activity of the physical system; hence there can be no unsoundness of mind, in a medical sense, without unsoundness (disease) of body.

In connection with the subject of the diagnosis of insanity, it should be borne in mind that, as already intimated, the range of normal mental action is by no means a narrow one. That is to say, the mental operations of the brain may be disturbed temporarily by causes of a transient nature, such as variations in the quality or quantity of the blood-supply, overwork, excessive emotional excitement, reflex irritations, etc., and yet not transcend the limits of physiologic mentality. For instance, if a man under the influence of wine, or on the receipt of exceedingly good news, should exhibit signs of mental exaltation quite unusual to him we would not call it mania, or if he evinced mental depression on account of bad news or misfortune we would not call it melancholia. It is only when the physiologic limitation is passed and the individual enters into a pathologic state, mentally, that we may consider him insane. In other words, whenever an individual is found to have undergone a *prolonged* departure from his normal mental state and the departure is unexplainable on any other ground, such as drunkenness, delirium, the effect of narcotic drugs or other toxic agencies, a diagnosis of insanity will usually be warranted. Alcoholic intoxication and delirium tremens do not constitute insanity in a medical sense, although the law recognizes the latter as an excuse for crime, and some writers have classed it among the so-called toxic insanities.

It should be borne in mind, too, in the diagnosis of insanity, that the patient's statements regarding himself are often unreliable and misleading owing to delusional ideas or misinterpretation of what actually took place, even though in other respects he may be perfectly truthful. Again, the truth or falsity of certain statements made by the insane can only be determined by evidence

from other sources; hence we should not regard every unusual or extraordinary declaration of a patient as indicative of delusion. For instance, a man may assert that he is the victim of a conspiracy, or that his wife is unfaithful to him; or a woman, that she is pregnant, all of which may be true or it may be delusion, so that before determining the diagnostic value of such declarations, corroborative evidence should be sought for from sources other than the patient himself, as by so doing we may avoid the humiliating predicament in which a medical friend of mine once found himself through certifying that an allegation of pregnancy made by a young woman was an insane delusion, when she was in fact pregnant, as an examination would have disclosed had he taken the precaution to make one.

On the other hand, many of the delusions and hallucinations expressed by the insane are so manifestly irrational as to need no further corroboration, as, for instance, when a man declares that he is a king or the Saviour, or that his legs are made of glass and he refuses to walk lest he may break them, or a woman that she is the Virgin Mary or a queen or an empress, etc. Again, we occasionally meet insane persons who are capable of concealing their delusions for a time, realizing that the exhibition of them may result in their being declared insane and deprived of liberty and the control of their affairs; but the deception in such cases rarely fails of detection at the hands of a skilled observer, if time and suitable opportunity for observation be had. Dangerous patients, suicidal and homicidal cases, frequently endeavor to conceal their intentions and their delusions relating thereto; and while cases are occasionally met in which for the time being the most careful scrutiny fails to disclose the existence of any definite or verbally expressed delusion, I have yet to find a case of insanity proper that did not at some stage of its progress reveal the presence of delusion or a *delusional state*, as evinced by the declarations, manner or conduct of the individual. It need scarcely be said that the most common delusion among the insane is that they are not insane.

In the diagnosis of insanity it is important to take into account certain negative symptoms, as reticence, obstinacy, sullenness or stupidity, any of which may be significant with reference to diagnosis, especially if such condition is not natural to the individual. Note should be taken also of the facial expression, the contrast in facial expression in mania and melancholia is in itself a lesson in diagnosis, the expression of the eyes and their pupillary reactions to light and accommodation, the speech, writings, motor functions, reflexes, etc., any of which may in themselves be indicative of certain forms of mental disease. The pulse and temperature should also be observed, as persons laboring under the delirium of fever, meningitis, etc., have occasionally been committed to institutions for the insane through inattention to these points.

Other conditions which have been mistaken for insanity are prolonged intoxication, delirium tremens, the delirium of meningitis, and of the various continued fevers, sunstroke, hysteria, injuries of the head and the delirium which sometimes precedes death in certain diseases, and in old age. Most frequent among

the prodromes of mental disease are insomnia and constipation. In fact, so common are these symptoms in the onset of acute insanity that the experienced observer comes to anticipate their presence, and to expect an affirmative answer to his interrogations respecting them in substantially every case that comes before him.

Thus I have attempted to portray briefly the most frequent and most important mental and physical indications of the onset of mental disease. These indications may not present in the order mentioned, nor will all of them be observed in every case, but more or less of them will be found in most cases if carefully sought for, and the physician must be prepared to recognize and define the particular departure from the normal state so distinctly and clearly as to satisfy himself and the friends of the patient that the deviation actually exists and that the case has reached a point at which the good of the patient and the welfare of the family and of the community render medical interference imperative. It is doubtless true that an impending attack of acute insanity could frequently be warded off if the prodromes, which I have characterized as danger signals, were promptly recognized and timely measures for their relief applied. Prevention is better than cure, and to recognize mental disorder in its incipiency will often enable us to adopt remedial measures at the most, opportune time for arresting its progress.

The importance of promptly instituting measures for the relief of insomnic states whenever met with in practice, and particularly if the insomnia, as frequently happens, is associated with slight mental depression and constipation, can scarcely be overestimated. The insomnic habit, like many other habits, is easily acquired, and if allowed to go unchecked tends to produce brain malnutrition and consequent mental disease, especially in individuals who are predisposed thereto.

DUST AS A FACTOR IN DISEASES OF THE UPPER RESPIRATORY PASSAGES.*

BY

W. SCHEPPEGRELL, A.M., M.D.,

of New Orleans, La.

The subject of dust as a factor in disease is of interest not only to the hygienist, but also to the physician, and particularly to those who give especial attention to diseases of the respiratory passages. No one will dispute the fact that air is more important to the perpetuation of human life than water or food; for while cases are on record in which persons have lived many days without water, and even for weeks without food, we know that the cessation of respiration for even a few minutes is fatal to life. In spite of this, though we hear constantly of the measures taken to improve the water supply, and of legislative enactments to prevent the adulteration of food, the purification of the air which is so important for our comfort and health, is rarely referred to. We are becoming so careful in regard to our water, that many will drink only of that which is especially distilled, and

so particular about our food that we will eat only such as is prepared by men of special reputation for cleanliness and purity, but we take into our respiratory passages without a thought, air vitiated with millions of particles of dust:

Before studying its effects on the upper respiratory passages, let us first investigate the composition of the substance which we know as "dust." Microscopic examination shows that it is made up of vegetable, animal and mineral particles, which vary in size from those which may be seen only with the highest power of the microscope to those of considerable size which are thrown into the air by winds of high velocity, the quantity as well as the size of the particles being dependent not only on the material available for dust formation, but also upon the strength of the wind. While this dust is principally made up of substances which accumulate on the streets, it is largely augmented from the chimneys of factories and private houses, while all forms of manufactories add their quota to the accumulation.

The effects, as far as the organs of respiration are concerned, may be divided into the following heads: Mechanical, traumatic, chemical and pathogenic. While these divisions are made for convenience of study, it is more common in actual practice to find 2 or more of these effects present at the same time. The actual injury done to the respiratory organs will of course be influenced by the amount of dust present in the air inspired as well as by its composition, while the normal or abnormal condition of the respiratory passages, especially of the nose, will have a most marked bearing on the result.

While the entire absence of dust from the air is a condition difficult to attain, as shown by Tyndall in his most delicate experiments, still there is a great difference between this and the dust-laden air of most of our large cities. When only the mechanical effect of inhaling this dust be considered, we find that when these foreign particles come in contact with the delicate mucous membrane of the nose, they tend to produce congestion and hyperaemia, which easily leads to intumescence and hypertrophy; and when the normal condition of the nose has once been disturbed, it is not long before the effects are found in the organs below.

When we have added to the mechanical the traumatic effects, such as are produced by the inhalation of particles of glass, stone, iron and other sharp particles which are frequently found in the air, the effects are much more rapid and injurious than those described above. The chemical effects are most frequently observed when the dust from shell-roads, which contains a large proportion of calcium carbonate, is inhaled. I have seen a considerable number of patients in whom the diseased condition of the respiratory passages was due to the dust from shell-roads, and the possibilities from this are so marked, that shells should never be used for road purposes unless every precaution is taken to see that they are watered properly. The chemical effects of dust are also observed in the manufacture of certain drugs and of chemicals and of such articles in the preparation of which chemicals are largely used. In this category may be included the alkaline dust which is found in certain portions of the United States. The irritation produced by dust, largely

*Read February 23, 1901, before the Orleans Parish Medical Society of New Orleans.

composed of particles having chemical effects upon the mucous membrane of the respiratory passages and its secretion, is much more marked and rapid than those already described, and even atrophy of the mucous membrane, a condition most obdurate to treatment and injurious in its effects, is frequently due to the inhalation of such dust.

The pathogenic effects of the inhalation of dust is the most important which we have to consider. The ordinary dust of cities contains a large amount of various forms of bacteria, but in the majority of cases the mucous membrane of the nose is protective against these, and they act simply as mechanical impurities. Some of the pathogenic germs, however, have so strong a vitality that they resist the action of the upper respiratory passages, and it is undoubtedly in this way that many of our infectious diseases are contracted.

In normal respiration, the nose not only warms and moistens the inspired air but also frees it from mechanical impurities, thus acting as a barrier between the larynx and bronchi and the atmospheric air. The large percentage of cases of abnormal conditions of the nasal chambers has been the subject of remark by rhinologists ever since this branch of medicine has been carefully studied, and it is my opinion that dust is an important etiologic factor in a large number of these cases. Accepting, however, the fact that abnormal conditions of the nose are of frequent occurrence, we can easily understand the injurious effects of dust not only on the delicate mucous membrane of the nose itself, but also on the remaining portion of the respiratory tract which the nose protects when in its normal condition.

While pathogenic germs may be found in almost all forms of city dust, they are especially frequent in rooms or hospitals in which patients with infectious diseases have been careless with the disposition of infectious materials. In the houses of tuberculous patients, in which care is not taken to destroy the sputum, the bacillus of Koch has been found in large numbers in the sweepings from the floor and in the dust scraped from the walls, and a similar condition has been found in cases of diphtheria and other infectious diseases. Tuberculosis heads the list in this direction on account of the long duration of the disease and the abundance of the sputum which contains the infectious material. When this is allowed to dry, particles are blown into the air from part of the dust of the infected room. In this way not only is the room infected, but eventually the house, and if a sufficient number of such foci of infection exist, it will be easily understood why the bacillus of tuberculosis should be found in the ordinary dust of our streets.

Nature has given us various defences to protect us from the impurities of the air which we inhale; First the vibrissae which guard the entrance of the nostrils, and exclude the larger particles contained in the air; then the secretion which covers the mucous membrane of the respiratory passages, and especially the nose, which in its normal condition, has been found sterile to the cultivation of microorganisms, and to which even germicidal properties have been ascribed by some bacteriologists; the movements of the ciliated epithelium, the action of the leucocytes, and even the peculiar conforma-

tion of the nasal chambers which oppose the direct entrance of air; but these can be relied on only when the local parts and the general system is in its normal condition to protect us against the danger of contracting disease from the inspiration of infectious dust.

There are certain occupations in which the dust has especially injurious effect upon the respiratory organs, as in cigar and cigaret makers, grinders of metals and glass, workers in stone, coal miners, etc., but the limit of this article will prevent me from going into these in detail, and I simply refer to them as illustrating the danger to the respiratory organs from the inhalation of dust. In his investigations of this subject, Peacock (Schmidt's *Jahrbuecher*, Bd. CXVI, p. 57,) found in a London factory, in which grindstones were made and incident to which a large quantity of very fine dust was constantly present in the air breathed by the workmen, that 40% of the employes died of tuberculosis. What more striking example can be found of the injurious effect of dust upon the respiratory organs?

[TO BE CONCLUDED.]

Disposing of One's Own Corpse.—The Supreme Court of California has decided that a man cannot by will dispose of his corpse. A man requested the managers of a medical college, in the hospital of which he had been treated, to allow him to bequeath them his body to be used for scientific purposes. When he died the administrators proceeded in the terms of the will to take possession. The nearest of kin, however, claimed the body, and applied to the courts for an injunction restraining the medical college from taking the cadaver. The kinsfolk won; the court holding that the custody of the corpse and the right of burial belongs to the next of kin instead of the administrator.

Investigating Arsenical Poisoning.—All the witnesses examined by the Royal Commission agreed that in the recent outbreak of arsenical poisoning in England and Wales beer was the means by which the arsenic was conveyed. One witness suggested as preventive measures: (1) "That no glucose or invert sugar should be made with sulfuric acid unless it was made from sulphur and not from pyrites, and that the brewer should have a guarantee to that effect; (2) that the inland revenue should instruct excise officers to see that such guarantees were given and to collect samples of brewing materials for analysis, and (3) that additional powers for local authorities to seize contaminated beers should be given."

Smallpox Epidemic in Scotland.—Official reports show that since the outbreak of smallpox in Glasgow in April last there have been 1,435 cases with 167 deaths. The work of revaccination is being rigorously carried on among the people of the poorer districts where the greater number of cases arise. Other measures adopted by the medical and sanitary officials for the limitation of the disease are being actively executed and are attended with hopeful results. Five cases supposed to have arisen from Glasgow have occurred in Edinburgh. Evidence is wanting to prove that any of these patients have ever been adequately vaccinated.

The Mosquito Nuisance.—The mosquito having been adjudged guilty of spreading disease, the problem is to get rid of him. It is easier to kill him in the egg, than on the wing. General Wood has been giving attention to the matter in Cuba. Kerosene oil is put into or upon the pools during the hatching season, in the hope of killing the egg. It is also believed that the odor of the eucalyptus tree will drive away mosquitoes, so these are being planted. By some the castor oil plant is regarded as a remedy for the pest. But whether the two latter are effective remedies or not, the use of oil undoubtedly is, and there should be no quarter given to an enemy that has so little claim to benevolent consideration.

PRACTICAL THERAPEUTICS

Under the charge of
A. A. STEVENS, M.D.

Incompatibilities of Heroin and Heroin Hydrochlorid.

—According to the *Therapist* (January 15, 1901), the only incompatibilities of heroin and the hydrochlorid worthy of special mention are the alkalis, such as sodium bicarbonate and ammonium carbonate. On the other hand, salts of neutral reaction, such as potassium iodid or ammonium chlorid, may be used in the same mixture, and this also applies to acid salts, such as the hypophosphites or acid phosphates. The vegetable expectorants, as ipecac, squill, senega and sanguinaria, are entirely compatible with heroin and its hydrochlorid. Although many physicians employ heroin without admixture, very desirable results have been reported from combinations with potassium iodid, ammonium chlorid, and the vegetable expectorants. Owing to the insolubility of heroin in watery solutions it is necessary to add a few drops of some acid, acetic or hydrochloric, in order to affect its solution. This may be entirely obviated by using the hydrochlorid, which is freely soluble. The large doses at first recommended are no longer advocated by most authors, the average dose ranging from 1-24 to 1-12 of a grain in adults, and 1-120 to 1-60 of a grain in children. It is advisable not to employ larger doses until the smaller ones have been given a trial. Furthermore, many physicians now resort to the hypodermic use of the hydrochlorid in cases in which it is desirable to obtain an immediate effect, and especially in the treatment of spasmodic conditions, such as asthma, care being taken in the preparation of solutions not to add the drug until the water has partially cooled.

The Relation of Scurvy to Recent Methods of Artificial Feeding.—J. P. C. Griffith (*New York Medical Journal*, February 23, 1901) reports 16 cases of infantile scurvy which support the generally accepted view that the patented foods often produce the disease, and some of which show that recovery may follow the withdrawal of these foods without other treatment. Two of his cases throw suspicion on barley water. The cases indicate, too, that the sterilization of milk has an undoubted power to produce scurvy, but that this is a less prominent etiological factor than the last. In fact, one of the most striking features which the cases illustrate is that scurvy can readily develop on a diet of milk which is not long heated, or which is even raw. In some such instances we are led to suspect the action of a low percentage of proteids. Some of the cases also show that the beneficial action of fruit juice may begin and continue without any change in the food whatever. This is a valuable point, because in 379 cases collected by the committee appointed by American Pediatric Society (1898) there were only 3 which illustrated this fact. It is also important because it teaches that we must not always hasten to change the diet which has seemed to agree with a child with weak digestion, because symptoms of scurvy are appearing. Better far in most cases the danger of the development of a disease generally easily curable, produced possibly by a low proteid percentage, than to incur the far greater danger of a wasting diarrhea or other digestive disturbance, the result of overstrong food.

Analgesia from Spinal Subarachnoid Cocainization.

J. B. Murphy (*Journal of the American Medical Association*, February 9, 1901,) has collected 631 cases in which this method of inducing analgesia was employed. Of these the method was successful in 596, partially so in 14, while in but 21 cases did failure result.

Operation for the Relief of Ascites Due to Cirrhosis of the Liver. C. H. Frazier (*University Medical Magazine*, February, 1901,) reports the case of a middle aged man with hepatic cirrhosis in which a favorable result was obtained from opening the abdomen, rubbing the parietal peritoneum vigorously with a gauze pad, and suturing the thickened omentum to the parietal peritoneum and the edges of the wound. The incision was closed without drainage. Subsequent to the operation the patient was tapped twice within 36 days. After second tapping there was no reaccumulation, and the patient left the hospital at

the end of 4 months very much improved in general health. The reports of 13 other cases in which this operation has been performed are now on record. In some instances the operation has been carried out in cases in which the diagnosis was incorrect and in other instances unavoidable complications developed which materially affected the mortality. Excluding those cases of failure for which the operation should not be held accountable, we find 8 cases remaining in which the mortality was nil; of these, 6 patients were living and free from ascites at periods varying from 3 to 26 months. One was living and improved, 1 was living but unimproved. Thus recovery ensued in 100%; in 12% improvement followed, and in 12% no improvement.

The Treatment of Exophthalmic Goiter.—Nestor Tirard (A Text-book of the Medical Treatment of Diseases and Symptoms, 1900) writes as follows: Many remedies have been recommended for this condition, but in my hands the best results have been afforded by the conjunction of arsenic with digitalis or strophanthus, to check the rapidity of the heart's action. The amount of anemia frequently necessitates the use of iron. The success of the treatment is, however, extremely uncertain; and the remedies above mentioned must be continued for long periods, both with the view of curing the anemia and of maintaining a steady control over the rapidity of cardiac action. It is not advisable to increase the dose of digitalis or of strophanthus in the hope of obtaining a pulse of physiologic rate, since an increase in the amount of these remedies may produce irregularities of action and perhaps dangerous syncope. It is better to employ only moderate doses, and to be satisfied with general reduction in the rapidity of the pulse-rate. Occasionally I have used with some satisfaction ammonium or potassium bromid, with the view of controlling the nervous symptoms which are frequently so distressing in this disease; but with those drugs also it is desirable to employ only moderate doses, since although the irritability of temper may be diminished, the depression is certainly sometimes increased.

Sodium cacodylate.—W. Ewart (*Polyclinic*, October, 1900), states that sodium cacodylate is an arsenical organic compound which in the last 2 years has been introduced into therapeutics by French physicians. In it arsenic can be administered in enormous quantities without the usual risks. But how far large and long-continued doses are free from danger is not known. It contains 48% of arsenic and is relatively free from irritating and poisonous properties. In sodium cacodylate all odor and virulence are lost. This is a soluble, deliquescent, tasteless solid. In dilute solutions it is well tolerated by the stomach. Sodium cacodylate may be given by the mouth 3 or 4 times daily in half-grain doses, which may be increased. It may be given in pills or in solution, but as it is very hygroscopic the pills must be specially prepared. The rectal method of administration is much advocated abroad as less liable to give rise to reduction products which impart an odor of garlic to the breath. In chorea $\frac{1}{4}$ grain may be given in this manner dissolved in 1 to 4 drams of water. The hypodermic method of administration is the most scientific as the complications arising from possible reaction in the alimentary canal are avoided. One-third of a grain dissolved in 10 minims of water is a fair initial dose, and may be increased to 1 grain or more. By this method the writer has given the drug in cases in which its full powers are required—pernicious anemia, Graves' disease, etc. The maximum dose has not yet been determined. The drug may be given for long periods. The metabolic properties of arsenic being apparently increased, the uses of sodium cacodylate are manifold. Those in depressed health from a variety of causes soon after beginning a course generally feel refreshed and invigorated. The drug has been recommended as of much value in cancer, particularly of the stomach. It seems to be more efficient than arsenic in most conditions in which the latter is a specific, particularly in pernicious anemia, chorea, malaria, and Graves' disease. In tuberculosis, according to reports from abroad, cacodylate gives better results than have been obtained under any other medical treatment. In a case treated by the writer the tendency to hectic was checked, the cough and expectoration were greatly diminished, and the general condition of the patient rapidly improved.

The Action of Tellurium Compounds.—W. J. Gies (*Phila. Medical Journal*, March 23, 1901) from his experiments on dogs concludes that large but nontoxic doses of tellurium compounds do not materially affect metabolism in dogs brought to a state of nitrogen-equilibrium, even when dosage is continued for a week. These substances appear to stimulate proteid catabolism only slightly. They increase somewhat the weight of dry matter in the feces, and diminish, in a small degree, the absorption of fat. They render the urine dark brown in color, but do not affect it otherwise. Excessive doses induce somnolence and severe gastroenteritis. Tellurium compounds, even in small proportion, markedly arrest the secretion of the acid in the stomach—the direct cause, probably, of the indigestion brought about not only in dogs, but also in man. Tellurium is eliminated in metallic form in the feces; as methyl tellurid in the breath, urine, feces and epidermal secretions, and in a soluble form, in small quantity, in the urine and bile. Neusser, Pohorecki, Combemale and Dubiquet have found sodium and potassium tellurate in daily doses of $\frac{1}{3}$ to $\frac{2}{3}$ of a grain highly effective in controlling the night-sweats of tuberculosis. The experiments of Gies indicate that the alliaceous odor imparted to the breath is about the only objectionable feature constantly following the use of therapeutic amounts of tellurates.

Acute Catarrhal Rhinitis.—C. P. Grayson (*Therapeutic Gazette*, February 15, 1901), recommends as a local treatment in the early stage the spraying upon the engorged tissues of a few drops of a 2% solution of cocaine, followed in a minute or 2 by one of the alkaline sprays, such as Dobell's solution. Later, after the nose has been thoroughly cleansed, a solution of chloro-ton and suprarenal capsule is recommended. This last solution has the advantage of being both stable and nontoxic, and its effect combines the vascular constricting action of the suprarenal extract with the anesthetic action of the chloro-ton. Unlike cocaine, it is perfectly safe for home use. On the third or fourth day, when the secretion has become mucopurulent in character, cleansing of the nose may be succeeded by a spray of distilled extract of hamamelis, 1 part to 3 of water. This exerts a mildly astringent action. In a day or 2 more, when the active hyperemia has disappeared and left in its wake a sluggish, venous congestion, which is apt to be slow in departing, a stimulant, like Boulton's solution, may supplant the astringent. Boulton's solution has the following formula:

℞ Compound tincture of iodine 1 dram.
 Carbolic acid (crystals) 18 grains.
 Glycerin 2½ ounces.
 Distilled water 2 ounces.
 Mix. Place in a water-bath of 100° in tightly corked bottle until colorless. Filter. May be used as a spray or by means of the cotton-tipped applicator.

Oil preparations should be used only with or after some alkaline cleansing solution. One of the most generally useful of these oil formulas is that of Douglas:

℞ Thymol 10 grains.
 Menthol 20 grains.
 Eucalyptol 20 drops.
 Oil of eucalypt 40 drops.
 Benzoinol 6 ounces.

Oxycyanid of Mercury in Practical Antisepsis.—Deguy (*Journal des Praticiens*, November 3, 1900,) recommends mercury oxycyanid as a substitute for corrosive sublimate for general antiseptic purposes in the same strength solutions as the latter salt. The product employed by him is a yellowish-white, inodorous, crystalline powder of a neutral reaction and should never be acid. This is readily soluble in cold water, differing in this respect from other salts which vary according to the mode of preparation and to the proportions of the mixture of the oxid and cyanid and also to the purity of the salts. The advantages claimed for this oxycyanid are: that it does not alter instruments placed in its solutions, it can be made into compressed tablets and is not so irritant to the hands or other tissues while its antiseptic properties are equal to the same strength sublimate solutions.

The Real Value of Quinin in Labor. Fussell (*Therapeutic Gazette*, January 15, 1901,) thinks quinin is not so frequently used as it should be in cases of labor. It has never found it to fail when the labor pains were slow and inefficient from simple uterine inertia. Given in 15-grain doses the drug causes an increase of force and frequency of uterine contractions exactly resembling normal labor pains. Cinchonism did not occur in these cases and the employment of the drug frequently obviated the use of forceps.

Iron Cacodylate.—Gilbert and Lereboullet (*Le Mois Therapeutique*, September 30, 1900) have used iron cacodylate in chlorosis and chloroanemias, especially tuberculous chloro-anemia, with good results. Used hypodermically in the strength of a half grain in each cubic centimeter of water, of which 2 cc. or 3 cc. was used at each injection, the drug was well tolerated locally and produced no untoward symptoms. By the stomach the dose ranged from 2 to 4 grains daily although when administered in this way it proved less active than when given hypodermically.

Early Operation in Typhoid Fever With Intestinal Perforation.—Osler (*Lancet*, February 9, 1901) says that 50 % of deaths in typhoid fever are due to asthenia, 25 % to perforation, and 25 % to hemorrhage and other accidents. He believes that from 30 to 40 % of the perforative cases can be saved by early operation. Of 11 cases operated on in Johns Hopkins Hospital since January 1, 1900, 5 recovered. In doubtful cases he believes that the patient should be given the benefit of the doubt.

Treatment of Tuberculosis by Cinnamon.—Krompecher (*Ann. de VInst. Pasteur*, November 25, 1900, and *British Medical Journal*, 5, 1901) has conducted a series of experiments to test the value of Landerer's treatment founded upon Richter's researches. Cinnamic acid, according to Richter, caused the tubercles of inoculated rabbits to show fibrous transformation and a tendency to cure, instead of undergoing the usual course of caseation and softening. Krompecher inoculated animals with cultures of varying virulence, and, after an interval, injected soda cinnamate into the veins. He also investigated the question of preventive action by beginning treatment with the drug some days before the inoculation with tubercle. In all cases untreated animals were inoculated at the same time for purposes of comparison. Soda cinnamate was found to cause a temporary leukocytosis 3 to 4 hours after administration, with hyperemia of the bone-marrow. The stroma of the lungs was appreciably increased by a succession of injections, owing, it is believed, to mechanical irritation. Preventive treatment was found to give no immunity against infection by virulent tubercle-bacilli; and suitable animals inoculated with virulent bacilli died from tuberculosis, in spite of the treatment with cinnamate of soda, as rapidly as the animals used for comparison. The only animals inoculated for Richter's control experiment lived for 7 months afterwards. Hence it is likely that for his experiments cultures of small virulence were employed, and that the healing was merely due to natural tendency to recovery.

Tracheal Injections in Tuberculosis.—T. M. Murray, (*New York Medical Journal*, February 9, 1901) has treated 40 cases of pulmonary tuberculosis with tracheal injections. Every one was benefitted. For a period of from 4 to 8 hours after the injection there is no cough at all, and if given at bed time the whole night may be passed without a single paroxysm of coughing. The expectoration is reduced in quantity and becomes less offensive. The author uses Mundell's solution, the formula of which is as follows:

Oil of thyme } of each 80 minims.
 Oil of eucalyptus }
 Oil of cinnamon }
 Sterilized olive oil 3½ ounces.

Of this 45 minims are injected 3 or 4 times in succession.

The method of administering the injections is simple. The curved canula of the syringe is passed between the vocal cords, and the fluid is slowly injected into the trachea. The first effect is usually a slight explosive cough but the author has never seen glottic spasm follow even the first injection.

1.—Will be treated editorially.

2.—Hawthorne, discussing the occurrence of pyrexia in carcinoma and other diseases of the liver, and in cases of gallstone, refers first to the generally recorded opinions regarding the infrequency of fever in ease of malignant disease of the liver, and reports a number of cases of carcinoma of the liver in which fever was one of the clinical symptoms. Referring to cases of liver disease with jaundice, he states that neither a distinct degree of pyrexia nor the occurrence of rigors and intermittent febrile attacks is by any means conclusive against the existence of malignant disease, and he illustrates his statement by mention of cases under his own observation and reference to others in the literature. Mentioning hepatic intermittent fever, he quotes Charcot to the effect, that while the fever is most likely to occur in cases of dilation of the bile ducts in which the bile ducts contain mucus or mucus in a state of stagnation, fever may also occur in any case in which there is prolonged or permanent obstruction of the bile duct, as in fibrous stricture, carcinoma of the head of the pancreas, etc. From the occurrence of intermittent febrile attacks and jaundice, with physical signs of enlarged liver, both in malignant disease and impacted gallstone, the differential diagnosis of the 2 conditions becomes an important practical question, especially as modern surgery has rendered the relief of one of them a comparatively secure undertaking. The differential diagnosis is detailed. Finally reference is made to the occurrence of fever in hepatic disease other than carcinoma, gallstone, and abscess, such as bursting of a hydatid cyst, the entrance of lumbricoid worms into the biliary passages, and cirrhosis of the liver. [A. O. J. K.]

3.—Douglas, after a discussion of the nature and occurrence of digestion-leukocytosis, details his observations on digestion-leukocytosis in carcinoma of the stomach. In 11 cases examined digestion-leukocytosis was absent in 6 (54.54%), present in 4 (36.36%), and inconstant in 1 (9.10%). These figures coincide closely with those recently published by Osler and Maerea. Douglas concludes that digestion-leukocytosis is a broken reed on which to lean in the diagnosis of carcinoma of the stomach, and he concurs in the opinion of Marchetti, that digestion-leukocytosis depends essentially upon the digestive and absorptive powers of the stomach, and that it may or may not occur in carcinoma of the organ, according to the degree of impairment of its function. [A. O. J. K.]

4.—Leighton describes his treatment of a case of inoperable carcinoma of the cervix, his aim being to make the patient's life as long and comfortable as possible. Hemorrhage was always controlled by ergot administered internally or in a few cases of excessive flooding, by subcutaneous injection. For the offensive discharge in the early stages he used a solution of sulphate of zinc, but later a carbolic douche (1 to 40) was found more satisfactory. To relieve the pain which became constant

and severe 6 months after the first diagnosis, morphin giving only evanescent relief, Leighton remembering the remark of an old teacher, "If everything else fails the best thing you can do is to turn your patient into an unconscious opium eater," began the use of opium. The tincture of opium administered internally was found to have the most lasting effect. Under its use the patient was able to obtain refreshing sleep and showed a marked improvement in her general condition. The dose, however, had to be constantly increased until in the course of nearly 2 years, from 3 to 5 grains daily it became 200 and 300 grains per diem. He believes that this use of opium undoubtedly prolonged her life more than a year and that the last 18 months were far more comfortable than the preceding 12 had been. She never knew that she had taken any opium. [Very frequently ergot will prove absolutely useless in the control of hemorrhage from cancer of the cervix because of the character of the neoplasm, and nothing but the application of astringents directly to the ulcerating mass, or packing with gauze or cotton saturated in a hemostatic solution, will prove effectual. w.k.]

5.—Leishman thus summarizes the chief advantages of Romanowsky's stain in malaria: The specific action of the stain upon all red corpuscles infected with the tertian parasite; the greater certainty of the detection of very young intracorpuscular forms of all varieties of the malarial parasite; the facility with which the occurrence of a "mixed" infection may be detected; and after a little practice, the ease of its application and the certainty of the results obtained. For details and a slight simplification of the stain and an illustrative plate, reference must be made to the original. [A. O. J. K.]

6.—Sykes, in his concluding lecture, discusses the effects of construction and misconstruction of dwellings on health, and the effects of usage and misusage of dwellings on health. [A. O. J. K.]

7.—Amyot reports an instance of unusual idiosyncrasy to gelsemium—that of a woman, aged 22 years, who after a dose of 10 minims of the tincture experienced blurring of sight, headache, giddiness, and a feeling as if drunk. After 2 hours she passed into a semiconscious condition from which she could be roused to speak without incoherent speech. There were dilation of the pupils without response to light, drooping of the eyelids, feeling of numbness about the mouth, slight spasmodic quivering of the abdominal muscles, and when attempting to walk, a staggering gait. While there were no cardiac symptoms, the pulse was slow and feeble. After an emetic and a night's rest, the patient had fairly recovered. [A. O. J. K.]

8.—Williams thinks that though transitory vaginal hemorrhages in newborn children have hitherto been generally regarded as accidental occurrences, they may be more correctly considered as prototypes of the menstrual flux. This view is supported by the fact that mature Graafian follicles, corpora lutea, and recent ovarian cicatrices have several times been met in the ovaries of newborn children, and even prior to birth, so that congenital ovulation may be regarded as an established fact. [w.k.]

9.—Stanwell records a case of a woman, aged 46 years, who drank a half pint of turpentine without evidence of serious turpentine poisoning following. A half-hour after the ingestion of the turpentine, a stomach-tube was passed and almost all of the turpentine was recovered. The only clinical evidences were slight redness of the fauces, slight epigastric uneasiness for a short time, and a violent odor to the urine, which was otherwise normal. [A. O. J. K.]

10.—Hepworth records the case of a man, aged 42 years, who complained of irregularity of the cardiac action, precordial distress, pain in the left side, dyspnea, which with a pleural friction led to the diagnosis of pleuritis. About a week later he was suddenly seized with intense pain in the right side, rapid breathing, fever, expectoration of blood, and examination revealed a patch of tubular breathing. This was attributed to pulmonary infarction. Later there occurred several similar attacks. At the end of a month the patient suddenly collapsed, but finally rallied. Later there occurred marked edema of the right leg, and then of the left leg. Ultimately he improved and was able to resume his occupation. The interesting points in the case were the entire absence of cardiac murmur, the insig-

nificance of the physical signs in comparison with the symptoms, and the recovery of the patient. The diagnosis seemed to narrow itself to **malignant endocarditis**, as it was otherwise impossible to account for the numerous symptoms evidently due to embolisms. [A.O.J.K.]

11.—Gillam reports a case of a woman, aged 73, suffering great difficulty in breathing because of a **large ovarian cyst**. As she positively refused any radical operation, relief could be obtained only by tapping, to which she at length consented. In the course of 4 years this was repeated 151 times and about 1,500 pints of fluid were drawn off. There was undoubtedly adhesion between the cyst wall and the abdominal wall at the time of the first tapping which minimized the risk incurred. This instance shows that in such cases, when operation is refused, paracentesis for relief of tension may have to be performed an almost incredible number of times; and that, despite the dangers run in such a method of treatment, life may be prolonged in comparative comfort for a considerable period. [W.K.]

12.—Bleasdale reports the case of a man, aged 23 years, suffering with **diffuse scleroderma** of 5 years' duration. The trouble commenced with rheumatism in the hands and feet, accompanied with considerable swelling about the knuckles. At the end of several weeks it was noticed that the skin of the arms and legs was becoming hard and tense. At the time of observation the clinical picture was typical, the skin being firm, devoid of wrinkles, and tightly drawn over the bony prominences, where there was marked tendency to the formation of unhealthy-looking ulcers. The patient ultimately succumbed to pulmonary tuberculosis. [A.O.J.K.]

1.—In view of the well-established fact that for operations of surgery on the abdomen any method of determining the position of the viscera and their relation to each other should be as simple as possible and applicable to a body of any size or position, Addison presents a system of careful **mapping-out of the abdominal viscera** in their relation to clearly defined, uniformly-proportioned surface lines in order to demonstrate the manner in which the abdominal viscera alter their position or are displaced when they or the neighboring parts are enlarged or atrophied. [O.L.]

2.—Yeo, in a lecture on the **medical treatment of tuberculous peritonitis**, directs attention to the fact that primary tuberculous peritonitis is probably not so infrequent as is commonly held, and suggests that it may result from the ingestion of infected milk or infected meat, the bacilli being absorbed by the superficial lymphatics of the intestinal mucous membrane and attacking primitively the serous membrane. He reports 3 rather acute cases, occurring in young persons (between the ages of 10 and 20 years) 1 of which is believed to have been traced to the use of infected milk. The patients were given a

pill consisting of a quarter of a grain of iodoform and a half minim of creasote thrice daily, and an ointment consisting of equal parts of iodoform ointment and cod-liver oil was rubbed on the abdomen twice daily. The treatment was persisted in (in 1 case for 3 months), with recovery in each instance. He values highly the surgical treatment of tuberculous peritonitis (to which 1 of the patients was subjected) but he believes that it is inappropriate in some cases, and may be undertaken too early in other cases; the medical treatment, on the contrary, cannot be begun too early. He believes that when iodoform is rubbed on the skin of the abdomen iodine enters the blood, and if the former be regularly applied the latter is continuously eliminated by the secretions, including the secretions of the serous cavities. As these do not pass out of the body as the secretion of the kidneys does, they must in the course of time become somewhat richly charged with iodine compounds, at any rate sufficiently so to act as antitoxic to the tubercle toxin or antibacterial to the tubercle bacillus. This opinion is supported by clinical and laboratory investigations. He suggests that in our enthusiasm concerning antitoxins of animal origin we should not neglect the study of those to be found in the mineral and vegetable world. [A.O.J.K.]

3.—Tooth, in detailing some personal experiences of the **epidemic of enteric fever among the troops in South Africa, in the Orange River Colony**, discusses the origin of the epidemic, the dissemination of the disease, the general precautions taken to limit the spread of the disease, preventive inoculation, and the treatment in hospital. The disease is believed to have originated in the Modder river camp as the consequence of drinking contaminated water, that may have become infected from Kimberly. The dissemination of the disease is attributed to infection of the drinking-water, sandstorms, the agency of flies, and possible personal infection from man to man. Comment is also made of the probable effects of diseases antecedent to typhoid infection, as the onset of many of the cases of typhoid fever appeared in the course of dysentery. To prevent the spread of the infection certain well-known sanitary measures were adopted. Some interesting and encouraging statistics relative to preventive inoculation are given, but it is admitted that the procedure has not yet had a fair trial and its value is undetermined. With regard to the treatment, it was found advantageous as well as necessary in some cases to permit a more liberal diet than milk alone; alcohol was used most sparingly; digitalis and strychnin were of the greatest value. Headache and insomnia were usually relieved by phenacetin; for the insomnia, however, morphia was sometimes necessary. For the diarrhea, bismuth carbonate or bismuth salicylate and chlorodyn proved the most useful drugs, supplemented if necessary by suppositories of $\frac{1}{2}$ of a grain of morphia. [A.O.J.K.]

4.—Garrod, in a discourse on the **clinical and pathologic relations of the chronic rheumatic and rheumatoid affections to acute infective rheumatism**, pleads for a more exact use of the terms, rheumatism, rheumatoid, etc. He details what he understands by rheumatoid arthritis or osteoarthritis, under which are included 3 or 4 clinical entities, of which he relates instances, and which are probably distinct in nature the one from the other. He discusses the resemblance of rheumatoid arthritis in children to the fusiform variety of the disorder as it occurs in adults, and then speaks briefly of the results of certain postmortem examinations. Relative to the question whether or not rheumatoid arthritis, or the diseases included under that name, stands in any direct relation to acute rheumatism, while admitting the occurrence secondary to acute rheumatism, gonorrhoeal rheumatism, and even gout, of a chronic joint-affection clinically indistinguishable from the fusiform variety of rheumatoid arthritis, he believes that in the great majority of cases rheumatoid arthritis of any form appears as a primary malady and presents its characteristic features from the onset and that more often than not the patient has not suffered from any troubles that are suggestive of a truly rheumatic origin. With regard to the abarticular manifestations of rheumatism, such as endocarditis, pericarditis, etc., he believes that they are not more likely to be encountered in those the subject of rheumatoid arthritis than in those not thus affected. With regard to the nature of the disorder his opinion is well summed up in the

statement that of one thing only is he certain, and that is that he knows far less about the pathology of rheumatoid arthritis than he thought he did 10 years ago. [A.O.J.K.]

5.—Willecox, in a discussion of the **toxicologic detection of arsenic and the influence of selenium on its tests**, considers some points of importance in connection with the Marsh and Reinsch tests and the influence of selenium on them. He writes on the nature of the white deposit formed during the Marsh test, the prevention of the white deposit, the influence on the delicacy of the Marsh test when substances are introduced into the heated portion of the tube (within the clay chimney), and the influence of selenium on the Reinsch and Marsh tests. As the result of his investigations, he believes that the cases of arsenical poisoning recently found to be due to contaminated beer from Manchester, England, could not have been due to selenium primarily and arsenic secondarily, as has been suggested. [A.O.J.K.]

6.—Snowman reports a case of **septic disease in graduated attacks** in a woman, aged 34 years, at the time of first observation. She was then lying-in with her sixth child and had 3 or 4 severe rigors between the third and sixth days—her temperature rising to 105°F. Convalescence, however, was established normally, and the case was regarded as one of puerperal pyrexia of uncertain origin. About 2 years later the patient again became pregnant and aborted at the seventh week. She was again affected with rigors, high temperature (104°F), profuse sweats, and suppuration of several local bruises. Following curetting and irrigation of the uterus and incising of the suppurative foci, recovery ensued. At the end of a year and a half she again became pregnant but aborted at the end of the fifth week. There followed a repetition of the septic manifestations and in addition suppurative processes in different parts of the body, including several of the joints. Eventually, however, she recovered. It is thought that the patient's tissues possessed the faculty of producing an antitoxin inimical to the streptococcus; on the first 2 occasions this was produced sufficiently rapidly to overwhelm the coccus. On the last occasion, however, this was not the case, and general infection ensued. [A. O. J. K.]

7.—Addenbrooke makes a few supplementary remarks concerning several cases of **parotitis occurring after abdominal section** previously reported by Elder and himself. [A. O. J. K.]

9.—Pullen reports briefly a case of **nasal and pharyngeal diphtheria** occurring in a child, aged 4 years, and treated successfully by the administration of antitoxin some 96 hours after the invasion of the disease. [A.O.J.K.]

10.—Spencer records a rare case in which the diagnosis made was **general septic peritonitis following recurrent appendicitis and perforation**. An iliac incision revealed nothing abnormal outside the peritoneum. On incising the peritoneum there was a copious flow of a straw-colored serous fluid. The appendix was found freely floating over the pelvic brim and was not thickened. The appendix was excised and a rubber tube passed through the wound down into the pelvis drained serous fluid away freely for 3 days; the tube was removed on the fourth day. The pulse reached 130 on the first day, but became normal on the fifth. The patient had an attack of basic pneumonia 13 days after the operation and 1 month after was discharged apparently quite well. There was nothing found to account for the general serous peritonitis unless the attack of pneumonia indicated an individual predisposition to catarrhal inflammation. [O.L.]

11.—Jackson confirms by experience and observation in operative treatment of **vesical calculi** the surgical dictum that every stone weighing 2 ounces and over should be regarded as a large stone and treated by **lithotomy** rather than by lithotripsy. [O.L.]

2.—**Hyperacid chyle** cannot be rendered sufficiently alkaline in the duodenum for physiologic metabolism. Fermentative changes culminate in cellular stasis, cutaneous obstruction and peripheral atrophy. The duodenum's close relation with the skin is shown in ulceration following cutaneous burns. It is the paramount reflex center. Eczemas are healed by intestinal antiseptics in combination with drugs acting more directly on the skin. [H.M.]

3.—The variety described is pyogenic in character, universal in distribution, with complete loss of hair but not resulting in atrophy. There are but two other instances in literature, designated as **impetigo pustulosa**. [H.M.]

4.—One case of injury from **pressure of cicatrix and 4 from traumatic division of the median and ulnar nerves** are cited. The main conditions of successful operation are a sufficiently long incision along the nerve's course, freshening of the ends until healthy fibrillae are reached, accurate approximation by chromicized catgut with fine silk for the sheath, relaxation suture or position to overcome tension, nerve stretching or flap operation for loss of substance, strict asepsis with avoidance of the irritation of antiseptics when possible. Tables show the majority of operations are followed by cure and the majority of the remainder bring improvement. [H.M.]

5.—**Federal meat inspection** has been in operation 9 years. Condemnations per 10,000 are: cattle, .48; sheep, 8.1; swine 37. The ruling as to tuberculosis is more stringent here than abroad and the disease is less frequent. There are fewer tubercular swine than cattle but the disease is more generalized and carcasses must be more carefully scrutinized. Not only injurious but repugnant meats are rejected, i. e., those having non-transmissible diseases and those advanced in pregnancy. No microscopic examination is made. Of trichinosis cases in Germany 51% come from inspected meat. Non-prevalence of the disease here is due to different methods of curing and cooking the flesh. All butchers of a town should slaughter at the same place and offal feeding should be abolished to prevent the propagation of the echinococcus. [H.M.]

6.—**Fowler's method of amputation** is described, and **Noble's colopexy**. Matthew's operation for an old and large prolapse with much hypertrophy of tissue was a 6 inch incision in the left inguinal region, the reduction of the mass by an assistant whose fingers lifted and held the bowel taut against the abdominal wall while a 3 inch running suture of chromicized catgut was inserted, anchoring the gut to the wall. The operation was permanently successful. [H.M.]

8.—Freer reports the tenth recorded case of **extension of thyroid tissue to the larynx or trachea**. In his own case the swelling was diffuse and subglottic. Only partial operation for removal was submitted to; tracheotomy was performed for dyspnea. [H.M.]

9.—Reference is made to C. H. Mayo's case of **open treatment of suppurating kneejoint** reported in 1895. Ankylosis does not follow in all cases, sometimes from 15% to 60% of normal motion being retained. As ankylosis is inevitable without this operation, its possibility is never a contraindication. When compared with other methods the subsidence of the phlegmonous process is astonishing. [H.M.]

12.—The solution of the problem lies in the attainment of

social purity through more thorough education in sexual hygiene and physiology in medical schools and of children in their homes, and in making the breeding of offspring not an incident of sexual gratification, but the object of intelligent desire, thus changing the character of inherited tendencies in the race. [H.M.]

13.—Statistics are given showing the frequency of chancre on prepuce and furrow and the comparatively low percentage of syphilitics among Jews. Circumcision is devoid of mortality and will lessen syphilis by 50 to 75%. [H.M.]

14.—The report specifies the questions sent to gynaecologists as to the proportion of cases of sterility and pelvic inflammation due to gonococci and records the widely divergent answers. There is unanimity among the genitourinary specialists as to the curableness of gonorrhoea, but diverse opinions as to the time required. All agree that tests to determine cure should be searching and repeated. Sentiment as to legal restriction on marriage is divided. Those in favor are not agreed as to methods. Public sentiment is not ready to enforce regulations and needs education on sexual matters by able physicians. This is best given privately. The committee emphasizes the necessity of every physician treating each case thoroughly until cured and cultivating general intelligence as to the insidious, remote and most grave consequences of the disease. [H.M.]

15.—Paracentesis should be performed promptly during the serous stage to prevent pus-formation. Before operation the meatus should be sterilized by watery carbolic solution and after puncture drainage established by a strip of gauze powdered with boric and salicylic acid and retained by a gauze pad and adhesive plaster. Retention of adenoids and enlarged tonsils, misuse of the nasal douche and snuffing up of fluids are frequent causes of otitis media. [H.M.]

Boston Medical and Surgical Journal.

March 28, 1901. [Vol. CXLIV, No. 13.]

1. Embryological Basis of Pathology. CHARLES SEDGWICK MINOT.
2. New Method of Treating Fractures. LEONARD F. HATCH.
3. Mumps in Pneumonia. Boroglyceride. CHARLES W. DULLES.
4. Brief Summary of 9 Cases of Lobar Pneumonia Treated by Ice Pack. GEORGE L. COLLINS.

1.—Minot, in an able paper read at the Middleton-Goldsmith lecture, presents some of the more important conceptions derived from embryologic study in regard to the processes of cell differentiation and suggests the bearings of these conceptions on the problems of pathology. It is impossible to review the paper adequately in our limited space. [G.C.C.H.]

2.—Hatch, in the treatment of fractures, adopts as principles; first, to convert all compound fractures into simple ones and second, to operate on simple fractures, making them compound and then apply the first principle, making them simple. In his cases he has used drainage only once, in a compound fracture of the thigh. Fractures treated by the operative method are comparatively devoid of pain. The sharp spicules of bone sticking into the soft parts and the swelling are the principal causes of pain, and both of these are avoided by operation. In operating hold the extremity in a vertical position for a few moments, then apply a rubber constrictor. Fit a sterile anterior and posterior splint of any suitable material. The points of selection for the incision are, for the tibia along the crest, for the femur on the outer side of the thigh, for the radius behind the supinator longus, for the ulna along the ulnar side of the arm where the bone is most superficial, for the humerus along the outer side of the arm. Make a good free incision, wash out all clots and debris, removing shreds of soft tissue and fragments of bone. Secure perfect coaptation, removing all bone that might interfere. Apply one splint before closing wound; use catgut sutures without drainage; apply second splint and bandage. On seventh or eighth day apply ambulatory splint or plaster cast. The procedure shortens the repair process at least a week; reduces chances of deformity and nonunion to a minimum; relieves pain and swelling, etc. [G.C.C.H.]

3.—Dulles praises boroglycerid in inflammatory swellings especially in incipient boils and carbuncles. [G. C. C. H.]

4.—Collins summarizes 9 cases of lobar pneumonia treated by the ice pack and concludes that the treatment had no particular effect in either shortening or prolonging the duration of the physical signs, these clearing up the fourteenth day. In only one case did the pack cause discomfort, and in no case was the crisis accompanied by dangerous collapse. The pack has been used to abort beginning cases, in cases with well marked signs and in cases showing resolution. Contemporary signs of bronchitis were not considered contraindicatory. High temperature and not physical signs was the indication for application and lowered temperature for removal. The white count invariably fell with the temperature but reached normal in no less than one week after the temperature was normal. [G.C.C.H.]

Medical Record.

March 30, 1901. [Vol. 59, No. 13.]

1. Some Fallacies of Therapeutics. GEORGE L. PEABODY.
2. Ionization in Its Physiological and Pathological Relations. MARTIN H. FISCHER.
3. Creasote in Pneumonia: A Resume. J. L. VAN ZANDT.
4. Orchid Culture in Its Relation to a New, Improved and Completely Effective Method of Disinfection. J. M. W. KITCHEN.

1.—Popular opinions as to certain drugs are disputed. Peabody believes bitter substances in pills are inert and aid appetite and digestion only by their effect on taste and the secretion of saliva and through the alcoholic vehicle. Boric acid is too much despised. Though not antiseptic, bacteria cannot develop in 2.5% solutions and it is useful in infected wounds, especially when germs have penetrated beyond reach of bichlorid and carbolic acid as it is more diffusible and less poisonous than these. Tannin in weak solution causes swelling of organic tissues and in any solution, dilation of capillaries by direct action on the walls. No diminution of secretion is observed, nor stypitic effect after absorption. There is no proof that ergot contracts pulmonary vessels and, as it increases pressure, it is contraindicated in pulmonary hemorrhage. Lithium is valueless as a uric acid solvent. Arsenic in ordinary lethal doses is not preservative, but aids decomposition through inflammatory changes. Calomel is a hepatic sedative. It does not aid the removal of inflammatory products of serous membranes; neither will potassium iodid, which is useless in arthritis deformans, gout and lead poisoning. Creasote benefits in tuberculosis only by improving intestinal digestion. [H.M.]

2.—The article begins with a review of the gradually developed theory of the dissociation of electrical conductors when in solution into radicals with opposite affinities. The second part sums up the evidences that in dealing with the action of dilute solutions of inorganic on organic substances we deal with the action of anion or kation alone or with these in conjunction with an undissociated remainder. The theory is exemplified (1) in the action of electrolytic products on germinating seeds; (2) on muscle tissue in relation to absorption of water; (3) in the analogy of (2) with the combination of water with soaps; (4) in the discovery that striped muscle fiber contracts rhythmically only in solutions of electrolytes; (5) in the toxic effect on protoplasm of ions, even those of NaCl, when present in pure solution, protoplasm being probably a proteid in combination with several ions; (6) in the occurrence of salt-albumin compounds whose stability is explainable only by supposing combination with both ions of a given salt. Electrical conductivity in living tissue is dependent upon migration of ions. The taste of a solution of an electrolyte depends upon the contained ions, and upon the development of the latter hangs the germicidal action of mercurial and other salts. The characteristics of dissociable organic compounds apparently at variance with the laws of ionization is explained by their supposed transformation in living tissues into compounds in harmony with those laws. [H.M.]

3.—Van Zandt gives his own experience and a resume of the literature of creasote administration in pneumonia, showing rapid control or abortion of symptoms and physical signs, with relapse on too early discontinuance of the drug. [H.M.]

New York Medical Journal.

1. Congenital Dislocation of the Shoulder, with Report of 2 Cases of Dislocation Posteriorly. DANIEL W. MARSTON.
2. The Pathology of Intrauterine Death. NEIL MACPHATTER.
3. The Comparative Pathology of the Jews. MAURICE FISHBERG.
4. The Causes and the Significance of the Obstetric Hemorrhages. J. CLIFTON EDGAR.
5. Tropical Dysenteries. STEPHEN M. LONG.
6. A Dressing for Colles' Fracture. CHARLES L. DEMERITT.
7. A Requisite to Increase the Usefulness of Ambulances. FREDERICK GRIFFITH.

1.—Marston concludes his article on congenital luxation of the shoulder as follows: It is of the utmost importance to distinguish between cases of dislocation and true obstetrical paralysis. The treatment of the former condition is immediate reduction; by manipulation if possible, otherwise, operative. Every infant should be carefully examined at birth, for it is at this time that reduction is easiest performed. From the facts that a fracture of the glenoid cavity has often been found, and that the history of nearly all cases shows difficult labor, he is led to believe that these cases are not of paralytic origin, or due to nondevelopment, as affirmed by Scudder, but are due to traction made in the axilla by the finger or vectis, or to the arm being caught in some unusual position and dislocated by the contraction of the uterus. Paralysis may be coincident, but it cannot be a primary factor in causing dislocation posteriorly. The prognosis of the operative treatment is excellent. The earlier the operation the more hopeful the outlook. Like congenital dislocation of the hip, these cases of the shoulder are little benefited by mechanical treatment. [G.C.C.H.]

2.—Will be abstracted when concluded.

3.—Will be abstracted when concluded.

4.—Edgar divides obstetric hemorrhages into antepartum, intrapartum, and secondary postpartum hemorrhages. In the first he enjoins careful confirmation of diagnosis from examination of symptoms since treatment must vary widely with the cause. Intrapartum hemorrhages may be caused by premature separation of the placenta, rupture of uterus or cervix, fibroid tumors, malignant disease, uterine inertia, lacerations of genital tract, insufficient contraction of lower uterine segment, partial or complete inversion, etc. Postpartum hemorrhages he defines as those occurring between 6 hours after the completion of the third stage of labor and the completion of the normal period of involution, 6 weeks. They depend almost wholly upon the management of the second and third stages of labor and on the care the woman receives during the first few hours or days of the lying-in state. The article is very synoptic and should be read in the original for a knowledge of all the points. [G.C.C.H.]

5.—Long holds that dysentery is a disease that should be well studied since there is embraced in this vague term 4 or 5 or more different types, and as a war and famine disease it has for centuries been one of the deadliest enemies any people can encounter, as may be seen by comparing the records of deaths from wounds and those from dysentery in war statistics. He gives a brief description of the etiology, symptoms, pathology, sequels, etc., of 5 types seen in the Philippine Islands and considers (1), the fulminating catarrhal dysentery, the most fatal, as no treatment has availed to save the patients, who die in 4 to 7 to 11 days. Its causation has been ascribed to Shiga's bacillus and the disease is confined to the large intestines, the entire tract of which on autopsy presents one homogeneous necrotic mass. The solitary glands are abolished and no ulcers visible macroscopically; (2) simple acute dysentery often associated with malarial fever and in the beginning easy to cure; (3) the anebic type which is prone to cause liver abscesses and is due to the ameba, to *Trichomonas intestinalis*, *Cercomonas intestinalis* complicated with the presence of *Bacillus pyocyaneus*, *Staphylococcus aureus* and *S. albus*; (4) chronic dysentery; (5) gangrenous and diphtheric—which is generally fatal from perforation, peritonitis or from toxemia. The sequels are many and grave. In his opinion alcohol should not be regarded as a prophylactic but rather the reverse. The proper treatment of dysentery requires not only an extended

knowledge of the action and nature of drugs but also of the different types of the disease and this calls for an acquaintance with the use of the microscope and the methods of identifying bacteria and infusoria, but he mentioned the 4 drugs easily carried and procurable in any part of the world which in his experience have been most effectual—calomel, magnesium sulfate, bismuth subnitrate and ipæcaquanha, and gives a detailed account of their administration. [O.L.]

6.—DeMeritt describes a simple splint for Colles' fracture, which can be made in a few minutes with materials and tools that can be found anywhere and possesses the advantage of being always an exact fit. [O.L.]

7.—Griffith suggests a thermometer and heat appliance as necessary in the equipment of an ambulance with a view to combating shock, especially in cases demanding immediate operation. He details several methods in which this may be done. [G.C.C.H.]

Medical News.

March 30, 1901. [Vol. LXXVIII, No. 13.]

1. Report of the Committee of the Medical Board of Bellevue Hospital, Appointed January 2, 1901, to Investigate and Report Upon Questions Relating to the General Administration of the Hospital.
2. Vaccination, Clinically Considered. FRANK S. FIELDER.
3. The Method of Preparation of Vaccine Virus in the Vaccine Laboratory of the New York City Health Department. J. H. HUDDLESTON.

1.—The Committee of the Medical Board of Bellevue Hospital finds the reception office utterly inadequate and that attendance there by the house staff seriously interferes with their duties elsewhere. The death-rate is increased by ambulance cases from other hospitals but while the average mortality of all the city hospitals is 9.44% that of Bellevue is 7.08%. The insane pavilion should be under the care of a qualified and paid physician with a paid assistant. Pupil nurses are not fitted for care of the insane. The alcoholic wards are overcrowded. Repeaters should be sent to the workhouse. Epileptics, cases of surgical mania, etc., are assigned for lack of room to the alcoholic wards. Recently completed pavilions have serious errors of design and construction. The building for lying-in cases is utterly unfit. Those in charge of the dispensary are unfit for the position; a paid superintendent of this department should be appointed. Proper food for convalescents is lacking. Nursing outside the insane and alcoholic wards is satisfactory. The defective execution of laws is due to division of authority. The superintendent should have supreme control over nurses. The pay, accommodations for and character of the "help" should be improved. The quarters of the house staff should be enlarged. The per capita allowance should be increased. [H.M.]

2.—The clinical course of vaccinia with variations and complications is described, and statistics as to immunity conferred to smallpox and vaccination are given. Methods of inoculation are discussed. Fielder believes natural immunity to vaccination is practically unknown; atypical primary cases are due to poor virus; a dark purple areola is due to mixed infection; generalized vaccinia, aside from autoinoculation is rare; the duration of immunity to smallpox is extremely variable, but one immune to smallpox may be successfully vaccinated; revaccination should always be performed in an epidemic; the protective power is in proportion to the quality of the scar, and is as effectual as smallpox itself against subsequent attack; the virus before issuance should be tested on human subjects previously unvaccinated, and retested monthly; vaccination shields are often harmful; infected sores should be treated by the physician. [H.M.]

3.—Female calves, healthy and with good quality of skin are chosen. An autopsy follows vaccination, and if this shows disease the virus is rejected. Tuberculosis and skin diseases are the most important. The posterior abdomen and inside of the thighs are shaved, cleansed and washed with alcohol, stronger antiseptics roughening the skin too much. Linear incisions $\frac{1}{4}$ inch apart over the shaven area are made and humanized virus or bovine glycerinated virus at least 2 months old is rubbed in. The virus is collected on the fifth to the seventh day and emulsified with diluted glycerin, tested on children and sealed. [H.M.]

Philadelphia Medical Journal.

March 30, 1901. [Vol. 7, No. 13.]

1. **Atmokausis: Its Value in the Treatment of Severe and Uncontrollable Uterine Bleedings (Uterine Arteriosclerosis.)** SAMUEL W. BANDLER.
2. **The Coexistence of Carcinoma and Fibroma in the Corpus Uteri.** W. A. NEWMAN DORLAND.
3. **Shock in Abdominal Operations.** FENTON B. TÜRK.
4. **A Practical Modification of the Phenylhydrazin Test for Glycosuria.** ROBERT N. WILLSON.
5. **How to Prevent Stammering.** G. HUDSON MAKUEN.
6. **Bell's Palsy Associated with Complete Anesthesia in the Territory of the Fifth Nerve.** JAMES HENDRIE LLOYD.

1.—Bandler advocates the use of **atmokausis**, since the results in his own experience have been uniformly excellent. He says, however, that the limits and absolute indications for this method are not yet defined. The generally accepted indications are those followed by Fehling, who has obtained good results in bleeding due to endometrial changes, and in climacteric bleedings. On the fourth to sixth day after curettage he uses atmokausis for 5 to 20 seconds at a temperature of 110°–115°C. This method was used in the clinic of Dührssen generally for uterine bleedings, not controlled by the curet and by local treatment. The procedure in treating patients with this method is as follows: A positive diagnosis of the condition at hand must be made in all cases. Dilatation of the cervix is an all important preliminary for many reasons. It permits the examination of the uterine cavity with the finger. If no local changes are present, and if there is no retention of fetal membranes, not infrequently vaporization suffices without previous curettage. Retained membranes and malignant changes must be excluded before using this method. Only the finger can prove absolutely that the uterus is empty, and only curettage aided by examination with the finger makes it certain that we have removed those portions of the endometrium which are abnormal, and which are to be examined for malignant changes. In addition, dilatation of the cervix changes the three cornered uterus into a circular canal so that subsequent use of steam affects all parts of the lining equally. In addition, dilatation of the cervix permits of the use of a larger uterine tube, so that when the metal catheter, through which the steam passes, is introduced there is sufficient room in the uterine tube for the exit of the liquefied steam, and coagulated blood and serum. Lastly and equally important is the fact that a dilated cervix permits of a readier natural drainage of the uterus during the subsequent period. A necessary preliminary, then, not alone for the sake of a positive diagnosis, but for the other reasons mentioned, is dilatation of the cervix, for which, in all cases when feasible, laminaria are used. For performing vaporization narcosis is never necessary, since the uterus loses its sensitiveness on the contact of steam. It is only when this is applied to the cervix that some pain is experienced. While the value of atmokausis in other conditions is still a question of personal experience, there is no doubt that uterine bleedings, especially the bleedings of climacterics, and the uncontrollable hemorrhages occurring at this period, and in earlier years, are positive indications for its use, especially when curettage and other local methods are of no avail. [w.k.]

2.—Dorland reports an interesting case of the **coexistence of carcinoma and fibroma in the corpus uteri**. He performed a hysterectomy upon the patient primarily for the relief of carcinoma of the fundus uteri, the diagnosis having been made from a microscopic examination of the scrapings removed 2 weeks before the major operation. The uterus at the time of the abdominal section was found to be infiltrated with small, nodular, fibromatous growths, one of which, submucous in situation and projecting well into the uterine cavity, had become involved in a cancerous process. He presents the result of the pathologic examination of the specimen which was made by Drs. Kirkbride and Deal, reviews the literature of cancerous degeneration of uterine fibroids, and sums up the histology and pathology of uterine fibromas and myomas, concluding that it is possible for fibroma and carcinoma of the

uterus to coexist 3 distinct ways: (1) Fibromyoma of the corpus uteri with carcinoma of the cervix; (2) fibryoma of the corpus uteri with the associated adenocarcinoma of the endometrium; and (3) true cancerous degeneration of the adenomyoma. [w.k.]

3.—Türk claims that 2 important factors have not been sufficiently investigated. One is the **decreased resistance against infection when shock is present**. The second is increased resistance against infection produced by the internal application of heat within the stomach or abdominal cavity. To determine the changes of the blood during shock, the serum of animals in shock was injected into healthy animals. Experiments on 30 animals showed that the ones thus injected soon manifested the symptoms of shock. The conclusion reached is that shock is connected closely with the phenomena of altered metabolism. [A.G.E.]

4.—Willson describes 2 original modifications of the usual **phenylhydrazin test for glycosuria**. Both are considerably shorter than the older methods and the author claims equal if not greater sensitiveness. In the first method, which is a modification of Williamson's, instead of placing the tube in the rack after boiling for 2 minutes, a drop of the mixture is placed upon a slide where it is allowed to cool and then examined under a low power. Typical crystals of phenylglucosagon are seen to form if the reagents have been thoroughly mixed and dissolved before boiling. In the second method the author prefers to boil the solution in a test-tube, using a beaker containing water as a water-bath. After boiling from 5 to 10 minutes a drop of the solution is examined under the microscope as before. [H.H.C.]

6.—Lloyd reports a case of **Bell's palsy complicated by complete anesthesia** in the region of the fifth nerve, the former being due to a neuritis and the latter probably to hysteria, since the anesthesia extends beyond the territory supplied by the fifth nerve. [H.H.C.]

Sundry German Journals.

1. **The Surgical Treatment of Carcinoma of the Stomach.** KONRAD BRUNNER (Correspondenz-Blatt für Schweizer Aerzte, February 15 and March 1, 1901).
2. **The Treatment of Tuberculosis of Joints.** O. HILDEBRAND (Correspondenz-Blatt für Schweizer Aerzte, January 15, 1901.)

1.—Brunner gives his experience during the years 1896 to 1900 in the **treatment of carcinoma of the stomach**. During this time he had under observation 47 cases of carcinoma of the stomach and he has performed 8 resections of the stomach and 9 gastroenterostomies. With regard to resection of the stomach he states that in none of the cases had an early diagnosis been made; that is to say, the growth in all cases was extensive, almost to the limit of possible operation. In 2 cases carcinomatous glands were removed; in one case the abdominal wall and the mesocolon were affected, although not extensively; in another case the disease had extended far into the duodenum; in still another case the lesser curvature was affected high up. One patient was reduced almost to a skeleton, and was operated upon in 2 stages; 1 patient was suffering from chronic bronchitis. One of his fatal cases was in a woman aged 67 who had atheromatous arteries with a very irregular pulse. The conditions for operation were decidedly unfavorable in all except 2 of the cases. The operations were by both Kocher's and Billroth's method and the time required was from 2 to 3 hours in each case. Of the cases that survived operation, 1 died of recurrence a year later. In 1 death followed a half year later and the cause was unknown; in a third the patient died after a year and 3 months from metastasis; in a fourth case probably from recurrence though no necropsy was made. One patient is living and well 5 months after the operation and 1 is perfectly well 2½ years after the operation. This patient is a woman who was 42 years old at the time of operation. More than half the stomach together with carcinomatous glands were removed. Brunner believes that this case demonstrates the possibility of successful operation even in case the disease is considerably advanced. That the recovery will be permanent in this case is not certain, but with the entire impossibility for successful treatment by any other means and with 2½ years of complete health the operation cannot be considered unsuccessful. Brun-

ner also refers to 2 cases operated upon by Kocher, 1 of whom is living 10 years, the other 5 years after operation and a case operated upon by Czerny with the patient living 7 years after operation. He believes with Kocher that the time has come when we can say that permanent and satisfactory results are possible and that operative treatment is indicated in these cases. The patients in whom gastroenterostomy was performed were all suffering from decided pyloric stenosis at the time of operation and would have scarcely lived a month without operation. In 5 of the cases Wölfler's method was used with 4 recoveries. In 1, death resulted from persistent vomiting after the operation. The 4 remaining cases were operated upon by von Hacker's method and of these 1 died from collapse the day after the operation during an attempt to wash out the stomach and a second died 15 days after the operation without any apparent cause. The gain in length of life in these cases is not very great. None of the patients lived more than a year. However, Brunner considers the operation justifiable in cases in which distressing symptoms of stenosis are present. In other cases he does not favor the operation and believes that it is too frequently performed at the present time. A thorough review of the literature of this subject is given. [M.N.T.]

2.—The treatment of tuberculous joints is quite different in children from that in adults. In children the more conservative methods of treatment are usually advisable because of the possibility of disturbance of growth which may result from more extensive operations. Hildebrand believes that experience has shown the value of iodoform injections. It has a certain influence in inhibiting the growth of the bacilli and by its irritating effect tends to develop the blood vessels and scar tissue, thus limiting the action of the bacilli. He speaks favorably also of formalin injection, but believes that it is too early to say definitely what the ultimate results will be. The formalin destroys the tuberculous tissue and the bacilli and by its caustic action promotes healthy granulation but it is extremely painful and should be preceded by the free use of cocaine. The method of producing venous stasis as was first suggested by Bier is also mentioned favorably. In case the bone is primarily affected these methods are ineffectual. In advanced synovial disease extirpation of the joint-capsule may be necessary. In a large percentage of cases, however, comparatively permanent healing may be secured with a good functional result by the conservative means of treatment. In case these methods fail resection is justifiable but it should be almost never performed at the knee because of the great disturbance in growth; in the wrist, the elbow and ankle very seldom. On the contrary, it may frequently be beneficial in case of severe forms of hip-joint tuberculosis affecting the acetabulum. Amputation and exarticulation are very seldom required in children. Orthopedic treatment is extremely important among the conservative measures. In the treatment of joint tuberculosis in adults the conditions are quite different. The economic standpoint must be considered. A conservative treatment should not be long continued for resection even in the less severe cases gives a certain result with a short confinement under treatment and an excellent functional result. In adults he strongly favors operative treatment and believes that successful results are obtained in from 70 to 80% of the cases. In connection with the local treatment, fresh air, careful attention to nourishment of the patient and the use of certain remedies, particularly tonics, creasote and guaiacal is recommended. In a discussion of this paper Koehler said that a cure in the sense of removing every possibility of subsequent general tuberculous invasion cannot be reached through purely conservative methods. Numerous instances have shown that frequently a long time after conservative treatment with apparent health resulting, operation is demanded because the disease lights up anew. He speaks more favorably of Bier's method of treatment than that by iodoform injection. The only treatment which will produce a radical cure is operative and consists in the complete elimination of the entire tuberculous deposit. This must usually be done by an atypical operation. In the beginning of the treatment operative measures should at least be suggested. The permanent results of total resection of the joints are very favorable, and unfavorable results usually occur because operative treatment is undertaken late, after the disease is far advanced. [M.N.T.]

Bulletin of The Johns Hopkins Hospital.

February, 1901.

1. Preliminary Note of a Case of Infection with *Balantidium Coli* (Stein). RICHARD P. STRONG and W. E. MUSGRAVE.
2. Hyperextension as an Essential in the Correction of the Deformity of Pott's Disease, with the Presentation of Original Methods. R. TUNSTALL TAYLOR.
3. Two Examples of Bence-Jones Albumosuria Associated with Multiple Myeloma. LOUIS P. HAMBURGER.
4. Report of a Case of Fulminating Hemorrhagic Infection due to an Organism of the *Bacillus mucosus capsulatus* group. GEORGE BLUMER and ARTHUR T. LAIRD.

1.—The authors give a brief historic sketch of the occurrence of the infusorial parasite *Balantidium coli*, Stein., of which some 20 cases only are on record. The case observed by them had a history of continuous diarrhea, growing steadily worse for a period of 4 months. For some days before death each drop of the patient's feces contained over 100 of the parasites. [C.S.D.]

2.—Taylor describes in an illustrated article two recumbent **kyphotones** adapted to carry out the same mechanical principles of **hyperextension** as secured by his original apparatus, presented to the American Orthopedic Association in 1899. Both of the later devices meet the need of acute or early cases or those with external pachymeningitis with paraplegic symptoms, in which it is detrimental to even sit up momentarily. The article is accompanied by a list of the recent bibliography of Pott's disease. [C.S.D.]

3.—Blumer and Laird describe a fatal case of a relatively rare disease, **fulminating hemorrhagic infection**; due to an organism of *Bacillus mucosus capsulatus* group, of interest on account of the proliferative changes in the lymphatic apparatus of the intestine and on account of the exceedingly rapid course. The organism isolated failed to produce gas in saccharose bouillon and in this respect differed from all those previously described. [C.S.D.]

American Journal of the Medical Sciences.

March, 1901. [Vol. CXXI, No. 347.]

1. The Surgical Treatment of Ascites due to Cirrhosis of the Liver with Report of two Cases. FREDERICK A. PACKARD and ROBERT G. LE CONTE.
2. Splenic Myelogenous Leukemia with Pulmonary Tuberculosis. HENRY L. ELSNER and WILLIAM A. GROAT.
3. Hemorrhagic Typhoid Fever. AUGUSTUS A. ESHNER and T. H. WEISENBERG.
4. A Study of Congenital Sarcoma of the Liver and Suprarenal. WILLIAM PEPPER.
5. A Case of Sarcoma of the Thigh, for which Disarticulation was Performed Through the Hip-joint, with the Formation of a Posterior Flap. JOHN CHALMERS D'ACOSTA.
6. Stereognosis and Allied Conditions. CHARLES W. BURR.
7. Clinical Study of Acute Myocarditis. BEVERLEY ROBINSON.

2.—Elsner and Groat, commenting upon the rarity of the association and referring to the literature on the subject, report a case of **splenic-myelogenous leukemia with advanced pulmonary tuberculosis**, occurring in a man, aged 40 years. Symptoms referable to increase in the size of the spleen and liver were the initial manifestations and were present almost a year before the advent of cough, expectoration, and other pulmonary symptoms. Examination revealed consolidation of both lung apices, a tuberculous ulcer of the pharynx, tubercle bacilli in the sputum, and great enlargement of the spleen and liver. The hemoglobin varied at different examinations from 49% to 64%, the erythrocytes from 2,680,000 to 3,320,000, the leukocytes from 121,500 to 320,000. Myelocytes varied from 16% to 38%, the average being 26%; lymphocytes varied from 4.1% to 7.5%, eosinophiles from 3.5% to 6.5%, polymorphonuclear neutrophils from 55% to 64%, and basophiles from a few to 4.5%. While the blood retained the characteristics of splenic-myelogenous leukemia as the tuberculous process advanced, there was a gradual and steady decrease in the total number of leukocytes, but an increase in the percentage of polymorphonuclear neutrophils, a decrease in the number of myelocytes, and an increase in the number of lymphocytes. There was a decided increase in the elimination of uric acid by the patient. The authors discuss the changes occurring in the lungs in

leukemia and the resemblance they bear to tuberculosis. [A.O.J.K.]

3.—Eshner and Weisenberg report 2 cases of **hemorrhagic typhoid fever**. The first was that of a man, aged 39 years, who on the twenty-eighth day of an attack of typhoid fever, exhibited a hemorrhagic eruption of the legs. The same day the eruption extended all over the body, the blotches being bluish in color, irregular in shape, and from $\frac{3}{4}$ to $1\frac{1}{2}$ inches in diameter. There occurred also an extravasation of blood into 1 cornea, and blood was passed from the bladder and bowel. The man died the following day. The necropsy, in addition to the usual lesions of typhoid fever, revealed hemorrhagic extravasations into practically all the organs and tissues. The second case was that of a man, aged 28 years, who toward the close of the second week of an attack of typhoid fever, developed a peculiar, dark, rusty-red, papular eruption on the chest and abdomen. By the following day it covered the entire chest and abdomen and had spread to the arms and legs. The only other hemorrhagic manifestation was bloody tube-casts. Death occurred the third day after the onset of the eruption. Necropsy revealed the usual lesions of typhoid fever, but no internal hemorrhagic extravasations. It is suggested that possibly the cases represent a type of hemorrhagic purpura occurring in the course of, and perhaps predisposed to, by the typhoid fever. [A.O.J.K.]

4.—Pepper reports a case of **congenital sarcoma of the liver and suprarenal** in a female child aged 6½ weeks at the time of death. A review of the literature revealed reports of 5 cases of striking similarity. The points of interest and similarity are the occurrence of symptoms at or very soon after birth; the early death of the patients, none living longer than 16 weeks; the extreme rapidity of the tumor growth; the sex of the patients—5 being females and the sex of the other not being mentioned; the clinical manifestations—abdominal distention, wasting, absence of ascites, of jaundice, of marked pain, of fever, and of evidences of syphilis; infiltrative proliferation of the sarcoma tissue with practically complete destruction of the entire normal liver tissue; the hemorrhagic character of the growth in the suprarenals; and absence of involvement of any other organs or tissues by the tumor formation. In the case reported as well as in another case the diagnosis was lymphosarcoma; in 3 cases, round cell sarcoma; and in 1 case, myxosarcoma. In 3 cases the tumor was thought to have originated in the liver, in 2 in the right suprarenal. A table of 46 cases of primary sarcoma of the suprarenal is appended by way of contrast; these tumor formations are entirely dissimilar from those the subject of the detailed report. [A.O.J.K.]

6.—Burr, after a thorough discussion of **stereognosis and allied conditions** and the report of 2 illustrative cases, concludes as follows: (1.) The ability to recognize objects by handling them depends upon the integrity of the afferent nerves, the cortical sensory area, and the cortical perceptive area; (2.) disease of either of these will make it impossible for the patient to recognize objects by handling them; (3.) we may dismiss from consideration here the inability to recognize objects because of disease of the sensory nerves or of the sensory tracts in the spinal cord, medulla, and pons. Such inability is due to anesthesia of one or more types; (4.) there is a distinct area of the cortex in which sensations produced by handling objects are grouped together to form tactile memory images, the tactile perceptive area, in the parietal lobe, which is not the same thing as the sensory area, though it may be located within the boundaries of the latter; (5.) it would be well to limit the term stereognosis to cases in which the inability to recognize objects by contact is due to some failure of sensation caused by brain-disease either in the cortical sensory area itself or in the fibers going to it; (6.) tactile amnesia includes the case in which, on account of disease in the tactile perceptive area, the tactile memory images are destroyed. It is not infrequently associated with mind-blindness, and, indeed, it is probable that always in recognizing objects by handling them we recall from memory a more or less faint recollection of the visual appearance of the object. Auditory memories are less frequently recalled, because less frequently needed to make a complete percept, and those of smell and taste quite rarely. (7.) The form of sensation most necessary for the recognition of any given object depends upon

the qualities of the object. Tactile anesthesia, if sensibility to stronger pressure is preserved, causes little or no difficulty. The space sense, the localizing sense, and the sense of position, are probably the most important, for by them we learn the form of objects—the most important element in recognition. (8.) When in the cerebral palsies of children there is inability to recognize objects in the paralyzed hand, it is often caused, as Oppenheim states, by the fact that tactile memory images were never acquired. (9.) Granting that the tactile perceptive area is not the same as the cortical sensory area, such cases as the second reported can be explained upon the hypothesis of a lesion cutting off the fibers joining the 2 areas. [A.O.J.K.]

7.—Robinson discusses in detail the clinical phenomena of **acute myocarditis**, especially as it occurs in certain infectious diseases, notably diphtheria, typhoid fever, and pneumonia. In the treatment, he has seen the best results from the administration of strychnin and inhalation of antiseptics, especially creasote. Drugs such as digitalis and strophanthus should be given cautiously and their action guarded with nitroglycerin or the nitrites. The iodid of potassium is a very serviceable remedy even in the very acute stages. In cases of pneumonia benefit may accrue from the local application of cold. The changes that follow influenza and the means of recognizing and properly treating a concomitant endocarditis or pericarditis are pointed out. During convalescence from acute myocarditis the Schott treatment judiciously carried out meets the indications. It is thought that acute myocarditis in children does not differ much from the same condition in the adult. The prognosis, however, is better in the young. [A.O.J.K.]

McGuire, *Charlotte Medical Journal*, December, 1900, deals with **retrodisplacements of the uterus** from a practical standpoint. He is favorably impressed with the **Alexander operation**, employing it in all uncomplicated cases. The advantages of this operation are less risk; it is to be preferred from the standpoint of pregnancy; it seeks to support the uterus by its natural ligaments, and forms no intraperitoneal adhesions which may be a source of danger. The disadvantages are, 2 incisions are required; the risk of hernia is increased; the operation proper is limited in its application to a mobile uterus; in cases associated with marked descent, while the operation cures the version, it does not lift the uterus to a higher or to the normal level, thereby falling short of the indication for an operation; in ovarian prolapse especially if the ovarian ligaments are long, it cannot be depended upon to raise the ovaries to a normal position; the possible absence or attenuation of the ligaments. [F.C.H.]

THE PUBLIC SERVICE

Changes in the Medical Corps of the U. S. Navy, for the week ended March 30, 1901:

- LEDRETTTER, R. E., assistant surgeon, detached from the Constellation, April 1, and ordered to the Chicago, via the Dixie, April 3, as relief of Assistant Surgeon J. R. Whiting.
- CRAWFORD, C. A., assistant surgeon, detached from the Dixie, March 28, and ordered to the Constellation, April 1, as relief of Assistant Surgeon R. E. Ledbetter.
- WHITING, J. R., assistant surgeon, detached from the Chicago, upon reporting of relief, and ordered to the Dixie.
- PICKRELL, G., surgeon, detached from the naval hospital, Mare Island, Cal., and ordered home.
- DAVIS, E., assistant surgeon, detached from the naval hospital, Mare Island, Cal., and ordered home, with permission to delay en route.
- McCLANAHAN, R. K., assistant surgeon, ordered to the Asiatic Station, via the Solace, April 12.
- MERRITT, W. A., passed assistant paymaster, detached from the Hartford, April 15, and ordered to the bureau of supplies and accounts, Navy Department.
- DECKER, C. J., surgeon, order detaching from the Monocacy and ordering to the Oregon, revoked; ordered to the Newark.
- LEACH, P., surgeon, order detaching from the Oregon and ordering to the Monocacy, revoked.
- HIBBETT, C. T., surgeon, detached from the Newark and ordered to the naval hospital, Cavite, P. I.
- SPEAR, R., passed assistant surgeon, detached from the Isla de Luzon and ordered to the Concord.
- EVANS, S. G., passed assistant surgeon, detached from the Concord and ordered to the Monocacy.

GROW, E. J., assistant surgeon, detached from the Glacier and ordered to the Isla de Luzon.

Changes in the Medical Corps of the U. S. Army for the week ended March 30, 1901:

COWPER, Captain HAROLD W., assistant surgeon, is relieved from temporary duty at the Presidio and will report to the commanding officer third battalion, 10th infantry, in camp on the Presidio reservation, for duty with that battalion.

BAILEY, Captain GUY G., assistant surgeon, is relieved from temporary duty at the Army general hospital, Presidio, and will report to Colonel Philip I. Ellis, 24th infantry, commanding provisional battalions, for duty with the first battalion, 30th infantry, in camp on the Presidio reservation.

MULLINS, THOMAS K., acting assistant surgeon, is relieved from temporary duty at the Army general hospital, Presidio, and assigned to temporary duty with troops on the horse transport Paking, during the voyage to the Philippine islands.

SHIMER, First Lieutenant IRA A., leave granted is changed to leave on surgeon's certificate. Lieutenant Shimer is authorized to apply, if necessary, for an extension of 1 month.

BRUHL, CHARLES E., acting assistant surgeon, is granted leave for 1 month, with permission to go beyond the limits of the department of Cuba.

WILLIAMS, ADRIAN D., acting assistant surgeon, now awaiting orders at Governor's Island, will report to the commanding officer, first battalion, 11th infantry, at Fort Columbus, to accompany that battalion to the Philippines.

VAN TUY, Captain WILLIAM R., assistant surgeon, recently appointed, will proceed from Fort Thomas to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

TANNER, Captain WILLIAM T., assistant surgeon, is assigned to duty with the third battalion, 11th infantry, and will proceed to Washington barracks and report to accompany that battalion to the Philippine islands, where he will report for assignment to duty.

CARTY, GEORGE S., hospital steward, Fort Douglas, Utah, is transferred to Fort McDowell for duty with the hospital corps school of instruction.

BEASLEY, Major SHADWORTH O., surgeon, recently appointed, now in San Francisco, Cal., will report for transportation to Manila, P. I., where he will report for assignment to duty.

ALLEN, Captain IRA A., is granted leave for 1 month from about April 20.

HICKS, Captain GEORGE L., JR., assistant surgeon, recently promoted from first lieutenant, assistant surgeon 38th infantry, U. S. volunteers, is assigned to the 38th infantry, U. S. volunteers.

REIFSNYDER, Captain JOSEPH C., assistant surgeon, recently appointed, will proceed from West Point, N. Y., to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

BARTLETT, COZAM J., acting assistant surgeon, is relieved from further duty in the department of Alaska, and will proceed to San Francisco, Cal., and report for assignment to duty.

GARLINGTON, JOSEPH C., acting assistant surgeon, is relieved from duty at Fort Mott, to take effect upon the arrival at that post of Acting Assistant Surgeon Josiah W. Richards, and will then proceed to Fort Terry for duty to relieve Acting Assistant Surgeon John J. Gilhuley, who will proceed to his home, Bridgeport, Conn., for annulment of contract.

CARR, Major LAWRENCE C., surgeon, chief surgeon, in addition to his other duties, is detailed as sanitary inspector of the city of Santiago, Cuba, relieving First Lieutenant Ira A. Shimer, assistant surgeon, who will remain on duty as assistant until the transfer is completed.

FIELD, P. C., acting assistant surgeon, now on duty at the headquarters of the artillery defenses of Havana, is upon his own application relieved from further duty in the department of Cuba, and will proceed to Washington, D. C., for annulment of contract.

CROSBY, Major WILLIAM D., surgeon, in addition to his present duties, will relieve Major Henry S. Kilbourne, surgeon, of his duties as medical superintendent, army transport service, New York city, and upon being thus relieved Major Kilbourne will proceed to the Presidio for duty.

LONGINO, Captain THOMAS C., assistant surgeon, recently appointed, will proceed from Fort Clark to San Antonio, Tex., and report to the commanding officer, department of Texas, for duty to accompany troops to be sent from that department to San Francisco, Cal., where he will report for transportation to the Philippine islands, and upon arrival at Manila will report for assignment to duty.

HACK, Captain CHARLES W., assistant surgeon, recently appointed, will be assigned by the commanding officer of Columbus barracks, to duty with the first detachment of recruits to be sent from that post to San Francisco, Cal., where he will report to the commanding general, department of California, for transportation to Manila, P. I., where he will report for assignment to duty.

FOGG, Captain JOHN S., assistant surgeon, recently appointed, will, upon the arrival at Fort McHenry of Major Alexander N. Stork, surgeon, proceed to San Francisco, Cal., and report for transportation to Manila, P. I. where, upon arrival, he will report for assignment to duty.

STEER, SAMUEL L., and PINKHAM, EDWARD W., first lieutenants, assistant surgeons, are relieved from duty in the division of the Philippines, and will proceed to San Francisco, Cal., and report by telegraph to the adjutant general of the army for instructions.

LEHARDY, JULIUS C., acting assistant surgeon, will proceed from Savannah, Ga., to Fort Wood, to relieve Captain Charles R. Gill, assistant surgeon.

GILL, Captain CHARLES R., assistant surgeon, recently appointed, will proceed from Fort Wood to Fort Totten, and report for duty to accompany the battalion of engineers to be sent from the latter post to San Francisco, Cal., where he will report for transportation to the Philippine islands, and upon arrival at Manila will report for assignment to duty.

JAMES, Captain WILLIAM F., assistant surgeon, recently appointed, now at San Francisco, Cal., will report for transportation to Manila, P. I., where he will report for assignment to duty.

HALE, ROBERT E., hospital steward, (appointed March 26, from acting hospital steward), Manila, P. I., will report to the commanding general, division of the Philippines, Manila, for assignment to a station.

RIESS, HERMAN W., hospital steward, now on furlough, will, on expiration of furlough, be relieved from further duty at Fort Apache, and will report to the surgeon general of the army for instructions.

Changes in the U. S. Marine-Hospital Service, for the 14 days ended March 28, 1901:

MURRAY, R. D., surgeon, granted leave of absence for 5 days from April 9-March 23.

AUSTIN, H. W., surgeon, detailed as chairman of a board, to be convened from time to time as necessary, for the purpose of re-examining rejected immigrants—March 28.

EAGER, J. M., passed assistant surgeon, upon expiration of leave of absence to proceed to Naples, Italy, for duty, relieving Assistant Surgeon V. G. Heiser—March 25.

MATHEWSON, II. S., assistant surgeon, granted leave of absence for 3 days from March 26. To rejoin station at San Juan, P. R., March 27.

CLARK TALIAFERRO, assistant surgeon, granted leave of absence for 30 days on account of sickness—March 22.

LAVINDER, C. H., assistant surgeon, granted leave of absence for 10 days from March 28—March 27.

McMULLEN JOHN, assistant surgeon, upon being relieved from duty at Wilmington, N. C., to proceed to Mullet Key Detention Camp, Florida, and assume command—March 22. To report at Washington, D. C., en route to Mullet Key, Fla.—March 22.

RUSSELL, II. C., assistant surgeon, granted leave of absence for 18 days on account of sickness, from February 21—March 22.

HEISER, V. G., assistant surgeon, upon being relieved from duty at Naples, Italy, to proceed to Washington, D. C., and report in person for duty—March 25.

GOODMAN, F. S., hospital steward, to report to the director of the hygienic laboratory, Washington, D. C., for duty—March 20.

AMERICAN MEDICINE

1321 Walnut Street

Philadelphia

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may begin at any time. Volumes begin with the first issue of April and of October.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles, will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is one dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to American-Medicine Publishing Company. Address all correspondence to 1321 Walnut Street, Philadelphia.

American Professional Patriotism is fully justified by our history and is a laudable sentiment. We doubt if a judicial summing up of the contributions of national physicians would show for any country a greater share of discoveries made and of beneficent professional work done than by Americans. It may not be forgotten that the first cholecystotomy, the first nephrectomy, the first gastrectomy and the first ovariectomy were performed by American physicians. Many similar things might be mentioned, especially, of course, the discovery of anesthesia by an American. Pathology is the scientific branch *par excellence* of medicine and in 1839 Dr. Samuel D. Gross brought out the first textbook on this subject. None knows better than we that in its last analysis science has no nationality nor geographical limits, and yet scientific temper and methods do, as a matter of fact, differ in different countries, and the progress of our science and art is colored if not conditioned by these distinctive differences. It was not without a recognition of the characteristic advantages and excellencies of American medical science that we chose the title of the present journal. We wish it to reflect, stimulate and unify our national medical progress, a progress well prepared and as certain of a great future as of a distinguished past.

"Love thou thy land, with love far-brought
From out the storied past, and used
Within the present, but transfused
Thro' future time by power of thought."

Partisan Politics and Charitable Institutions.—The action of Governor Odell of New York in consenting to the withdrawal of the bill for the abolition of the State Board of Charities, is most praiseworthy. The hope of salvation of democratic institutions may almost be said to consist in the willingness of good men and women to give their lives in part or entirely to work for the public good, without reward or salary of any kind. There are 70,000 unfortunates in the reformatory, charitable and correctional institutions of New York, and these have been on the whole well managed by the practical philanthropists in charge of the State Board of Charities. To turn them out and place these charges of the community in the hands of the politicians would have proved an expensive crime. When this has been done there has developed a condition too horrible to be endured. The State of Indiana, after struggling many years with the old system of political administration of State charities, during which every form of abuse and

corruption that was possible pervaded the institutions, adopted the system of a State Board of Charities composed of unsalaried persons appointed without regard to their political beliefs. The result has been a gradual and most decided uplifting of the morale of the institutions and also a great reduction of expenses. The Indianapolis *Sentinel* says:

"For a number of years the Board of State Charities has studied the problems of official poor relief. The results of its studies have been formulated as laws. The showing concerning township poor relief is remarkable. In six years there has been a reduction from \$630,168.79 to \$209,956.22, which is \$420,212.57, or over 66%. There has been an equally striking reduction in the number of persons aided, a general lessening in the tax levy for poor purposes. Notwithstanding all these reductions, there has been a decrease in the poor asylum population and no gain in the number of dependent children. With all this reduction, we are assured that no injustice has been done any needy person."

Increase and Care of the Insane.—There is little doubt that the increase of the total number of the insane is in large measure an increase in the registered cases rather than in new ones. It is equally certain that the number of institutional cases is increasing, because of the decrease of the public disinclination to commit. This is a tribute to the beneficence of their work. On the other hand there is a danger of overcrowding, or its actual existence in many parts of the country. Of the 7,417 patients in public hospitals and asylums of Massachusetts on October 1 last, something over 13% were sleeping on cot beds made up each night in the corridors and the day rooms. This, of course, was detrimental to the health of the patients. In addition to the annual increase, the State is to assume the care, after 1903, of all the insane in city and town almshouses. These now number about 900. In Connecticut, too, the number of insane is in excess of the public accommodations. There are 2,135 patients in the asylum at Middletown, which is 500 more than there is room for, and the number is being added to at the rate of 100 a year. The building is crowded with humanity like cattle in a pen, a legislative committee reports, and in a garret they found 100 men packed in where there was room for but 20. The presentation of these facts hastened the appropriation by the Legislature of \$165,000 to increase the accommodations.

The Leukocyte Count in the Diagnosis of Small-pox.—Leukocyte counting has become something of a

fad in many places. Although it is no doubt sometimes of little value and many times overdone, there can be no question that considerable important information may be obtained by this means in a considerable number of cases. Weil (*La Semaine Medicale*, 1900, Vol. 20, p. 222) reports a study of 36 cases of variola in all its forms, with and without complications, which show that this affection is accompanied by leukocytosis, as has been previously pointed out by Courmont and Montgard. Very often the leukocytosis is slight, but generally moderately high. It appears at the beginning of the illness, increases at the time of the vesiculation and diminishes gradually after this. In character this leukocytosis resembles myelogenous leukemia. He believes that this is a diagnostic point of considerable value and that by differential counting it is possible to diagnose variola from the other exanthems at the time of the appearance of the rash.

In case of an epidemic of smallpox the diagnosis of the disease is usually not difficult, but the recognition of sporadic cases in time to prevent an epidemic is of great importance and any diagnostic point of value should not be overlooked. This suggestion with regard to leukocytosis seems to deserve the attention of those specially concerned with the treatment of contagious diseases.

Improved Sanitary Conditions and Lowered Mortality Rates.—Since the recent United States census has determined more definitely the exact population of our large cities, and the reports on vital statistics may be considered to show more accurately the percentage of diseases than formerly, the examination of the reports of our large cities shows a very marked improvement upon the condition of affairs which existed 10 years ago. Although the physician may be considered the man who is most likely to benefit by the misfortunes of others in the way of disease, it is almost entirely through the efforts of medical men that this decrease in the mortality rates has been brought about. The Monthly Bulletin of the Department of Health of the City of Chicago, for December, 1900, must be remarkably satisfactory to the inhabitants of that city. A comparison with the death rate in the other large cities of the United States and the large cities of foreign countries is most favorable to Chicago. The number of deaths per thousand in Chicago has been only 14.68 as compared with 20.61 in New York, 20.11 in Paris, 19.10 in London and 18.77 in Berlin. Dr. Arthur R. Reynolds, the Commissioner of Health assigns the following causes for the lessened mortality rate; medical school inspection, better water supply, the supervision of food supplies, vaccination and the bacterial diagnosis of disease. He finds that medical inspection of schools, has done a great deal to restrict the contagious diseases of childhood and notification, isolation and disinfection have helped such restriction of these diseases at all ages. The better water-supply has reduced the mortality from typhoid fever and the acute intestinal diseases, and the supervision of food supplies, specially milk and ice, have also aided in this reduction. The aid of the city laboratory to physicians in the bacterial diagnosis of such diseases as diphtheria and typhoid fever has facilitated prompt and scientific medical treatment, thus tending to lessen the death rate. The vigilance of the

chief medical inspector with regard to the vaccination of the people has restricted the spread of smallpox. Above all, he places the growing interest and intelligence of the public in sanitary measures and preventive medicine which have made more effective each and every one of these agencies in the restriction of disease and the protection of the public health.

Furfurol and the Next Morning's Headache.—Sir Lander Brunton and Dr. Zunicjiffe conclude that the furfurol constituent of whiskey is that which causes the violent headache of intoxication. Experiments upon animals and man demonstrated that furfurol has a temporary paralyzing action upon the voluntary muscles, with tonic and clonic convulsions, followed in man by throbbing headaches for 24 hours. In aging, the amount of the furfurol in whiskey grows less, and hence old whiskey causes less headache than the fresh spirit. With a perfectly furfurol-free whiskey the secondary symptoms of drunkenness in man and animals were absent. If the truth of this should seem probable the prohibitionists should at once institute researches to disprove such "science," and gold-cure people may once more pluck up their courage. But we cannot help suspecting some flaw in the argument. To have the fun and not have to pay the fiddler is hardly according to the wisdom and precedents of physiology. There is a sort of tipsy leer about headache-free drunkenness that is decidedly suspicious. We should not be too trustful of these scientists! In the interests of morality we candidly advise the freshly distilled article, moreover, it is so much cheaper.

Urotropin as a Urinary Antiseptic.—Urotropin is one of the very few new remedies upon which reports as to efficacy have been well-nigh uniformly favorable. While it has proved of no value as a solvent of uric acid calculi, a purpose for which it was originally introduced by Nicolaier, it has shown itself more effective than any other drug in ridding the urine of pathogenic organisms. When taken internally in daily doses of from 20 to 30 grains it rarely excites any ill-effects, but it is rapidly absorbed and rapidly eliminated in the urine. Casper attributed its virtues as a urinary antiseptic to the liberation of formaldehyd, but the recent researches of Cammidge (*Lancet*, January 15, 1901) indicate that this view is erroneous. According to this last observer urotropin alone by prolonged heating may be made to yield formaldehyd, but that this decomposition does not take place at body-temperature; that acids, acid-salts and alkalies when heated with urotropin also liberate formaldehyde but not at 37° C.; and finally, that the acid urine of persons taking 30 grains of urotropin a day does not contain free formaldehyd. The readiness with which urotropin is decomposed by acid and acid-salts, together with the more marked inhibitory power over the growth of microorganisms shown by the acid urine over simple urotropin solution or an alkaline urine, would suggest that it is not urotropin itself but some derivative of urotropin formed in the presence of acid urine that is the important factor in rendering the urine antiseptic.

The Study of Diphtheria.—Among the infectious diseases, diphtheria may be considered the one concerning which we have the most complete information. While to the investigator it at present offers few, if any, problems of interest, as a guide to the study of other infectious diseases, a knowledge of the diphtheric process is indispensable, and it is largely to the study of diphtheria that we may attribute the recent advances in our knowledge of the bacteriology, pathology and serumtherapy of infectious diseases in general. On this subject Councilman, Mallory, and Pearce have lately contributed a most instructive and important monograph (*Journal of the Boston Society of Medical Sciences*, Vol. V, No. 5). It deals with the results of the study of 220 fatal cases of diphtheria—the largest number of cases that has as yet been subjected to detailed anatomic and bacteriologic study. To the pathologist, the exhaustive study of the histologic alterations occurring in diphtheria summarized in the monograph will prove of extreme interest; to the clinician, the alterations found in the heart and kidneys are of practical importance. In 67 hearts examined, fatty degeneration of various degrees was found in 46. There was no definite relation between the duration of the disease and the presence of this degeneration, but in the cases of great severity in which death ensued early, it was as a rule the only lesion of the myocardium. Segmentation and fragmentation of the myocardium were not observed. In 13 hearts extensive fatty degeneration accompanied by disappearance of the contractile substance, vacuolation and hyaline transformation occurred. These were found only in the later stages of the disease—about the fifteenth day. Acute interstitial myocarditis, due to accumulation of large numbers of plasma cells between the muscle fibers occurred in 6 cases—generally about the tenth day. Chronic interstitial myocarditis with proliferation of endothelial cells and formation of connective tissue occurred in 14 cases with an average duration of 17 days. In the kidneys degenerative alterations—fatty, granular, and hyalin—were found in 112 cases, with an average duration of seven and a half days. Of 40 of these cases in which the urine had been examined albumin was found in 33, and hyalin and granular casts in some. Acute interstitial nonsuppurative nephritis, marked by infiltration of plasma cells and lymphoid cells, was found in 43 cases, with an average duration of about sixteen days. The most extensive lesions occurred in children of about 11 years of age; the slight lesions in those of about 2 years of age. Of 15 of these cases in which the urine had been examined albumin was present in 14. In 13 cases glomerular alterations were detected; in 9 they were proliferative in character and involved both the tuft and the capsule; in 2 they were acute inflammatory. As compared with other changes in the kidneys, the glomerular alterations occurred in the older children and at a much later stage of the disease. One of the characteristic lesions of the diphtheric process is the infiltration of almost all the tissues with plasma-cells, but the condition is especially well exemplified in the heart and kidneys where it becomes most marked. This with the other alterations noted constitutes the anatomic basis of the serious symptoms of the disease aside from the local

manifestations. Altogether the monograph is a most creditable and valuable one—consisting of 180 pages, and containing 67 photomicrographs and a complete bibliography of over 200 references.

The "Sport" of Pigeon Shooting should be looked after, if possible, by physicians, so long as the S. P. C. A. people feel that they must fritter away their energies in sham agonies over scientific unceruelties. Last week in an eastern State, about 20,000 pigeons were shot or maimed by several hundred "sportsmen," in the interests chiefly of gun-manufacturers and powder-makers. The atrocity of this cruelty is a thousand times as great as that in all the laboratories of the world during years, and almost rivals that of the shipments of cattle and horses across continents or oceans. If the antivivisectionists only hated cruelty as much as they hate medical science they would have long ago secured the passage of laws prohibiting trap-shooting. The shame of live pigeon shooting is heightened by the fact that by mechanical devices, clay-pigeon shooting is as perfect a test of markmanship.

Orthopedic Corsets in Lateral Curvature of the Spine have been used quite extensively by very good surgeons, but at present they seem to be coming into disfavor. Hüsey (*Zeitschr. f. orthopädische Chirurgie*, viii Bd., 2 H.) discusses the action of corsets in scoliosis at considerable length. From the results of a study of the literature and of a series of cases of his own he concludes that orthopedic corsets as a routine means of treatment should not be considered. He believes that the corsets may still be used in certain cases in which the deformity is very great or in cases accompanied by severe pain. But even in such cases the treatment should be supplemented by gymnastic exercises and the treatment should at all times be carried out strictly under the supervision of a surgeon familiar with orthopedic work. In the dispensary treatment of these cases in which gymnastic exercises are not available and in the milder forms of scoliosis the use of a corset is a mistake and the corset should never be used under such circumstances.

Nearly all progressive American surgeons will agree with these conclusions in the main, but it is surprising to see how many plaster-of-paris casts are still applied in cases in which common-sense should teach that such measures are illogical. We agree with Hüsey that if curvature be due to muscular weakness or improper development, the rational treatment is to prescribe exercises to strengthen the muscles of the back, and those movements which tend to obliterate or lessen the existing deformity are the suitable ones without the necessity for consulting empirical and confusing rules.

Danger to Life and Hardships to Travelers by Lack of Port Quarantine Facilities.—Recent public health reports state that the report on international quarantine, adopted by the Pan-American Medical Congress in the City of Mexico, November, 1896, provided among other measures, that each government should maintain quarantine stations at its domestic ports. That this provision is essential not only for protecting the several

countries from the introduction of contagious disease, but as an act of justice to the crews and passengers of an infected ship, is instanced by the narration in the annual report of the Marine-Hospital Service for 1893, Volume II, pages 7 and 8, of the experience of the 4 vessels which left Naples while cholera was prevalent there for ports in South America. Developing cholera en route, they were not allowed to land at any Brazilian port, but were obliged to return to Naples, many deaths from cholera occurring on the return voyage. A similar instance is that of the injustice to passengers and crew by reason of the lack of quarantine stations with facilities for the care of an infected ship which was refused harbor at port after port on the west coast of South America, the passengers being subjected to the dangers of yellow-fever infection with no possibility of escape from the vessel for a period of more than one month.

The Results of the Antitoxin Treatment of Diphtheria.—While the treatment of diphtheria by antitoxic serum has long since passed the experimental stage, and new reports but increase one's conviction regarding its efficacy, it is still a pleasure to read the splendid report by Otto Jelinek, of the State Institute for the Preparation of Diphtheria Antoxin in Vienna, which has just come to hand as a reprint from *Das osterreichische Sanitatswesen*, No. 52, 1900. The report, designed to be as complete as possible, concerns itself with a collation of the published reports of all observers in all parts of the world to the close of 1898. Its completeness and extensiveness are apparent from the fact that it comprises 568 references to reports published in Austria, Hungary, Bosnia, Germany, France, Italy, England, Russia, Switzerland, Holland, Belgium, Denmark, Norway and Sweden, Spain, Portugal, Roumania, Turkey, Egypt, United States of America, Canada, Cuba, India, Japan, and Australia. In all there are reports of 52,785 cases with 8,525 deaths, a mortality rate of 16.15%. Of these there were treated in hospitals, 35,095, with 6,398 deaths, a mortality rate of 18.23%, and in private practice and partially also in hospitals, 19,647, with 2,429 deaths, a mortality rate of 12.16%. To these Jelinek has added a number of collective reports from Austria, Hungary, Bosnia, Germany, Belgium, Russia, and the United States of America—127,359 cases, with 18,088 deaths—a mortality rate of 14.2%. An extremely interesting table is that which shows the influence of the early treatment with antitoxin upon the mortality rate. Thus of a total of 52,521 cases with 8,026 deaths—a mortality rate of 15.28%, there were treated on the first day 5,970, with 304 deaths—a mortality rate of 5.07%; on the second day 17,088, with 1,451 deaths—a mortality rate of 8.49%; on the third day 13,203, with 2,055 deaths—a mortality rate of 15.56%; on the fourth day 6,744, with 1,576 deaths—a mortality rate of 23.36%; on the fifth day 4,238, with 1,286 deaths—a mortality rate of 30.02%; after the fifth day 3,313, with 924 deaths—a mortality rate of 27.89%, and on some day not specified 1,965, with 430 deaths—a mortality rate of 15.28%. With regard to the ages of the patients it is noteworthy that under 2 years of age there were 4,264 deaths, with 1,442 deaths—33.81% (under 1 year of age 773 cases, with 305 deaths—

39.45%); from 2 to 5 years of age, 11,353 cases, with 2,165 deaths—19.06%; from 5 to 10 years of age, 9,628 cases, with 1,120 deaths—11.63%; over 10 years of age, 5,929 cases, with 350 deaths—5.9%. This exhaustive study demonstrates anew what has been already conclusively shown—that there results from the use of the diphtheria antitoxin a considerable reduction in the relative mortality from the disease. This reduction has occurred in all parts of the world, in all climates, in large cities as well as in the country, among the well-to-do and among the poor, at the commencement as well as at the termination of epidemics of diphtheria. The single exception is found in the reports of some English observers, but their relatively poor results are attributed to inefficient serum. The study shows conclusively also the necessity of prompt treatment if the best results are to be attained. An increase in the mortality rate of 5.07% when treatment is instituted on the first day of the disease to a rate of 23.36% when the antitoxin is given on the fourth day, and 30.02% when given on the fifth day, should certainly be sufficient to convince the most skeptical.

The "Irreconcilability" of Medicine and Christianity.—The Fulton Apostolic Church of New York City, and its pastor, the Rev. John W. Daugherty, have joined the antis. Their official journal, *The Everlasting Gospel*, says:—

"To our way of thinking medicine and Christianity are opposed to each other, and are utterly beyond reconciliation. It is a continual stumbling block to faith, and is frequently the cause of painful failure on the part of those who pray sincerely.

"Our personal experience has led us to inquire into the cause of our own personal failure in certain cases, and we believe it was all because physicians were in charge and medicines in use. We ask no one to give up the physician or the physic; for they will not and cannot do so from the heart, unless it is a matter of genuine faith, but we have definitely decided never to pray with the sick for healing where the people retain the services of a physician or use medicines. We may pray, but not for healing."

Mr. Daugherty explains this by saying that, while he holds to the teaching that Christians should obey the Scriptures in regard to sickness and call for the elders of the church and let them do as prescribed, they should not have the services of the elders and the physician at the same time. They should hold on to the doctor until they can fully trust God and let the services of the elders alone.

"There are two well-known physicians in my church," said Mr. Daugherty, "but neither of them takes medicine themselves; but, when needed, call for the services of the elders to pray over them and anoint them with oil, as required by the Scriptures."

What a pity this man, and his people, and his editor, have such a meager knowledge either of English grammar, of science, of civilization, or of Christianity. A little acquaintance with any of these subjects would have enabled them to avoid an exhibition of themselves painful alike to sensible, educated, or religious minds.

The surgical treatment of ascites due to cirrhosis of the liver, originally suggested by Talma but first carried to a successful issue by Drummond and Morison, has attracted considerable attention during the past few years. Of the several articles on the subject, one deserving of special commendation has lately been published by Packard and Le Conte (*American Journal of the Medi-*

cal Sciences, March, 1901). These authors, reporting two personal observations, contribute also a thorough review of, and an analysis of 20 other cases from, the literature. The treatment finds its rationale in the fact that it has been thought feasible to relieve the ascites, generally considered to be due almost exclusively to portal obstruction rather than to toxemia, by providing means for a collateral circulation. The establishing spontaneously of a collateral circulation has been observed in many cases of cirrhosis of the liver, and it has been known to occur in other cases in consequence of the formation of peritoneal adhesions due to repeated tappings. In addition, the significance of peritoneal adhesions in forming a collateral circulation has been demonstrated experimentally in dogs. What more natural than to cause the formation of peritoneal adhesions and provide the means for a collateral circulation by operative procedures? In the article by Packard and Le Conte alluded to, the results of the operation in the cases so far reported are tabulated. The statistics are susceptible of varying interpretations depending upon whether or not complicated cases are excluded; but, contrasting the worst view with the best possible construction that can be placed on the tables, there appears to be an operation-mortality of between 23% and 7%, and a recovery-rate of between 41% and 64%. The authors, recalling that the patients subjected to operation had been for weeks or months under careful medical treatment and had been repeatedly tapped, and their condition had been unimproved or progressively deteriorating, believe the statistics to be very encouraging and the operation to have won a distinct place. They point out that patients with cirrhosis of the liver, if unrelieved, are doomed to a life of continued invalidism. In general such patients are poor subjects for operation, and as the exact amount of degeneration of the organs, including the liver, is difficult or impossible to estimate, it is to be expected that the operation-mortality should be relatively high. In future, however, it may be possible to form a clearer conception of the suitability of a particular case for operation. They believe further that when the diagnosis of pure portal cirrhosis of the liver can be made, and when persistent and well-directed medical treatment is productive of insignificant results, the operation should be strongly recommended. On the other hand, it would seem that the operation is scarcely indicated, if not contraindicated, in cases of ascites associated with other kinds of cirrhosis (Hanot's, syphilitic, mixed, etc.), or with chronic peritonitis. It is to be hoped that these extremely practical as well as conservative opinions will receive that serious consideration on the part both of physicians and surgeons that they merit. And that the scope as well as the utility of the operation may be definitely determined, it is also to be hoped that observers will report all their cases, even should they terminate fatally, as did the two cases of Packard and Le Conte. Their example is worthy of emulation.

The Causation of Cancerous and Other New-growths.—To the *British Medical Journal* for March 16, Prof. J. George Adami has contributed an extremely thoughtful and instructive address upon the causation of

cancerous and other newgrowths—an address that well repays the reading. While he devotes dispassionate attention to the various theories that have been propounded to explain the origin and growth of tumors, he has bethought himself especially to follow his own advice to study anew the entire field of oncology. This he has done particularly with the idea of ascertaining if there be “a common denominator as it were, associating the various groups of tumors.” He begins the elucidation of this problem with the facts that certain tumors arise from misplaced cells, whereas other tumors arise from cells originally in normal position, and he asks, What is the cause of either category of cells taking on excessive growth independently of the needs of the organism? Naturally the alluring parasitic theory immediately suggests itself. His statements with regard to this, while they tend to shatter the hopes of the supporters of the theory, scarcely allay the prejudices of those who oppose it. He does not entirely discountenance the parasitic theory; indeed he refers to certain tumors arising from normal and functional tissues through known microbic agency, such as, coccidiosis of the liver of the rabbit and bilharzia tumors of the bladder and rectum. This class of tumors, however, he places at one extremity of the list of newgrowths, and with them he contrasts others that he places at the other extremity—tumors that assuredly arise independently of parasitic intervention, such as teratomas and various so-called benign tumors. Between these extremes we have the broad debatable territory wherein we encounter the main mass of neoplasms. He asks, How are we to regard them? Do they belong to the one or to the other class? Discussing then the relation of growth and functional activity of cells, the influence of environment on cell activity, and inertia of cells, he finds that all forms of tumors have a starting point in common. This “is that condition in which the cells of the part, whether functional or lying latent, upon being stimulated and as a consequence undertaking active assimilation and anabolism, cannot from their relations carry on their peculiar functions to a corresponding extent, so that the accumulated energy is instead utilized in mitotic changes and cell division, rather than in normal katabolism.” As a consequence of the continued action of the primary stimulus there develops a colony of cells all tending actively to proliferate. Thus is acquired the “habit of growth,” the factor common to all tumors. The views of Prof. Adami are summed up as follows: Whatever the origin of the tumor proper, however, it is started, what makes the tumor is the assumption by the primary cells of that tumor of the habit of growth in place of the habit of work, and, according to this replacement, do we get the various grades of tumor formation from the most benign to the most malignant. Finally he admits that microbes and their products may be one of the causes originating localized cell proliferation provided they bring about stimulation rather than irritation, and provided they continue to act sufficiently long to bring about the habit of growth. We heartily commend the address to all desirous of learning more of the assumption of the “habit of growth” by the cells of tumors; of assimilation and mitosis, the 2 functions retained and impressed

upon these tumor cells; and of all that is to be said dispassionately in favor of the parasitic theory of tumor formation—a theory that the future has yet to justify.

The Solidarity of the Race.—After reading Dr. John Inglis' paper in the *Journal of the American Medical Association* for March 30, on "Sanitary Conditions of Peking," one is tempted to wish that the "open door" in China could be closed as tightly as before the days of Marco Polo. The train of evils which is likely to accompany and follow the return of the allied armies will certainly prove China to be a veritable Pandora's box. The "yellow peril" looms up in a new aspect and christendom may then realize how one touch of filth infection makes the whole world kin. It is fortunate for the peace pursuing citizens of America that her soldiers have a chance to sterilize themselves in the Philippines before proceeding farther. Think of 4,000 years of civilization which still dumps all its garbage, excrement, and dead and dying babies into the public street; which sprinkles its dusty thoroughfares with the water of cesspools and stagnant sewers; which draws all its drinking water from wells sunk in these same reeking, unpaved roadways; which keeps its adult corpses until only starving beggars can be hired to carry them to burial; a place in which cholera, smallpox and diphtheria have the eternal freedom of the city; from which typhoid, typhus, malignant malaria and dysentery are never absent. One wonders that the palace spider needed anything more fatal in dealing with the legation flies. While the American army was in Cuba it had a Colonel Ludlow with it, but it does not seem to have occurred to the snarling concert of the Powers that anything but a China-smasher of the von Waldersee type was required to make Peking a healthful place for foreigners. How many milleniums must roll around before the world will have an International Board of Health with power to cleanse all such threatening plague-spots.

Infection of the Embryo with Tuberculosis without Infection of the Mother.—Dr. Joseph B. Greene, of the Marine Hospital Service, reports to Surgeon-General Wyman that recent experimental studies conducted by Dr. Friedrich Franz Friedmann in the Biological Institute of the University of Berlin, prove the direct infection of the embryo with tubercle bacilli, without infecting the mother. Clinical evidence has tended to prove the possibility of direct transmission of tuberculosis from the male, but it has been difficult to exclude all possibility of infection through the mother. It would be easy to overlook a small focus of infection in the lungs, genital tract, or elsewhere.

Dr. Friedmann has used for this purpose healthy rabbits, and has injected into the vagina of the female, immediately after copulation, a few drops of a virulent culture of tubercle bacilli, which are suspended in a slightly alkaline salt solution. After the lapse of 6 days, before the appearance of the first signs of placental formation, the rabbit was killed, and the embryo with the adjoining part of the uterus was placed in absolute alcohol, and finally imbedded in paraffin. Very fine transverse sections were then made perpendicular to the

long axis of the uterus. The specimen was then stained according to Ehrlich's method, the tubercle bacilli assuming a beautiful rose-red color, while the tissues remained blue. The bacilli were for the most part found within the cells lining the embryo, though some were found in the coagulated fluid within the embryo, and others in the zona pellucida. Dr. Friedmann succeeded in finding the bacilli in 48 different places, which would tend to eliminate the chance of accidental occurrence or error of observation. The organs of the mother were next examined and found healthy. No bacilli were found in the mucous membrane of the uterus, and only in 2 cases were they observed in the cavity of the uterus, and then situated near the embryo. These experiments of Dr. Friedmann correspond to the well-known clinical fact in regard to syphilis—that a child can inherit the disease from the father without the mother becoming infected.

The Value of Quinin in Labor has frequently been discussed, and many contradictory reports have been elicited. Its power to initiate uterine contractions is a much debated question, but its value as a stimulant is undoubted; and it has frequently proved useful in maintaining general strength and good uterine contractions. Fussell (*Therapeutic Gazette*, January, 1901,) has used the drug in over 100 cases and finds that it produces strong intermitten, quickly recurring contractions, exactly resembling normal labor pains, and entirely different from the tonic contractions produced by ergot. He has found it much more useful in multipara than in primipara, and has never observed that it possessed a tendency to produce bleeding, although Hirst claims that in certain susceptible individuals it will occasionally cause violent postpartum hemorrhage. He administers the drug in doses of 15 grains, and considers that it prevents rather than produces hemorrhage.

Acute Interstitial (Nonsuppurative) Nephritis.—Our present concise knowledge of this form of nephritis we owe largely to the work of American investigators. Although first described by Bierner in 1860; it was not until 1898, as the result of Councilman's extensive study, that the true nature of the lesion was understood. Occurring as it does as a complication of the acute infectious diseases, especially scarlet fever and diphtheria, and therefore accompanied by parenchymatous degenerations of the kidney, the clinical picture is still obscure. The examination of the urine has not been of much assistance; albumin is generally present; leukocytes and occasionally hyaline casts are found in the sediment, but there is nothing to distinguish it from other acute lesions of the kidney. Oftentimes the urine is normal.

The pathology of the lesion is, however, now well known. The most extensive and complete description of the lesion is that contained in the recent study of the "Pathology of Diphtheria," by Councilman, Mallory, and Pearce (*Journal of Boston Society of Medical Sciences*, Vol. V, No. 5). In the study of 220 fatal cases, acute interstitial lesions were found in 43. Omitting 3 cases of 42, 53, and 136 days respectively, in which other complications prolonged the illness, the average duration

was 16 days. Age seems to have a singular relation to the degree of the lesion. The less marked lesions occurred at an average age of $2\frac{1}{2}$ years; the moderate at $7\frac{1}{2}$ years, and the severe lesions at $11\frac{1}{2}$ years. The interstitial lesion was much more common than the glomerular lesion, the latter being present only in 11 cases.

The essential lesion is an extensive infiltration of the interstitial tissue with plasma-cells; other organs also are frequently affected by a similar infiltration. The cells are derived from the lymphoid cells or possibly from the cells of the bone marrow, the proliferation being due, in all probability, to the action of some toxic substance produced during the course of the disease. Excluding the degenerations of the parenchyma, which occur in any acute infectious disease, this lesion must be considered the most frequent change in the kidney in diphtheria. This clear understanding of the pathology of the lesion, the systematic examination of the urine in diphtheria and the infectious diseases, controlled by postmortem examination may lead to the recognition of the condition clinically.

Blessed be the Postmaster-General!—An order is expected soon formally granting authority to post-masters to allow carriers, during the heat of summer, to clothe themselves in a humane manner. We have often wondered at "the inhumanity of man to man" displayed in no more striking manner than in the regulations as to clothing in the public services. The men are not allowed sufficient clothing in winter unless they put on several suits of underclothing beneath the uniform, which makes them look like bloated toads or overfat boys about to burst through their coverings. In summer the brutal stupidity of their roasting should, if real cruelty appealed to their sensibilities, long ago have aroused the antivivisectionists to an upsetting of political parties. As all physicians know, this abuse has a distinct medical aspect. Protecting the body and feeding it are the two oldest of all human functions, and yet of all our arts and trades there is nothing so blunderingly and badly done as our clothing and cooking. If the Postmaster-General shall issue the proposed order, the American people should make him President if he desires the office, or give him a dozen or two good sized islands in which to set up a new empire. We should be able to hope that our policemen, firemen, soldiers, sailors, etc., might in time, by imitating the good custom, be allowed to clothe themselves as if their rulers had some innate kindness of heart combined with some acquired common sense.

Criticism of and Advice to the Editor follows a law, the reverse of that of gravitation. The strength of the force of gravity is inversely as the square of the distance, but the volubility of the critic and of the adviser of the medical editor positively increases with the distance—the financial distance, we mean. Among thousands of enheartening letters we have received, there have been less than a dozen offering pages of well-meant but trivial advice about trivial things. At the end of all such letters appears the inevitable "I wish you success, but owing to etc., etc., I am unable to subscribe etc., etc."

The person who subscribes liberally has no advice to offer, except perhaps a jolly "I'm wid yez," or an encouraging "More if you need it!" The old story will apparently never lose its point: "I am sorry for the widow this sack of flour and this barrel of potatoes; how much are you sorry?"

EDITORIAL ECHOES

Liquid Air in Medicine.—*The Medical Press* concludes that on the whole it would not seem that liquid air promises to extend greatly the therapeutic field, and it would be unwise to have too sanguine an estimate on its uses in medicine, however interesting a product it may be to the physicist.

Circumcision as a Preventive of Venereal Disease.—"It is not likely that the practice of circumcision will ever become universal—any more than, for instance, preventive removal of the vermiform appendix—but the reasons that have been put forward should be sufficient not only to warrant its continuance when once the practice has been instituted, but to extend the field of its application. For those who see in it no religious justification, there is abundant reason of a less spiritual character for its performance; and the physician has placed at his command a potent means for restricting the ravages of a disease that he cannot hope ever entirely to eradicate, and which, while ordinarily amenable to treatment, is still capable of causing much suffering to innocent and guilty, to transgressor and victim alike."—*[The Medical Record, April 6, 1901.]*

A Suggestion to Generous Millionaires.—"What this great continent needs, and needs very badly, is something that very few men seem to realize our lack of. It sadly wants endowments devoted to the acquisition of scientific knowledge. In European countries governments maintain huge laboratories, defray the expenses of men sent upon scientific missions, see to it that the principal educational institutions do not lack funds wherewith to carry on important work. In this country, with its vast wealth, the man of science, the man who lives not for the prospect of riches, but in order that he may add to the storehouse of knowledge, has had little encouragement unless his researches had for their object the discovery of something that might prove of ultimate financial value.

"We may need a few more hospitals and a few more colleges, perhaps, and undoubtedly we will get them in good time. But our crying need is for money to be under the control of the heads of our scientific institutions, to be devoted to pure scientific research, which must, eventually, result in the greatest good to the greatest number."—*[Internat. Jour. Surgery, April, 1901.]*

"Kissing the Book."—We are glad to see that some progress is being made toward the abolition of the uncleanly and dangerous English practice of administering the oath by requiring a witness to "kiss the Book." * * * * "If you have got a fad about microbes you should say so, and I will swear you Scotch fashion," said a judge. This offer marks a distinct advance, although it would have been more satisfactory had the judge set an example and carried out the law in a more gracious fashion. * * * * The *City Press* is responsible for the statement that the two Testaments in the City of London Court are kissed by 30,000 persons annually, while a police court usher is said to have stated that the covers of his New Testament had been worn smooth and well polished from the pressure "of numberless lips,

bearded and beardless, blooming and faded, honest and lying, foul and sweet,' as some 49,760 witnesses were sworn in that court annually. There can be no question whatever about the right to be sworn in the Scotch fashion. * * * We are informed that the members of the Leyton Medical Society have agreed invariably to adopt this form, and the matter is one upon which the medical profession might very well continue to preach by example.—[*Brit. Med. Jour.*, March 23, 1901.]

The Prevention of Venereal Diseases.—"In the course of a discussion on the 'Ravages of the Venereal Diseases,' recently held before the Physicians' Club of Chicago, Judge Lorin C. Collins pointed out the difficulty in reaching an agreement as to proper legislation to be enacted for the purpose of controlling and diminishing venereal diseases, and the obstacles likely to be encountered both in its enactment and in its enforcement. In the course of the same discussion, Dr. Edmund Andrews struck the keynote of the situation in urging education of the public upon the subject of venereal diseases, in order that it may for itself realize the dangers, and intelligently apply the preventive and corrective measures, individually and collectively. * * * The question is a most important one, and its regulation is likely to continue, as it has in the past proved to be a most difficult undertaking. It is clear, however, that the desired results are to be secured, not through any single means, but from a combination of all. The most important of these, as striking at the root of the evil, includes a full knowledge of the nature of the diseases, the methods by which they are conveyed, as well as the means by which such conveyance is to be prevented, and the adoption of all possible measures of prophylaxis, moral and physical, together with the most rigorous and systematic treatment in private and public alike."—[*Jour. Am. Med. Assoc.*, April 6, 1901.]

The Punishment to Fit the Crime.—"We are getting to a state in which we cannot work our criminals to advantage because the trades unions forbid it, and we cannot keep them in idleness and confinement because that means mental breakdown and is, in the eyes of the philanthropist, the worst alternative of all. Every member of society, even in a prison, should have his utility, and the author in question sees this for the incorrigible in making him of benefit to the race in deciding scientific questions, in other words a subject for experimentation for scientific purposes. It has been said that the worst use to which a man could be put is to hang him, and this idea was doubtless in the mind of the sociologic student in question. While it is a little odd that the idea should be seriously propounded—at least to all appearances—it is much more likely to come from such a quarter than from anyone even remotely connected with the medical profession. It would not be surprising, indeed, if it should receive the endorsement of some antivivisectionist zealots, for zoophilism and genuine philanthropy, understanding by the word a real love for their own species, are sometimes mutually exclusive. Science can get along with the necessary occasional sacrifice of the *corpora vilia*, and certainly does not ask for human sacrifices, even of murderers. The days of Herophilus and Erosistratus have not yet come again, and it is to be hoped never will."—[*Jour. Am. Med. Assoc.*, April 6, 1901.]

The National Hospital (London) for the Paralyzed and Epileptic appears to be endeavoring to exclude the members of the medical profession from voice or power in the management of the institution. The "Secretary-director" seems to be gathering to himself all power, governmental and medical. The medical staff demands some representation on the Board. The demand is denied, as we gather, on the ground that if 2 members out of 12 should be physicians the hospital

would become "a mere scientific laboratory." This is a grossly untrue and calumnious statement, without a particle of warrant in professional animus or history.

The real point for which the staff is contending is the right of a specially deserving class of poor sufferers to all the benefits which medical science in its highest developments can confer on them. These they can obtain only if the eminent men whose knowledge and skill are recognized by the whole world are allowed to do their work in the way their experience has taught them to be the best in the interest of those under their charge. They do not ask to have the government of the hospital transferred to them. They only wish to have such a share in the management of its affairs as shall safeguard the interests of the patients and ensure that the treatment shall be carried out under the conditions which they consider necessary for its success. The governors will incur a very heavy responsibility if, by allowing themselves to be influenced by the antiscientific prejudices to which appeal has been skilfully made, they imperil the usefulness of an institution which has done so much for the relief of suffering and the furtherance of knowledge of the highest use to mankind.—[*Brit. Med. Jour.*, March 23, 1901.]

The Defeat of the Medical Bill in Minnesota.—"The medical bill has been defeated. This outcome of the bitter fight that has been waged is disappointing, yet there is a considerable degree of comfort in the reflection that the osteopathic bill also met with defeat. The causes of the failure of the efforts of the legislative committee of the State Medical Society to secure the passage of a blanket law covering all forms of healing can be summed up in a few words: First, the opposition of a certain number of medical men to a bill which apparently lowered the dignity of the profession by requiring that irregulars should come up to the same standard of qualifications as regulars, and, second, the virulent and bitter opposition of Senator Horton, a lawyer of St. Paul, an active partisan of osteopathy, and an enemy of regular medicine. It is apparent that the profession of Minnesota is not wholly agreed as to the kind of medical legislation that it wishes. There does not seem to be an unanimous opinion on the principles which should underlie all medical laws. So long as the profession is lacking in harmonious agreement upon the principles of legislation, and is guided by expediency and selfish policy, there can be no concerted effort made. The opposition of the osteopaths and other irregulars was not of serious consequence. The chief cause of the defeat of the medical bill was the active interference of those within the profession, who at the last moment threw obstacles in its way and undermined the support of senators whose votes had been practically pledged in its favor. Before further legislation is attempted it would be wise for the State Medical Society to specifically determine what legislation it wants, to definitely instruct its legislative committee and to pledge the united support of its members to the measure."—[*St. Paul Med. Jour.*, April, 1901.]

The "Refracting Optician."—"Every man can instance many examples where harm has been done by the pseudo-profession of opticians. A case, reported elsewhere, recently occurred in this city. A mother, at the instance of a teacher, took her son, a lad of 8 or 10, to one of these fakirs with the history of dullness in school and poor vision. Unable to improve the visual acuity of the boy by any glass, he jumped at the conclusion that there was some cerebral trouble, and, telling the mother that there was inflammation of the optic nerve, advised her, not as one would suppose, to see a physician, but, instead, to give the boy some strychnia. She obtained from a druggist some tablets containing $\frac{1}{30}$ of a grain of strychnia and proceeded to feed the boy upon them, thinking that the prescriber was a doctor and that he

would not advise her to do anything that was harmful to the boy. As a result convulsions occurred and a dangerous termination was only averted by a timely knowledge of the treatment he was undergoing. The vision was easily improved by proper lenses and no further trouble was experienced. A lad with a vision of $\frac{5}{10}$ was wearing concave spherical glasses of 12 diopters, with no improvement of vision, while his refraction was hypermetropic and required for correction a convex glass of 9 diopters, a difference of 21 diopters. A man recently came to the Rhode Island Hospital with a diagnosis of 'inflammation of the optic neuritis,' another with a detached retina for an operation for cataract; a lady recently had her glasses changed 4 times in as many months, with a steady impairment of vision, who was suffering from albuminuric retinitis and who died within a few weeks after the diagnosis was made and the condition ascertained; and so example after example might be quoted where injury to the patient resulted both by incorrect adaptation of lenses and failure to recognize existing morbid processes. This is not, however, a plea for special legislation, but an appeal to the profession of this State to discourage the practice of consulting incompetent men for ocular defects. There is no selfish or pecuniary consideration to this question; on the contrary every one of the dozens of incompetent men who are doing this work are manufacturing future patients for the physician; but the welfare of the community demands that the profession take a decided stand on this question. They have it in their power to control this evil within at least moderate bounds."—[*The Providence Medical Journal*, April, 1901.]

Quotation Without Comment.—

Appropos of "modern medicine," a newspaper the other day, while commenting on the tuberculosis congress, or congress for the suppression of tuberculosis, or whatever be its name, said that there was hope that modern medicine "would conquer tuberculosis as it had so many other diseases." This shows the childlike credulity of the average editor, for can he, or the sophisticated ones, name any disease that modern medicine has conquered?

Homoeopathy, not modern, but old Hahnemannian homoeopathy, is as sorely needed by the world today as ever.

Medical paternalism [Medical Practice laws] is a bad thing, a hundred times worse than the harmless "quack" who dare not kill by his "treatment."

From an article taken from a Victorian (Australia) journal we learn that through their greed and brutality the vaccinating doctors in that colony are getting in bad odor with the public. For instance, some of these brutes vaccinate an infant, just delivered, simply to secure the fee; the infant, of course, has little chance of living, but what is that when compared with the fee! The Victorian troops that went to South Africa suffered horribly from the enforcement of this idiotic old superstition.

A medical journal controlled by a vaccine maker says: If we could only establish a law that every person should be vaccinated every five years we could stamp out completely the scourge of smallpox.

Also make a colossal fortune for the vaccine makers. Probably if it were not for the money in it vaccination would have been a mere memory by this time. But there is money and power in it, hence the grip it has on that patient beast of burden, the public.

Cancer follows where vaccination is enforced.

Paul Paquin, M.D., one of them, at the recent meeting of physicians, riddled the "hypocritical" claim of "public welfare" and said that the brethren were out for the dollars like any one else.

Be not swift to take offense;
Let it pass!
Anger is a foe to sense!
Let it pass!
Brood not darkly o'er a wrong;
Which will disappear ere long!
Rather sing this cheery song—
Let it pass!
Let it pass!

—[*Homeopathic Envoy for Propagating the True Medical Faith*, April, 1901.]

AMERICAN NEWS AND NOTES

GENERAL.

An Ingenious Swindle.—The postoffice authorities of Washington are now investigating the case of a doctor who advertised to cure deafness, without fail, for \$18.50. Persons sending this amount were forwarded 2,000 pills, with instructions to take 1 each day, and on no account to miss a day, or the charm would be broken and it would be necessary to start all over again. As the truth of the doctor's claim cannot be proved until the end of 5½ years the authorities are puzzled what course to take.

Scarlet Fever, in a light form, has broken out in Maryland Agricultural College, and the students have been dismissed. The cases are being cared for in the building.—The Kingston, New York Board of Health has ordered all day and Sunday-schools closed on account of the rapid increase of scarlet fever and livermen have been ordered to fumigate their carriages after the funerals.—The superintendent of the New York Bureau of Contagious Diseases has been troubled over a case of scarlet fever of which he had had notification recently at the Grand Hotel on Broadway. The parents of the child left with him in a private car during the night.

Cattle Diseases.—Reports do not indicate that there is any diminution in the extent of foot-and-mouth disease which has prevailed in almost every country in Europe for the last 3 years, and the United States Government is refusing to admit cattle, sheep or swine except from the British Isles. As a result of negotiations between Secretary of Agriculture Wilson and the Canadian Minister of Agriculture an agreement has been reached between the administrations by which Canada is to have a first-class veterinarian stationed in England to test for tuberculosis all British cattle shipped to this country via Canada. The Canadian Government wanted all cattle admitted from Canada without tests at the border by American experts. To this the department at Washington would not agree. It is officially stated that about 10% of live stock in the United States and about 40% in Great Britain have tuberculosis.

The Improvement in the Sanitation of Rio Janeiro for the year 1900 is noteworthy. The general mortality has decreased. If we accept the figures of the sanitary authorities we find a total mortality of 17.97% per 1,000, against 23.3% per 1,000 for the year 1899. This indicates an extraordinarily favorable result. The mortality among children of 1 year or less, in relation to the general mortality, is also favorable; it is 17.4% against 18.6% of the preceding year. This death rate would show very favorable sanitary conditions. The birth rate, however, is just the reverse: it amounts to 17.7% per 1,000, against 35% per 1,000 in Europe. Very remarkable is the number of stillbirths; it is equivalent to 77% per 1,000 of the number of births. Compared with the average number in European statistics we find that the number of stillbirths is about 38% per 1,000 of all births and about 55% per 1,000 of the illegitimate births.

To Suppress Yellow Fever.—At a recent meeting of the International Medical Association at Havana, Dr. Edouard Wilde, Minister of Argentine Republic at Washington, presented a scheme for international cooperation in suppression of yellow fever. His idea is to negotiate a treaty to be signed by all American nations, establishing a uniform system of quarantine regulations and systematic cooperation for removing the sources and suppressing the causes of yellow fever. He suggests that a tariff or tonnage tax or quarantine restrictions be imposed by all other nations against those which shall refuse or neglect to do their share in the work. His suggestions were adopted and a committee, appointed to carry them into effect, has issued invitations for a convention to meet at Havana February 6, 1902. The invitation to the United States is now under consideration by Dr. Wyman, of the Marine Hospital Service. Each American colony is to send 3 delegates, including bacteriologists, sanitary engineers and specialists in economics. The subject will probably be taken up at the Pan-American conference to be held in Mexico in October.

Rudolf Virchow Fund.—The following circular letter is self-explanatory and we trust will meet full response from the medical profession:

On October 13, 1901, *Rudolf Virchow* will be 80 years old. When he completed his seventieth year a fund was started in his honor to enable the great master to facilitate scientific research by establishing scholarships, and by encouraging special medical and biological studies. Contributions to that "*Rudolf Virchow Fund*" were furnished by those in all countries interested in progressive medicine, as a homage to the man whose name is always certain to arouse admiration and enthusiasm. In Berlin a large committee containing amongst others the names of A. Bastian, v. Coler, A. Entenbun, B. Fraenkel, O. Israel, Fr. Koenig, C. Posner and W. Waldeyer has been formed to call for contributions which are to be added to the original "*Rudolf Virchow Fund*" so as to increase its efficiency. The committee expresses the opinion that in no better way, and in none more agreeable to the great leader of modern medicine, can his eightieth birthday be celebrated, and ask for the sympathy and cooperation of all those engaged in the study and practice of scientific medicine all over the globe. The undersigned have formed a subcommittee for the purpose of making the American profession acquainted with the intentions of the Berlin committee, and

urge their colleagues to participate in honoring the very man who has done more, these 50 years, than any other to make medicine a science, and international. Subscriptions should be sent to their secretary, who will receipt therefor. CHARLES A. L. REED, President of the American Medical Association; HENRY P. BOWDITCH, President of the Congress of American Physicians and Surgeons; WILLIAM K. WELCH, Johns Hopkins University; ROBERT F. WEIR, President of the New York Academy of Medicine; A. JACOBI, 110 West 34th street, New York, Secretary.

Smallpox.—In Indiana, April 2, the secretary of the State Board of Health reported 472 cases of smallpox in the State and in Wisconsin there is computed to be about 200 cases, many of them among the mining and lumbering camps. Some fears are entertained that there will be a spread of the disease as the lumbering camps are breaking up and these infected men will be scattered among the community. A case of smallpox has been discovered among the men of the Eleventh Infantry and 2 companies of the regiment are to be detained at Angel Island until danger of the spread of the disease is past and the regiment will not sail for Manila on the day planned. At St. Joseph, Missouri, the Health Department thought smallpox was stamped out, but 35 new cases have been recently quarantined there and in the opinion of the city physician Tygert the disease is spreading throughout the northern part of the State. In Parkersburg, Va., 12 cases of smallpox, fully developed, were recently discovered which had been diagnosed as chickenpox. At Lynchburg a delirious negro lately escaped from the pest house and ran amuck in the town, but was pursued and shot. Kentucky will quarantine against the State of Tennessee for smallpox. This quarantine will be absolute in that no person will be allowed to cross the Kentucky State line coming from Tennessee who cannot show a certificate of recent vaccination. Persons buying a railroad ticket in Tennessee will be compelled to show a vaccination certificate before being allowed to board the train. If necessary, the Kentucky State Board of Health has determined to place guards along the State line to prevent people without vaccination-certificates from slipping over. At Clarksburg, Tennessee, the outbreak has been more violent than has ever been known and has been chiefly confined to the negroes. The management of the situation has required almost superhuman efforts, but it has been efficient and now there is only 7 patients under treatment. At Colmesnell, Texas, smallpox was reported April 2 as prevailing to an alarming extent. The Ontario, Canada, Health Board reports 1,765 immigrants examined, and 797 vaccinated at the Sudbury smallpox camp. The hospital patients there number 117, of whom 65 are defined cases. In New York the *Bulletin of the State Department of Health* for February, lately issued, states: There were 33 deaths from smallpox during February, of which 32 occurred in New York City and in Watertown and its environs, and in Luzerne. During March about 80 cases of smallpox have been reported up to and near the end of the month in the metropolis.

Obituary.—GEORGE HAYWARD of Boston, March 30, aged 81.—R. A. FERIN of Nelson, Canada, April 1.—WILLIAM A. DUCKETT of Montreal, March 30.—F. B. W. HURDMAN of Brandon, Canada, March 28.—JAMES C. LARSH of Baltimore, April 3, aged 80.—WILLIAM TALIAFERRO HORD of Washington, April 1, aged 80.—JAMES O. CAMPBELL at Winslow, Arizona, March 20.—CALVIN M. GUERNSEY, of New York, April 9.

EASTERN STATES.

The Delaware State Board of Health met April 4, at Newark, and elected Dr. E. W. Cooper president and Dr. Alexander J. Lowber secretary and executive officer. Dr. Robin was re-elected State bacteriologist.

A Competitive Essay.—Dr. J. B. Learned, of Northampton, Mass., has offered to pay \$100 for the best essay containing some method for inducing sleep, without the use of drugs, in insomnia. Representative men of scientific medicine are to be the judges in the competition.

Maine Eye and Ear Infirmary.—By an almost unanimous vote the House of Representatives killed recently the resolution to appropriate \$5,000 yearly to the Maine Eye and Ear Infirmary, and adopted a report declaring that a reform was needed in the management of the infirmary.

Cigaret-smoking and its increasing tendency among growing boys is deplored in the annual report of the Superintendent of the Somerville (Mass.) schools. He urges the school authorities to make an effort to enforce the existing statute which forbids the sale of cigarettes to children under 16 years of age.

Mosquitos.—The petition before the Committee on Metropolitan Affairs for a bill to place \$50,000 at the disposal of the Metropolitan Park Commission with which to improve Alewife brook and certain other small streams in Cambridge, Somerville, Arlington, Belmont or Watertown, Mass., which have been shown by the Board of Health to be in a filthy condition and injurious to the public health inasmuch as they breed mosquitos—met with opposition.

A Typhoid Epidemic, has broken out in New Haven, Conn., and was first thought due to a barnyard situated near one of the small lakes which form a part of the water supply of the city. The heavy spring rains had deluged the barnyard, washing the refuse into the reservoir. Later investigation has shown as a cause that in a poor German's home near a small brook feeding the Woodbridge reservoir there were 3 cases of typhoid fever in last January, and that the excreta from the patients was buried in a ploughed field about 150 feet from the brook. There is a total of 300 cases.

Cigaret Legislation.—On April 5 in the Boston Legislature leave to withdraw was reported on the bill which forbids the manufacture and sale of cigarettes. A bill raising the age limit as those to whom cigarettes could be sold from 16 to 18 years was also reported.—In the New Hampshire Legislature the lower house passed a bill providing that no person, firm or corporation shall make, sell, or keep for sale any form of cigaret in New Hampshire, nor shall any one under any circumstances make a gift of a cigaret to a minor. The penalties are to be \$10 for the first and \$50 for each subsequent offense. The upper house has not yet considered this most drastic measure.—The Pennsylvania House has just passed a bill requiring all dealers in cigarettes and cigaret-paper to pay an annual license tax of \$250 to the treasurer of the place where the articles are sold. To pay this tax 250,000 cigarettes would have to be sold annually, since the retail profit is \$1 a thousand. It is thought this will effectually wipe out cigaret traffic in small stores and prevent many children from contracting the dangerous habit.

Connecticut Sanitary Science.—The annual report of the State Board of Health, after noting the improvement in sanitary administration during the last few years, calls attention to the rapid increase in pneumonia, which has now outstripped consumption in mortality. Out of 16,263 deaths from all causes in Connecticut during 1900, there were 1,631 victims of pneumonia, as compared with 1,476 from consumption and 1,341 from heart-disease. During the decade from 1890 to 1899, inclusive, the average annual mortality from pneumonia has been 1,296, as compared with an annual average mortality of 776 during the 13 years previous. The disease is in close accord with the development of late years of influenza and grip. The tables indicate that consumption is slowly lessening.

The **death-rate for Connecticut** during the year 1900 was 17.9 per 1,000. In 10 years, notwithstanding the fuller returns of deaths, the rate has fallen from 19.2 per 1,000 to 17.9 per 1,000. Births, in spite of fuller returns and increase of population, have been almost stationary for 8 years, there being 20,395 in 1900, as compared with 20,296 in 1893. In the birthrate of the State the town of Bradford leads with a rate of 35.6 per 1,000, and Greenwich is lowest, with a rate of 14.7.

Some remarkable figures are given to show the **large mortality from typhoid fever in private practice** as compared with hospital treatment in 1900. Returns from 6 hospitals with 693 typhoid-fever patients show a mortality of but 6.8%, while 1,163 cases in the whole State showed a mortality of 20%. An official report of the Forestville epidemic of typhoid fever resulting in 50 cases and 7 deaths is given, showing clearly that the disease originated from river water contaminated by human excreta from a factory, the water being pumped into the regular Forestville supply owing to a break of a pipe where it crossed the stream.

The report strongly urges the **employment of sanitary inspectors**, other than the health officers, for economic and

other reasons, and emphatically objects to requiring complaints of nuisances to be made in writing over the signature of the complainant. No citizen should be compelled to complain of his neighbor in order to have a nuisance abated that is dangerous to the health of his family. It also urges the importance of local hospitals in every considerable town and city, for the isolation of primary cases of contagious diseases, as a means of preventing their spread and saving life, and gratuitous examinations of morbid specimens for the early and positive detection of suspected infectious diseases. It recommends strongly the more general practice of systematic inspection of school children.

The report strongly opposes sewerage into running streams and favors intermittent filtration as the method best adapted to Connecticut conditions under supervision of the State Board of Health. It says that an anti-spitting law is sure to reduce tuberculosis. A State hospital for consumptives is strongly favored.

Some modification of the Registration Act of the State should be made so as not to exclude old and skilled physicians not technically up in the minute points required in the examinations. On this matter the report says: "If present conditions continue the profession in this State will be almost a close corporation, limited to those who join it while they are fresh from their college work, and their memory is still retentive of chemical formulas and of minute points in anatomy and physiology."

NEW YORK.

New York Eclectic Medical Society.—The annual meeting was held in Fiskill Landing on April 4. Over 100 members attended.

Bronx Hospital.—Senator Hennesley's bill providing for the construction of a hospital by New York City, in the borough of the Bronx, the cost not to exceed \$200,000, was passed by the Assembly on March 29.

Cigaret Smoking.—On April 3 a young Cornell student, who 3 years ago had won a free medical scholarship, was removed to Bellevue Hospital, suffering from paralytic dementia, caused by cigarette indulgence.

The Anti-Vice Committee of New York, at a meeting held April 3, decided to issue a report April 13, which will explain all their work to that date. They will show how vice is protected throughout the city, who is responsible for the protection and how it is accorded.

Dr. Abraham Jacobi celebrated on April 5, at the New York Academy of Medicine, the semicentennial anniversary of his graduation in medicine, invitations having been issued by the Fellows of the Academy. Dr. Jacobi was graduated from the University of Bonn, Germany, in 1851.

Prostitution in the Tenement-Houses will be investigated exclusively along lines which concern the physician as a practitioner by a committee of 7 members of the County Medical Society. This committee consists of P. A. Morrow, S. A. Knopf, H. D. Chapin, C. W. Allen, L. D. Buckley, L. Weiss and G. B. Fowler.

Drug Habits.—A special department of neurology, for the study of neuroses and psychoses due to alcoholism and drug habits, has been established by the New York School of Clinical Medicine and Dr. T. D. Crothers elected professor, and a course of clinical lectures on inebriety from alcohol, opium, chloral, cocaine and other narcotics by him is announced.

Baths for Immigrants.—The Immigration Bureau has about completed on Ellis Island a great cleansing establishment for the benefit of prospective citizens who have just landed. There are 2 bathrooms capable of accommodating 1,000 bathers each day, and a laundry capable of cleansing 20,000 garments in a day. It is the intention of the Government to send the immigrants into society clean and sweet.

Ingenious Advertising.—It is reported that a New York physician evades the unwritten law of the better physicians that they shall not advertise, without technically breaking it. He does not advertise; he writes letters to his clients thanking them for their appreciation of his services and outlining what he has done for them. Accidentally the letters are misdirected and sent to those whom the doctor desires as patients.

The Charitable Annex in connection with the Loomis Sanatorium, at Liberty, New York, was opened March 22 with 12 patients. The present capacity of this annex is 24 patients. The patients receive their board, lodging, medical attendance, laundry, and medicines, the deficit between the sum charged to them and the actual cost of maintenance being made up by a maintenance fund raised annually by subscription. The nurses are furnished from the training school at the main sanatorium, and the patients receive practically the same treatment as is given at the main sanatorium. The various medical examinations from the main sanatorium will also examine applicants for admission to the annex, but the rules for receiving only

incipient cases are even more rigidly enforced than at the main institution. The plant of the Liberty, New York, Electric Light and Power Company has been purchased by J. Pierpont Morgan for about \$40,000 and presented to the Loomis Sanatorium. It furnishes light and power for the Sanatorium and for the entire town of Liberty.

Bell Practice Bills Not Accepted.—The bill entitled "Medical Practice Bill" brought into the Assembly at Albany, N. Y., became so changed in its passage through the Chamber, that only a new name would probably designate it. It was intended to prohibit Christian Scientists and Osteopaths from giving treatment, but it was amended so as to permit Christian Scientists to practise except in infectious diseases and when surgery is required. The fact that the Christian Scientist disregards these distinctions, rather denies sickness of any kind, makes the bill ludicrous to the sane and easy to the Scientists. It was remarked by Dr. Henry, chairman of the Health Committee, that while the Scientists professed great faith in prayer and absent treatment, they had used other means in Albany to defeat the bill, and had not trusted to absent treatment. The bill not meeting the wish of the promoters, was killed.

The Spitting Nuisance.—The crusade against the "spitters" continues to hold the interest of the New York public. On April 4, President Sexton, of the Board of Health, appointed 180 policemen of the sanitary squad to arrest all persons caught violating the spitting ordinance. A number of arrests were made, and with the exception of 1, who was discharged, the offenders were all fined, or held in anywhere from \$50 to \$500 bail for examination. The officers will report from time to time the results of their work and observations to Dr. Roberts, the sanitary superintendent. Dr. Cosby, commissioner of the Board of Health, in a public statement on the above date, fully explained how diseases of the respiratory organs are carried by means of indiscriminate spitting. He declares the authorities should use every means in their power to enforce the law and thus decrease the spread of disease. A resolution has been passed by the Board of Health directing the sanitary superintendent to have the stairways leading to stations inspected for the purpose of preventing spitting on the same.

A Home for the Scientific Societies of New York.—These various societies have needed a home where their collections and libraries could be kept and their research work carried on, and it is now proposed to collect enough money by subscription to erect a building of sufficient capacity to accommodate the New York Academy of Sciences, the Torrey Botanical Club, the New York Microscopical Society, the Linnean Society of New York, Mineralogical Club, the New York Section of the American Chemical Society and the New York Entomological Society. Two weeks ago a number of scientific men, members of the societies interested, secured a committee of wealthy men to take charge of the subscriptions and to identify themselves with the undertaking. This committee has as members: Andrew H. Green, Andrew Carnegie, Abram Hewitt, Samuel Sloan, William E. Dodge, Edward D. Adams, John S. Kennedy, Frederick W. Devoe, J. Hampden Robb, D. Willis James and Colonel John J. McCook. J. Pierpont Morgan has promised \$25,000, provided the whole amount needed—\$500,000—is raised.

PHILADELPHIA, PENNSYLVANIA, ETC.

Physical Culture in Schools.—Steps are being taken towards the introduction of a system of physical education into the schools of Philadelphia in accordance with the recent act of Legislature making such training compulsory.

Dr. Frederick A. Packard, of Philadelphia, has been elected to the Board of Trustees of the University of Pennsylvania. He succeeds to the place made vacant by the death of Dr. J. M. DaCosta. Dr. Packard was graduated from the department of arts in 1882 and from the medical department in 1885.

The Public Bath and Wash-House of Philadelphia has closed its third year under favorable circumstances, and the report of the superintendent for 1900 shows that in 3 years 105,248 bathers and 3,668 washers have patronized the bathhouse, and that a business which grows 40% in 12 months may justly be called successful. During 1900 the patrons paid 65% of the running expenses—the deficit decreases each year. On January 1, 1901, the total indebtedness was \$2,633.98.

Excitement Reproduces Past Experience.—A curious recurrence of memory caused Chas. Washburne, of Allegheny, Pa., to disown wife, children and home. Seventeen years ago he was injured in a railway accident and was taken to a hospital where he recovered completely. He married in Pittsburg and has children. A few evenings ago a lighted lamp fell in his home. Fearing a conflagration Mr. Washburne became excited and was unconscious till the next day. When he awoke he fancied himself back in the hospital and denied his wife's claim to be his; nor did he know his children.

A New Operation.—Gastronomy is an operation that every surgeon is familiar with, but gastrectomy was first attempted as late as 1883 by Dr. Connor of Cincinnati.—*Philadelphia Press*, April 7.

The Women's Sanitary League of Philadelphia, at a meeting on April 1, adopted a resolution urging the Legislature to make an appropriation for the Free Hospital for Poor Consumptives. Another resolution petitions for the enactment of a law providing for the imposition of a penalty on all persons who expectorate in public conveyances or places. And another requests the Faculty of the Medical School of the University of Pennsylvania to make it compulsory for all students to visit the Municipal Hospital prior to graduation. Dr. J. Madison Taylor made an address on the work of the Board of Health.

Generous Gift to Hahnemann Hospital.—Mr. and Mrs. George C. Thomas, of Philadelphia, recently presented the property adjoining Hahnemann Hospital on the north, to the trustees of the hospital. The property is 76½ feet front by 196 feet in depth, and is valued at \$60,000. The buildings now occupying the ground will be razed and a house for nurses built. This building will front on Fifteenth street and will contain a tablet in memory of Bessie Moorehead Thomas and the late Dr. A. R. Thomas. The trustees also propose to build a maternity hospital and probably an operating amphitheater, north of the present hospital and college. A special committee has been appointed to provide plans for the proposed buildings. The State Legislature has been petitioned to appropriate \$100,000 to help defray the expenses of erecting these buildings, this having been approved by the State Board of Public Charities. Until building operations are commenced the grounds will be converted into a temporary park for convalescents.

Vital Statistics of Philadelphia for the week ended April 6, 1901:

	Cases.	Deaths.
Total mortality		490
Brain—abscess 2, congestion 3, inflammation 13, softening 2		20
Apoplexy 23, paralysis 3, epilepsy 1		27
Convulsions 19, puerperal 3		22
Diphtheria	72	12
Heart—diseases of, 31, fatty degeneration 1, neuralgia of, 5, pericarditis 1		38
Kidneys—Bright's disease 9, dropsy 3, uremia 7, diabetes 2, nephritis 14		35
Casualties		12
Lungs—inflammation of, 73, edema 3, tuberculosis 66, congestion 2, inflammation of pleura 3		147
Inanition 18, debility 6, teething 1		25
Scarlet fever	96	7
Typhoid fever	43	8
Stomach and bowels—inflammation 20, obstruction of bowels 2, diarrhea 1, dysentery 1, carcinoma of, 3, peritonitis 6		33
Measles		13
Old age		10
Aneurysm of aorta 1, alcoholism 1, asthma 1, anemia 1, atheroma 1, burns and scalds 1, carcinoma of face 1, of breast 2, of liver 1, of pelvis 1, of tongue 1, of uterus 2, eyanosis 2, drowned 1, eczema 1, erysipelas 3, uterine hemorrhage 1, homicide 1, influenza 1, appendicitis 7, cystitis 2, bronchitis 7, laryngitis 2, whooping cough 6, coroner's case 2, tumor 1, sarcoma 2, suicide 5, syphilis 2, suffocation 4, stricture of esophagus 1, smallpox 1, septiemia 1, pyemia 1, arterial sclerosis 1, rheumatism 1, pyemia 1, poisoning 2, jaundice 1.		

SOUTHERN STATES.

New Orleans Polyclinic.—Dr. Isadore Dyer announces that on account of various requests the session of the Polyclinic will be continued to May 31, instead of May 11, as announced in catalogue.

Mad Itch is the name given to a disease of cattle reported to have made its appearance in Kentucky. It first attacks the hoofs and causes an intense itching superseded by a pain so severe that the animals become wild. It is claimed to be contagious and to result in death in many instances.

Pigpens Within City Limits.—A very bitterly contested municipal election was held lately at Elkton, Md. The issue at stake was the upholding or abolishing of a town ordinance prohibiting pigpens within the city limits. The candidates who were in favor of sustaining the ordinance were elected.

Tuberculosis Sanatorium.—The State Board of Health of Louisiana recommends the building and equipment of a sanatorium, supplied with tents, and all necessary paraphernalia for

the treatment of those suffering from tuberculosis in New Orleans, where the mortality from this disease has been high.

Refund Under Protest.—Dr. B. W. Bizzell, of the Board of Health of Atlanta, refunded on March 29, \$195, paid him by the city for professional services. He made this return under protest, stating that the money was justly due to him. The city attorney advanced the opinion that the city could not make such payments, but the physician may bring suit and make a test case of the matter. Three other Board members were also asked to refund money paid them.

Reformatories for Children.—On April 3, Judge Riley, of Lexington, Ky., declared that reform schools throughout the State were being made a refuge for children whose parents wanted to shirk the responsibility of their support. Prior to the establishment of these schools there was seldom a child in his court with the plea of refractory conduct. He therefore ordered a colored boy whose mother said she could not control him, to be given a whipping. The lad was taken to a cell, and the mother gave him a sound thrashing.

Program of American Gastroenterological Association. The fourth annual meeting will be held in the banquet hall of the "Shoreham," Washington, D. C., May 1, 1901. The following papers will be read and discussed:

The German Clinics of Today, J. C. Hemmeter; The Etiology of Hepatic Sclerosis, A. L. Benedict; Treatment of Gastric Ulcer, D. D. Stewart; The State of the Gastric Secretions in Chronic Rheumatism and Rheumatoid Arthritis, Frank H. Murdoch; Some Cases of Tetany, William Gerry Morgan; Report of 2 Cases of Acute Dilation of the Stomach, Julius Friedenwald; Experiments in Peristalsis, Fenton B. Törck; Some Clinical Studies in Gastric Secretions, G. W. McCaskey; Treatment of Atonic Gastric Splanchnoptosis by Means of Abdominal Strapping, A. Rose; Hyperchlorhydria, John A. Lichty; Report of a Case of Cancer of the Cardiac End of the Esophagus at a Distance of 20 Inches from the Incisor Teeth in a Man 5 Feet and 3 Inches Tall, C. D. Spivak; Digestive Disturbances in Formes Foustes, John P. Sawyer.

Marine Medical Inspectors.—The Louisiana board of health has adopted a new regulation to take effect with the commencement of the annual quarantine restrictions on April 1, between the port of New Orleans and Central and South America. Nine registered physicians have been appointed to act as marine medical inspectors on fruit vessels engaged in carrying passengers from tropical points. Their duty will be to reside aboard the vessels plying between New Orleans and Central and South America and to accompany the ships through the round trips. They have been specially instructed to see that the quarantine restrictions are enforced, and that no passengers are taken on the ships other than from regular embarking points. The marine inspectors are to work in harmony with the board's resident physicians who have been detailed to various ports in Central and South America. The latter are to see that the baggage of passengers has been properly fumigated, and the former have been entrusted with the duty of daily recording the temperature of the passengers and crews while they are on the ships en route to the city.

WESTERN STATES.

Typhoid Fever.—The prevalence of typhoid fever in Sheboygan, Wis., is ascribed to the water which is not in good condition, and an effort is being made to have an improved water supply.

A Woman Coroner.—On April 3, the County Court of Franklin County, Nebraska, appointed Dr. Ella E. Summers, of Omaha, coroner. She is probably the only woman coroner in the United States.

Children's Hospital.—The new hospital for children to be operated in connection with the City Hospital of Cleveland, Ohio, will be formally opened March 27. The new hospital has a capacity for 120 beds, but only 40 will be used at present.

Women in Medicine.—Victor C. Vaughan, of the University of Michigan, has but little commendation for women as medical students. He claims that in textbook work a woman student is superior to a man, but in original work requiring personal judgment she fails in efficiency.

Strict Marriage Laws.—The Tri-State Medical Society, composed of members from Iowa, Illinois and Missouri, in a recent convention held at Keokuk, appointed a committee to present petitions to the Legislatures of the respective States for the enactment of laws prohibiting the marriage of well-recognized mental and physical degenerates.

The Gift of a Hospital.—Mr. Z. G. Simmons of Kenosha, Wis., has announced his intention of presenting to that city one of the best hospital buildings in the State, thoroughly equipped for the care of the sick. Two sites are under consideration, but

the selection has not been made. Plans are being drawn, and it is purposed to have the hospital completed by the end of the summer.

Disease Germs in Books.—Dr. Kuplewski, chairman of the special committee appointed by the Chicago Public Library Board to investigate the books and to consider the necessity of adopting some plan of sterilization to prevent the spread of contagious disease through them, has reported that all the 50 books examined by him were more or less infected by bacilli and he advises the immediate adoption of a system of dry sterilization.

Compulsory Vaccination.—Judge Adams of the Circuit Court, Kalamazoo, Mich., has issued a peremptory injunction against the action of local school authorities who excluded the children of George Matthews from school because their parents refused to have them vaccinated. This was a test case entered into in a friendly spirit between the school authorities and Matthews, with the understanding that the losing side would appeal to the Supreme Court.

Farm Home for Juvenile Delinquents.—A bill is before the Illinois Legislature to appropriate \$100,000 for a home for juvenile delinquents under the age of 16, who might be amenable to such a life as could be maintained on a sort of farm colony where freedom would be subjected to limits, but rather wide ones, and where the life would be out of doors and occupied but with a reasonable proportion of class work. The bill provides that the site shall be donated by some individual or organization.

A Physician's Lawsuit.—The Supreme Court of Indiana has rendered a decision recently that a licensed practising physician is not legally obliged to attend any patient for whom he is called, although he may in the past have served as family physician for the family to which the patient belonged, nor does his refusal to answer the call lay him liable for damages. The case in point was that of Dr. Weddingfield, who refused to attend a patient, although called 3 times. It was charged that the woman's death lay at the doctor's door, and he was sued for \$10,000 damages.

The American Academy of Medicine will hold its twenty-sixth annual meeting at Hotel Aberdeen, St. Paul, Minn., June 1, 1901, and will continue through Monday, June 3. The principal features of the meeting will be a symposium on Institutionalism and Reciprocity in Medical Licensure. Interesting papers on some other subjects will also be read. The president (Dr. S. D. Risley, of Philadelphia) will deliver an address on the evening of June 1, and the Annual Social Session will be held on the evening of June 3. Members of the profession will be welcomed to the open sessions of the academy.

Plague at Ann Arbor.—The reported single case of plague at the University of Michigan, in a medical student who has been taking a special course in bacteriology and became inoculated from handling culture tubes, will no doubt cause more consternation there and elsewhere than the occasion warrants. The final outcome of a case of diphtheria, scarlet fever or measles might be worse, but not have such an effect on the imagination. With Dr. Frederick Novy on the ground, fresh from his investigation of the disease in San Francisco, it is unlikely the disease will pass beyond this single case. Even in San Francisco, with its filthy Chinese quarter and more or less grave dereliction on the part of the local authorities, although existing among the Chinese for over a year the disease has made no headway.

Reason in Animals.—In a recent decision of the Supreme Court of Iowa practical importance has been given to the mooted question whether animals can be said to reason. Suit was brought against the Chicago, Milwaukee and St. Paul railway for killing stock at a crossing. It was shown that the engineer had failed to warn the animals by whistling. The railway company contended that the whistle signal required by law was intended only for the protection of human beings. The court, however, instructed the jury that animals were also entitled to such warning, and a verdict was returned for the plaintiff. The railway company took exception to the ruling and appealed to the Supreme Court which sustained the decision of the lower court, and held that animals have sufficient reasoning power to enable them to recognize the approach of danger and take measures to avoid it.

The plague situation in San Francisco is summarized in the Public Health Reports of the Marine-Hospital Service, which has been issued recently. This report is that of a commission of experts appointed by the Secretary of the Treasury, which made a special investigation, and which shows that there have been 10 cases of the plague in San Francisco since the beginning of the year, all being fatal. It has been confined almost exclusively to the Chinese quarter and the prevailing type has been a mild bubonic form. Recognizing the danger

that this might give rise to graver cases a committee representing the business interests of California consulted with the commission at Washington and determined on measures of suppression. This committee, on its return to San Francisco, raised funds for immediate work, such as disinfecting houses, providing hospitals for suspects, houses for detention, and morgues, and a general disinfection of Chinatown. It is reported that this work has been pushed and is doing much good.

Licensing Opticians.—A bill to insure the better education of opticians, to regulate the practice of opticians in the State of Illinois, and to create a State Board of Opticians, has been introduced into the House of Representatives at Springfield. The bill provides that after 6 months from the passage of the act it shall be unlawful for any person not a registered (or licensed) optician to practise as an optician, and any violator shall be liable to a penalty of not less than \$25 nor more than \$100 for the first offense, and for each subsequent offense to a double penalty. The proposed State Board of Opticians is to consist of 5 practising opticians of recognized standing and ability of at least 5 years' practice in the State, appointed by the Governor, to hold office for 5 years. Its duty will be to report annually to the Governor and to the Illinois Optical Society upon the conditions of the optical profession and trade in Illinois and furnish the names and places of business of all opticians registered under this act. The bill provides that every certificate of registration, or license, shall be conspicuously exposed in the place of business of the optician possessing it; and every person holding a license shall have it recorded in the office of the clerk of the county in which he resides or does business, within 3 months of its date, and until the license is recorded the holder is forbidden to practise or to sell his goods.

CANADA.

Druggists Charged with Practising Medicine.—The appeal of the Toronto druggists, charged with having practised and professing to practise medicine, was sustained in the higher court. The men were convicted in the Police Court. Judge McDougal, who gave the decision, declared that having prescribed in a single instance, did not sustain the charge of practising medicine.

Physicians' and Surgeons' Supply-House.—An Association of Practitioners in Medicine and Surgery in the Province of Ontario has just been formed under charter issued by the Ontario Government, with its headquarters in the city of Toronto. The organization is unique inasmuch as the stock or share capital of the association can only be subscribed to by medical practitioners, with a maximum fixed upon the number of shares that will be allotted to any one subscriber. As the name indicates, the association will deal in and supply all kinds of drugs, instruments, etc., required by the profession. The financial advantages of this cooperative movement will doubtless lead to the upbuilding of an establishment of Dominion-wide connection.

Vaccination.—A militia general order has been issued at Ottawa for the inspection of all recruits and of all men, women and children occupying militia buildings and for the vaccination of all those who require it. At Hamilton 5 physicians have been appointed by the Board of Health to proceed at once with the vaccination of the public school pupils whose parents have expressed their willingness to have the work done by these appointed physicians. There are over 1,100 children to be vaccinated.—**Revaccination** is under consideration by the Ontario legislature. The bill provides that persons having religious scruples with regard to vaccination shall not be required to have their children vaccinated before they can attend the public schools. There is very little likelihood of the bill becoming law since it is being energetically opposed.

Quebec leads the Provinces of the Dominion in respect to birth-rate and progressive legislation in regard to tuberculosis. According to the law passed June 7, 1900, every householder in that Province in whose household a death occurs from consumption must notify the local board of health within 48 hours from the occurrence of such death. Then it is imperative upon the municipality to order and cause to be made a disinfection of the premises and apartments which may have become contaminated through the patient. In this way does Quebec hope to check the ravages of consumption. The city of Quebec has the smallest death-rate from tuberculosis of any of the Canadian cities, and Ottawa has the largest. Quebec's rates is 1.99 to each 1,000 of the population; Ottawa's is 3.12, Montreal's 2.87, Toronto's 2.41, Kingston's 2.17, and London's 2.67. Paris is said to have a death-rate from this cause of 4.90, and New York one of 3.60. The recorder of statistics can take a justifiable pride in the birth-rate of the Province. In 1898 it was 35.70, as against that of Ontario, 20.4. In 1899 it was 33.46, a decrease of 3,585. Even with this decrease, Quebec's birth-rate is larger than that of any country in the world, except Germany's, which was 36.2 in 1898.—*New York Medical Journal*.

FOREIGN NEWS AND NOTES

GENERAL.

Obituary.—G. RITTER v. HOCHBERGER, the oldest medical practitioner in Austria, aged 98. WENZESLAUS MANASSEIN, editor of the *Vrateh*, February 13, aged 60. GEORGE FRANCIS FITZGERALD, of Dublin, distinguished physicist and mathematician.

Trains to Fly Yellow Flag.—As a further precaution against the introduction of the plague in Pretoria, a military doctor has been specially appointed to meet all trains arriving from Cape Town. All these trains have been ordered to fly a yellow flag.

Famine in Shensi.—Messengers who have arrived in Peking from Si-Ngan confirm the reports of the ravages of the famine in that province. It is estimated that 3,000 persons are dying daily from starvation. Sixteen public soup kitchens have been established, but they are utterly insufficient to relieve the hunger.

Plague at Cape Town.—The total number of deaths reported April 3 was 107 including 22 Europeans and there had been 315 cases. The outlook seems very grave where more than 20,000 refugees from the Transvaal have flocked to the overcrowded city and where the habits of some of the colored races make a complicated problem in sanitation and isolation.

A Peculiar Disease of the Scalp.—Stuart Eldridge, Acting Assistant General of U. S. M. H. S., in his report from Yokohama, February 26, 1901, tells of a peculiar disease of the scalp. It was first noticed in Osaka, but has since spread rapidly throughout a large portion of central Japan. Its dissemination is attributed to the native barbers. It is found to be intensely contagious and when stricken the victim becomes totally bald in a few days, whether permanently or not remains to be seen. The nature and progress of the disease is being investigated. Numbers of new cases are constantly being reported from all the larger towns in communication with Osaka. Though not of the gravity of ordinary quarantinable diseases it is both interesting and important.

Vaccination Statistics.—There occurred annually in the city of London from 1771 to 1780, prior to the introduction of vaccination, 5,020 deaths from smallpox among every million of the population; from 1801 to 1810, after the introduction of vaccination, 2,040; from 1831 to 1835, 830; from 1854 to 1871, 388; from 1883 to 1892, 73. For the whole of Great Britain the annual death rate from smallpox has diminished from 1,064 per 1,000,000 in 1838 to 27 per 1,000,000 in 1894; in 1889 it was 1, in 1890 nil and in 1891, 2. Vaccination came into use in England at the beginning of the last century; provision for its gratuitous performance among the needy was made in 1840; it became obligatory in 1853, and legislation for its systematic enforcement was enacted in 1871. —In Prussia, where vaccination had been generally employed, and revaccination became obligatory in the army in 1834 and in the community also in 1874, the mortality from smallpox ranged from 43.8 in 1865 to 262.4 in 1872, while in 1873 it was 35.6, in 1874 9.5, and in 1880 1.4 per 100,000 of inhabitants. In Austria, on the other hand, where vaccination was optional, the mortality was in 1865, 22.8; in 1872, 189.9; in 1873, 314.7; in 1874, 174.3; in 1884, 50.8. Since 1886 vaccination has been obligatory among recruits in Austria.—There occurred in Sweden between 1774 and 1801, before vaccination was practised, an average annually of 2,050 deaths from smallpox per 1,000,000; between 1801 and 1810, when vaccination was optional, 686 deaths, and from 1810 to 1855, when vaccination was obligatory, 169. From 1884 to 1894 the mortality averaged 2.—These statistics could be multiplied indefinitely, but it will suffice to add the announcement that the Imperial Government of Japan has decided to make vaccination compulsory.—[*Ledger*.]

GREAT BRITAIN.

Antivaccinationists.—In the County of Leicester 60,000 people refused to heed the vaccination acts and the assizes have begun the prosecution of the defaulters.

Woman Surgeon.—Miss Marion Ross, aged 27, has been appointed junior surgeon of the Macclesfield, Eng., Infirmary. She took high honors at Glasgow University.

London's Water System.—It was announced in the House of Commons recently that the government would introduce a bill granting authority for the establishment of a state water supply for the whole of London. The scheme will include the purchase of all the existing water supply companies.

Housing the London Poor.—The London County Council is now considering 4 systems of relief for congested city neighborhoods, which together involve the immediate erection of homes for 54,250 persons. Two of these plans provide for the building of separate cottages of various grades and each one furnished with its own garden in suburban neighborhoods

accessible by tramways to the centers of the city. The other plans provide for the erection of tenement blocks 5 stories high, having suites of apartments of 2, 3 or 4 rooms each, wherein light and ventilation have been carefully considered.

Insuring Children in England.—In some of the congested districts of the larger English cities, it has been proven that among children whose lives are insured the mortality is higher than those not insured. And this has been particularly noted with the increase of insurance facilities. For this reason the forces of humanity have made persistent warfare against child insurance. Mr. Waugh, Secretary of the National Society for the Prevention of Cruelty to Children, has in recent years led this movement. He admits that the abolition of child insurance may work hardships occasionally to respectable parents who need such help as insurance offers, but thinks the evil is small compared with that which is made possible to unscrupulous parents who secure insurance on their children.

CONTINENTAL EUROPE.

Professor Grassi had the distinction of the Golden Crown conferred upon him by the Society of Italian Agriculturists in consideration of the services rendered by him in the investigation of malaria.

Typhus Fever is reported as raging in Russia in those provinces which have been famine-stricken in consequence of failure of the crops last year. In some places 20% of the population being stricken.

The Famine and Typhus Fever situation in Russia is growing more serious. The reports of April 4, from Cherson, Bessarabia and parts of Kieff and Taurida state the mortality is 30% of the population.

Women Medical Students in Russia.—In consequence of the student riots the Medical Institute of the University of St. Petersburg has closed indefinitely and by official orders all the higher courses for women.

A New Preservative it is claimed has been discovered by a Danish dairyman, which is not injurious to the health and which it is believed will revolutionize the shipping of butter and other perishable merchandise.

Christian Science imported from America and spread by Americans residing in Germany, especially in Berlin, is reported and deplored as making rapid progress among the higher and even the highest classes, although exclusively confined to women thus far.

Smallpox in Naples.—The official report for the week ended March 30, 1901, notes the steady increase of smallpox in Naples so that it had become quite general. In Caivana, 10 miles from the center of the city, a small epidemic of typhus fever prevailed, one of the attendant physicians had died and one was dangerously ill.

German Surgeon's Birthday Celebration.—Surgeon-General Van Coler celebrated his seventieth birthday on March 15. His has been a career of unusual activity and usefulness in connection with the medical department of the German army, into which he introduced many systems by means of which military surgeons are enabled to keep in touch with the most recent medical thought and practice.

Carlsbad Salts.—A copious new hot spring is said to have burst forth at Carlsbad—where already the hot water rises to the surface in 17 places. Sodium sulfate is the dominant mineral in the Carlsbad Springs but some of them contain a good deal of carbonate of lime. Whether the water of the new spring agrees in composition with those already in use we have yet to learn, for it does not always follow that neighboring springs are of identical composition.

A Surgeon's Sewing Machine was exhibited by Dr. Paul Michel at the late Congress of Medicine. The instrument is quite small, easily held in the hands, and has received the Barbier prize of the Faculte de Medicin. In future a surgeon need not slowly stitch the edges of a wound. With the left hand he keeps the 2 lips together, and with the right he fastens it by means of little clasps or "agrafes" of nickel having points which only penetrate the epidermis, and are not painful. These catches are applied to the machine, a species of pincer armed with them, which can be disinfected by heating it red-hot.

First Women Physicians.—Russia claims the distinction of first introducing women physicians. Marya Bokoff and Nadezhda Susloff are cited as pioneers who did much to open up medical instruction for their countrywomen. In 1870, Mme. Shanyawsky gave 50,000 rubles to be used for the instruction of women in the higher medical studies. These special courses were started in 1872, in connection with the Military Medical Academy. Twenty-four successful students were sent in 1877 to the seat of war during the Russo-Turkish campaign. They did so well that they received the imperial permission to call themselves "women physicians."

ORIGINAL ARTICLES

THE MEDICAL ASPECTS OF CARCINOMA OF THE BREAST, WITH A NOTE ON THE SPONTANEOUS DISAPPEARANCE OF SECONDARY GROWTHS.

BY

WILLIAM OSLER, M.D.,

of Baltimore, Md.

Professor of Medicine, Johns Hopkins University.

[Concluded from page 19.]

CASE VI.—*Tumor of breast in 1896; operation by Dr. Tiffany February, 1898, scirrhus; good health until August, 1899, when she had nerve-root pains, and an attack of shingles; severe pains all winter; in March, 1900, complete paraplegia, with semiconscious condition, and the patient lay at death's door for days. Gradual improvement; disappearance of the paraplegia; slight recurrence in the scar; complete recovery of power in the legs; no disturbance of sensation; in fairly good health at the end of 1900.*

In 1896 Miss Y., aged about 30, whose sister I had seen a year before with cancer of the breast, consulted me for a lump in the left breast. I urged her to have it operated upon at once. I saw nothing more of the case for more than two years, when she called upon me with her nephew, who had anorexia nervosa. She had been operated upon by Dr. Tiffany on February 19, 1898.

I did not see her again until October 10, 1900, when she came to town to consult me about the possibility of getting rid of the morphia habit. She gave the following remarkable history.

She did well after the operation until August, 1899, when she began to have pains in the chest and back, more particularly in the right shoulder blade, where the pain was very acute and intense. She had excruciating pains around both sides, most intense at night, and agonizing attacks of pain down both arms, particularly the right. In November she had a severe attack of shingles over the left chest and shoulder. She had a winter of great suffering and the pains increased up and down the back. In March she became completely paraplegic, with retention of urine. Her physician, Dr. Lockwood, has kindly given me the following statement about this paralysis. "March 23, 1900, she complained of difficulty in walking and using the lower limbs, and she became completely paralyzed as to motion and sensation from about the middorsal region down a few days thereafter (I think March 25th). The abdomen became greatly distended, with apparent complete paralysis of the bowel. On April 6 respiration dropped suddenly to 8 or 10, the pulse was barely perceptible, and the patient was semi-conscious. She remained in what seemed a most critical condition for some days. Nausea and vomiting were persistent from the onset of the paraplegic attack, and up to the time of my last visit (May 6) she was able to take or retain very little food."

She was desperately ill, and neither Dr. Lockwood nor Dr. Tiffany expected her ever to recover. She had a great deal of pain up and down the spine, and for several days she was unconscious. She was moved to the country in June. In July she began to get better, and since then she has steadily improved. The paraplegia has gradually disappeared, and though she is very stiff, she is able to get about with a cane, and has been walking very much better.

When I saw her she looked very thin, color fairly good. She walked stiffly, and with a slight stoop. She has a good deal of stiffness at first when she begins to walk, but she gets more limber as she goes on. She has had to continue the morphia, and she takes now about 3 grains a day. There is a slight local recurrence, which Dr. Tiffany did not think advisable to remove. The spine is bowed, but it can be twisted perfectly well in all directions. The right shoulder blade is natural.

There are no glands enlarged above the clavicles. There are two small recurrences at the margin of the scar. She has recovered power in the legs perfectly; no disturbance of motion or sensation. The kneejerks are greatly increased. Babinski's reflex is not present.

CASE VII.—*Neuralgic pains in the arms, legs and sides; gradual loss in weight; paraplegia dolorosa; scirrhus of the right breast.*

On November 16, 1894, Father S., aged 46, of Watertown, Mass., was admitted to Ward C, of the Johns Hopkins Hospital. He had been in Florida, and there had become so ill that his physician had been sent for. On their way back he had become much worse, and when they reached Baltimore they decided to stop over for a few days to consult me.

About the middle of July he began to have severe pain in the right shoulder blade and subsequently this affected the right arm and hand. About 8 weeks ago he noticed that there was some loss of power and atrophy in the right hand. At times he has had pain in the left arm and about the elbow. A week ago for the first time he noticed numbness in the legs and abdomen. Three days ago he began to have difficulty in walking, but until today he could walk with a little assistance.

He was a large framed, well built man. After he had removed his night shirt I stood at the foot of the bed to get a general survey, and my attention was at once attracted to his right breast, which stood out prominently. He had not noticed it himself, nor had any of his physicians. He had had no pain, and nothing to call attention especially to it. On examination he had a firm, hard tumor, evidently a scirrhus. There was no secondary enlargement of the glands, and there was nothing to be detected in his spine. The kneejerks were increased. The pains were very characteristic of pressure on the cord—those of a paraplegia dolorosa. Finding the breast tumor, there was no question then as to the nature of the spinal cord trouble. I did not hear of the subsequent history of the patient.

The special interest in the case lies in the fact that no complaint had been made of the tumor in the right breast, and I am quite sure it would not have been discovered had he not been stripped for a thorough preliminary inspection.

CASE VIII.—*Carcinoma of left breast; complete removal; 6½ weeks later stiffness of the back and girdle pains; for the next 3 months progressive increase in the pains; onset of paraplegia dolorosa; secondary masses in the ribs and in the spine; death; autopsy.*

W. L. C. B., aged 47 (Surg. No. J. II, H., 8117), I saw repeatedly in Ward E, when he was under the care of my colleague, Dr. Halsted. He had a tumor of the right breast, the size of a walnut in 1897, which grew rapidly, and became sore, and the glands in the axilla became involved. When seen September 15, 1898, he was a healthy looking man, with a disc-like, hard growth in the left breast and enlarged axilla.

On September 21st, Halsted's complete operation was done. The skin graft took well, and the patient was discharged October 2. On October 18 he returned complaining of pain in the epigastrium and along the costal margin on each side. The pain came on in paroxysms, and was often severe enough to keep him awake. There was no nausea or vomiting. He remained in hospital until October 23, when he went out, feeling better, although still suffering with the pain. On November 3 he returned complaining of great stiffness of the back, and pain in the epigastrium, and very severe girdle pains in the course of the ninth and tenth ribs. The rigidity of the back had been present for 2 weeks, and was steadily increasing. On examination there was no curvature, and the spine was held very rigid.

He was seen again on February 6, 1899, complaining a great deal of paroxysms of intense pain, in which he would have to double up, and of trouble with the bladder. He had recently begun to have stiffness of the left leg, and sensations in the soles of the feet as if walking on cotton-wool. The sixth and seventh

dorsal spines were prominent, and there was swelling about them, and there was a small, painful mass the size of a lemon at the level of the eighth spine. Both legs gradually became weak, and ultimately completely paralyzed. He died February 22. The autopsy showed secondary nodules in the sternum and ribs. On the floor of the spinal canal, opposite the seventh dorsal body, was a saddle shaped mass, 2 cm. by 1½ cm. projecting into the canal, and causing a well marked compression of the cord at this level. From the fifth and eleventh vertebrae there were also small nodules projecting into the canal, but not far enough to exert any pressure on the cord. It is interesting to note the small size of the mass which caused the pressure.

Shields makes the significant remark that some of these cases are only too apt to be mistaken for hysteria. In the following instance the symptoms were supposed, for a time at least, to be due to functional disturbance.

October 1, 1900. I saw to-day with Dr. Atkinson, Mrs. Y., aged 37. Dr. Halsted had removed the left breast for carcinoma about 2 years ago. She had done very well until about April, when she began having attacks of pain in the back and side. With these she had a great many nervous symptoms, so much so that she was sent to Dr. Sinkler, in Philadelphia, for a rest treatment. There she gained 10 pounds in weight, but the pains did not subside. Since her return from Philadelphia she has been getting gradually worse, and has had to have morphia, and is scarcely able to stir without great pain. The patient was thin, looked badly, not specially cachectic. She was highly nervous. It was very difficult for her to turn in bed. The pain was chiefly on the left side and down the left leg in the region of the sciatic. There was no local recurrence, but just above the outer margin of the scar there was a slight induration, which possibly was a gland, and just above the left clavicle there was a distinct induration. She moved her head with difficulty, and it was very painful above the left clavicle, but it was very hard to say how much of this was genuine pain. She certainly, however, could not move the head freely from side to side.

I saw her again November 26, 1900, with Dr. Atkinson. She has grown weaker, still has the severe pains, and speaks of committing suicide and wishing to die. She moves the head a little more freely than she did, but she has not been able to get up on her feet, and it was impossible in her condition to make an examination of her back. She complains of difficulty in swallowing, of a lump in her throat.

March 9. This patient has now well marked paraplegia dolorosa and the organic nature of the whole trouble is manifest.

II.—THORACIC MANIFESTATIONS.

Naturally, from the proximity to the original disease and the intimate connections between the lymphatics of the chest wall and those of the pleura and mediastinum, secondary disease is very common within the thorax. There are 3 groups of cases; the pleural, the glandular and the pulmonary.

(a) *Pleural.* With pains in the chest and sometimes with signs of an acute pleurisy there is a gradual effusion, and the case may be seen first with all the signs of a large exudate. The effusion may be the result of a cancerous pleurisy, or it may come from pressure of enlarged mediastinal glands on the azygos and other veins.

CASE IX.—*A small nodular scirrhus in left breast; enlargement of the cervical and axillary lymph glands on the same side; effusion in left pleura; condition mistaken for tuberculosis.*

In the spring of 1891, just as we were interested in the use of Koch's tuberculin, the late Dr. Christopher Johnston sent into the hospital a woman, aged about 29. The supraclavicular and

the axillary lymph glands on the left side were enlarged, forming quite prominent bunches. They had been noticed about 3 months before, and had gradually increased. She was very well nourished, and had a very good color. She received the tuberculin injections, and the reaction on each occasion was active. About 10 days after admission signs of pleurisy were noted on the left side, and she gradually had quite an extensive effusion. She grew worse, and was taken to her home, where she died some few months later. Dr. Councilman performed the autopsy, and found a small nodular cancer the size of a walnut in the left breast, with cancerous involvement of the left pleura, and of the axillary and subclavicular lymph glands.

CASE X.—Mrs. B., aged 56, seen January 8, 1893, with Dr. James Carey Thomas. She had had a cancer of the breast removed 2 years before. She had had pain in the chest, gradual increase in shortness of breath, slight local recurrence in neighborhood of the scar, and at the time of examination the left side of the chest was full of fluid. She was tapped repeatedly with great relief, but she died ultimately from gradual exhaustion.

In Case V, under the cerebrospinal manifestations, the effusion was very possibly due to pressure, and not to direct involvement of the pleura, as the fluid was gradually absorbed, and she has got so very much better.

There are many instances of hydrothorax referred to in the literature.

(b) *Glandular.* By far the most distressing secondary features of breast cancer are seen in the cases in which the bronchial and mediastinal glands are involved, and in which the patient dies from gradual suffocation. Some years ago I was impressed with the terrible character of this possibility by the death of 2 friends, a mother and daughter, within a few years of each other, with secondary disease of the bronchial glands. Case V, mentioned under the cerebrospinal manifestations, illustrates how even a mediastinal growth which has begun to penetrate the bone can undergo involution. There may be no external signs of tumor, but the features are most characteristic of intrathoracic tumor; pain, paroxysmal cough, gradually increasing dyspnea, signs of pressure, usually upon the veins, causing great lividity, and sometimes hydrothorax. The features are very much indeed like those produced by pressure of an aneurysm. The literature as given in the Index Catalogue (both series) contains reference to many cases of this variety. The following distressing instance I saw a few months ago.

CASE XI.—Mrs. A., seen June 1, 1900. The patient had had the breast removed about a year and a half or 2 years previously. She was in a most pitiable condition. She had had cough for many weeks, and progressively increasing dyspnea and orthopnea. She was sitting up in bed, livid, respirations very labored. There had been slight local recurrence. The superficial glands were not enlarged. It was impossible to make a very satisfactory examination, as she was in such distress, and evidently was desperately ill. The pulse was extremely feeble, and she suffered at times a great deal of paroxysmal pain. She sank very rapidly through the night, and died at 8 a. m. on the day after I saw her.

(c) *Pulmonary.* Secondary scirrhus of the lungs is not very common, except the presence of scattered nodules, which I have seen not infrequently postmortem. Encephaloid is, I think, more frequent. I remember seeing a postmortem in which the lungs were stuffed with secondary masses following an encephaloid of the breast, and I see in the Index Catalogue a reference to a case reported by Delbarre of encephaloid of the breast with generalization in the lungs¹.

III.—ABDOMINAL MANIFESTATIONS.

The cases may be divided into 2 groups, the peritoneal and the hepatic. Throughout the literature there are many references to cases of secondary growths in the omentum and peritoneum, with nodular masses in the mesenteric glands, with or without ascites. In the following case the masses appeared to be in the omentum and peritoneum.

CASE XII.—*Cancer of the left breast; tumor in the abdomen probably omental and peritoneal.*

Mrs. R. L., aged 59, was transferred from the surgical side on October 26, 1900. She was admitted with cancer of the left breast, but as tumor masses were found in the abdomen, it was decided not to operate. She had been a very healthy woman, of active habits. Her weight was 137 pounds. She noticed the growth in the breast in August, and very shortly afterwards she began to have pain in the upper left half of the abdomen. With this there was belching of gas and some nausea, and twice she had vomited. She had lost much strength, and slightly in weight. Since admission the pain in the abdomen had been the special symptom.

The patient was fairly well nourished; complexion sallow. The conjunctivas had a slightly yellow tint. There was a firm, hard, sclerous mass in the left breast. The abdomen on admission looked a little full, symmetrical. On palpation there were nodular masses—one in the upper umbilical region, and a second just to the right of the navel. On inflation the lower stomach level was about an inch below the navel. The question was whether these masses were in the stomach or on the omentum and peritoneum. The test meal, given twice, showed once no free hydrochloric acid, and once a slight trace. There was no lactic acid. The Oppler-Boas bacillus was not present. The patient constantly complained of the gastric pain. The abdomen increased in girth. There was flatness in the flanks, evidently some effusion of fluid. The tumor masses in the abdomen were very evident. In all probability they were connected with the omentum and peritoneum rather than with the stomach.

Cancer of the liver secondary to disease of the breast is very common. I have seen a great many cases in the postmortem room. The following are illustrative cases:

CASE XIII.—*Tumor of the right breast for some years; rapid growth within the past year; gradual distension of the abdomen; tapping, blood-stained ascitic fluid; enlarged, nodular liver.*

Mrs. D., aged 64, was admitted to Ward G, February 14, 1900, with swelling of the abdomen and an enlargement of the right breast. She had been a very healthy and strong woman until 4 months ago, when she had vomiting, and the abdomen began to swell, since which time she has been confined to bed. The abrupt onset is an interesting feature of the case. There has been a tumor of the right breast for some years, she does not remember how long. At first it was as large as the end of her finger. It has grown within the past year with a great deal of rapidity.

She was an elderly woman; some emaciation; slight respiratory distress. There was nothing of special moment in the examination of the chest except that there was a little flatness on the right side, probably due to exudate. In the right breast there was a tumor the size of a large pear. The mass was freely movable, not tender. There was no retraction of the nipple. The tumor was lobulated, measured 17 cm. vertically and 11 cm. transversely. The glands in the axilla were not enlarged. There was a little irregularity in the heart's action, nothing noticeable.

The abdomen was distended, prominent in the umbilical region, and bulged in the flanks. The walls were infiltrated and pitted on pressure. The fluctuation wave was distinct. Circumference of abdomen, 125 cm. There was edema of the legs. She had no leucocytosis; hemoglobin was 83%; red blood corpuscles just under 5,000,000.

On the 19th the abdomen was tapped, and 5½ litres of a dark yellow turbid fluid removed. After tapping, the edge of the liver was just palpable 1 cm. above the umbilicus, 7 cm. below costal margin in the parasternal line. Two distinct notches could be made out, and there was a distinct nodule above the edge of the right lobe. The surface, too, was slightly irregular. The spleen was not palpable.

The sediment in the ascitic fluid was blood stained; microscopically, red blood corpuscles and fine fat globules. There were no mitotic figures seen in any of the cells.

The patient went home March 16. There was no special change in the condition. On the surgical side it was thought that the breast tumor was probably an intracanalicular myxoma.

CASE XIV.—*Removal of right breast for carcinoma in May, 1896; local recurrence in May, 1897; through the summer and autumn pains in the joints and sciatica; swelling of abdomen in March, 1898; loss in weight; April, 1898, ascites; drainage; large nodular liver; at autopsy secondary carcinoma of the liver.*

Miss O., aged 40, admitted April 12, 1898. In May, 1898, the right breast was removed by Dr. Hartley for carcinoma. In May, 1897, a small lump appeared at the edge of the axilla, which was removed by the doctor. Shortly before this she had an attack of influenza, and in May an attack of sciatica in the right leg, which was very severe. Later in the summer she had sciatica in the left leg. She had pains in several of the joints, but no redness or swelling. She failed gradually, and in September and October she was a complete invalid. At the New York Hospital, under the care of Dr. Peabody, she improved, and gained in weight. On November 30 she went to Atlantic City, and she again had pains in the joints, and sciatica and high fever. She gradually recovered, and was able to get up and about. About the middle of March, 1898, she noticed that her clothing was very tight, and she found that her abdomen was swollen, and this of late has been increasing. She has had nausea and vomiting, particularly in the morning. She has also had some swelling of the feet. She has lost in weight in 3 months from 125 to 103 pounds.

On admission she was very weak and exhausted, and had an anxious, careworn expression. She was most comfortable when propped up in bed, though there was no great dyspnea, and she had no cyanosis. On the right side of the chest there was the scar of an operation wound, extending to the axilla. There was a hard nodule at its center the size of a chestnut. The abdomen was distended, symmetrical; fluctuation was easily felt. The edge of the liver could be felt on "dipping." There was marked tenderness over the region of the spleen.

On April 18 Dr. Cushing opened the peritoneum, and drained off 1000 cc. of a chylous fluid, which, after centrifugalizing, showed a number of cells 2 or 3 times the size of leucocytes, some of them very granular, others with a row of granules about the nucleus. A most careful search was made for mitotic figures, but none were found.

She was much relieved by the operation for 24 hours. Then she gradually sank and died on the evening of the third day.

The autopsy showed an enlarged liver, with numerous masses of cancer. There were no peritoneal growths.

NOTE ON THE SPONTANEOUS DISAPPEARANCE OF SECONDARY GROWTHS.

The phenomena presented by Cases V and VI are among the most remarkable which we witness in the practice of medicine, and illustrate the uncertainty of prognosis, and the truth of the statement that no condition, however desperate, is quite hopeless. The references in the Index Catalogue show that there are a good many similar instances in the literature. Two of the most remarkable I may quote. One of the most extraordinary is that reported by Mr. Pearce Gould². A woman had

noticed a tumor in 1888. Dr. Collins removed a scirrhous in 1890. The tumor was examined microscopically. In 1892 the glands in the axilla were removed. In 1894 there was recurrence in the scar, and a third operation. In the same year recurrent nodules about the scar, and she had dyspnea. In 1895, when aged 43, she was admitted to the cancer ward of the Middlesex Hospital. She then had enlarged glands above the clavicle, dyspnea, paroxysmal cough and hemoptysis. There was a large tumor in the left femur, supposed to be secondary cancer. She gradually improved, her dyspnea subsided, and the tumor in the femur reduced in size, and she slowly recovered, and Dr. Nunn, who also mentions the case, states that she was shown at the Clinical Society in the spring of 1899.

Vulpian³ gives the case of a woman, aged 32, admitted November 3, 1883. Eighteen months before she had noticed a tumor of the breast, which had increased in size, and had ulcerated. The other breast had become involved. She was admitted in a state of advanced cachexia. The axillary and clavicular glands were involved; there were nodules of secondary cancer in the abdominal walls, and she had an exudate in one pleura. She gradually improved, the secondary masses disappeared, the tumors in the breasts became atrophic, and she left the hospital apparently well on February 23. He quotes a somewhat similar case of Gluck's, in Berlin.

The spontaneous involution which we see occasionally in the primary growth in the breast, affords an explanation of the disappearance of the symptoms in some of the cases with secondary metastases. Without any obvious reason a tumor of the breast, which may have been growing rapidly, ceases to increase in size, slowly and gradually a diminution takes place, the nipple becomes retracted, and in the course of a year or two there is a small, hard, puckered mass, about which, as in Case I, the patient may forget, and even the attending physician may overlook. The metastases in the bones of the spine may undergo precisely similar shrinkage, with complete disappearance of the pressure symptoms, as in Case VI.

The diagnosis of these cases is, as a rule, easy enough when once it is recognized that paraplegia dolorosa and nerve root pains are exceedingly common sequences of cancer of the breast. I have already referred to the statement made by Shields and others that in the early stages the cases may be mistaken for hysteria or neurasthenia, more particularly as there may be no evidence whatever of secondary growths. The autopsy referred to on Case VIII illustrates how severe may be the symptoms, and how extensive the paralysis, with comparatively small growths.

The treatment is most unsatisfactory. Morphia alone gives relief, and it often has to be used in increasing doses. Many patients, however, are fairly comfortable with 3 or 4 quarter or half grain doses in the 24 hours. It is one of the conditions in which the physician has to bow to the inevitable, and in which to relieve the pain is his plain duty.

GASTROJEJUNOSTOMY IN GASTRECTASIS.*

BY

A. H. CORDIER, M.D.

Of Kansas City, Mo.

President Mississippi Valley Medical Association; Professor Abdominal Surgery, University Medical College.

Abdominal surgery as practised today by American surgeons is a typical demonstration of surgical ingenuity and application of methods approaching perfection. The peritoneum is as "sacred" today as of old, but modern asepsis has robbed invasion of this sac of most of its dangers. Dirty operations and imperfect technic bring disasters the same as in former years. The peritoneum is filled with hollow viscera, most of which are essential to life. These naturally contain myriads of pathogenic germs, hence the opening of one of these organs is fraught with many dangers unless the surgery is most skilfully performed. The improper application of a single stitch may lead to the loss of a life.

Until recent years most of the operations on that part of the alimentary system situated in the abdomen have been performed as emergency procedures and directly for the purpose of saving life. The successes in that class of cases led naturally to an extension of surgery to operations having as the indication not primarily the saving of life, but the relief of suffering, the restoration of function and prolongation of life.

While gastrectasis in the majority of instances is due to some form of pyloric obstruction there are other cases in which the stomach is dilated from purely a muscular atony-myasthenia. One of the frequent causes of pyloric obstruction is carcinoma, yet it must be remembered that dilation of the stomach is a slow and gradual process, and that cancerous extension of the muscular coats of the stomach may take place early and that these patients frequently die before any obstruction with dilation takes place. I call attention to this phase of cancerous obstruction because so many cases of noncancerous stenosis with dilation are refused relief by surgeons. An erroneous diagnosis of malignant pyloric obstruction has cost many a patient his life by robbing him of the opportunity offered by a gastrojejunostomy. In the majority of cases the dilation is not due to a cancerous obstruction. A pathologic closure of the pylorus that leads to the retention of the stomach's contents (isochymia) will sooner or later produce changes incompatible with comfortable and healthful existence.

The muscular coats of the stomach are first thinned by the dilation, but retain for some time considerable contractile power. The organ under some circumstances is capable of making an approach to its natural size in its efforts to expel its contents through the pylorus or esophagus. Later the organ becomes permanently dilated with thinned or thickened walls in an atonic state, and with very little power of self-emptying.

The pyloric and duodenal fixation is at a much higher point than the bottom of the sacculated stomach. Any operation having as its object the relief of the distention and retention must be made with a recognition of the

* Read by invitation before the Medical Society of the State of New York at Albany, January 29, 1901.

above facts and a site selected for the opening near the dependent portion of the dilated organ.

In reports of many cases of pylorotomy and pyloroplasty the symptoms have not disappeared after operation; the same is true when gastroenterostomy is improperly performed. The weight of the retained food produces a downward displacement of the stomach; decomposition, gas-formation, chemical and bacterial changes are constantly going on, resulting in chronic ptomain poisoning and starvation. These are briefly the unnatural conditions to be overcome in the treatment of a pyloric obstruction regardless of the character of the pathology.

Stomach atony may be determined by the salol test. The salol passes into the intestines where it is mingled with the alkaline intestinal secretions, salicylic acid being the result; this in turn manifests its presence in the urine at the end of 2 or 3 hours, as detected by the addition of a drop of tincture of ferric chlorid to the urine, showing a violet color. This test may be misleading in cases of pyloric stricture, as the salol might remain for days in a nonabsorbing stomach. Atony of the walls of the stomach as a source of dilation when acting as a cause of chlorosis, should receive the same surgical aid as the other forms of gastrectasis, especially if other treatment has been tried and failed.

After the operation I have noticed in most of my cases that the normal secretory function of the stomach has been restored and that disagreeable intestinal indigestion has disappeared, decomposed and improperly prepared food leaving the stomach, as such will not be digested or assimilated by the intestines. In most of my cases, at the end of 2 or 3 months the patients have gained much in weight, uncomfortable symptoms have disappeared and the size of the stomach has materially diminished and lost motility has been restored. I have noticed that a stomach which before operation extended several inches below the umbilicus has in the course of several months postoperative, receded to nearly its normal position. After the operation these patients eat anything they desire and are not aware of the fact that they have a stomach. Intestinal indigestion, a frequent companion to a dilated stomach, usually disappears. The capacity of the stomach may vary from the usual 4 pints to a much larger quantity and yet remain functionally normal (megastria). This condition does not call for surgical intervention unless, by pressure on other organs, symptoms are induced demanding relief.

The application of gastrojejunostomy is not limited to cases of dilated stomachs, but has a much wider scope, as in some cases of gastric ulcers, etc. The use of the stomach tube, proper dietetics, and tonics, should not be depreciated in the management of the atonic variety of dilation yet their use should be discarded after a faithful trial has demonstrated their futility. Even though the obstruction is malignant and is accompanied by a dilation of the stomach, the relief of suffering and prolongation of life warrants the operation. Stomach-washings should be practised for a few days before operation.

The incision is made in the median line above the umbilicus. In none of my cases has it been necessary to make the cut in abdominal walls longer than 3 inches. A small incision shortens the time of operation, prevents

handling of the bowels, and extrusion minimizes the dangers from leakage of fluids into the peritoneum.

Loreta's operation, introduced in 1883, has not demonstrated by time and a fair trial all claimed for it by its originator. Any operation having for its aim the permanent dilation of a cicatricial narrowing of a canal must of necessity extend over a long period of time, and that, too, with frequent divulsions or stretchings. The history of all cicatricial tissue, especially when the process of healing extended over a large mucomuscular area, is to return to its contracted state after divulsion. This is notably the case with a cicatrix of the pylorus following a healed gastric ulcer. The operation of Loreta is certainly not applicable to the closure of the pylorus due to malignancy.

Pyloroplasty, or the operation devised by Heineke-Mikulicz, is one that promises very good results. It consists in making a longitudinal incision on the anterior wall of the duodenum and stomach, in all about 3 or 3½ inches in length. This incision is closed in a vertical direction, or transverse to the way in which the cut was made. By thus closing the wound a new pylorus is created, with the cicatricial tissue on its posterior wall. This is a very good procedure, but is attended by unnecessary difficulties to be encountered by the surgeon, and dangers to which he is not warranted in subjecting the patient. Time is an important factor in the success of any abdominal operation, and especially is this true in the case of patients much debilitated from any cause. Many of these patients are much run down as a result of the prolonged suffering, lengthened starvation, and chronic poisoning from decomposed food, etc. Much surgical time is occupied in doing a pylorotomy or a pyloroplasty.

Malignant disease of the pylorus, giving rise to an occlusion or partial closure, with a resulting dilation, is best relieved by the operative procedure recommended in this paper. It must be remembered that when malignant disease of the pylorus has advanced to a period when it produces a closure of the pylorus, it has also advanced beyond the limit of probable total extirpation; hence temporizing and comfort-giving surgery (by methods entailing the least danger to life) should be applied in the case.

Pyloric resection for cancer, while a brilliant procedure, has not been crowned with success, as far as cure is concerned, such as would entitle it to be placed on the list of advisable and warranted surgical operations. This statement, I fully recognize, is at variance with the writing and practice of some of the world's greatest teachers and surgeons.

Dreydorff reports a series of collected cases of pyloroplasty with a mortality of 20%. The same author (1894) tabulates 188 pylorotomies with a mortality of 70%, the average duration of life in those recovering from the operation being only 11 months. Czerny's mortality from this operation is 41%. Any operation having an immediate mortality of from 50 to 60%, with an average duration of life of only 11 months following the procedure, should be banished from the list of legitimate surgical operations. Especially is this true when a less dangerous and more satisfactory method is offered as a substitute.

In leaving a large cicatricial mass at the pylorus there is, as is claimed by some surgeons, a disposition to malignant degeneration at the site of this fibrous tissue, but this rare change is best averted by diverting the source of irritation (the passage of the stomach's contents) in a direction furthest removed from the scar.

Nomadic surgical procedures, or wandering surgical operations, usually result in half-doing any or all methods tried.

With a few surgeons the new and untried technic presents a seductive persuasion hard to resist, but the adoption of this technic is only too often disastrous to the patient. Surgical calisthenics ("keeping the hand in") in inoperable cases of any nature, should be, and, as a rule, are condemned by the majority of operators. It is useless and unsurgical to perform a pylorotomy for far advanced malignancy when it is known that nothing but a specimen and a little "surgical exercise" can be expected.

Surgical procedures of long duration on anemic patients are fraught with much danger. Malignant disease of the pylorus soon induces profound anemia and cachexia, both militating against successful surgical work. A pylorotomy or a pyloroplasty requires too long, as a rule, for a low mortality in anemic patients.

The importance of gastrojejunostomy as a drainage operation has not been dwelt on sufficiently. The direction of the motion of the stomach makes no difference in this operation; the intestine above the site of anastomosis atrophies to quite an extent after the operation as its only function is conducting the bile and pancreatic fluids downward. Intestinal peristalsis will divert any tendency of the fluid to go upward.

While in most cases it is desirable to make the anastomosis at the lowest point of the stomach on its posterior wall, equally as satisfactory results have been obtained by an anastomosis at the most dependent point on the anterior wall. Some of these patients are in such desperate physical condition that the shortest possible time of operating should be obtained. It takes a few minutes longer to perform the operation when the anastomosis is made in the posterior wall.

A coil of the jejunum should be selected as the portion of the intestine to be used in the anastomosis. If the anterior wall of stomach is selected, the intestine will, of course, have to cross in front of the transverse colon; and enough "slack" should be allowed to prevent any undue compression on the colon or dangerous tension at the site of the gastrointestinal union. In one of my cases the anterior wall of the dilated stomach had descended below and in front of the transverse colon, making not only the anterior anastomosis easier, but most desirable. The colon in this case was anchored by adhesions that prevented its descent with the stomach. The one important practical truth to keep in view in the selection of the site of anastomosis, is that the operation is a drainage or "emptying" one and that the opening must be at the bottom. A barrel will not empty itself through the bung hole while sitting on its end.

I have used the Murphy button in all my cases. Its selection does not demand an apology, as all surgeons are familiar with its uses, as well as intestinal suturing, and

can and do use either as thought best. Neither does the technic of the application of the button need any explanation. It is not my intention to enter into any discussion of the selection of the mechanical means of relieving the symptoms in these cases, as Dr. B.⁶ will get good results with the button, Dr. A. by suturing, etc., etc. The point I do desire to lay some stress upon is the uselessness of the complicated operations of twisting the intestine with multiple anastomosis and the resection of healthy bowel to obtain a theoretic physiologic intestinal circulation of the bowel-contents. Some operations, Baum's, for instance, remind one of a complicated piece of plumbing or automobile machinery.

The following cases present points of much interest:

CASE I.—Mr. L., aged 66. This man, some 8 years ago, had an attack of hepatic colic lasting several hours. This was followed by a jaundice that persisted for 3 weeks. He soon regained his former good health and remained well up to 2 years ago, at which time he had another colic attack, not so severe and not followed by jaundice. One year ago he began having more or less pain in the region of the stomach, or rather, as he expressed it, uneasiness after eating. Two or 3 months later he began losing his weight and had occasional attacks of vomiting, but did not vomit blood at any time. At my first visit he could not digest nor retain much solid food (muscular action was good). He was greatly emaciated, weighing only 120 pounds, although he formerly weighed 240. His appetite was fairly good and liquid nourishment was taken with a relish and fairly well taken care of. Solid food caused much pain and nausea, until relieved by vomiting. On examining him I found that his skin was flaccid and "swarthy," not of a cachectic appearance. Pulse and temperature were normal. An examination of the abdomen revealed a greatly dilated stomach; its peristaltic action could be plainly seen through the thin parietes. There was no pain on pressure at any point, only in the vicinity of the pylorus there existed a sense of unnatural resistance, covering an area the size of the palm of the hand. A test meal when examined revealed an absence of hydrochloric acid. Malignant stenosis of the pylorus was the most probable diagnosis, yet I did not believe there existed a malignant condition. He was given a tonic of strychnia and iron and nutrient enemata were ordered each 4 hours. Under this course he gained 8 pounds in a month.

At operation a median parietal incision 3 inches long was made above the umbilicus. A loop of jejunum was pulled into the incision after pushing the omentum to the left. The anterior wall of the stomach was delivered and a site selected at the lowest point of the dilation, an opening made, puckering stitch applied and $\frac{1}{2}$ of a Murphy button put in. The jejunum was treated in like manner and the halves of the button put together; a continuous Lembert suture was applied around the button for additional safety. Time of operation, 15 minutes. The patient left the table in good condition, and vomited for the first time 10 hours after operation, large quantities of bile. Two days later he had a similar attack. The bowels moved on the second day, and there was no distention at any time.

At the end of 12 days I could feel the button near the cecum, it had evidently completed its work; the button passed on the fifteenth day. His symptoms all disappeared and he gained 60 pounds. No evidence of malignancy could be found at the time of operating. This case was one of nonmalignant stenosis of the pylorus. The patient lived 4 years and died of pneumonia.

CASE II.—Mr. R., aged 67, of Salina, Kan., came to me January 17, 1900. Four months ago he began losing weight and complained of some uneasiness in region of stomach, but had no severe pain at any time. His bowels were very much constipated; in fact there had not been a natural bowel-movement in 3 months. Enemas had been used and even then only a little mucus and fecal stained fluid was passed. The obstruction at the pylorus has been complete for the last 2 months, during which time the stomach-tube has been used twice a day and the

contents of the organ removed by these washings. He had not vomited much. At no time had there been hematemesis. Pain had not been a prominent symptom at any time. He had formerly weighed 180 pounds but I found him much emaciated and very weak, with calcareous arteries. He had no fever or increased pulse-beats. The abdomen was flaccid and free from tenderness; no cachexy.

In the recumbent position nothing abnormal could be detected on palpation. When he was placed in the sitting posture, by deep firm pressure I could detect a hard mass in the right side near the umbilicus. This mass was the size of a 2-ounce, round, prescription bottle, and was quite freely movable, the range of mobility representing an arc of a circle, the axis of which appeared to be near the normal fixed point of pylorus. When the stomach was filled with water (6 pints) it descended an inch below the umbilicus. He was starving, as the stomach could not prepare and absorb the food necessary to hold his health's standard.

An operation was advised and preparations were begun at once. Nutrient enemata were given every 4 hours. Small quantities of concentrated nourishment were given day and night, and the stomach was washed by tube twice per day. Large saline injections were given by the rectum 2 or 3 times in 24 hours. Chloroform was administered and a median incision 2½ inches long was made above the umbilicus. The intestines were empty, hence, it was an easy task to find the jejunum and pull it into the incision; the stomach was easily and quickly found and also delivered, in part, through the incision. In this case time was a most valuable consideration, as the patient was in such a condition that any prolongation of the duration of operation meant death to the patient. After the intestine and stomach had been well surrounded with gauze in the incision, an opening was made in the jejunum some 15 inches below its fixed upper part.

The opening of the bowel of course was made on the convex surface, the purse-string suture having been introduced before opening the gut. The portion of the button holding the spring was introduced into the bowel and the puckering string tied snugly about the stem of the button. A point near the lower side, or better, bottom of the stomach was selected and treated the same as the bowel and the halves of the button were pushed together; a continuous Lembert suture was used about the button to give additional strength in case of severe vomiting.

The anastomosed stomach and jejunum were replaced and the abdominal incision was closed with silkwormgut sutures. Duration of operation, 18 minutes. During this short period of operating the patient's pulse and respiration ceased 4 times, requiring artificial respiration, and during the entire operation his chest and head were kept lowered. Following operation he did not have an ugly symptom. He was nourished by the rectum for 48 hours, after which he took beefsteak and other concentrated foods daily. No vomiting occurred, and only 2 stomach-washings were necessary, on fourth and fifth days. The bowels moved on the third day. At the end of 2 weeks he sat up in bed, at end of 3 in a chair, and in the fourth week he returned to his home.

This man died 11 months later from an extension of the malignant disease. He had no return of his obstructive symptoms after the operation.

I am surprised that the operation has not become more popular, as the indications for its performance are so plain, the relief brought so prompt and permanent, the mortality so low, and the patients requiring it so numerous. Some of our most widely known surgeons have never, they write me, performed the operation.

I recognize how few of the important features of this subject can be embodied in a paper to be presented before a medical society. I trust the discussion may elucidate the omitted phases.

CONCLUSIONS.

1. Cancer of the pylorus, even though removed, returns quickly, and always kills. Pylorotomy is

attended by a high mortality and is not a justifiable surgical procedure in advanced carcinoma of the pylorus. Gastrectasis due to a malignant closure of the pylorus is best treated by a gastrojejunostomy. The operation as advised by Wolfler or Von Hacker best meets the indications.

2. It is not necessary to twist the bowel, in making the anastomosis, to prevent bile from entering the stomach.

3. The anastomotic opening in the stomach should be at the most dependent point of the dilated organ. The operation is attended by a low mortality. In all cases in which marked dilation of the stomach exists, accompanied by emaciation, pain, and invalidity, the operation of gastrojejunostomy should be performed. The relief of pain, due to the effort of the stomach to relieve itself, follows this procedure at once. The patient gains rapidly in weight, and if the disease is nonmalignant his former good health is restored.

THE MORTALITY OF OPERATION FOR OBSTRUCTIVE JAUNDICE.

BY

JOHN B. DEEVER, M.D.,
of Philadelphia.

[Concluded from page 20.]

It would seem then that operation, and *early* operation, offers the best safeguard to the destructive possibilities of obstructive jaundice due to cholelithiasis. Strictures or obliteration of the duct, tumors closing the orifice of the duct or growing into its interior, pressure from without by tumors of contiguous organs, or by enlarged glands in fissure of the liver, present indications so unmistakably surgical that it is hardly necessary to argue the point.

Marked jaundice, and especially if of long duration, offers a serious obstacle to operative interference, and yet in some cases we must assume the increased risks. The class of cases in mind are the fulminating type of the disease; they run a course similar in onset, duration and termination of the attack to the fulminating form of acute appendicitis. A differential diagnosis is oftentimes difficult to establish, yet the one most important fact can be established as a rule; *i. e.*, general peritonitis, which is the usual accompaniment of fulminating appendicitis and unusual in the disease of the biliary apparatus. In either case operation should be synchronous with the establishment of a diagnosis, or even with a strong suspicion of the trouble; under these circumstances it is better to open an abdomen and find little or nothing wrong, than to do so later on in the attack and find an irremediable condition of affairs.

The time which elapses between the onset of an attack of fulminating obstructive jaundice and its fatal termination is, at the most, a very few hours, and even in this short time it is usual to find gangrenous destruction of not only the gallbladder and ducts, but of the contiguous organs and tissues and especially the duodenum and liver. Here the only hope is prompt relief of the obstruction and adequate drainage.

The important fact to be learned by this study and which to me seems to be the only logical deduction, is that early operation not only in the acute exacerbation of the disease, but in the early days of the disease itself, not only offers the best and surest prognosis as to recovery, but as to the mortality as well.

The 5 cases reported in this paper are used as a text; they represent the mortality of this affection in the German Hospital during 1898, 1899, 1900 and for January and February, 1901:

A. W. was operated upon in 1898 for obstructive jaundice caused by a stone in the common duct. He had consecutive hemorrhage which was controlled by packing; 4 days after operation a secondary hemorrhage occurred, and in spite of packing he died of shock due to hemorrhage.

C. L. was operated upon in 1899 for obstructive jaundice. The urine was loaded with bile and the gallbladder was enlarged and filled with sanguineous pus; 5 stones were removed from the gallbladder and 1 from the cystic duct. The patient died of exhaustion 2 days after operation.

C. P., aged 38 years, married, was admitted May 22, 1899, with a diagnosis of cholelithiasis. His father, mother, 1 brother and 3 sisters are living and well; he uses alcohol very moder-

ately. He has been married 13 years and has 2 living children, 2 died in infancy.

He has had usual milder diseases of childhood, had enjoyed excellent health until 3 years ago, when he had an attack of enteric fever. The present trouble began 1 year ago, although he had not been feeling well since his attack of enteric fever 2 years before. He has lost 50 pounds within the past 2 years. The present trouble began with severe cramp-like pains in the right hypochondriac region. These remained localized in this position and did not radiate. At the same time he became nauseated and for several days continued to vomit small quantities of biliary material. At this time he was confined to bed for a period of 10 days, although his pains had greatly moderated after the fourth day of onset of the symptoms. During this period and for an indefinite time hereafter, his stools, which were infrequent, were of various colors, varying from a light grayish clay color to dark brown. During this attack his skin became yellow, but gradually faded out until he became perfectly white again. Urine was at times of a deep brown color, staining his underwear. After a time he became better and finally resumed his work and continued at it until November, 1898, when he again had a similar attack with pain, biliary vomiting, constipation and jaundice, differing only from the former one in severity. This attack did not confine him to bed, but since then he has never been free from jaundice, or pain and tenderness over the region of the gallbladder. During the next 4 months he continued moderately jaundiced, but does not know whether his jaundice moderated or became more intense at times. His stools were of a variable color, at times clay colored, at others of a deep brown color.

His present condition began 4 weeks ago with severe pains in the left hypochondrium, followed by nausea and biliary vomiting. Fecal passages and urine had the above mentioned characteristics. This attack like the preceding one did not confine him to bed, but prevented him from continuing his occupation. His pain (although moderate) and soreness in the region of the gallbladder, have continued until his admission to the hospital. His jaundice was gradually becoming more intense.

Upon admission, temperature and pulse were normal. He has the above symptoms with slight tenderness upon deep pressure just below the costal arch 3 inches to the right of the median line. It seems that faint gallstone erepitus can be felt in this position. The gallbladder and area of liver dulness are not enlarged.

OPERATION was had May 24, 1899. The patient was prepared and etherized, using 480 cc. of ether. An incision was made through the rectus muscle. The gallbladder was partly visible and projected slightly below the anterior hepatic border; it was only slightly distended. The peritoneal cavity was packed off with wet, hot sterile gauze and the region of the gallbladder was explored by the finger. The finger inserted in the foramen of Winslow disclosed a large stone about the size of a pigeon's egg, occupying a position in the common duct, behind which the cystic duct and gallbladder were slightly distended by bile. An incision about 1½ inches in length in the common duct released the stone and many smaller triangular ones which had collected in the duct. The duct was then mopped out with iodoform gauze and the incision closed with a row of continuous sutures. The area just behind the common duct was drained by rubber tubing and 2 pieces of gauze. The gallbladder was opened by an incision barely large enough to admit a small rubber drainage tube; the latter was packed around with 2 strips of gauze, the tube emerging at the lower end of the abdominal incision. The tube draining the area behind the common duct came out just below the tube draining gallbladder. The gauze packing was removed and abdominal wound closed by interrupted, through-and-through silkworm-gut sutures, silver foil and iodoform gauze dressing.

On May 25 the abdomen was greatly distended, not tender. Distention diminished after a turpentine enema. Pulse was very feeble. Faeces drawn and pinched. On the 26th the pulse had become more feeble and was at times barely perceptible; the skin was cold and clammy. The patient had begun to vomit small quantities of greenish material. This was kept up without interruption during the day. Delirium in a mild form

had set in and altogether patient was in a very poor shape. The abdomen was greatly distended and tympanitic; hepatic area of dulness not marked. Partial necropsy showed localized fibrinous peritonitis; no pus in general peritoneal cavity. Death probably due to cholemia.

W. J. P., 54 years. Operation. Was admitted January 26, 1901, with a diagnosis of gallstones. Mother living and well. One brother died of enteric fever, one brother living and well. One son and one daughter living. Wife living. No history of carcinoma or phthisis. The patient was very weak when admitted. He was emaciated, exceedingly nervous, extremely jaundiced, no fever and fair pulse. His illness began in February, 1900, with a diagnosis of catarrhal jaundice. Gallstones were considered, but he never had pain in any way resembling biliary colic. In the following May he was improving from the attack and had a slight attack of colicky pain lasting 12 hours, which suggested biliary colic. After this he began to fail; he lost flesh, had marked anemia, leukocytosis, constant nausea and appearance of cachexia. Malignant trouble was positively diagnosed.

In July he had a second attack of colicky pain of short duration followed by rapid improvement. He gained weight, was free from jaundice and he thought he was cured, when on his return to Philadelphia in November, the jaundice, weakness, loss of flesh and nausea returned. Gallstones were diagnosed. Operation was considered, but was deferred hoping for improvement. He steadily lost ground until he was admitted on January 26 with above symptoms and leukocytosis of 15,400. Pruritus was marked and distressing. Three days after admission he was operated upon under ether anesthesia. Incision was made through the right rectus muscle into the peritoneal cavity. The gallbladder was felt to be smooth, not markedly enlarged, and the seat of a large stone. The intestines were walled off with gauze. The gallbladder was opened on the anterior surface and a large stone (of size of first joint of thumb) was removed. The stone was free. Another stone was felt in the common duct. This was also movable. It was removed by making an incision into the common duct. A rubber drainage tube was placed into the gallbladder and one in the opening in the common duct and held in place by a chromicised catgut ligature. A piece of iodoform gauze was placed under the gallbladder in both tubes. The large pieces of gauze were removed and the wound was closed by through-and-through silkworm-gut sutures except at the upper part where the 2 tubes and gauze were placed.

He did well for 2 days after the operation; his mind was clear and alert, pulse and temperature normal. He slept fairly well, expelled flatus and took nourishment. There was slight but continual oozing of blood from the wound and a free discharge of bile. He could not urinate voluntarily. The next 2 days he became nauseated, restless, passed scanty amounts of urine, pulse more rapid, mind not so clear. The slight oozing from the wound was not checked by packing; the gauze was removed on the third day, but the oozing continued. It was checked at once with a 1 per cent. solution of suprarenal extract. On the fourth day he became delirious, semicomatose; pulse was weak; was nauseated, with occasional vomiting; abdomen was flat and he passed flatus. He was transfused, with temporary improvement for 12 hours, at the end of which time he was again transfused. After repeated enemias he had a slight bowel movement on the fifth day. After this he gradually sank and was unable to take food by mouth or rectum, pulse weak, was semicomatose, extremely jaundiced, pruritus marked even in delirium. He died while in this condition. Permission for an autopsy was refused. This was, I think, a death from cholemia.

Mayo Robson cites the following cases of deaths from the causes indicated:

No. 283.—Obstructive jaundice; several loose stones in common duct; cause of death was violent and persistent hematemeses. Death on second day after operation.

No. 264.—Obstructive jaundice for months; pressure from cancer of pancreas. Died on fourth day of cardiac failure. No peritonitis.

No. 178.—Obstructive jaundice. Common duct thickened and contained gallstones. Death from exhaustion and shock on third day.

No. 149.—Obstructive jaundice of 4 months' duration. Cancer of pancreas and common duct. Death from extraperitoneal and intraperitoneal hemorrhage without peritonitis. Lived 1 week.

No. 141.—Obstructive jaundice. Cholelithiasis; 18 stones, dense adhesions. Gallbladder removed. Ligature slipped on second day. Extravasative peritonitis.

No. 243.—Obstructive jaundice. Stone in ampulla of Vater; removed through duodenum. Pus collection between liver and diaphragm, not discovered until autopsy.

No. 255.—Obstructive jaundice. Stone in common duct and 1 in ampulla. Well until fifteenth day; died on seventeenth day of heart failure. No peritonitis.

No. 277.—Obstructive jaundice; stone in common duct, which was immensely distended. Numerous adhesions; violent hematemeses 12 hours after operation.

No. 272.—Obstructive jaundice. Stone in gall bladder; 2 stones in common duct; many adhesions; persistent vomiting and death from exhaustion on fourth day.

No. 236.—Obstructive jaundice. Stones in common duct, hepatic duct and cystic duct removed. Patient died on sixth day of heart failure and exhaustion.

No. 177.—Obstructive jaundice. Stone in common duct removed by incision and duct sutured. Died at end of 5 weeks from exhaustion.

No. 59.—Obstructive jaundice. Stone in common duct; adhesions removed, incision and then sutured. Death from peritonitis due to fecal extravasation from a small hole in colon caused by adhesions.

No. 250.—Obstructive jaundice; no stones or tumor felt; cirrhosis of liver and some swelling of head of pancreas. Disease probably cancer of papilla and subsequent cholangitis. Died of shock and exhaustion on third day. No autopsy.

No. 274.—Obstructive jaundice. Cholelithiasis. Patient weak and no attempt to remove stones. Bladder drained. Died on second day. Hemorrhage, which was in the form of persistent oozing.

No. 143.—Obstructive jaundice with hemorrhage from various localities. Stricture of common duct. Death from hemorrhage and shock in 24 hours.

No. 51.—Obstructive jaundice. Distended gallbladder; no stones; head of pancreas hard. Died of shock on second day.

No. 33.—Obstructive jaundice. Cancer of pancreas with gallstones. Hemorrhage from nose, bowel, etc. Died of shock promptly.

No. 11.—Obstructive jaundice. Cancer of pancreas, distended gallbladder. Death on ninth day of hemorrhage.

No. 235.—Obstructive jaundice. No stones in gallbladder or common duct. Death in 7 days of syncope. Kidneys granular and capsules adherent. No peritonitis.

No. 159.—Obstructive jaundice. Adhesions, gallstones and infective cholangitis. Death from general oozing at site of torn adhesions.

No. 92.—Obstructive jaundice, with 18 stones from ducts; infective cholangitis; adhesions. Death on twelfth day from exhaustive persistent vomiting; no peritonitis.

Richardson* reports 13 deaths in cases of biliary calculi and about 100 recoveries. He claims that early operation is not attended by any mortality, but the fatal cases were those operated on late or after cholemia had become a factor.

* Paper read before Surg. Sect., meeting of American Medical Association, June 5 to 8, 1900.

PHELPS' OPERATION FOR CLUBFOOT WITH A REPORT OF 1,650 OPERATIONS.*

BY

A. M. PHELPS, A.M., M.D.,

of New York City.

[Concluded from page 24.]

In the management of clubfoot, it often becomes necessary for the operator to apply more force than can be done by the hands, not only during the time of the

with his canting lever 3, in his hand, flexes and rotates the foot, breaking it across the adjustable fulcrum 6, while his assistant holds the heel firmly with the other lever. As flexing force is applied by the larger lever, the leg is prevented from slipping by the adjustable slide 14.

The machine will not only be found useful in all cases of clubfoot, but more particularly so in those severe forms of clubfoot requiring operation. The operator from time to time can adjust the machine and apply any amount of force, breaking ligaments which he would find it difficult or impossible to cut. In the after treatment of clubfoot it will be found useful.

The operator should not cease operating until the foot

Fig. 13.

Fig. 14.

Fig. 15.

operation, but in the subsequent treatment of the foot as well.

In nearly all cases of varoequinus there is a shortened condition of the ligamentous contraction posterior to the ankle joint, and also an inward rotation of the os calcis. In such cases there is not sufficient power in the hand of the operator to overcome the ligamentous contraction.

To fulfil all of these requirements, I have devised a machine which will be found useful. It can be used in the class of cases above indicated, or several hands can be substituted.

It consists of a combination of levers and screws, so adjusted as to apply the force in the proper direction, varying from a single pound to one ton in force. The bed-piece (Fig. 11) is fastened to a table by means of a clamp 15; 14 is an adjustable slide working upon the cross part of the bed-piece. After having etherized the patient, he is placed in the machine with his leg flexed, as seen in Fig. 11.

The slide 14, is adjusted to prevent the leg from slipping. The straps 10, 11 and 12, hold the leg in a firm position on the bed-piece; 16 is a fulcrum, into which the end of the lever 1, is inserted for the purpose of making the pressure upon the os calcis by means of the pad; 4, 5 is the adjustable fulcrum into which the end of the other lever is inserted. The foot is attached to this lever by means of straps 7, 8 and 9 (Fig. 7), and 5, 6 and 7 (Fig. 12). The straps 5 and 6, are attached to the nuts 4, 4, by turning the screws 2, 2, which are held in the proper position by the framework 3.

Any amount of force can be applied to the heel and instep. The jack can be adjusted to the lever as seen in Fig. 11, the strap 7, passing around the foot as seen in Fig. 12, secures the toes firmly. The operator and his assistant turn up the screws, applying any amount of force required. The operator now,

is supercorrected, otherwise a relapse may be looked for, beginning with manipulation, either with the hand or the clubfoot machine or both, and concluding if necessary, with extensive osteotomy, pursuing the order of procedure as recommended above. Failures occur because the operator concludes his work before the foot is straight and overcorrected, and guesses that he can correct the deformity left by proper after treatment, which, as a rule, he cannot do.

Another source of failure is bad dressing. The desire

Fig. 16.

to use some pet splint, or devise some new scheme, accounts for the disappointment with results.

Failing to supercorrect by operation, and using some worthless wood or metal splint, so adjusted as to make undue pressure upon the resisting foot, produces sloughing, or even gangrene. When the foot has been once

*Paper read before the British Medical Association, August, 1900.

supercorrected, it will then rest in proper dressings without resistance or pressure, and sloughing is never seen.

THE OPERATION.

Prepare the foot by scrubbing, scraping, and antisepticizing with bichloride of mercury solution, 1 to 1,000, the night before. Carefully see that every detail of antiseptic surgery is followed at the time of operating. Then cleanse the foot with iodoform, 1 part; sulfuric ether, 8 parts. Apply the Esmarch bandage.

Keep up a constant irrigation with bichloride solution, 1 to 2,000, during the operation. After strong manipulation, either manual or instrumental, and subcutaneous tenotomy, make the open incision already described in Fig. 6, cut in the order already suggested. Use strong force after each tissue cut. Nothing will be gained by dividing soft parts more extensively than suggested above. If the foot still resists and cannot be placed in a supercorrected position, linear osteotomy, and

finally cuneiform resection should be done (see Fig. 8). In 2 cases, in adults, I found it necessary to remove both cuboid and scaphoid bones. Open incision in children under 1 year of age I have seldom found necessary. Flaps of skin can be turned into a wide gap.

The Dressings. Sponge out the wound, then apply, (1) Lister's protective, not rubber tissue; (2) antiseptic gauze, large quantity; (3) antiseptic bandage; (4) absorbent cotton to knee; (5) over all a plaster-of-paris bandage, holding the foot in the supercorrected position, until the plaster sets; avoid making pressure either by dressings or twisting the foot too far outward; (6) remove the Esmarch bandage; (7) sling the foot to a nearly perpendicular position for 6 hours or longer. Organiza-

Fig. 17.

tion of blood-clot usually occurs, but it is not essential to a good result.

My last cases were dressed as indicated, but the wound was filled with chopped-up fine catgut. Organization was perfect in each case. Fig. 13 shows scarring in a foot 4 weeks after the operation. Fig. 14 shows position of scar and appearance of the foot at the fourth week; Figs. 15 and 16 the condition before and 3 weeks after the operation, and Fig. 17, 8 years after the operation, Figs. 18 and 19 the deformity and method of after-treatment by means of hooks and plasters 1 year after.

After Treatment. The plaster-of-paris shoe and the hooks and plasters or adhesive plaster answer well. The hooks and plasters are well adapted to children under 2 years of age. Fig. 19 represents the plaster and hooks as applied to the feet, the bandages removed. The upper hook connects with a belt above the hips by means of a tape, which tape is secured to the side of the leg at the knee with a strap. The lacings between the hooks hold the foot in the normal position. The results of my series of cases and of those which I have compiled will be found in the table pages.

Equinovarus, after any operation, or mechanical

treatment, is quite likely to relapse. For months and even years, the surgeon will need to carefully look after many of his patients. I have seen relapses following mechanical treatment which have been carried out for years, in every form of osteotomy, and more particularly excision of the astragalus. In my travels through

Fig. 18.

Germany I made casts of feet which had relapsed after these osteotomies in the hands of some of the most eminent and distinguished German surgeons, and the same observations are to be made in every country. An operation only straightens the feet; when this has been accomplished, the treatment (and not until then can treatment be said to begin) is only commenced. The slight twist in the neck of the astragalus will not be found a serious obstacle in the way of cure, unless excessive, in which class of cases it should have been divided with a chisel at the time of operating.

What are the limits of the application of this operation? (1) Eliminate all cases which by the hands can easily be placed in a normal position; (2) eliminate all of those cases which can by subcutaneous tenotomy be perfectly relieved with accompanying proper after management. Then open incision will find its legitimate place in surgery. The age of the patient has nothing to do with the indications for the operation.

What are the advantages of the operation? (1) cutting parts as they offer resistance in their respective order prevents the operator from needlessly cutting tissue not deformed by contraction; (2) after the subcutaneous ten-

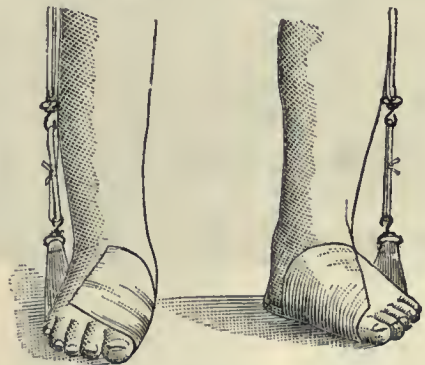

Fig. 19.

otomy of the tendo-achillis the tibialis posticus tendon is easily cut, through an open wound, near its attachment to the scaphoid, ligamentous contraction at this point can also be divided; (3) through this open wound contracted parts can be extensively cut without wounding the external plantar artery or nerve; (4) after all contracted

soft parts have been divided, including the skin (which, by the way, in this class of cases is always short, and from its intimate connection with the plantar fascia would defeat the object of the operation if not divided), the operator can ascertain the amount of the deformity of the bones, and if any considerable amount exists it can be easily remedied with a chisel; (5) it restores the foot to its natural length by lengthening the shortened side; (6) it makes the surgeon master of the situation; he advances step by step in a proper order, and need not stop or retreat until the deformity is overcome, beginning with manipulation and subcutaneous tenotomy, and ending with osteotomy, if necessary.

I desire again to state that osteotomy should not be resorted to as a primary operation, and not until after the contracted soft parts have been lengthened for the reason that in primary osteotomy the bones of the foot must be shortened in proportion to the amount of shortening of the soft parts.

Fig. 20 is of my first open incision operation, before, after, and 12 years after.

Fig. 21, my second case, 3 years old, 3 weeks after operation, 6 years old, 14 years old, and 21 years old.

Fig. 22, my third case, 3 years old, before, 3 weeks after, 4 years after, 10 years after.

Figs. 23 and 24, a case treated 6 years by interrupted traction, 9 times a day, showing results, and the final result after an open incision operation.

Result in a case 34 years of age (Figs. 25 and 26).

I will say that relapses, when they occur, take place during the first years after the operation.

There were performed 10 linear osteotomies, 5 linear osteotomies with cuneiform resection from os calcis or

Fig. 20.

cuboid, and 2 linear or cuneiform osteotomies, together with removal of both cuboid and scaphoid bones, making in all 17 osteotomies.

These results vary but little from Dr. Kaptyn's, of Abcande, Amsterdam, who has kindly furnished me with statistics of 42 operations in 36 cases in Holland. In this series 34 were very good, 1 materially improved, fair results in 6, and 1 still under treatment. In other words, good results were obtained in 36 feet, with useful feet in all the others, except 1, which is unknown.

I find in looking over the literature on the subject, the following reported cases: Hoffe, 6; Schede, 20; Nunchen, 13; Oliva, 6; Postemp-ski, 1; Schreiber, 11; Lowenstein, 2; Jones, 19; Roman, 3; Giordane, 1; Motta, 7; Volkman, 21; Kirmison and Rochard, 7; Ambrose, 1; Phillipson, 3; Levy, 9; Kaptyn, 42; Post, 2; Hamburg Medical, 1884, 12; Hingston, 4; the writer, 161, making in all 342. Bradford and Lovett, of Boston, have made interesting reports endorsing the operation, as has also nearly every member of the American Orthopedic Association and nearly every surgeon of prominence not only in America but in every civilized country on earth.

In my series all the cases at the time of reporting upon them were good results. In no case did I find a sensitive scar, a flat foot, or paralysis following the operation. No considerable atrophy of the muscles of the limb followed the operation in any case; the motion of the toes was preserved in nearly all cases. In those with loss of flexion of the toes, locomotion seemed to be as perfect.

In this series of 1650 cases, the majority had already

Fig. 21.

To summarize my results (I have operated on 1650 cases), I find that the average age was 7 years; the average time of healing of the primary wound was 4 weeks; there were 60% of blood-clot organization, 60 cases of catgut in the series.

The average duration of after treatment was 5 months; on the fourth month after operating, the feet were all straight. Out of the 140 cases traced after one year, 10 cases were found relapsed, or partially so, from neglect.

run the gauntlet of tenotomy and instrumental treatment, with a relapse in each case.

The proportion of relapses in the whole series I have been unable to determine after 1 year, on account of

charitable institutions, and we again make a record of the case. We seldom see a relapsed case. Possibly such cases fall into the hands of some of my colleagues in other institutions.

Fig. 22.

the difficulties encountered among the lower classes in the slums of New York. In my first series of 161 operations, there were 6% of relapses, and I dare say that even so large a percentage would be found in my last series. The first series was made up of cases largely in private practice, and from the better classes of the poor one could trace them easily, but the wandering

Fig. 23.

hordes, with which we now come in contact in our clinics, are from every part of the city and country, and move so often that it would take an army of assistants to trace them. We usually see them with perfectly straight feet for a few months, then with the plaster-of-paris shoe they disappear. Frequently they turn up at the clinic again after a year, with another member of the family, who comes to again impose upon the generosity of the

Fig. 21.

	46
Walking with braces	16
	60
	13.81% failures.

My series shows 6% of failures only, and these by relapses through lack of care.

First Case.—Ida M. Thornton, 14 years old last April, single talipes equinovarus, congenital. Consulted an orthopedist in New York when 6 weeks old. He put a brace on when the child was 3 months old, and did nothing till that time. She wore the brace till 2½ years old, then put on a shoe and a side brace and he taught the mother to apply the stretching machine 3 times a day for 15 months. Took her then to his dispensary 3 times a week for 9 years. Assistants there applied the stretching machine for 15 minutes with the application of electricity. Two years ago was discharged; was told nothing more could be done for her except braeing. The mother informs me that she has worn braces made at that institution since then, and her feet are essentially now as they were when she left the dispensary and hospital.

I photographed this case. Figs. 27, 28 and 29 show the amount of deformity without brace; Fig. 30 the brace on, and Fig. 31 a photograph taken 3 weeks after the operation. The foot now is nearly perfect. When she was 4 years old a tenotomy was done; when she was 5 years old the plantar fascia was cut. The traction machine did not seem to work "its miracle", and owing to the fact that an insufficient operation was performed, the child of 14 years led a crippled life.

Fig. 25.

Fig. 26.

Second Case.—December 31, 1892, M. H., 17 years old, came to my clinic at the Post-Graduate School and Hospital. Consulted Dr. — when 2 years old, as a private patient at his house. Applied extension braces of several kinds until she was 6 years old. Twice a week was attended by Dr. — personally. When 6 years old the father, having suffered from financial reverses, sent his daughter to the dispensary and hospital, where she remained 5 years, till 11 years old. Went

walking before the anterior segment of the foot does. Such feet will take the weight of the body in such a direction as to turn them still further outward and prevent relapse.

5. Clubfoot shoes of every name and nature I have entirely discarded. The human hand is the best club-

Fig. 27.

Fig. 28.

Fig. 29.

Fig. 30.

home when she was 11 years old, unimproved. She had suffered from synovitis of knee joint, possibly due to wearing braces, the mother says, and the toes had become seriously deformed from the pressure applied. She was discharged, wearing heavy braces, and returned to the dispensary for care as often as she was directed to. She came into my clinic at the Post-Graduate Hospital when she was 14 years old.

Fig. 31.

I made casts of the feet before operating, and Fig. 32 is a correct photograph, showing the amount of deformity. She was a lamentable cripple, and when her shoes were removed could stand with difficulty. Fig. 33 is the same case, taken a few weeks after the operation. The mother states that her feet had remained the same as when she left the dispensary before I operated.

My observations have led me to the following conclusions:

1. All feet at any age after the fourth month, with shortened skin and ligaments, should be operated upon by open incision.
2. Prolonged medical treatment covering over months and years in any case is wrong.
3. While I am prepared to admit that many of such cases can be benefited or cured, the surest and easiest plan for the patient is to operate.
4. The operation is not completed until the foot is placed in the supercorrected position flexed upon the leg and the heel prominent so that it strikes the ground in

foot shoe ever devised, and by manipulation the foot is carried to the supercorrected position and fixed there with a plaster-of-paris shoe or adhesive plaster.

6. The treatment just begins after the operation is completed.

7. Osteoclasis should be performed in all cases of inward twist of the tibia or a relapse may be looked for.

8. Bone operations should never be performed primarily.

9. Open incision should supplement all cases of subcutaneous tenotomy when it fails to supercorrect.

10. Short tendons and ligaments should be cut and not stretched, because prolonged stretching results in deformity of the entire tarsus.

Fig. 32.

11. A case cannot be said to be cured and free from the dangers of relapse until the heel strikes the ground first in walking.

12. A cure is effected when new facets are formed on the tarsal bones.

13. Pirogoff's amputation was required in $\frac{1}{4}$ of 1% in my series of cases.

14. Open incision should never be performed unless the skin resist and will not stretch sufficiently to allow of supercorrection and the proper unfolding of the foot.

15. The weight of the body falling upon any clubfoot shoe or brace nullifies the action of the apparatus. This was the reason why the late Mr. Adams treated one foot at a time with his shoe, putting the patient on crutches until the foot was cured.

Fig. 33.

would nullify the action of any clubfoot apparatus; which is a fact. With this idea I fully agree and not following out this plan is the reason why so many failures occur in treatment and years are required to prevent relapse by means of cumbersome braces. Any clubfoot appliance which does not take its base of support at the pelvis is worthless, because it will turn round upon the leg and can exercise no considerable force upon the varus. Mr. Clark also states that thousands of cases would be ruined by publishing these ideas. This is also an error, because any man endowed with average surgical knowledge can straighten these feet permanently and can easily keep them straight; whereas by not publishing the idea, hundreds of thousands of cases would be condemned to a cripple's life by the application of braces and mechanical contrivances, the principles of which originated during the ages of surgical ignorance. I have already in my paper indicated the class of cases suitable for operative procedure and those which should be treated by manual force and fixation, and those conclusions are arrived at after treating thousands of cases, both in private and hospital practice during the past 30 years.

In answer to Mr. Tubby; he states that the operation is a bad surgical procedure. His position is identical with that of the doctor who states that the operation for appendicitis is useless and bad practice. He opposes his personal opinion, not based upon an actual personal experience against that of our most distinguished orthopedic surgeons and surgeons in America, notably that of the Sayers, Gibley, Bradford and Lovett, of Boston; Sherman, of San Francisco; Wilson and De Forrest Willard, of Philadelphia; Senn, of Chicago; Bryant, Weir and Myer, of New York; Sir William Hinxton, of Montreal; nearly every surgeon of Europe; Mr. Edmund Owen, of London; and hundreds of others, had I time to mention them. He says that the large gap produces a scar which will contract. The late Mr. Adams said; the operation left a large scar which would stretch. This is my understanding of the action of scar tissue under pressure, verified by observation. He would not operate at the fourth month. If skin and ligament is short and will not stretch sufficiently an operation is imperatively demanded and no bad result will follow. If mechanical treatment is continued for years in such cases, a hopeless deformity of the tarsus or a relapse clubfoot will be the result. I differ with him, and know that my results are better from the operation than I ever attained from any mechanical means whatever.

DISCUSSION BY DR. PHELPS.

Mr. President, Mr. Clark states that the feet after the cutting operation are not elastic. This is positively an error, because I have not observed this result in 1,650 operations. He quotes Mr. Adams' work. We are all familiar with it and also with the work in many of the orthopedic institutions in London, where the teaching of Mr. Adams, I am informed, is not carried out to the letter. Mr. Adams taught that the patient should be put upon crutches and one foot strunged at a time by his orthopedic apparatus, because as he stated: "The weight of the body

He states that these cases are not followed and seen years afterwards to determine what the final result is. In answer to that, I present here a series of photographs out of the scores of cases which I have observed until they have grown to womanhood and manhood, which contradicts this statement absolutely. Mr. Smith states that by my rule there would be no cases to operate upon. I stated in my paper the rule for operation. I again state here that 90% of cases occurring in babies do not require operation. The other 10%, which would require bracing for years, resulting in a failure in 9 out of 10, require the operation. Of the 1,650 cases upon which I operated, nearly all of them have been handled in the orthopedic institutions of New York, or in private practice, where they follow precisely the same kind of treatment followed in many of the orthopedic institutions of London. Mr. Smith has a fear of nonunion of tendons. Unless infection takes place the fear is entirely unfounded. The specimen which he presents is an excellent result after years of careful mechanical work and suffering and inconvenience upon the part of the patient. An equally good result could be attained within 2 months by resorting to open incision. Mr. Williams cannot find cases to operate upon. Every case that he has treated by mechanical means for more than 6 months, which still has a shortened inner side of the foot, should be operated upon by an open incision, or else, sooner or later, a large per cent. of such cases drift into the hands of the surgeon, who will operate with varying results, because, as a rule, he is not so well equipped to carry out the after treatment as the orthopedic surgeon. He states that they get these relapse cases at the large hospitals. I have already stated one of the reasons why. In America, these cases which come from the large hospitals to my clinic, after an open incision operation, had already served their years of apprenticeship in some orthopedic hospital. He says the operation is fascinating, which is true, and if he will permit me to add that when the operation is performed, as I have already described, and the after treatment judiciously followed by an orthopedic surgeon, the results are more fascinating. The orthopedic profession of every country on earth has accepted the operation as one of the surgical procedures in our specialty, excepting England. By so doing, they have prevented these cases from drifting to the large hospitals and falling into the hands of the general surgeon. The operation belongs to orthopedic surgery, and not to general surgery.

DECEMBER 18, 1900.

My Dear Sir:—I was much interested in the account of your latest operation for equinovarus at the annual meeting of the British Medical Association. I have spoken with favor upon that operation in my book on Operative and Practical Surgery, and, having read your original description in one of the American Transactions, I believe I was the first to carry out your latest operation in Great Britain, and I recently showed 3 feet operated upon in that way to a surgical society.

One child, aged 8, was brought to me in irons with considerable rigid deformity; he had worn the irons for 3 years. The following particulars are interesting: "Operation" at 4 months. Operation at 10 months, followed by splints, etc. Then seen privately. At 1 year and 9 months in one of the London Orthopedic Hospitals; remained for 6 months, and subsequently went home a year until he was 4. He had 3 or 4 operations and wore "scarpa's by night and irons by day," and had his feet "pulled." Has worn irons since he was 2. Mother counted 21 marks of operation. I performed your complete latest operation first on one and then on the other foot, with excellent results. I wished to test case properly and left off all apparatus, trusting to plantigrade progression. This year, 2 years after operation, I exhibited patient. He had perfect plantigrade progression, with a good arch, and could run and jump well. In fact he could hop and jump well 2 months after the operation.

When an operation on the bones is required I have no hesitation in saying that I regard your latest (complete) method as far and away the best. So you have one advocate in England, at any rate.

Yours faithfully,

[Signed]

THOS. CARWARDINE.

AN OBSCURE CASE OF HYSTERIA WITH ASSOCIATED RIGHT MYDRIASIS AND AMBLYOPIA AND LEFT MYOSIS.

BY
H. A. HARE, M.D.,
of Philadelphia.

Professor of Therapeutics in the Jefferson Medical College; Physician to the Jefferson College Hospital.

[Concluded from page 25.]

On January 24, three weeks after Dr. de Schweinitz saw her first, she told me that she had seen out of her mydriatic eye for the first time in 11 years. Dr. de Schweinitz's report is as follows, and because of the unusual ocular findings is the most interesting part of this paper:

First examination January 8, 1901, patient being in bed and convalescing from a surgical operation. V. of R. E. equaled light perception in all portions of the field; pupil widely dilated 8 mm. in diameter, reacting slightly to direct and indirect light stimulus. The media were perfectly clear, the disc was small, slightly grayish in color; the central veins full and streaked with slightly distended lymph-sheaths; the arteries normal in size. There were no retinal lesions.

V. of L. E., roughly tested, 20/C, and ordinary print and written characters could be read. There was myosis, the pupil being contracted to about 2 mm.; no view of the fundus. There was intense ciliary pain.

The following day the examination was repeated, scopolamin solution, having been instilled into the left eye. This dilated the pupil, but not *ad maximum*. The ophthalmoscope revealed a practically healthy fundus, the nerves and vessels presenting appearances similar to those described upon the opposite side. The field of vision as taken with the hand was normal; the color field was not tried. The rotations of both eyes were ample in all directions. The right conjunctiva was distinctly anesthetic, the left, if anything, hyperesthetic. There was some loss of sensation of the skin surrounding the amblyopic eye. With the ordinary prism test and Harlan's test, it was easily demonstrated that the patient, although she claimed only light perception for the right eye, could see quite as well with that eye as with the other. The diagnosis of hysteric amblyopia seemed warranted by the ocular examinations.

Second examination February 8, 1901, patient greatly improved in general health and sitting in a chair. V. of R. E. equaled shadows; other ocular conditions unchanged. V. of L. E. about 20/C; field of vision had very slight concentric contraction for white; moderate contraction for blue and red, the color lines coinciding on the horizontal meridian on the temporal side, but no reversal; extreme contraction for green.

Third examination February 13, 1901, patient showing continued general improvement, in the refraction room of the hospital some distance from her own quarters. V. of R. E. at first counting figures, but when +3 D. lens was placed before the eye 20/CC was acknowledged. The ophthalmoscopic appearances were unchanged and the mydriasis previously noted unaltered. V. of L. E. with +3 D., 20/L; no changes in the fundus. The pupil, under the influence of atropine, dilated to 5 mm. The visual field of the right eye, mapped by Dr. H. Haden, showed decided contraction for white, marked contraction for colors, with a tendency to reversal of lines. The visual field of the left eye was similar to that of the right, but somewhat more contracted and also exhibited a tendency to reversal of the color lines.

Fourth examination February 14, 1901, the patient being again removed from her own room to the refraction room of the hospital with the eyes under the influence of a mydriatic. This did not increase the mydriasis already existing in the right eye. The total refraction of each eye was determined by means of retinoscopy and proved to be

$$\begin{array}{l} \text{R. E.} + 3 \text{ } \overset{\text{S}}{\text{C}} + 0.25 \text{ axis } 105 \\ \text{L. E.} + 3 \text{ } \overset{\text{S}}{\text{C}} + 0.25 \text{ axis } 60. \end{array}$$

With these lenses the patient promptly obtained a vision of 20/XX with either eye. Through these glasses at 20 feet there was an exophoria of 2° and a right hyperphoria of 5°. The following combination was ordered for constant use.

$$\begin{array}{l} \text{R. E.} + 2.25 \text{ } \overset{\text{S}}{\text{C}} + 0.25 \text{ axis } 105 \\ \text{L. E.} + 2.25 \text{ } \overset{\text{C}}{\text{C}} + 0.25 \text{ axis } 60. \end{array}$$

Fifth examination February 24, 1901. Like the two preceding ones, this examination was made in the refraction room. V. of R. E., 20 XX, the letters of the line being read slowly but correctly; amplitude of accommodation 5.5 D. The pupil was still dilated, but not so greatly as on former occasions. V. of L. E., 20 XX, the letters of the line being read promptly; amplitude of accommodation 6 D. The visual fields were: For the right eye decided contraction for white; contraction for red and blue, with coincidence of the lines on the temporal side, but no reversal; great contraction for green. For the left eye moderate contraction for white; only slight restriction for blue and red; great contraction for green. The mydriasis of the right eye is gradually disappearing, the pupil being about 4 mm. and freely acting to all impulses; the myosis of the left pupil remains as before.

Remarks by Dr. de Schweinitz.—Hysteric amblyopia, which, as Parinaud said, "may be styled an anesthesia of the organ of vision," is doubtless the most frequent of all the hysteric anesthetics, and is, as it was in this case, usually accompanied by other disorders of sensation. As is well known, Briquet regarded anesthesia of the conjunctiva as characteristic of the hysteric state. Generally the left conjunctiva is affected; in the present case it was the right one. Loss of sensation around the amblyopic eye is common. The pupils in hysteria may be contracted or dilated; if dilated the reflexes are usually preserved. Such phenomena are often of temporary duration. Long-standing mydriasis of one eye has been reported a number of times, and myosis is also described, especially according to Galezowski, when there is an associated spasmodic myopia. But complete mydriasis on one side, with slight preservation of the reflexes, and equally complete myosis, without spasm of accommodation and usually without marked photophobia, as exhibited by this patient, is unusual if not unique. Concentric contraction of the visual field, i. e., an insensibility which develops from circumference to center, is the rule in hysteric cases, and nearly always is accompanied by a corresponding contraction for colors. Sometimes, however, the field for white is more restricted than that for colors. The last color affected in hysteria is red, in other words, the normal sequence of the color lines may be more or less reversed, the red field being the largest. In the present case this concentric restriction of the visual field was well-marked, but inversion of the color fields was not positively demonstrated; it was only indicated in one examination. The green field was always greatly contracted, in this respect confirming an observation of John K. Mitchell and G. E. de Schweinitz that the green field is, relatively at least, more and more often contracted than the others. The map of the visual field made in the patient's room was wider than the one obtained in the refraction room of the hospital. This is probably to be explained by the fact that physical tire resulting from the journey from one room to the other found some expression in retinal tire. To explain the disappearance of monocular amaurosis in binocular vision, somewhat complicated hypotheses have been advanced by Bernheim, Frankl-Hochwart, Pari-

naud and others, which need not now be discussed. The gradual restoration of the vision of the right eye was due to the improved general condition and to the glasses; as Mr. Swanzy well puts it, "the psychological inhibition to the function of sight in the eye has been withdrawn by the suggestion provided by the spectacles." In this case not only did the glass provide the suggestion, but it permitted accurate retinal stimulation. Furthermore the lenses fully neutralized the refractive error, relieved a long-standing eye-strain and thus aided in the recuperation. High hypermetropes often have small pupils, and it may be that the myosis of this patient's left eye is normal to its refractive condition. The dilation of the right pupil has been reduced more than half and it is likely that this pupil will finally equal in size the other. The sphincter of the iris is regaining its power in connection with the restoration of power elsewhere in the general nervous mechanism, and it responds to all stimuli in a normal manner.

Under Swedish movements and massage with proper medical treatment the patient speedily improved. Her restoration of vision has been permanent and she is able to stand on the left leg and to walk with crutches, although she is using these less and less as she acquires confidence in her ability to walk. The pain has practically disappeared and she has returned to her home.

INDICATIONS AND LIMITATIONS OF THE VAGINAL OPERATION IN PELVIC DISEASES IN WOMEN.*

BY

J. RIDDLE GOFFE, M.D.,
of New York City.

Professor of Gynecology in the New York Polyclinic Medical School and Hospital; Visiting Gynecologist to the New York City Hospital, Etc.

By a strange shifting of ideas vaginal section for the treatment of diseased appendages, which was devised in this country by Battey, of Georgia, was extended and enthusiastically adopted in France, but has lately been employed so extensively by the German operators that they have obtained quite a monopoly in this line of work. On the other hand, laparotomy for the treatment of pelvic disease, which was formerly advocated by the Germans, and employed extensively in England, especially by Lawson Tait, has been adopted more completely by the French operators, by whom it is now known as the American operation. In the latter sense it is applied more particularly to the treatment of fibroid tumors. The vaginal method, in its wide application to pelvic disease, is, however, gradually obtaining a foothold in this country, and the indications for its employment are rapidly extending, in accordance with the acquired efficiency and skill of the operator, to cover the treatment of all pelvic diseases, when confined to the true pelvis.

Speaking broadly, it may be affirmed that any operation that can be done as safely and satisfactorily, for the patient, by the vaginal route as by the abdominal, should be done by the vaginal method. The dangers are less, incomparably less; the convalescence is smooth and the after-treatment simple, the patient being relieved of

annoyance of stitches, adhesive plaster, bandage and dressings; there is no visible scar to remind her continually of her experiences; and above all, there is no danger of hernia. The removal of stitches, the repeated application and removal of adhesive plaster, and finally, the wearing for 6 months or a year of the inevitable abdominal supporter, all this is a great wear and tear upon the nerves of a woman already depleted by the disease, for the relief of which the operation was performed. Practically, no such thing as hernia or enterocele has been known to follow as the result of vaginal section; while following abdominal section, even for the relief of the simplest forms of pelvic disease, cases of ventral hernia are constantly presenting.

Accepting the dictum, then, that from the standpoint of the patient the vaginal operation is preferable, it but remains to be considered what are the indications for the operation and what may be its limitations.

CANCER OF THE UTERUS.—Personal experience and the careful study of the experience of operators in the wide fields of gynecology and general surgery have led me to the conclusion that the only justifiable radical operation for uterine carcinoma is vaginal hysterectomy. From the operative standpoint carcinoma of the uterus has two stages; first, the stage in which it is confined absolutely to the uterine tissue; and second the stage in which the cancer-cells have wandered out into the surrounding tissue. During the first stage of development an absolute cure may be hoped for through the operation of hysterectomy. In this condition vaginal hysterectomy is a comparatively simple procedure; simple for the patient and simple for the operator. Moreover, there is far less danger of infection of the surrounding parts by the cancer-cells than is necessitated by the abdominal operation, and this danger is one that has been distinctly recognized and pointed out by the most careful investigators in this line of work. In this connection one point in the technic may be quite worthy of mention. I refer to the importance of removing the uterus intact, instead of bisecting or quadrisecting it, as has been recommended recently by Dr. Howard A. Kelly, and for the very reason that I have just mentioned, namely, the danger of infecting the surrounding tissue with the cancer-cells.

In the second stage it must be recognized that the disease is beyond even the hope of cure. Although Cullen tells us in his recent incomparable work on "Cancer of the Uterus," that the cancer-cells wander first into the connective tissue and in some cases tarry there for a definite period before being taken up by the lymphatics, the impossibility of determining when the expiration of that period has been reached robs us of all reasonable prospect of a cure when once the cancer-cells have passed beyond the limit of uterine tissue. Some operators are still performing what is called the radical operation for cancer, which consists in ligating through an abdominal incision the large bloodvessels of the pelvis, rimming out all of the cellular tissue and lymphatics in connection with a panhysterectomy, with the hope of heading off the invasion before it shall have involved the general system.

Examination of their statistics reveals the fact, as Richelot says, that the patients thus operated upon, pro-

* Read at the Ninety-fifth annual meeting of the Medical Society of the State of New York, held at Albany, January 30, 1901.

vided they have survived the operation, are either all dead, are about to die, or enough time has not elapsed since the operation to indicate just when their demise may be expected. To my mind, these men are following an *ignis fatuus*. The analogy so frequently drawn between the lymphatics of the breast and axilla and those of the pelvis is misleading. In the former the lymphatics follow definite lines and lead to a central depot, while in the pelvis they lead to no common center but are widely diffused in all directions.

The only hope in the operation for cancer of the uterus is in forestalling absolutely the first invasion of the cellular tissue, and it is for that reason, as well as the danger of cancerous infection when the operation is done from above, that I am ready to stand upon the dictum that the only justifiable radical operation for cancer of the uterus, is vaginal hysterectomy.

FIBROID TUMORS.—The value and importance of myomectomy as contrasted with hysterectomy in case of fibroid tumors of the uterus has been gaining ground rapidly in connection with the general trend of conservatism, and in every case the question presents: Shall the operation be myomectomy or hysterectomy? Quoting from a recent paper of mine upon this subject, "There are staunch advocates of myomectomy as the operation of choice, as the dominant operation in the treatment of fibroid tumors of the uterus; on the other hand, there are strong advocates of the sweeping and uncompromising dictum that in all cases of fibroid tumors of the uterus nothing short of hysterectomy should be entertained. For myself, I believe in conservatism in all departments of gynecologic surgery. If, in addition to saving the menstrual function by retaining ovarian tissue, there is prospect of conception, gestation, and motherhood, my rule is to save at least a portion of one tube also and preserve for it a patulous canal. If part of an ovary can be saved and the menstrual function preserved to a woman throughout her natural menstrual period, it is my custom to leave one healthy ovary or part of an ovary in case of panhysterectomy for fibroid tumor. Extending this principle to the uterus (a uterus affected with a fibroma or a number of fibromas) the following rule holds: Remove the diseased portions, as many fibroid foci as can be discovered, but save the uterus."

In dealing with this class of cases vaginal section has its indications and also its limitations. Experience and facility of operation on the part of the operator can alone determine this question, although the location of the tumor or tumors plays a large part in its solution. To illustrate the question at issue a few typical cases selected from my list of the past year may be of interest:

CASE I.—In this case there was a large retroverted uterus, with a hard, round fibroid an inch and a half in diameter in the posterior wall just above the junction of the cervix with the body, complicated by firm adhesions of the uterus to the rectum. An incision was made into Douglas' pouch for the purpose of breaking up the adhesions, then an incision through the anterior fornix, through which the fundus was delivered into the vagina. By drawing down firmly upon the uterus the tumor was brought into easy reach, was enucleated, and the excavation stitied with tier sutures of catgut. The round ligaments were then shortened through the same incision and the uterus restored to the peritoneal cavity, where it has

remained to the present time in normal position and the patient has been relieved of all her symptoms.

CASE II.—A woman of 43, the mother of 4 children, and whose general health had been wretched for a number of years, was found to be suffering from a bilateral laceration of the cervix, extensive laceration of the perineum, a retroverted and immovable uterus wedged in place by a number of fibroid developments on the posterior wall and at either side. The uterus was ennetted and packed with gauze, a trachelorrhaphy was performed, the anterior lip being amputated, and an incision made through the anterior fornix. Through this, by careful, patient and persistent manipulation, the uterus, with its fibroids, was delivered into the vagina. Two of these were found to be pedunculated and were readily pinched off. After this smaller neoplasms, to the number of 5, making 7 tumors in all, were shelled out; the incisions being so made as to facilitate the shelling out of 2 tumors through the same incision in each of 2 instances. The round ligaments were then shortened through the anterior incision and perineorrhaphy performed. The temperature remained normal throughout her convalescence, and on the nineteenth day she left for her home at Elmira. Being the wife of a physician, I have had accurate reports of her steady improvement to complete restoration of health.

CASE III presented a large retroverted, adherent uterus with a small fibroid in the anterior wall, between the bladder and the uterus. The operation was performed as in the 2 previous cases, but the tumor was removed previous to delivering the fundus into the vagina. By lifting up the bladder on a strong retractor and dragging down the uterus with vulsellum forceps, the tumor was brought into full view and 2 smaller tumors were revealed, one at the side and the other a little higher on the anterior wall. The three were removed in the usual way; the fundus was then delivered in the vagina and the round ligaments shortened to cure the retroversion.

These are simply typical cases demonstrating the fact that when the tumors are small, no matter in what part of the uterus they may be located, the vaginal incision affords opportunity for their complete and satisfactory removal.

Two other cases which have passed through my hands recently, in each of which the tumor weighed something over 2 pounds, were coextensive with the fundus—that is, a generally diffused myoma. In this condition there was no hope of preserving a functioning uterus, and in both instances morcellation per vaginam was adopted. The procedure went forward without untoward incident, both patients making such prompt and smooth recovery that they presented no indication of the radical procedure that had been done. In both these cases, however, the tumor was in the true pelvis.

When the tumor is sufficiently large and so located that the patient presents the appearance of a woman at the fourth or fifth month of pregnancy, I believe the limit is reached at which it is desirable to operate through the vagina, and in those cases I invariably perform supra-vaginal hysterectomy through the abdominal incision.

The indications, then, for vaginal section are small multiple fibroids of the uterus, or larger tumors filling the pelvis but not rising into the abdominal cavity. The limitations are reached when the tumor has attained the size of a 5 months' gestation.

SALPINGITIS AND OVARIAN ABSCESS.—These cases are best treated through the vagina, the posterior or the anterior incision being first used as an exploratory procedure to determine what the character of the operation shall be. If the disease involves the appendages of one

side only, the other appendages being amenable to conservative work, then the pus is evacuated, the diseased appendages removed, and such conservative work as may be indicated done upon the remaining organs. If, on the other hand, the appendages of both sides are hopelessly diseased, panhysterectomy is immediately decided upon and the entire pelvis is relieved of all diseased tissue.

As a point of technic, I might say that I am using the angiotribe almost exclusively in these cases and find that it greatly facilitates the work in cases in which adhesions render it difficult or impossible to drag down the broad ligaments within reach of ligature. In these cases it is quite possible to shell out the diseased organs, leaving intact the roof of plastic exudate which shuts off the general cavity from the pelvis. There is then no soiling of the peritoneum; convalescence is smooth and satisfactory. In my experience the plastic exudate promptly absorbs and the intestines become freely movable.

DISPLACEMENTS OF THE UTERUS.—But while the vaginal method in the various conditions already discussed gives most satisfactory results and is to me far and away the method of choice, the procedure has its ideal application in the cure of displacements of the uterus, whether they be simple or complicated by moderate disease of the appendages, with adhesions.

The operation consists in opening through the anterior vaginal fornix, breaking up adhesions, delivering first the uterus and then the appendages into the vagina, performing upon the appendages such conservative work as may be indicated to preserve the function of one or both ovaries, and finally curing the displacement by shortening the round ligaments. I have now on my records some 70 cases that have been treated in this way, in which the results are so satisfactory that I am led to pronounce it, as I have said, the ideal operation. In this field of work the method must be contrasted with the Alexander operation and with abdominal fixation or suspension, and to sum up the whole matter briefly in one sentence, my experience justifies me in saying that it accomplishes all of the good results of either the Alexander operation or abdominal suspension and is free from all the objectionable features of both.

DEEP BREATHING AS A CURATIVE AND PREVENTIVE MEASURE.*

BY

JOHN H. PRYOR, M.D.

Of Buffalo, N. Y.

Some observation and experience have led me to the following conclusions, briefly stated:

The efficacy of deep breathing as a curative and preventive measure has not received the recognition which it deserves as one of the most important and rational measures we possess, and it seems fair to state that more attention should be devoted to the value of this remedial agent in medical literature and practice. No method of treatment promises so much in certain affections, and none is so often disregarded. While oxygenation as a

physiologic function is taught and understood, its therapeutic merit is not emphasized sufficiently. Time will not allow anything more than a reference to the many forms of malnutrition characterized by that complex group of symptoms ascribed to nervous exhaustion, toxemia, indigestion, anemia, etc. Scientifically, we know that diminished oxidation is an important causative factor, yet how many times is the patient told to increase the respiratory function or taught how? While iron and arsenic may improve impoverished blood, more oxygenation is a necessary part of thorough treatment. In many cases inhalations of oxygen are used with some benefit, but the result depends largely upon the frequency of its employment and the increase in respiratory effort. Can any one doubt that inexpensive fresh air, which can be obtained at any time, will furnish all the oxygen needed, if the lungs are made to perform their function? Many women never take a full breath after adult life is reached, and the average man, who has given up vigorous exercise, rarely fills his lungs to their full capacity, unless a life-insurance examiner insists upon a full inspiration. As a rule breathing becomes a moderately exercised function after childhood. The conditions of modern life may not demand greater activity, but at times the interdependence of functions is disturbed, and respiration does not perform its part in the labor of repair and waste. Thorough ventilation requires a habit of occasionally filling and emptying the lungs as completely as possible. A certain percentage of individuals are so unaccustomed to forcible breathing that an attempt is followed by exhaustion, dizziness or palpitation of the heart. They may be obese, flabby or chlorotic and short of breath, and the daily practice of respiratory exercises not only relieves these symptoms but helps to remove the cause. The chief object is to direct attention briefly to the usefulness of deep breathing in diseases of the lungs and pleura. The greatest benefit is obtained in subacute or chronic affections, and the results may be developmental, preventive and curative. In the first class we may include the small or deformed chest, with respiratory incapacity. A considerable number of deformities due to rickets might be prevented or overcome by increasing gradually the size of the chest-wall.

In the second group may be included subacute or chronic bronchitis, pneumonia, and consolidation or collapse of lung-tissue due to delayed or incomplete resolution, and fixity or pressure caused by adhesions or presence of air, gas or fluid in the pleural cavities. When forcible or deep breathing is employed at the proper time, the benefits to be derived may be summarized as follows: Increased oxygenation and improved nutrition; changes of a mechanical nature, ventilation and disinfection, massage of the lungs and pleura, and a method of drainage. In the acute diseases of the respiratory organs there is a time for rest and a time for action. This fact can be illustrated by the management of so-called atypical attacks of pneumonia. Of late years the physician meets more cases of pneumonia, with a history of prolonged illness, slow recovery and delayed resolution than the textbooks would lead one to believe. A large percentage of patients suffering from lobar pneumonia or bronchopneumonia do not present the classical symptoms,

* Read at meeting New York State Medical Society, January 19, 1901.

and it is probable that epidemics of la grippe and influenza may explain to a certain extent this clinical observation. To be sure, a knowledge of the causative factors and the recognition of mixed infection help to elucidate a puzzling clinical history, but the lengthy course of the disease, with subacute manifestations, checked or slow resolution, persistent fever, accompanied by relapse or recurrence, are exasperating and often cause perplexity and anxiety. The physician's efforts to secure or hasten recovery are many times unavailing or disappointing. The physical resistance is insufficient, and the infection, reinfection, and invasion of new territory continue. Rest and the exhibition of drugs cease after a time to be beneficial, and the accepted plan is to support the patient, and wait.

There is a time when free, forcible action of the affected lung will be more successful than all other methods of treatment combined. After the acute symptoms have subsided and the period of expected resolution has passed, deep breathing may be tried and gradually increased. The idea is to stimulate return of function and promote the removal and absorption of morbid material. I have repeatedly seen more improvement in a few days by obtaining a forced entrance and expulsion of air than other methods have accomplished during long periods. Normal circulation is promoted and absorption encouraged, air is made to enter collapsed or occluded portions of the lung, and cough, if increased temporarily, assists in removing the exudate and inflates closed areas. It must be remembered that the tendency is to recovery, and the stimulating effect of action is much like motion to a long-disused joint.

Many times the victims of protracted pneumonia or bronchitis are kept too long indoors. When the weather will permit the patient should be made to go into the open air as soon as consistent with wisdom. The dangers of unheated air are apt to be exaggerated, and patients are occasionally kept in heated rooms and deprived of fresh air indefinitely until decided weakness and mental and physical apathy supervene. Pure air and sunlight are the natural and most efficient remedies in thoracic disease. The precautions to be mentioned are warm clothing, protection from inclement winds and accustoming the invalid to the change. It is sometimes entirely unnecessary to wait for a normal temperature before venturing into the outer air. Slight fever may continue much longer if the trial is postponed. In some instances outer air can be supplied through a tin tube extending from the window to the bedside and a number of deep inspirations practised several times a day.

The breathing exercises must be taught and watched, otherwise the effort will be feeble and partial. It should be made a form of hard work, administered several times a day. The patient must be made to take 5 or 10 deep, full inspirations and expire the air as completely as possible. Observation will show that complete expiration of air is much more difficult to obtain than a full inspiration. Paroxysms of coughing produced by distention of unused lung-tissue should not be regarded as a contraindication. The number of respirations may be gradually increased and the task performed with greater frequency. Some device, such as a tube or inhaler, may hold the

patient's attention and insure cooperation. The belief that some medicament will prove beneficial may incline the indolent patient to conscientious trial when admonition fails. Various remedies used in inhalers may soothe the upper air vessels, but any direct effect beyond this has no physiologic or clinical basis. The remarkable results claimed for inhalations in diseases of the chest depend very largely upon pulmonary exercises. Quackery is not always associated with ignorance.

Delayed resolution and lasting consolidation are sometimes regarded as an effect rather than a phase of pneumonia. The fact cannot be emphasized too strongly that recovery is not complete, and no case should be dismissed until conditions which cripple the lung, cause chronic invalidism, and endanger the life of the patient have vanished. Resolution may be delayed for days, months or years. It is difficult to decide when incomplete resolution is permanent. Too often, consolidation with pleuritic adhesions are allowed to remain without a radical attempt to ameliorate or remove them and thus avoid loss of function. The respiratory capacity is lessened, the play of the lung limited, ventilation is inadequate, and chronic changes occur in the form of interstitial pneumonia, bronchiectasis, phthisis and pulmonary collapse or carnification. The symptoms appear soon after an attack of pneumonia. The patient complains of shortness of breath or dyspnea on exertion, palpitation of the heart, weariness and pain over the affected side, often increased by deep inspiration. There is frequently neuralgia of the intercostal or subscapular nerves, and occasionally neuralgia is the only symptom of continued discomfort. These unfortunate conditions do not at all times receive proper attention. They are overlooked or neglected, and proper means are not used to prevent or correct them. The patient should be warned of the danger, and efforts made to eradicate them at an early and opportune time. Functions should be restored, if possible, before irreparable changes occur.

While fully realizing the necessity for constitutional treatment, it is not prompt or effectual as a rule unless the lung is urged to resume its work. If we could handle a consolidated piece of lung tissue, fettered by fresh adhesions, we would squeeze the mass to expel exudate, force air into collapsed vesicles, establish free motion by stretching or tearing adhesions, and, in a word, use massage. The only method by which these simple rules of action can be enforced is by forcible respiration. The exudate is removed principally by absorption, but its expulsion and removal by expectoration can be promoted. The forcible expiratory act and the cough is our only system of direct drainage. If the cough is persistent and troublesome, then the nose and pharynx should be examined and treated. Cough not accompanied by expectoration is almost invariably due to an irritable pharynx and a sedative application will remove the annoying feature.

In considering the benefits of a change of climate, the importance of new scenes, environment and habit must be remembered; but the essential requisites are an atmosphere which will allow out-of-door life and free use of pure air. It is a serious mistake to expect climate alone to cure, and send invalids away with scant instruc-

tion. Most people are naturally inclined to restricted or partial breathing, and a person with a crippled lung is only too likely to complain of difficulty in respiration and shrink from added exertion which may cause discomfort. He must be taught that a change of climate gives an opportunity for proper treatment which must be utilized, for the reason that motion is applied to a joint that may otherwise become ankylosed. The fear of hemorrhage from a free use of a partially collapsed or consolidated lung is slight. Congestion is diminished and the circulation equalized, unless the air admitted is unduly rarefied. Aneurysms of small arteries are not found associated with the conditions described.

When pleuritic adhesions are stretched or the roughened surfaces of the pleura are subjected to greater friction, discomfort may be produced and there may be complaint of pain. This is usually mild in character and evanescent. The greatest deformity and most complete and lasting loss of function follow from continued pressure from effusion in the pleural cavity. This is sometimes unavoidable, but there can be no doubt that needless damage is done by neglecting to remove the fluid before great distention and pressure occur, and by failing to procure expansion of the collapsed lung while it is possible. Compensatory curvature of the spine and retraction of the ribs are permitted to fill a vacuum when repeated and vigorous efforts to repair the damage to the lung might prevent loss of power and usefulness.

It is extremely interesting to observe the return of the breath-sounds and an increase followed by gradual disappearance of friction-sounds when respiratory exercise is successful. Any part of the lung structure which can be made pervious to air is a distinct gain, and it is very important as a matter of relief and compensation to increase the capacity of the unaffected and overburdened lung so far as possible. The residual pulmonary tissue often only supports life under irksome conditions. The respiratory power can be enhanced to a remarkable degree and the chances for a useful life greatly improved by securing supplemental activity and development. In every case when relief is possible, the attempt should be made to lessen or prevent the distress of chronic invalidism. The results may be tardy and the treatment often prolonged. Time, patience and determination are required. The most prompt and promising results are noticeable in subacute bronchitis. Deep breathing removes secretions and the sibilant breathing, particularly if the respiratory effort is thorough. Normal circulation is promoted and local congestion disappears.

No attempt has been made to present the technicalities of this subject, such as pneumatic differentiation and its application in emphysema and asthma. Some years ago the pneumatic cabinet was much employed in the treatment of pulmonary disease and extravagant results have been claimed by enthusiasts. At present its importance as a method of administering aerotherapy is disregarded and underestimated. When the patient can come to the physician's office the pneumatic cabinet will yield results superior to any other method of respiratory exercises. The inspiratory and expiratory effort may be made difficult or easy and graduated as to time and the amount of exertion. The atmospheric pressure

upon the chest wall can be diminished to about 14 pounds to the square inch, and greater expansion can be obtained than by the patient's unaided efforts. The blood is driven out of the congested lung into the general circulation when the air about the patient has been rarefied. As a rule the treatment can be given but once a day, and should be supplemented by instructions to practice at home or in the open air. Physical exercises combined with deep breathing are described by several authors, and a valuable hint is to advise the patient to take a deep breath while walking and count 10 slowly during the inspiration and expiration. The effort can be gradually prolonged or timed by the watch. The voluntary muscles must be called into play and strict attention paid to the expiratory effort.

I purposely refrain from advising or discussing exercises which compel rapid breathing. The subject is too extensive, but a final hint may be of value, viz., strenuous general exercise which increases the heart's action and the depth and frequency of the respiratory efforts may be beneficial or quite harmful if overdone. My remarks have been limited to a simple therapeutic measure and a reference to methods which are safe and applicable in the class of cases mentioned.

"THE MOST USEFUL CITIZEN:" A STUDY IN HUMAN DYNAMICS

BY

F. W. LANGDON, M.D.
Of Cincinnati, Ohio.

The problem, "what constitutes the most desirable unit of our modern civilization?" is one of which a solution is of great importance to the anthropologist, the political economist and the philanthropist.

The physician is, or should be, in a position to point the way to its solution since its more important factors come almost continually under his observation. Even the medical man, however, needs an occasional broadening of his field of vision if he desires to avoid that modern tendency to anthropological hysteria, which seems to pervade the school, the stage, the press, and even the pulpit; and by reason of which only the marvelous is deemed worthy of serious consideration.

An attempt to define the characteristics of "the most useful citizen of the United States" demands consideration of two main factors, namely: the *organism* and the *environment*, for it is quite evident that, even in our own country and lifetime, the environment is subject to gradual and sometimes to sudden changes; nor is it at any one time precisely the same over any great area of the Commonwealth. We are met at the very threshold of the problem, therefore, by the plain proposition that the term, "most useful citizen" cannot apply to any precisely limited type, except in relation to a specified environment, in other words, the ideal citizen must not be out of place nor out of time.

The ideal *organism*, however, from which "the most useful citizen" for this varying environment *may be developed* is, perhaps, susceptible of definition; and may be characterized, according to the writer's conception, as follows:

The organism which is potentially "the most useful citizen," may be considered from 5 points of view, namely, the PHYSICAL, the INTELLECTUAL, the ETHICAL, the SOCIAL, and the ECONOMIC.

1. *Physically* considered, this ideal individual should possess that combination of congenital factors known as "a sound constitution," which implies a physical vigor correctly proportioned to the mechanism which is to exhibit it. *Physical strength* therefore, is the basis of usefulness in any capacity. Here, however, it may not be amiss to direct attention to the fact that physical strength, in its true meaning, is not synonymous with mere muscular power, or mental capacity, or great size of frame; for any or all of these may exist in an individual of defective makeup and of slight value to the state. True physical strength implies a harmonious development of the organism in all its organs and parts, such an adjustment of structure to function as will admit of the highest efficiency of action in each part with the least wear and tear of itself and of others. In other words, *conservation* as well as *production* of energy must be attained. Nutrition should balance the results of activity; removal of by products should be amply provided for; briefly, metabolism should be as perfect as possible.

As examples of damage to one part by the excessive activity of another, may be cited the risk to bloodvessels and viscera from the action of an overdeveloped heart; and functional strain leading to organic damage of the kidneys by excessive muscular activity, as in the athlete. On the other hand a powerful brain may be compromised in its integrity by a weak or diseased bloodvessel, incapable of withstanding the blood pressure accompanying great mental or physical activity. *Organic balance* then, is an essential element of sustained physical strength. "A chain is only so strong as its weakest link," applies here as forcibly as it does in mechanics.

Next in importance to organic balance, comes *plasticity of organization*, by reason of which the individual organs may adapt themselves to a varying environment, without noteworthy change in organic balance. This implies a capacity for modification in response to changes of climate, season, and occupation, without material damage to the organism as a whole.

Size is another physical factor of importance. While this may vary within certain limits without detriment, it is sufficient to note that any great departure from the average (about 5 feet 8 inches in height to 150 pounds weight) would be likely to contravene one or both of the preceding essentials.

Of *color*, it may be stated, that extreme types are unfavorable to the organism, physically; hence very dark or very light complexion, hair and eyes, would not be desirable features.

Physiognomy is a characteristic of some importance, which, however, admits of such wide variation that it may be dismissed with the general statement that a weak or repulsive physiognomy would not exist in the ideal citizen.

Viability, the chronologic measure of function, is a necessary factor in the aggregate of usefulness. Longevity alone, however, is not sufficient in the ideal citi-

zen, but rather a prolongation of the active and progressive adult period of life. Since the law requires the citizen to be at least 21 years of age, the organism should reach its greatest physical efficiency as near that age as possible, and should preserve its organic power and balance late in life. Mere senile longevity *per se* is of little or no value to the state; is really a detriment from a dynamic point of view, and the same is obviously true of prolonged childhood or adolescence.

2. From the *intellectual* point of view, "the most useful citizen" must conform to the physical standard already laid down. He should possess *vigor* and *balance* in structure of nervous system, training of sense and motor organs, and development of mental powers. This implies the highest possible culture of *all* peripheral sense organs and sensory centers, the possession of quickness and accuracy in the perceptive and associative functions, the basis of reason, judgment, and ideation, and finally, such power, adjustment and relation of the *volitional*, the *coordinating* and the *inhibitory* faculties as will result in harmony and power of concentration in thought, as well as appropriateness (decision, prudence) in its expression by means of equally well balanced motor apparatus; for it is hardly necessary to call attention to the fact that the only useful outcome of thought is through its expression in action, and all expression is by motion, whether it be mechanical, gestural, vocal or graphic.

Such mental balance would necessarily exclude not only the defective and depraved, but also the so-called "crank," the enthusiast, and even the genius, for such are but departures from an ideal type of citizen and useful only in a limited environment. Viewing the matter in another light, some of these may be of great value to the ideal type, but could never replace it with advantage to the state.

The education and training of most value to the mental equipment above sketched, should be characterized by *breadth* in *elementary principles*, not mere acuteness in special lines.

Specialization is not desirable as a *foundation*, but rather a capacity for special development in various directions as may be required by the environment.

To be complete, the education should include *manual training*, as an essential to the proper development of the visual, tactile, and muscular senses. Other senses commonly neglected are those of smell and taste, hence, probably the tendency to their degeneration which exists markedly in the otherwise cultured classes.

Since sensation is the basis of all thought and its expression, the education of the ideal citizen should neglect no sense-organ or sensory center, including in these the esthetic senses generally. To sum up these mental attributes, accuracy, power, and originality in ideation should be complemented by inhibition, tact and harmony in its expression.

3. From an *ethical* point of view the most useful integer of the Commonwealth will not be an extremist in small matters, since morality is not an absolute but a comparative attribute which must vary with circumstance and period. Any absolute standard, therefore, must fail at times to meet the requirements of "the most

useful citizen." He should possess, however, a well-developed moral sense, governed by prudence, liberality and tolerance in its application to the affairs of life.

Toward certain *institutional instincts* as they may be termed however, his code of morals must be most rigid; for instance: marriage relations, the family and the domestic instincts generally; the rights of person and property, and the respect for law and order, also belong in this category, as does the inclination to vigorous effort in some useful direction, variously termed "ambition," "energy," "progressive spirit," "initiative," etc., and which might be equally well-defined as being a state of discontent with existing conditions, joined to a determination to improve them in a lawful manner. *It is the discontented man who moves the world.* A desire for ownership of land to some extent, and a preference for fixity of habitation as opposed to the nomadic tendency as implied in the proverb, "A rolling stone gathers no moss," should also characterize the average well-balanced unit of modern civilization.

The religious instinct, probably possessed in some form by all men, no matter what their professions of it, is important in effect, as a means of enforcing a correct ethical code; hence, leaving out of consideration any further influence claimed for it, its possession and exercise within proper limits, will add to the moral balance and consequently, to the usefulness of the citizen. Finally, it may be stated that true moral strength is only acquired by exposure to, and resistance of, temptation. Hence, the physical appetites and instincts which favor departure from established ethical standards are essential factors in the development of "the most useful citizen."

4. *Socially*, "the most useful citizen" should possess in a high degree that instinct or desire for *permanent organization* which is a marked characteristic of man as compared with the lower animals in general, and is the necessary basis of all civilization, *esprit de corps*, patriotism, and good government. The importance of the *family*, as the social unit in modern civilization has already been referred to under ethical characteristics; and the domestic instincts are essentials of the best social, as they are of the most useful ethical constitution. Equally essential is the vast social network known as "society" of which in some of its forms, political, industrial, religious, fraternal, educational, etc., "the most useful citizen" must be an active member. *The hermit is of slight value as a citizen.*

The comparative importance of social organization is well expressed in the aphorism of Bacon, "Reading maketh a full man, writing an exact man, conference a ready man."

History seems to show, however, that exclusiveness, or "caste" in some form, has been the social rock on which most ancient civilizations have been wrecked; and which threatens also the integrity of some modern ones. It is probable therefore that, while "the most useful citizen" may belong to "the social 400," his usefulness will never be due solely to that fact. *To be of the greatest developmental value the social environment should not be limited in scope*; hence, the most useful citizen should be "persona grata" to the largest possible

number of other useful citizens, whereby his potential usefulness may meet with opportunity to exercise to its highest degree.

5. The *economic* phase of the subject comprises all the means of application of the preceding forces and characteristics that may subserve the best interests of the community of which the citizen is a unit.

Economically considered the organism above sketched would be valuable to the Commonwealth: First, by reason of great capacity and inclination for long sustained force production and its effective expenditure, which necessarily would be, under the conditions cited, in useful directions. *Wasted or misdirected energy is of no value to the state.*

Secondly, because of its adaptability to a varied environment and diversity of occupation, thereby insuring the best development of the Commonwealth in all possible directions.

Thirdly, by reason of its tendency to reproduce and thus transmit to succeeding generations its own type of constitutional vigor and functional versatility. *The sterile are of brief value to the state.*

It is evident that "the most useful citizen," under all preceding conditions, must be of the male sex, not merely because of artificial laws to that effect, but by reason of the possession by that sex of more physical vigor and a nearer approach to organic balance for a greater portion of its life, other conditions being equal.

Since a number of the postulates already laid down, however, e.g., organic balance, the domestic instincts, marriage and the family relations, etc., require woman for their complete evolution, it is equally evident that a highly developed, well balanced female organism is an essential complement to "the most useful citizen" as well as necessary to a continuance of the type. There is consolation for woman, therefore, in the thought that, from an economic standpoint, she is a specialist of the highest type, essential to the greatest usefulness of "the most useful citizen," if not his equivalent potentially as a citizen.

Compared with the existing average, the ideal "most useful citizen" we have postulated may be said to excel in physical and intellectual vigor and training, in organic balance and plasticity of organization, while he should approach the average closely in size, color, general proportions and ethical tendencies. Socially and economically he should exceed greatly in value (usefulness) the present average.

Any marked variation from this ideal type, leads inevitably to degeneracy, which may be briefly defined as a *tendency to extinction*.

Some may object that this ideal type is but a synonym for mediocrity. If so, we may do well to recall the fact that throughout the biologic series it is the "average type" that prevails and gives its characteristics to the Species. The "sports" and "freaks" tend to extinction, as do the corresponding "degenerates" of the human species. In humanity, as elsewhere, it is the great average type that "holds the species true;" perpetuates its kind; does the work of subduing nature and makes possible the march of civilization. True progress, therefore, lies in the improvement, along parallel lines, of the

organic balance in this type, rather than in wide departures from it.

In short, "the most useful citizen," potentially and actually, is the *best developed* and *best balanced* citizen, physically, mentally, morally and socially; for on such depend the safety, the strength and the progress of the Republic.

"He wages all battles and wins them,
He builds oil turrets that tower
Over walls of the city to tell,
Of the rulers and priests of the hour.
Without him the general is helpless,
The earth but a place and a plan.
He moves all, and clothes all, and feeds all,
This sad smiling average man."—GARLAND.

DUST AS A FACTOR IN DISEASES OF THE UPPER RESPIRATORY PASSAGES.*

BY

W. SCHEPPEGRELL, A.M., M.D.,
of New Orleans, La.

[Concluded from page 37.]

In endeavoring to prevent or minimize the effect of dust, which has been shown to be so inimical to health, there are two considerations which require especial attention: First is the normal condition of the nasal chambers and throat. With these in a healthy condition, we are prepared to receive the least injurious effect from the irritation produced by dust. Until recently, the nose has received but little consideration for its preparatory and protective function for the organs of respiration and, even now, the world is but slow in recognizing its importance in this direction. It is a common occurrence when patients present themselves for some disease of the throat or bronchial tubes to find them difficult to convince that the real cause exists in the nasal chambers. Many will even insist that they can have no nasal disease as they have never felt any discomfort in this region, not realizing that the disturbance of the function of one organ is quite frequently felt only in its effect upon some other organ. With the respiratory organs in a proper condition, we are best equipped to oppose the effect of the dust which is in the atmosphere.

The second consideration refers to domestic cleanliness and to public hygiene. Not only should the houses be kept clean, and as free as possible of dust, but the usual method of dusting should be corrected. The sweeping should be so done that as little dust as possible is thrown into the air, and the ordinary dusting-brush should be banished from the household, as it simply distributes the dust which first vitiates the air and eventually falls again upon the surrounding objects. There should be used instead either damp or oily cloths, a method that may occupy more time, but is more thorough and requires less frequent repetition.

In cases of illness every precaution should be taken to avoid contaminating the air with infectious material, and the members of the household should be shown how easily infection may take place, and how by ordinary care it may be avoided. The sputum not only of tubercular patients but of all forms whatsoever, should be

deposited in vessels containing some simple antiseptic solution, and should never be allowed to become dry in cuspidors or on cloth, as is so frequently the case. The same precautions should be taken in diphtheria, scarlet fever, and in all forms of infectious diseases, and were such measures but carefully carried out, they would materially assist the boards of health in stamping out such diseases. Were it but properly understood that in cases where almost entire families die of tuberculous disease, the result is due more to the inhalation of tuberculous-infected dust than to inheritance, the records of such cases would be of far less frequent occurrence.

In regard to public hygiene, the properties for dust-formation should be considered in the very formation of roads. As already stated, oyster-shells for this purpose have objectionable features unless regularly sprinkled, and wooden paving-materials of all kinds should be avoided, as the dust from these, especially when the wood begins to decay, has been found to contain decomposing animal and vegetable debris to a marked degree.

The most practicable roads, which I have seen, are the macadamized roads of northern Europe which are hard and firm, drain well, and yet retain sufficient moisture from occasional sprinkling to be free of dust. The asphalt roads which are becoming so popular in America and which certainly make excellent drives, are especially objectionable in this direction, unless great care is taken to keep them clean. They do not retain moisture, and are therefore dusty a short time after sprinkling or after rain, and these effects can be minimized only by systematic and persistent cleaning.

A source of danger from dust, which is not so conspicuous as the dust in our streets but which is far more pernicious in its effects, is that in the street-cars where hygienic laws regarding spitting on the floors is not enforced. The expectorated material mixes with the dirt of the floor, soon dries and becomes a part of the dust of the air which is inhaled by the passengers, this being especially the case in winter when the windows are closed. Bacteriologists have repeatedly shown the presence of pathogenic microorganisms in the sweepings of car-floors and the possibility of contracting disease from this source is no longer disputed. When the system has been debilitated by sickness, or the normal resistance has been lowered from any source whatsoever, the chances of obtaining disease from this source are enormously increased. In my opinion, many of the sequels of grippe of which we now hear so much, are not due to the effects of this disease directly, but to the lowering of the vitality and normal resistance thus allowing the entrance of pathogenic germs from such sources as I have here described.

This condition of affairs refers not only to cars, but to all forms of public carriers, as railroads and ferries, and to public halls and places of amusement, each of which may be instrumental in causing disease when the laws of hygiene are not observed.

In an interesting communication on this subject in the *Journal of the American Medical Association*, Dr. Elner B. Borland, of Pittsburg, shows that in the last 5 years, New York and Brooklyn, Newark, Columbus, Cleveland, San Francisco, Pittsburg, Washington, D. C.,

* Read February 23, 1901, before the Orleans Parish Medical Society of New Orleans.

Rochester, Louisville and Baltimore have enacted laws prohibiting the spitting on the floors of public carriers, public halls and places of amusement, and Dr. Dillon Brown, of New York, in a recent issue of the *Pediatrics*, states that "2 years of rigid persistence in the same course would have a marked influence on the number of reported cases of tuberculosis and acute infectious diseases, and we should by that time be wondering how we were ever able to condone or endure such a simulation of the pig-sty as now confronts us on every trolley car."

It would be ludicrous were it not pathetic, to see cities spending millions of dollars for drainage, sewerage and other measures intended to improve sanitation, and neglecting the hygiene of the street car, which daily carries its thousands of passengers, whose possibilities for infection is clearly recognized by bacteriologists and hygienists, and the correction of which would cost practically nothing. All that is needed is to pass an intelligent law on this subject and then insist upon its enforcement.

In conclusion I would state that while dust may be a necessary evil in the hurry and rush of the twentieth century, still it may be very much diminished and the effects minimized by using proper precaution. Our houses, offices and buildings should be so cleansed as to avoid the distribution of dust, and every precaution should be taken in cases of illness to prevent the vitiation of the air with germ-bearing dust. Our streets should be frequently watered and cleansed so as to prevent the dust from rising into the air, and the laws of hygiene should be enforced regarding spitting on the floors of public carriers, places of amusement and even the sidewalks. The respiratory passages should be kept in their normal condition as far as possible, and the apathy regarding chronic disorders of the upper respiratory passages overcome. Under such conditions, dust would soon become a far less prominent factor in diseases of the upper respiratory passages.

Domestic Sanitation.—Miss Martha Van Rensselaer, of Ithaca, N. Y., chairman of the department of domestic science in the Western New York Federation of Women's Clubs, is stimulating her fellow-workers to the study of home sanitation. Her aim is to induce farmer's wives and daughters to study it in a practical way, paying attention to the vital questions of water supply, drainage, care of the cellar and disposal of refuse. She suggests practical courses of reading and the formation of clubs to meet and discuss these matters.

"The practice of injecting cocain within the meninges of the spinal cord has already been designated by a remarkable number of names," says the *New York Medical Journal*. "Some of them are the following: 'Spinal-canal cocainization,' 'cocain analgesia from subarachnoid injection,' 'intraspinal cocainization,' 'subarachnoid injections of cocain,' 'intradural injections of cocain,' 'endomeningeal spinal cocainization,' 'medullary injections,' 'subarachnoid cocainization,' the 'subdural infiltration method,' 'subarachnoid injections,' 'medullary narcosis,' 'Corning's method of medullary narcosis,' the 'spinal subarachnoid method,' and (from what evolved we cannot imagine) 'Chicago chloroform.'"

Tuberculosis in Rio Janeiro.—W. Havelburg, Acting Assistant Surgeon U. S. M. H. S., states that 19.5% of the total mortality of Rio Janeiro is due to tuberculosis. During the last year a propaganda was established for combating tuberculosis. General interest in the question was aroused, money was collected, but no definite result has yet been reached. A practical measure for raising money has been adopted by the tramway companies. They issue coupons which are offered to passengers when they pay their fare. Several of the companies are now paying a small sum for the coupons. This money to be used for the benefit of the liga against tuberculosis. One company has offered to pay to the liga the sum of 100 contos (\$20,000) a year, provided all passengers accept the coupons.

SPECIAL ARTICLE

THE DUTY OF THE PUBLIC TO THE MEDICAL PROFESSION.*

BY

ANDREW H. SMITH, M.D.,
of New York City.

The student of sociology at the opening of the twentieth century finds many curious things to engage his attention. Not the least curious of these is the coexistence of two opposing facts touching the subject of this evening's discussion. The one is that the last two decades have witnessed an unexampled advance in the science and practice of medicine and surgery amounting almost to a revolution, and the other is that the popular mind is daily growing more prone to return to old superstitions in medicine, or to invent new ones even more absurd. On the one hand we have the keenest and best trained minds competing in the field of science and reaching discoveries bewildering in their frequency and their importance to the human race. On the other, we see on a large scale a complete repudiation of the results of science in favor of ideas that had their fitting development in medieval times. Side by side with the astounding achievements of bacteriology, of antiseptics, of skiagraphy, we have the inane drivel of "Christian Science" and the ridiculous pretensions of "osteopathy;" and the public seem to be about as much impressed in one direction as in the other, and entirely incapable of forming a rational judgment in the matter.

That this should be the case at a time when the general intelligence is developed to the extent that it now shows that for some reason or other scientific medicine has failed to be adequately interpreted to the public mind. Otherwise, it would be impossible that persons who discriminate so sharply in other things should be so utterly imbecile in this.

That blame attaches to the medical profession for this anomalous situation cannot, I think, be successfully denied. No idea, however meritorious, is ever sufficiently championed by those not directly engaged in its development. No subject will ever be thoroughly understood by the world, or fully enlist the interest of the public unless those most conversant with it will act as educators in its behalf. Indeed in the absence of such education the importance of a subject, however great, is certain to escape recognition and be overshadowed by baseless claims that are pressed with clamor and persistence.

And this, I believe, is the explanation of the failure of scientific medicine to obtain that hold upon popular recognition and respect which it obviously deserves, while the most impudent and absurd parodies upon it are eagerly accepted by a public which is credulous in this respect only because in this respect it is ignorant. And for this ignorance who is responsible if not the medical profession itself? We have been content to develop our science by original investigation and by accumulation of clinical experience, and to keep the results to ourselves as if they had no interest for those without the pale. And this attitude on our part has been met by a corresponding attitude of the world at large. The world has outgrown the mental habits of the scholastic age, and refuses to accept important conclusions on the simple dictum of authority. It demands to be taken into the confidence of the schoolmen and at least to have the compliment paid it of being thought competent to understand what it is asked to believe. In all other branches of science this is freely accorded. The utmost publicity is given to each new discovery, and the

*Read at the meeting of the Academy of Medicine, New York, on April 4, in a discussion upon this subject.

principles involved are fully discussed in popular language for the benefit of the public. Only in medicine is it considered unprofessional and undignified to give out anything to satisfy the interest of the laity in matters concerning which they are assumed to be incompetent of judging.

A dead language, even, is employed in writing prescriptions. Consultations are conducted in secret, and conversation between medical men in the presence of a layman is veiled in technical terms which are calculated to inspire him with awe, or perchance, distrust. Popular writings or popular lectures on medical topics are frowned upon as ill-disguised attempts at advertising. It seems to be no concern of the profession that the public should have correct ideas in regard to medicine, or in fact, any ideas at all.

Contrast with this the methods of, for example, Christian Science. Here all they have is fully discussed, the only trouble with them being that there is so little of it. If they had more they would tell more. Their candle is not hid under a bushel, but put upon the highest candlestick they can command. Their principles, such as they are, are open to inspection, and many people imagine that they find them sufficient and conclusive. There can be no doubt at all events, that they are thoroughly interpreted by those who stand for them.

To very many fairly intelligent persons this open discussion, however unsound the premises may be, appeals more strongly than the shadowy glimpse they are able to obtain of legitimate medicine. And this will come to be more and more the case unless the profession awakens to a sense of the obligation that rests upon it to impart to the public the information needed for a correct judgment upon matters of this kind. Until this is done the responsibility for the pitiable results of these delusions, as they are constantly being reported to the daily press, will rest chiefly on us.

Papers and lectures in popular language on medical subjects, by medical men of recognized position and ability, and published by the daily press, could be made extremely valuable in bringing the profession and the public into mutually helpful relations. An intelligent comprehension of what medicine has accomplished and what it aims to accomplish, together with its necessary limitations, would remove a great deal of popular misapprehension. This misapprehension includes in about equal proportions extravagant ideas of what medicine can do, and scepticism as to its ability to do anything. It is certainly very desirable that the laity should be able to settle down to a just medium between these extremes. It is as regrettable, for instance, that the notion should find credence that the x-ray has opened to view all the morbid phenomena occurring within the body, as that the idea should take possession of the public mind that in reality we know little or nothing about these phenomena.

The world has a right to know, and it is our duty to tell just what progress we are making day by day; the steps by which results are obtained, the difficulties we meet, the uncertainties which are still to be cleared up, the problems which are pressing for solution; even the errors we have fallen into in making our deductions. Such a frank and open course would command confidence and silence criticism and blatant charlatanry, and thus open the way to greater liberality of feeling and a more complete fulfilment of the duty which the public owes to the medical profession.

No Advantage in Life Insurance.—Having been solicited to insure his life, a puzzled man wrote as follows:

Sur i have reconsider the mator over sem time a go also told Mr. Alen Hofman that i cod not go in that compy under the present sirstance. When you insure for life if one shod die the first year he dont get no advantage of the rest of his life. So i have abanded sutch though And will remain ware i am yours as ever

PRACTICAL THERAPEUTICS

Under the charge of

A. A. STEVENS, A.M., M.D.

Formalin in Glycerin.—Jordan (*Lancet*, February 16, 1901) states that the irritation caused by formalin may be overcome to a great extent by using glycerin instead of water as a medium. For 10 months he has used a mixture of formalin in glycerin, from 1% to 4%. This preparation is useful as an application to the throat, as a mouthwash, as an application to the skin, and as a urethral injection. The author believes that in follicular tonsillitis, formalin is almost a specific. The mixture (2%, 3% or 4%) may be applied with an ordinary pharyngeal brush. No drink should be taken for from a half-hour to an hour after the treatment. After this a simple gargle containing potassium chlorate is all that is necessary. In aphthous stomatitis and thrush a 2% solution should be used and followed by glycerin and boric acid. In ulcerative stomatitis the following combination is recommended:

℞	
Formalin	1 part
Iodin	2 parts
B. Eucain	2 parts
Glycerin	To make 100 parts

With this and the internal administration of potassium chlorate good results are obtained. Formalin is useful in all parasitic diseases of the skin, especially ringworm. The whole area should be thoroughly cleansed with turpentine, followed by soft soap and water, and 4% formalin in glycerin rubbed carefully into the part. The application does not require repetition. The author has never known it to fail. He is not so confident in recommending formalin for general use as a urethral injection.

The Treatment of Acute Rheumatism.—A. P. Luff (*Practitioner*, February, 1901), believes that the best results are obtained by combining an alkaline carbonate with some salicylic compound. He recommends sodium salicylate (20 grains) with potassium bicarbonate (30 grains) every 2 hours until pain is relieved, when the same quantities should be given every 4 hours until the temperature has become normal. Later, sodium salicylate (15 grains) and potassium bicarbonate (20 grains) should be given until the joint symptoms have disappeared, and then 3 or 4 times a day until 2 weeks have elapsed. Absolute rest should be enforced throughout. If sodium salicylate is not well borne salicin may be substituted. If after the lapse of 24 to 36 hours the joints are painful, small blisters around the joint will, as a rule, rapidly remove the pain and swelling. Tincture of iodine over the joint is also useful, but methyl salicylate as a local application is more effective. For the relief of pain, Dover's powder or phenacetin may be employed. Brandy is indicated as heart stimulant, especially when there are cardiac complications. The disease is rarely cured within 4 or 6 weeks, and hence patients should not be allowed to move about after the pain has subsided. The slightest exertion is liable to cause a relapse or to induce cardiac complication, when there is latent rheumatism. In the treatment of children, especial caution against exercise is necessary. Opium is of great value in the early stages of cardiac inflammation, and strychnin and ammonium carbonate are considered to be more efficacious than digitalis when there is dilation and failing heart-power. Ice-bags, leeches and opium are valuable remedies in pericarditis. Hydrotherapeutic procedures are necessary in hyperpyrexia.

Cough in Phthisis.—Daly (*New York Medical Journal*, January 5, 1901,) recommends for the hard, dry cough of phthisis the following combination:

℞	
Camphor	2 grains
Heroin	$\frac{1}{2}$ grain
Creasote	1 drop.

To be made into a pill with a proper vehicle. The camphor does away in large part with the general depression.

Acute Intussusception in an Infant Aged 4 Months; Laparotomy; Recovery.—Tynms (*British Medical Journal*, February 9, 1901) reports the following case: A well-nourished suckling infant, aged 4 months and 10 days, was suddenly seized with colic and vomiting, quickly followed by collapse. On examination an hour later a tumor was discovered on the left side of the abdomen. The vomiting became more frequent, and tenesmus developed with the passage of bloodstained mucus. No injections were given or sedatives administered. The abdomen was opened and the invagination reduced 5 hours after the onset. A few hours after the operation the temperature rose to 102° F., but it soon returned to normal. Recovery was uninterrupted.

Bromids in Epilepsy.—L. P. Clarke, of the Craig Colony for Epileptics (*Buffalo Medical Journal*), draws the following conclusions concerning the use of bromids in epilepsy: (1) bromids still hold a very important place in epileptic treatment. (2) tonics must be given constantly while administering bromids; (3) bromid salts should be given gradually to find the epileptic's sedative level; baths, high enemas, alimentary antiseptics, massage and electricity are absolutely essential to successful bromid-medication; (5) bromin is a worthy successor to the bromids in many cases; (6) salt-starvation or semisalt starvation is a great adjuvant to the bromid-treatment.

Serotherapy in 1,778 Cases of Diphtheria.—Richardière (*Rev. men. des Mal. de l'Enfance*, September, 1900,) presents a study of 1,778 cases of diphtheria treated in the Hôpital Trousseau. Of these cases 280 died, a mortality of 15.7%. Including the cases which ended fatally within 24 hours after admission, the mortality was only 11.5%. Of 1,115 cases in which no operation on the larynx was required the mortality was only 5.5%. The mortality of the operative cases was 27%. The treatment consisted in the injection of Roux's serum, and washing the fauces with calcium permanganate (1 to 4000). No serious complications resulted from the use of the serum. Eruptions—erythematous, urticarial, roseolis, purpuric—were observed in 198 cases, arthralgia or slight arthritis occurred in 15 cases. The chief cause of death was bronchopneumonia, and the next in frequency toxemia. Heart failure was treated with spartein sulfate, and copious injections of artificial serum.

The Value of Rest and Potassium Iodid in Case of Aortic Aneurysm.—Byron Bramwell (*British Medical Journal*, January 12, 1901) reports the case of a man, aged 68, who 24 years ago had been under the care of Balfour, suffering from weakness, cough, severe, persistent pain in the chest, shooting from the left shoulder down the arm, and difficulty in swallowing. He was treated for 14 weeks with rest and potassium iodid, and was then discharged free from pain and cough, but still complaining of some dysphagia. After 6 weeks he returned to work, and for nearly 24 years he was employed as a hawker, walking 12 to 20 miles a day and carrying a pack weighing from 20 to 40 pounds. The pain and cough recently returned, and when seen by Bramwell the physical signs of aneurysm of the transverse and descending thoracic aorta were well marked. The author states that he has seen many cases of aneurysm which were remarkably benefited by the iodid plan of treatment, but had not met with any case in which the aneurysm had been so completely cured by the treatment that the patient had been able to follow an occupation involving much strain and hard work for a period of 24 years.

Chloreton as a Hypnotic.—Stevens (*New York Medical Journal*, January 23, 1901) presents a clinical report on the use of chloreton as a hypnotic. The best results were obtained in the insomnia which was unassociated with organic disease. In neurasthenia, chronic heart and kidney diseases, and in sleeplessness occurring during convalescence of acute diseases, the results were very favorable. In acute febrile diseases, painful affections and delirium tremens the drug was commonly ineffective. In none of the cases did chloreton give rise to any untoward symptoms or to unpleasant after-effects, except in a few instances in which it caused a feeling of drowsiness on the day following its administration. Nausea and vomiting were

never excited by it. As a hypnotic its action is prompt, sleep usually following in from half an hour to 2 hours after its administration. The drug seems to have little effect on the circulation; even in chronic heart disease there was no evidence of a depressed action. It often lost its power to induce sleep when used continuously, and in this respect it was probably inferior to opium, chloral, sulfonal, or paraldehyd. In ordinary doses it appears to be a safe drug. The author has never given more than 30 grains at a single dose, but Houghton and Aldrich state that as high as 60 grains have been given at one time without producing any untoward symptoms. The conclusions are that we have in chloreton a safe hypnotic of moderate power, which rarely gives rise to unpleasant after-effects, but of which a toleration is quite rapidly acquired; which is specially adapted for use in cases of insomnia unattended with pain, high fever, or pronounced nervous excitement.

Calomel Injections in Syphilis.—Fournier (*Revue de Therapeutique*, November 1, 1900,) considers calomel injections the best means of obtaining a powerful action on syphilis. This method must not be regarded as a routine treatment, but only as an exceptional one to be used in certain severe conditions; such as spinal and cerebral syphilis, iritis, phagedena, chronic plantar and palmar syphilids, ulcerating tuberculous syphilis, glossitis and tertiary laryngeal and pulmonary syphilis. Technique.—The needle should be introduced deeply into the gluteal muscles, and a short interval allowed to elapse before the calomel is injected in order to see if any blood comes; if there is blood, no injection should be made, as there is danger of pulmonary embolism. The calomel employed should be sublimed and not precipitated, as the latter is apt to form lumps. It should be washed carefully in boiling alcohol and then dried. The best vehicle is sterilized olive oil. The average dose to begin with is $\frac{3}{4}$ of a grain and if this is well borne it may be increased up to $1\frac{1}{2}$ grains. The injections are made weekly, or every 10 days, and 4 to 6 are usually sufficient. The author quotes the following cases in his clinic: (1) Phagedenic chancre of tongue, cured in 15 days by 2 injections; (2) case of malignant syphilis cured quickly; (3) tuberculous syphilid of face, improved after 3 injections; (4) enormous phagedena of nose, previously rebellious to all mercurial treatment, cured in 3 weeks; (5) tertiary glossitis, cured; (6) syphilis maligna, with laryngitis and impending asphyxia, cured by one injection. Good results do not always follow; in many cases calomel fails to cure and is sometimes dangerous. The chief complications of the treatment are stomatitis, gastroenteritis, toxic effects, local reaction and pain. With doses of $\frac{3}{4}$ of a grain the author has seldom observed more than a slight stomatitis, gastroenteritis or intoxication. In women he advises doses of $\frac{1}{2}$ a grain. Local reaction includes swelling of the buttocks and abscess; the former is common, but usually subsides in a few days. Induration at the seat of puncture may occur and last for some weeks. Abscess is rare, and its frequency diminished by antiseptic precautions. The author concludes that the frequent occurrence of severe pain is the chief objection to the treatment, but that the method should not on this account be condemned in the cases in which he considers it useful.

Hemostatic Medication.—Vaquez (*La Presse Medicale*, December 22, 1900,) in discussing the methods of controlling hemorrhage classifies them into those which act by promoting vascular constriction, by lowering arterial tension and those increasing the natural coagulability of the blood. Among the drugs which produce vascular constriction the author considers ergot as variable in its results and limits it to some cases of uterine and pulmonary hemorrhage. Digitalis has been used but its employment is best restricted to cases of circulatory troubles of central origin associated with pulmonary stasis (cardiac hemoptysis). The salts of quinin and hydrastis canadensis have been employed as hemostatics but are neither powerful nor reliable. Ipecacuanha and antimony have been employed as hemostatics by lowering arterial tension. Of the drugs which increase the coagulability of the blood, the salts of calcium and of strontium, certain colloids and gelatin have been most commonly used.

1.—Dr. Clubbe in referring to the **diagnosis and treatment of intussusception** states that during the last 7 years he has operated on 49 cases with a mortality of 45.5%. In those in which recovery followed, the operation was performed 24 hours after the onset of the symptoms—showing the importance of the early recognition of the condition. Diarrhea may precede the attack, during which sudden, severe pain with the passage of small bloody slimy stools occur. A sausage-shaped tumor may be felt through a distended abdomen. The intussusception sometimes descends into the rectum and through the anus. In acute cases after 24 hours there will usually be symptoms of intestinal obstruction. Reduction, under anesthesia, with the buttocks elevated, by means of the injection into the bowel of a pint of warm water or oil should be tried. Should this fail the abdomen should be opened at once, and the invagination reduced by making gentle traction on the intussusceptum, and pressure on the intussuscipiens. Should the bowel be torn or this method fail, resection must be done. [J.W.M.]

2.—Walsham refers to a condition which he considers to be of not infrequent occurrence, that of **intestinal obstruction due to the reduction of a hernia en masse**. This may occur in the hands of the physician when it is usually recognized, or it may be done by the patient and the latter is the usual history. There are symptoms of obstruction, with a sense of fullness, and increased resistance and diminished resonance over the inguinal canal. An attempt should be made to reestablish the hernia by pulling down the sac and then returning the intestine. Should this fail, the abdomen must be opened, the strangulation reduced and the sac removed. [J.W.M.]

3.—In referring to the **diagnosis and treatment of gastric ulcer**, Maunsell states that statistics to date show that of those cases in which operation was performed within 12 hours after the occurrence of the perforation 45 to 50% recover. The diagnostic points are: Sudden epigastric pain, vomiting, collapse, which is variable, temperature normal or subnormal, and tympany with diminishing or absent liver dullness. Treatment should consist of the early opening of the abdomen, suturing of the perforation, followed by the toilet of the infected parts. [J.W.M.]

4.—Dr. Childe reports a case of **hourglass contraction of**

the stomach in a female aged 51, in which the symptoms, with the exception of the presence of free HCl, resembled those of malignant disease of the pylorus. On operation the pulsatile mass, which was felt in the pyloric region, was found to consist of the thickened and puckered up pancreas, to which the aortic pulsation was transmitted. Gastroenterostomy was done. On postmortem 5 days later, the stomach was found to be divided into 2 portions, united by a small opening. The cardiac portion, being hidden underneath the costal arch and diaphragm, was overlooked during the operation. [J.W.M.]

5.—Angus reports a case in which a young lady, who had frequently suffered from attacks of gastric pain and vomiting, was taken with an **acute hematemesis**. On operation, by opening the anterior wall of the stomach, the perforation was found and sutured. Convalescence was complicated by a thrombosis of both legs which was not believed to be septic. Recovery was complete. [J.W.M.]

6.—Althorp reports an operation for the cure of **gastric fistula**, in which the fistulous tract was excised by making an incision into the abdomen outside of all adhesions. The edges of the opening into the stomach, which was the center of a large ulcer, were freshened and the opening closed with silk sutures, as the condition of the patient would not permit of the excision of the entire ulcerated area. The patient developed pneumonia and died on the sixth day. Postmortem showed that there was no leaking from the wound, though it showed no disposition to heal. [J.W.M.]

7.—Horrocks reports a case of **perforated gastric ulcer** in a female, successfully operated upon, in connection with which the following points of interest were observed: The absence of any indications of the existence of an ulcer before perforation; the absence of any existing cause for perforation; the location of the pain and tenderness indicated the position of the ulcer; the movements of the patient after the perforation infected the whole abdomen. [J.W.M.]

8.—Campbell and Wood report a case of **subdiaphragmatic abscess**, successfully operated on which presented the following symptoms when first seen: Pain in the left hypochondria and epigastric regions which had existed 3 days; dullness which extended up to the fifth rib, displacement to the right of the heart apex, with diminished liver dullness, irregular temperature and wasting. An incision was made in the epigastric region, a walled-off abscess from which gas and pus escaped was found and drained. It is of interest to note that there never had been any symptoms of gastric trouble. [J.W.M.]

9.—Newbolt cites 3 cases of **intestinal anastomosis** and 1 of gastroenterostomy in which he used the Murphy button with satisfaction. In the latter the button probably dropped into the stomach, as it never passed. [J.W.M.]

10.—Savory and Nash report a case of **acute intestinal obstruction due to ovarian cyst, and cancer of the small intestine**. Both were successfully removed. Following the removal of the latter an end to end anastomosis was done, in which the Allingham bobbin was used. It was passed on the fifth day. [J.W.M.]

11.—Groves reports a case of **chronic intestinal obstruction in a child** which is of rare interest and importance. The patient was 1 year and 8 months old, of good family history, and during its first year enjoyed good health. When first seen there was much emaciation, with evidence of pain, abdominal distension, but no tenderness. There was no vomiting and the bowels were regular. The child while under observation grew suddenly worse and died before permission to operate was procured. On postmortem a stricture of the ileum which only admitted a probe was found. The condition is considered to have been congenital and is supposed to have arisen in connection with the involution of the embryonic vitelline duct. Had the condition been recognized, by feeding the child on soft, easily digestible food its life might have been prolonged. By way of operative treatment the intestine just above the stricture might have been brought out of the abdominal wound, opened, and a subsequent anastomosis done. [J.W.M.]

12.—Clarkson makes reference to the **anatomy and surgery of Meckel's diverticulum** a fetal relic representing the vitellointestinal duct and which usually undergoes

complete atrophy. When this fails to occur it may be entirely or partly patulous, or entirely fibrous. Statistics show it to be present in about 2% of cases, situated within the last 3 feet of the ileum, though this varies widely. It averages 3 inches in length. It is important surgically from the fact that when, due to the mobility of the ileum, the cord is severed and the umbilical portion atrophies, the intestinal portion may become adherent to some viscera and cause strangulation. It is important in such cases to determine whether the duct is patulous or fibrous. [J.W.M.]

13.—See the *Lancet*. Abstract 3.

14.—Mahomed in referring to **intestinal sand** mentions a case which he observed some years ago in which during an intractable attack of diarrhoea a patient passed in his bowel movements a quantity of sand granules. D. Baker states that when in Burmah he has frequently observed this but has been unable to attach special significance to it. [J.W.M.]

15.—Hildige mentions an interesting case presenting all the symptoms of **acute intestinal obstruction** which persisted for 2 days and for the relief of which an operation was about to be performed, when the obstruction was spontaneously relieved and the patient recovered. [J.W.M.]

16.—Bingham reports an **anomalous position of the rectum** found postmortem; it occupied the right iliac fossa. He also reports a case in which he found a complete horseshoe kidney. [J.W.M.]

17.—Power records 2 cases of **perforated gastric ulcer** which were operated upon 5 and 6 hours after the onset of acute symptoms and recovered. In the first the perforation was closed by Lembert sutures; in the second the stomach wall was much thickened and pliable and would not hold sutures, so a piece of omentum was sewn over the perforation and healthy stomach wall sewn over this by means of Mathew's sutures. The variation in the degree of shock following perforation is mentioned. [J. W. M.]

18.—Kempe records a case of **intestinal obstruction** due to nonremovable carcinoma of the ascending colon for the temporary relief of which he did an **ileocolic anastomosis** using a Murphy button. The subsequent progress of the case was slow, bearing out what has frequently been observed in such cases—that if the feces can be prevented from passing over the diseased area the progress of the disease and the development of cachexia are retarded. [J. W. M.]

2.—Bruce, in the second Lettsomian lecture on diseases and disorders of the heart and arteries in middle and advanced life, describes the clinical characters and course of the affections of the heart and arteries as he has observed them

in association with the various influences that may provoke them. Pointing out that the causes of cardiovascular disease in the second half of life are complex, he states that to discover the effects of each pathogenic influence as distinguished from the others we must begin our study with the simplest, or purest, or most definite of all, and proceed from it toward those that are more difficult, as well as to combinations of causes. He discusses in elaborate detail the clinical manifestations of the tobacco-heart, the heart in alcoholism, in gout, and in obesity and glycosuria, and he illustrates each with notes of cases under his personal observation. He then proceeds to discuss cardiac strain, its mode of production and clinical manifestations, and he directs particular attention both to cardiac strain occurring past middle life, and to that strain which, experienced in early life, impels the patient to seek advice in advanced life. Finally consideration is devoted to the relationship of syphilis to the more serious cases of heart-disease occurring in elderly people, and to the clinical aspect of cardiovascular disorders and disease the result of nervous strain. [A.O.J.K.]

3.—Stephens, in a discussion of **blackwater fever**, expressing the conviction that it is malarial in nature, considers briefly the evidence of malarial infection in a supposed case of ordinary "fever." This may consist of the presence of parasites in the blood. In the absence of parasites, the presence of pigmented large mononuclear leukocytes is a means of proof. Concerning the pigmented large mononuclear leukocytes it is only necessary to state that they may be very few. As regards the change in the relative proportion of the large mononuclear leukocytes, they often constitute 20% to 30% of the total number of leukocytes, and may constitute even 50%. The opinion is expressed that a value as high as 20% of large mononuclear leukocytes is proof of malarial infection. From the finding of such values the diagnosis of malaria has in some cases been possible even in the absence of parasites—the latter being found subsequently. This relative increase in the large mononuclear leukocytes bore an inverse relation to the tertian temperature curve; that is, during the pyrexia the value was normal or low, whereas during the apyrexia periods the value was high. Except the clinical features, the presence of pigmented leukocytes and the change in the relative proportion of the large mononuclears, may be the only means of diagnosis in a case of malaria, as for instance if the patient has been taking quinin. From his own observations of 16 cases as well as from a study of the observations of others, he adduces the following as evidence of the malarial nature of blackwater fever: (1) the existence of parasites during the attack; (2) pigment and mononuclear percentage increase; (3) parasites before the attack; (4) parasites after the attack; and (5) the postmortem evidence. The opinion is expressed that there can be no doubt that quinin is the immediate cause of blackwater fever, though it is admitted that other causes may occasionally induce the disease. Observations on the **isotonic point of the blood in malaria and blackwater fever**, revealed that in malaria the isotonic value is constantly increased, while in blackwater fever it is below normal. It is suggested that the raised isotonic value in malaria may give some indication of the extent to which the corpuscles of the patient have been subjected to an injurious influence and so give some indication of those cases of malaria in which it would be dangerous to give quinin. Another factor said to be of some use as an index of danger is the presence of albuminuria or a high-colored urine. It is stated finally that complete protection from malaria in Africa may be obtained without taking any quinin, by paying scrupulous attention to clothing and the use of the mosquito net. [A. O. J. K.]

4.—Richardson cites 3 cases of **acute fulminating appendicitis, followed by general septic peritonitis**, in which recovery followed operation. The symptoms presented in each case were: Slight abdominal pain, which in a few hours became intense; vomiting, high temperature, rapid pulse, with later abdominal distention and tenderness. Such cases differ only in rapidity and virulence from those which terminate in resolution, or abscess-formation. Early recognition of the condition and prompt action are emphasized. The following rule is suggested with regard to operation in these cases: Namely, in very acute cases which do not improve in all the symptoms in 24 hours the appendix should be removed. The

operation consisted in an oblique incision, upward, outward, and backward from the edge of the right rectus muscle, removal of the appendix, which was perforated in each case, the toilet of the abdominal cavity and the establishment of drainage by means of the strands of gauze, 1 into the pelvis, 1 amongst the small intestines, and 1 up to the liver. [J.W.M.]

5.—Dodd reports in detail 2 cases of **glaucoma**, in which he removed the **superior cervical ganglion** of the sympathetic nerves for their relief. The primary results were very gratifying, but the final results were *nil*, leading him to the conclusion that the operation will not prove successful. [J.W.M.]

6.—Knecht and Dearden, writing of the **elimination of arsenic through the hair and its relation to arsenical poisoning**, state that some method of detecting arsenic in the hair should prove of clinical value in the endeavor to discriminate between arsenic and alcoholic neuritis, as well as of medicolegal value in the postmortem examination of cases of chronic arsenic poisoning, and particularly in exhumed bodies, since hair is one of the last parts of the body to undergo organic decomposition. By the employment of the Sanger modification of the Marsh test, they were able to detect arsenic in the proportion of 0.3 in 10,000 in the hair of a patient who had been taking arsenic, and in the proportion of 0.3 in 10,000 and 1 in 10,000 respectively in 2 cases of arsenical neuritis. In the hair of 3 healthy individuals arsenic was found in quantities too minute to be estimated in 1 gram of substance. [A.O.J.K.]

7.—Maguire reports a **fatal case of laryngeal diphtheria complicating measles** in a child aged 18 months. The child ill with measles began to suffer with dyspnea that increased to orthopnea requiring tracheotomy, without there appearing any clinical evidence of diphtheria of the throat, or other cause to explain the embarrassed breathing. At the necropsy it was found that the larynx was almost occluded by a thick, tough membrane that bacteriologic examination revealed to be diphtheric. [A.O.J.K.]

8.—Curnow reports an instance of **wasted gulain pills**—a number of pills apparently unaltered being found in a stool provoked by enema several days after they had been administered to a typhoid fever patient. The pills were not coated, but had been made up with water, instead of glycerin. [A.O.J.K.]

9.—An interesting case of **hydropneumothorax** is reported, in which relief was not obtained after 3 aspirations and the removal of 4½ pints of fluid. The air still remained at the apex of the pleural cavity. This was removed by aspirating upward along the upper border of the third rib. The chest was then tightly strapped and complete recovery followed. There being no evidence of tuberculosis, or injury, the way in which the air entered the pleural cavity is a question.

10.—Longworth reports a case of **enteric fever with severe hemorrhage from the sigmoid flexure**, in a female patient, aged 36 years. The enteric fever ran a somewhat atypical course; the temperature reached 103.4°; there occurred 2 colapses with marked fall in the temperature (on the fourteenth and seventeenth days respectively), and followed by the discharge from the bowel of a quantity of dark red blood. On the nineteenth day another hemorrhage occurred and the patient succumbed. At the necropsy the sigmoid for about 6 inches of its course was dark purplish in color, its mucous membrane free from ulceration, but markedly thickened, and to this blood-clot was firmly attached. The remainder of the large intestine was normal, and the ulcerations in the ileum showed no signs of hemorrhage. [A.O.J.K.]

11.—Kemp reports a case of **encysted peritonitis** which simulated very closely an ovarian cyst. Laparotomy was performed, and on opening the abdominal cavity the parietal peritonium was found to be closely adherent to what appeared to be the cyst wall, but an attempt to separate it failed. Fluid amounting to 21 pints was drawn off and the tubes and ovaries apparently healthy were found within the sac. The wound was closed with a drain inserted in the lower angle. The condition was due to a serum-containing pseudocyst of encysted peritonitis. The interesting point is the difficulty of differentiating this accumulation from ovarian cysts. [W.K.]

12.—Short reports a case of **dermatitis** involving almost the entire body, and following **acute lichen planus**, in a woman,

aged 31 years, whose mother suffered with chronic lichen planus. [A.O.J.K.]

1.—Cases are cited to show that **chloralose** is prompter than any hypnotic except morphin, and is safe, though occasionally causing fantastic involuntary actions. The maximum dose is 5 grains in capsule repeated once after 1 or 2 hours. [H.M.]

2.—The **nervous phenomena of the artificial menopause** could be prevented by following operation with prolonged rest-treatment, massage, nonstimulating and nutritious diet and avoidance of drugs. [H.M.]

3.—The antiquity and world wide distribution of syphilis are presented with allusions to the epidemic of 1494 and others, when harsh legal measures were successfully used to hinder further dissemination, the disease not being looked upon as venereal. Owing to the thousands of cases of **syphilis insontium**, marital, hereditary and extragenital, Bulkley thinks physicians should labor to spread the knowledge that it is acquired otherwise than by sexual intercourse in order to remove the stigma and pave the way for the legal restriction of syphilitics. If members of a community are guarded from those infected until the contagious stage is passed the malady will cease to exist. Here there are no sanitary safeguards and few hospital opportunities for isolation as compared with Europe. The first step in legal control should be to make it as criminal to transmit syphilis wittingly as to communicate smallpox. [H.M.]

4.—Allen cites cases of his own and others which contradict the common statements of text-books, etc., and show that **tinea versicolor** is sometimes seen in children and on the face, palms and soles, and is not confined to those with pulmonary tuberculosis or those who have seborrhea and diphthesia. Many cases of recurrence are due to overlooked patches in the pubic region which have escaped treatment. Diagnosis without the microscope is not always easy. Iodin gives a mahogany-brown color to the lesions containing the fungus, distinguishing it from chloasma, macular syphilids, etc. [H.M.]

5.—A history of the **epidemic of rabies** beginning in 1898, and bacteriologic and physiologic verification of the nature of the disease, with observations on the peculiar actions of dogs affected by it are recorded. Popular misconceptions, skepticism, sincere and dishonest, in the profession, and the subject of municipal restriction are considered. Opposition to legislation is strongest among those to whom the possible discomfort of dogs is of more moment than the protection of human beings. Regulations should be such as would cause a decrease in the number of useless curs, thus benefiting the community as well as the breed of dogs. These should include registration, tagging, license, penalties, muzzling and leashing when at large,

stringent quarantine against infected localities, extra dog-catchers, shooting by police of unmuzzled and unleashed dogs, destruction of all bitten animals at once, disinfection of infected premises, cremation of carcasses, etc. [H.M.]

6.—Food legislation has failed from lack of comprehensiveness and a sensitive public conscience. The solution of the problem demands greater interest and intelligence on the part of physicians, the adoption of definite standards and the establishment of a national department of health to act as a sort of clearing house for the various governmental laboratories. When a bill has been formulated it should be submitted to all specialists and all the trades whose interests are involved before action by Congress. [H.M.]

7.—The combination of fixation, massage and in some cases passive motion is the most effective treatment for fractures. A splint of wood-plastic material, suitably cut, moistened, placed next the skin and bandaged on, gives immobility and is easily loosened in case of swelling and removed for inspection and massage. [H.M.]

8.—Allport gives the history of 14 real or apparent renal cases, his own and others, in which the diagnosis was tentatively or absolutely wrong owing to careless history taking or to relying too much on subjective symptoms or the patient's recollections, or on the preservation of the normal relation of organs, or on what seemed pathognomonic and neglecting certain accompanying signs and symptoms. Among operative errors he notes failure to perfectly care for the ureter after nephrectomy, injury to pelvis and ureter from too deep incision in kidney structure, closing wounds without drainage attempted preservation of a kidney riddled with sinuses. [H.M.]

9.—Traces of oxalates from food are found normally in urine. Crystals usually denote gastrointestinal fermentation after exclusion of foods rich in these. Hyperacidity on a meat diet contributes to putrefaction and indican and oxalic acid are increased. The symptoms of the oxalic diathesis associated with indicanuria are not due to the oxalic acid or indol but to other products formed during the fermentation. [H.M.]

10.—Fairchild continues the history of a case reported 2 years previously in which 5 operations were performed for relief of symptoms due to pressure of scar tissue on the median nerve with relapse a short time after each operation. Believing that the dense connective tissue formation was the result of trophic changes from neuritis he dissected out all this tissue again, lifted the nerve-end on a strabismus hook and surrounded it with gold sheet $\frac{3}{4}$ inch wide, $1\frac{1}{2}$ inches long and 1-500 inch thick, closing the wound with rigid asepsis. After 2 months the patient resumed work and at the end of $1\frac{1}{2}$ years there were no signs of nutritive irritation. [H.M.]

11.—A diamond-shaped denudation is made over the cystocele with one angle at the base of the urethra, one anterior to the cervix and the lateral angles so far apart that tension is required to make them meet. A purse string suture is inserted in such manner as when drawn to convert the middle of each side into the apex of a right angled triangle, the 4 apexes meeting in the center, the wound now forming a cross with the points of the original diamond at the end of each arm. This suture is partly in the denuded area and partly submucous, and silver wire is preferred. The margins of the wound are closed with a whip-stitch. The operation is illustrated by cuts, modifications are suggested and cases described. [H.M.]

12.—Mental depression, overexertion, habitual cleanliness, and protective clothing, as woolen underwear and rubber shoes, lower resisting power to germ infection. [H.M.]

13.—In the name of the New York Medico-Gymnastic and Massage Society, Bolin protests against the passage of Assembly Bill 759, as degrading the standard of education required in this branch of therapeutics. The bill, drawn in favor of the osteopaths, proposes to give independent practice to persons who may have taken only a month's course of training. In Sweden a 3 years' course is required and the government forbids independent practice, requiring the cooperation of legalized physicians. [H.M.]

1. Diseases of the Myocardium. HENRY JACKSON.
2. The Condition of the Myocardium as Affecting Cardiac Murmurs. H. D. ARNOLD.
3. A Further Note on the Treatment of Epidermoid Cancer. FRANCIS H. WILLIAMS.
4. Report of Cases from the Second Surgical Service of the Children's Hospital, Boston. I. Multiple Plexiform Fibromas; II. Paraplegia Existing from Birth. Laminectomy at the Age of $5\frac{1}{2}$ Months; III. A Case of Ununited Fracture of the Femur of a Child in which the Non-union was due to the Formation of a Cyst at the Ends of the Fragments. H. L. BURRELL, R. W. LOVETT, and J. E. GOLDTHWAIT.

1.—Pathologically, diseases of the myocardium are circulatory disturbances, inflammations, degeneration, neoplasms, hypertrophy and dilation. The article deals only with changes causing symptoms of heart disease. Coronary thrombosis or embolism may cause immediate death, or, if in the small branches, acute softening and rupture or slow connective tissue substitution, followed by aneurysm. Myocarditis is often due to general infectious diseases, or may be caused by arteriosclerosis. Fatty degeneration is usually found in dilation. Gummas are the only tumors usually presenting symptoms of heart disease. Hypertrophy is recognized by a strong pulse, heaving apex-beat and forcible heart-sounds, but causes no perceptible increase in area of cardiac dulness. Dilation does increase this area and when uncompensated causes gallop rhythm, or irregularity, or intermittence. The most important sign of weakness is discrepancy between heart and radial pulse-beats. The causes of enlargement within the heart are valvular disease, diseases of the wall, newgrowths. Those lying without are pericardial adhesions, kidney disease, chronic pulmonary disease, drugs and poisons, overwork, unknown causes, arteriosclerosis. Enlargement in renal disease and alcoholism may occur without arteriosclerosis. Nervous disturbances, hydremia and plethora may explain obscure cases. In arteriosclerosis the enlargement is much greater than in valvular disease; heart murmurs are often heard and the etiology, while largely due to alcohol, etc., is in many cases unknown. [H.M.]

2.—The importance of the condition of the myocardium in valvular disease is generally recognized. Theories as to the cause of murmurs are: (1) the vibration of a fluid forced from a narrow into a wider space; (2) the vibration of a stiffened valve; (3) changes in density and velocity as related to the vessel wall. The closure of the aortic valve depends on a fibrous mechanism, the mitral on a muscular mechanism. Weakening of either the cardiac or papillary muscle may account for mitral regurgitation. This weakening is generally curable because the cause is curable. When the valves themselves are diseased the condition of the myocardium is of still greater importance for on it compensation depends. A systolic apex murmur in rheumatism may not signify endocarditis but muscular weakness as in other toxin-producing diseases. Rheumatic endocarditis can be diagnosed absolutely only from murmurs of obstruction. Anemic murmurs are probably due to a poorly nourished heart muscle causing relative insufficiency. If left sided, even though showing various areas of distribution, they are probably due to mitral regurgitation, the paths of conduction being not yet understood. [H.M.]

3.—Cuts show a case of epidermoid cancer of the lip treated by radiation from an excited Crookes' tube. Cure was complete and healing without caustic action. Treatment can be stopped when improvement begins, the inference being that the rays destroy the life of that which causes the cancer. [H.M.]

4.—Burrell reports a case of multiple plexiform fibromas in a girl of 10. The left knee was swollen, involving the thigh and calf. A large tumor mass involved the popliteal space. This was found to consist of multiple plexiform fibromas apparently developing about nerve-bundles. The mass was encapsulated. Lovett's case was a child of $5\frac{1}{2}$ months who had paraplegia from birth. An incision was made at the dorso-lumbar junction and the spinous processes of 3 laminae were removed. A director was passed up and down the spinal canal

after the dura had been opened with the escape of much fluid. The nerves appeared small and adherent to the dura. They were partially freed and the dura left open. The child made a perfect convalescence and in a few weeks it was better as regarded the swelling of the legs and nervous irritability. Since that time there has been no improvement and the paralysis still continues. Goldthwait records a case of **ununited fracture of the femur** in a child of 11. The accident occurred in May, and in October the patient was operated upon. At the seat of the break was a cyst the size of a lemon containing a clear fluid under high pressure. The wall of the cyst was a plate of bone callus. The edges of bone were refreshed and healing has been normal. [A.G.E.]

Medical Record.

April 6, 1901. [Vol. 59, No. 14.]

1. The Relation of the Public to the Medical Profession. D. B. ST. JOHN ROOSA.
2. The Importance of Aseptic Vaccination, with Remarks on Vaccination in General. WILHELM KARL KUBIN.
3. The Field for Ethyl Chloride Narcosis. MARTIN W. WARE.
4. On the Diagnosis and Prognosis of Diabetes Mellitus. HENRY S. STARK.

1.—The fact that physicians may make or mar the physical fortune of the community in which they live should be sufficient inducement to that community to increase by endowment or otherwise facilities for obtaining a thorough **medical training**, and to prevent the practice of medicine by the irresponsible and ignorant. [H.M.]

2.—Kubin discusses the **importance of aseptic vaccination**. He quotes copious statistics proving the undoubted value of vaccination as a preventive measure. He mentions as causes which give rise to untoward results: (1) impure virus; (2) abnormal or paradoxical cause of the comox itself; (3) improper performance of the act of vaccination; (4) neglect on the part of the vaccinator to exercise supervision and control of the patient until the time of complete healing. (5) Coincident diseases: scarlatina, measles, etc. The following abnormalities as complications of vaccination are mentioned: Intensification of local reaction, alivary lymphangitis delayed healing, defective crust formation, ulcerated vaccinia, hemorrhagic vaccinia, hemophilia, keloid, tetanus, erysipelas, gangrene, paralysis, septicemia, syphilis and otitis media. His method of vaccination is by scarification, rubbing in of the virus and protecting by a shield. He insists on the patient returning for inspection at the end of a week. He concludes by suggesting the passage of a national law making vaccination and revaccination compulsory. Also that its importance be taught in the public schools, and that special instruction in vaccination be given in all medical colleges. The number of cases in which complications arise is small in comparison with the number of unvaccinated persons who die from smallpox. [J.W.M.]

3.—Wade, in a paper on the use of **ethyl chlorid as a general anesthetic** states that its death rate is 1 in 11,207 cases. His method of administration consists in spraying it onto a piece of gauze held in a tin or vulcanite funnel which fits the patient's face. On an average narcosis is produced in from 1 to 2 minutes after 10 cc. have been used. During narcosis the breathing becomes somewhat stertorous, the pulse accelerated with no appreciable fall in pressure. There is flushing of the face, followed by free perspiration, slight jactitation, followed by a spastic state of the muscles which subsides as the narcosis deepens. The chest muscles are not thus affected. Narcosis is reached when the pupils begin to contract, the muscular contractions to abate and the breathing becomes slightly stertorous. There is some variation in these phenomena in the case of drunkards, neurotics and children. He believes it to be preeminently the best anesthetic for minor surgery, its advantage being safety, rapidity of narcosis and recovery, small cost, and portability. [J.W.M.]

4.—Typical **diabetes mellitus** includes glycosuria and one or more classical clinical features, as polydipsia, polyuria, etc. Among evidences not mentioned in textbooks are periodic headaches in the obese, extreme and lasting fatigue after exertion, falling vision, acid saliva, receding germs, red and fissured

tongue, attacks simulating angina pectoris or cardiac hypertrophy, premature signs of age, etc. Anomalous types include those with the diabetic dyscrasia without glucose in the urine and those with glucose and no clinical manifestations. The tolerance for carbohydrates can be tested by means of the standard meal, increasing daily the carbohydrates in it until glycosuria is produced. Bremer and Williamson's blood-tests are described. No test for sugar is infallible, that with yeast being best. Many substances in urine, including drugs, will reduce copper. For clinical purposes Rudisch's test is one of the quickest, most delicate and most certain. The majority of cases are amenable to treatment. Prognosis depends on the power of assimilating carbohydrates. If sugar persists after complete exclusion of these from the diet, the case is severe. Early recognition is important. Early age, exhausting work, and presence in the urine of diacetic and B-oxybutyric acids or excessive amounts of acetone make the prognosis grave. [H.M.]

New York Medical Journal.

April 6, 1901. [Vol. LXXIII. No. 14.]

1. The Active Principles of Digitalis Leaves. JOSEPH W. ENGLAND.
2. The Comparative Pathology of the Jews. MAURICE FISHBERG.
3. The Pathology of Intrauterine Death. NEIL MACPIATTER. (Continued.)
4. Rectal Feeding in Throat Diseases. A. C. BARDES.
5. The Medical Aspect of Christian Science. W. M. POLK.

1.—An argumentative consideration of recent papers upon the **constituents of digitalis**, particularly deprecating a recent statement that digitoxin is the chief constituent of digitalis leaves. The digitoxin of the leaves and of the seeds differ in chemical formula. Digitoxin does not represent the medical value of the leaves; this may be proved by the fact that results are obtained from infusions of leaves, yet digitoxin is wholly insoluble in water. England reviews the action of tincture of fat-free digitalis and gives the method of obtaining it from the leaves. He thinks it seems clear from the properties of digitoxin—its difficulty of absorption, the length of time necessary to yield cardiac and renal effects, its slowness of elimination, and the relative rapidity of absorption of digitalis tinctures, that it cannot be the most important therapeutic principle of digitalis leaf. The severe local pain following hypodermic injections of digitoxin, the prolonged sensitiveness of injected tissues, and the slowness of physiologic effects indicate a great difficulty of absorption and assimilation. Digitalis is sometimes cumulative in action. When taken for a long time there are occasionally exhibited symptoms without any increase in the use of the drug. This has been thought to be due to the fact that the proximate principles of the drug were not excreted by the kidneys as fast as absorbed, and that they therefore accumulated in the body. But it would seem to be more reasonable to believe that cumulative action, when existent, is due to the slow absorption and elimination of digitoxin. [G.C.C.H.]

2.—After a careful and comprehensive study of the **comparative pathology of the Jews**, Fishberg concludes: (1) The death-rates of the Jews, at all ages, are relatively and absolutely lower than those of the people among whom they live. (2) The marriage rates and birth-rates of the Jews are smaller than those of the Christians; the Jews increase in number more rapidly than non-Jews because they bring more children to maturity. (3) The Jews are less liable than their neighbors to infection from cholera, smallpox and tuberculous. (4) Syphilis and alcoholism and diseases due mainly to their poisons are comparatively rare among the Jews. (5) Diabetes is very frequent among the Jews, 25% of all the recorded cases having occurred among them. (6) All the functional neuroses and psychoses, particularly neurasthenia and hysteria, occur more frequently among Jews than among non-Jews; while all the organic nervous diseases, as tabes, general paralysis, etc., are less frequent, commensurate with the infrequency of syphilis or alcoholism, among them. The greater majority of cases of amaurotic idiocy occur in Jewish children, and among Jews insanity is 2 to 5 times more frequent than among Christians.

(7) Blindness, colorblindness, trachoma and glaucoma, also varicose veins, particularly hemorrhoids and hernias, are very frequent among Jews. (8) These peculiarities are not due to any ethnic, biostatic or racial characteristics of a purely anatomic or physiologic nature in relation to non-Jews. They have their origin in the past history of the Jews and their habits of life, and in the rareness of syphilis and alcoholism among them. (9) When the Jew commingles with his Christian neighbors and adopts their customs and habits of life he sooner or later loses his "racial characteristics," and his comparative pathology presents no special peculiarities. [O.R.]

3.—Will be abstracted when concluded.

4.—Bardes, from observation of a number of cases which come under his care, is impressed with the importance of **artificial feeding in throat diseases**, as it obviates the irritation of the throat and shortens the progress of the disease. The danger of food entering the larynx is also avoided and the physician is able to give such food and stimulant as he wishes and the food is not bolted, as it is when swallowing is painful: struggling in children is also avoided. [O.R.]

5.—Polk shows that **Christian Science** is merely a reaffirmation of the spiritual as a therapeutic agent, a variety of psychotherapeutics, related to and a part of hypnotism, and familiar to all medical men. All physicians have long recognized the state of mind of the patient as having its influence upon morbid functional processes, and all use mental suggestion. But when this is pushed into command to ignore disease, in a state of mental exaltation, and "the line of safety has been passed," the limits and the laws of suggestion as a therapeutic measure are yet to be defined. The diseases affected are functional, the neuroses, the borderlands of insanity, etc. [G.C.C.H.]

Medical News.

April 6, 1901. [Vol. LXXVIII, No. 14.]

1. Advertising in the Profession. FRANK LYDSTON.
2. Resection of the Cervical Sympathetic. HOWARD J. WILLIAMS.
3. The Question of Drainage in Appendicitis. A. M. POND.
4. New Methods in Charity, with Better Results and at Less Cost. WM. P. SPRATLING.

1.—Lydston would substitute frank and respectable **advertising** for the surreptitious methods now in vogue as the giving of commissions, through college, hospital and free clinic routes, through church, secret societies, etc. The medical profession today has no particular social, commercial, financial or political importance and cannot command legislation because of the unwritten law that its members should keep themselves in the background. It should be considered ethical for doctors to write for newspapers, etc., signed articles of a quasi-scientific character for the instruction of the public. [H.M.]

2.—Williams discusses the value of the **removal of the cervical sympathetic** for the relief of glaucoma, exophthalmic goiter and epilepsy, and cites illustrative cases. The physiologic effects of sympathectomy have suggested its application in these conditions. The results in glaucoma are relief of pain, reduction of intraocular tension, widening of the visual field, with a doubtful improvement in vision. He concludes his reasoning with regard to its application in this condition as follows: "Sympathectomy is indicated in glaucoma simplex, inflammatory glaucoma where iridectomy has failed, hemorrhagic glaucoma early in the disease; and it should be tried in absolute glaucoma with pain, in preference to enucleation. In unilateral trouble the ganglion of the corresponding side should be excised. While sympathectomy may not be curative in every case of glaucoma, the results thus far have been sufficiently satisfactory to make it a desirable procedure in this much dreaded disease." In exophthalmic goiter bilateral removal of the 3 cervical ganglia is followed by decrease of the pulse-rate, relief of pericardial pain, retraction of the eyeballs and later a diminution in the size of the tumor, results which justify its performance after medical treatment has failed. The rationale of its application, and the results obtained when performed for the relief of epilepsy, are much less substantial and do not suggest the possibility of its adoption as a surgical procedure in

this condition. As yet no harmful results have followed the operation. [J.W.M.]

3.—Pond is an earnest advocate of **nondrainage in operations for appendicitis with pus**. He thinks that in any case the peritoneum takes care of the greater portion of the septic material. This method consists in attempting to dissolve and render sterile the pus and pus-forming elements and to increase the absorptive properties of the peritoneum. This he claims to accomplish by thorough irrigation of all parts of the abdominal cavity, and afterwards filling it with hot saline solution, stimulating hepatic activity, establishing postural drainage. He mentions 6 cases in which he successfully employed this method, and believes that the maxim "when in doubt drain" will soon be revised to read "when in doubt do not drain." [J.W.M.]

4.—**Cost of maintaining the dependent classes** can be lessened and **improvement in condition** achieved in 4 ways: (1) by legal prohibition of marriage among the insane, feeble-minded and epileptic; (2) by building less imposing structures; (3) by more economical methods of maintaining the incurable, leaving more to expend on those who may be cured; (4) by giving industrial training to all capable of receiving it. [H.M.]

Bulletin of the Johns Hopkins Hospital.

March, 1901. [Vol. XII, No. 120.]

1. The Genesis of Carcinoma of the Fallopian Tube in Hyperplastic Salpingitis. E. R. LE COUNT.
2. Report upon a Case of Gonorrhoeal Endocarditis in a Patient dying in the Puerperium. NORMAN MACLEOD HARRIS and WILLIAM M. DABNEY.
3. An Experimental Study concerning the Relation which the Prostate Gland bears to the Fecundative Power of the Spermatic Fluid. GEORGE WARKEL.
4. Further Observations on Epinephrin. JOHN J. ABEL.

3.—From his experiments Walker draws the following conclusions: (1) **Removal of the anterior lobes of the prostate gland** in rats has no effect on breeding; but in a certain number it diminishes the **fecundating power**; and in a few it is destroyed entirely; (2) complete excision has a very marked effect on fecundity, reducing it to almost nil when the gland is entirely removed; (3) partial or complete removal of the prostate has no effect upon the sexual desire and capacity; (4) complete removal of the gland in the adult animal has no effect on the histological structure of the testicles. Complete removal of the prostate in the young animal has no effect upon the subsequent development of the testes. [C.S.D.]

THE PUBLIC SERVICE

Changes in the Medical Corps of the U. S. Navy, for the week ended April 6, 1901:

- SCHOFFIELD, W. K., medical director, retired from active service, April 28, upon which date he will have reached the age of 62 years; with the rank and three-fourths the sea pay of the next higher grade, under the provisions of section 11, Navy personnel law.
- PICKRELL, G., surgeon, granted sick leave for 3 months.
- BLACKWELL, E. M., assistant surgeon, detached from the Abarenda, upon reporting of relief, and ordered home and to wait orders.
- MARCOUR, R. C., assistant surgeon, detached from the Havana Naval Station and ordered to the Abarenda, via temporary duty on the Philadelphia, May 4.
- DAVIS, E., assistant surgeon, granted sick leave for 3 months.
- STOKES, C. F., surgeon, detached from the New Orleans and ordered to the Solace, upon arrival of the Solace on the Asiatic Station.—April 3.
- BRYAN, S., passed assistant surgeon, order of February 8 modified; ordered to transfer accounts to Assistant Paymaster R. Nicholson, instead of to Arms.
- WINSLOW, G. F., medical director, detached from the Boston Navy Yard, April 18, and ordered home and to wait orders—April 4.
- BOGERT, E. S., medical director, retired, ordered to the Boston Navy Yard, April 18, as relief of Medical Director G. F. Winslow.
- STITT, E. R., surgeon, commissioned lieutenant from June 7, 1900.
- PECK, A. E., assistant surgeon, appointed assistant surgeon from March 27.

Changes in the U. S. Marine-Hospital Service, for the 7 days ended April 4, 1901:

- CARMICHAEL, D. A., surgeon, relieved from duty at Honolulu, H. I., and directed to proceed to San Francisco, Cal.—March 29.
- PECKHAM, G. T., surgeon, granted 20 days additional leave of absence on account of sickness—March 30.
- HASTINGS, HILL, assistant surgeon, to proceed to Bakersfield, Cal., for special duty—April 1.
- LAVINDER, C. H., assistant surgeon, granted leave of absence for 10 days from March 26—March 27.
- WHITE, M. J., assistant surgeon, to report to Surgeon J. H. White for duty—March 29.
- BILLINGS, W. C., assistant surgeon, to proceed to San Francisco, Cal., for special temporary duty—March 29.
- CURRIE, D. H., assistant surgeon, to proceed to San Francisco, Cal., for special temporary duty—March 30.
- PRIMROSE, R. S., acting assistant surgeon, granted leave of absence for 5 days from March 30—March 29.

Changes in the Medical Corps of the U. S. Army for the week ended April 6, 1901:

- BATH, THOMAS W., acting assistant surgeon, will proceed to his home, La Harpe, Ill., for annulment of contract.
- GREGORY, VERDO B., acting assistant surgeon, will proceed to his home, Dam, Wis., for annulment of contract.
- MADARA, JAMES W., acting assistant surgeon, will proceed to his home, Lexington, Ky., for annulment of contract.
- THOMASON, Major HENRY D., surgeon, will proceed to Benicia Barracks, Cal., where he will report for temporary duty at that post during the absence of Acting Assistant Surgeon Charles Y. Brownlee. Upon the return of Acting Assistant Surgeon Brownlee to Benicia Barracks, Major Thomason, surgeon, will stand relieved from temporary duty at that post, and will proceed to San Francisco, Cal., for further orders.
- KIERSTED, HENRY, acting assistant surgeon, is granted leave for 1 month.
- COX, Captain FREDERICK W., assistant surgeon, is relieved from temporary duty at the Army general hospital, Presidio, and will report to the commanding officer, squadron 6th cavalry, for duty with that command on the Army transport Hancock, to sail for the Philippine Islands. Upon arrival at Manila, Captain Cox will report for assignment to duty.
- KENYON, Captain FRANK P., assistant surgeon, is relieved from temporary duty at the Army general hospital, Presidio, and will report to the commanding officer, battalion 7th infantry, for duty with that command on the Army transport Hancock, to sail for the Philippine Islands.
- LITTLEFIELD, Captain HENRY A., assistant surgeon, is assigned to temporary duty with troops on the Army transport Hancock, to sail March 25. Upon arrival at Manila, Captain Littlefield will report for assignment to duty.
- JACKSON, FREDERICK C., acting assistant surgeon, is granted leave for 1 month, on surgeon's certificate with permission to apply for an extension of 1 month.
- ESTERLY, MILTON T., hospital steward is relieved from further duty at the muster out camp on the military reservation of the Presidio, and will proceed to Fort Lisicum, Alaska, for duty at that post.
- BOWEN, Major WILLIAM, surgeon, recently appointed, now in San Francisco, Cal., will report for transportation to Manila, Philippine Islands, where he will report for assignment to duty.
- HORR, Captain EDWARD F., assistant surgeon, recently appointed, now on duty at Manzanillo, Cuba, will, as soon as his services can be spared by the commanding general, department of Cuba, proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
- WINTERBERRY, Captain W. HOEPFNER, assistant surgeon, recently appointed, will proceed from Fort Mason to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
- ALLEN, Captain IRA A., assistant surgeon, recently appointed, is relieved from duty at the Army and Navy General Hospital, Hot Springs, Ark., to take effect upon the expiration of the leave granted him March 26, and will then proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
- DAYWALT, Captain GEORGE W., assistant surgeon, recently appointed, now in San Francisco, Cal., will report for transportation to Manila, Philippine Islands, where he will report for assignment to duty.
- JAMES, H. M., acting assistant surgeon, leave granted March 1, is extended 1 month.
- BAILEY, Captain GUY G., assistant surgeon, recently appointed, now in San Francisco, Cal., will report for transportation to Manila, Philippine Islands, where he will report for assignment to duty.
- The following changes in the stations and duties of officers are ordered: Major GEORGE W. MATTHEWS, surgeon, is relieved from duty in the division of the Philippines, and will proceed to Fort Warren for duty, to relieve First Lieutenant FREDERICK HARTSOCK, assistant surgeon. Lieutenant HARTSOCK will proceed to San Francisco, Cal., and report for transportation to Manila, Philippine Islands, where he will report for assignment to duty.
- The following changes in the stations and duties of officers are ordered: Major HENRY C. FISHER, surgeon, is relieved from duty in the division of the Philippines, and will proceed to Jackson Barracks for duty, to relieve Major AARON H. APPEL, surgeon. Major APPEL upon being thus relieved will proceed to San Francisco, Cal., and report for transportation to Manila, Philippine Islands, where he will report for assignment to duty.
- GILCHRIST, First Lieutenant HARRY L., assistant surgeon, is relieved from duty in the division of the Philippines, and will proceed to San Francisco, Cal., and report by telegraph to the adjutant general of the Army for further orders.
- BANISTER, Major JOHN M., surgeon, leave granted March 26, is extended 10 days.

WIATE, Captain JUSTUS M., assistant surgeon, recently appointed, will upon the expiration of leave granted him March 12, proceed to San Francisco, Cal., and report for transportation to Manila, Philippine Islands, where he will report for assignment for duty.

JACKSON, Captain FREDERICK C., assistant surgeon, recently appointed, now in San Francisco, Cal., will report for transportation to Manila, Philippine Islands, where he will report for assignment to duty.

MOSELEY, Major EDWARD B., orders of February 14 which assign him to duty at Fort Sheridan are revoked.

The following changes in the stations and duties of officers are ordered: Major EDWARD B. MOSELEY, surgeon, will upon the expiration of the sick leave granted him December 8, proceed to Denver, Colo., and report to the commanding general, department of the Colorado, for duty as chief surgeon of that department, to relieve Lieutenant Colonel HENRY LIPPINCOTT, D. S. G. Lieutenant Colonel LIPPINCOTT will proceed to Governors Island, and report to the commanding general, department of the East, for duty as chief surgeon of that department.

IVES, Major FRANCIS J., surgeon, is relieved from further duty with the United States forces in China and will proceed to Fort Sheridan for duty, to relieve Major George Adair, surgeon, who upon being thus relieved will comply with the requirements of previous orders.

CONN, Captain FREDERICK A. W., assistant surgeon, recently appointed, will proceed from Philadelphia, Pa., to San Francisco, Cal., and report for transportation to Manila, Philippine Islands, where he will report for assignment to duty.

The following named officers, recently appointed, now in San Francisco, Cal., will report for transportation to Manila, Philippine Islands, where they will report for assignment to duty: Major FREDERICK MADRA, surgeon; Captain FRANCIS J. FURCELL, assistant surgeon; Captain THOMAS W. JACKSON, assistant surgeon.

HENDERSON, CLINTON F., hospital steward, now at Fort Skaguay, Alaska, will be sent to San Francisco, Cal., for assignment to duty.

LEHARDY, Julius C., acting assistant surgeon, will proceed to Fort Wood and relieve Captain Charles R. Gill, assistant surgeon, and acting assistant surgeon Adrian S. Williams. The latter will return at once to Fort Columbus for duty with the 1st battalion 7th infantry.

BYRNE, Colonel CHARLES C., is granted leave for 1 month from April 7, with permission to go beyond sea.

MUNSON, Captain EDWARD L., assistant surgeon, is relieved from further duty at Washington Barracks, and will proceed to Buffalo, N. Y., and assume charge of the exhibit of the medical department of the Army at the Pan-American Exposition to be held in the latter city.

AMERICAN MEDICINE

1321 Walnut Street

Philadelphia

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may begin at any time. Volumes begin with the first issue of April and of October.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles, will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is one dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to American-Medicine Publishing Company. Address all correspondence to 1321 Walnut Street, Philadelphia.

APRIL 20, 1901

\$4.00 PER ANNUM.

The Recrudescence of Plague everywhere is an alarming fact. In China, Cape Colony, Mauritius, Russia, and especially in India, the reports are all the same. In Peking 10,000 deaths are reported in six weeks, and in Bombay 1,770 cases with 1,293 deaths in one week. Fully 1,000 people are dying of plague every day in India. In San Francisco, there can be no longer any doubt that bubonic plague has existed for several years; the number of reported cases is about 30 for the last year with perhaps three or four times as many unreported. According to the *Journal of the American Medical Association*, during the 13 days in which the Federal Investigation Commission (Drs. Flexner, Novy, Barker) inspected the Chinese quarters, 13 deaths occurred, of which 6 were proved due to the bacillus of bubonic plague. The fact that the disease has not spread argues no security for the future, because in Calcutta for two years there was a similar mild form of the disease prevalent prior to the general outbreak. While this is going on, we should note that almost all governments, civilized and uncivilized, are devoting almost all their energies to decivilization. War and ambition and national hatreds are wildly at work to produce ruin and disease. The old fires of barbarism are relighting, masked under the specious guises of national egotism and pseudopatriotism. The enormous sums of money, almost the whole energies of all peoples, are being expended in war, luxury, and expansion. It is not accidental, it is not merely intercurrent, it is absolutely a causal nexus that unites this with the awful increase of plague. We need first a national professional unity, then an international union of all medical men, to appeal to the submerged religious and humanitarian instincts of the people of all governments to recall the world to sanity. Let us as a profession throw our united influence against war and the waste of the world's energies in ruthless ambitions which are a mockery of civilization. Disease is the certain outcome, the unvarying punishment of sin. Ours is the duty to search out and to prevent the causes of disease.

Emasculating the Anatomy Act.—We call especial attention to the letter of Professor Forbes in our present issue. Much of modern legislation seems to be motivated upon anything except the public good. All public-spirited citizens have to be on the watch for dangerous legislation by their own misrepresentatives. Here is an instance: The "amendment" of House Bill 61, which

has passed the House, will amend the most beneficent law, secured by Professor Forbes in 1883, out of existence. The change is to make it possible for "friends" to claim the dead bodies, instead of, as now, relatives only. Thus the popular prejudice against dissection (the very foundation of medical science and art) will make it impossible for our medical colleges to obtain the requisite material. The present law is perfectly just and satisfactory, harms no one, and protects the feelings of all that would really be outraged by any other wording. The physicians of Pennsylvania are not alone concerned, but they at least should send a remonstrance to their Senators at Harrisburg.

Enlistment as Soldiers, of the Insane, according to the *New Orleans Times-Democrat* is not impossible. It cites four illustrative cases of "fitful insanity." The patients were recognized at the St. Elizabeth's Hospital, in Washington, by the superintendent of the State asylum of Kentucky as men who had escaped from his asylum two years ago. It was then found that these four men after escaping had been accepted by the recruiting officer and examining surgeon of a regiment in Louisville as volunteers in the army. In the Philippines each at once developed his peculiar type of insanity and they were, of course, sent home again. The story has some elements that make it seem improbable, but, if true, it points to the need of greater care in enlisting men as to their histories, personal and medical. If the probable pensions of these four men be added to the expense of their shipment to Manila and back, detention in hospital, etc., it will be seen how costly was the lack of the foresight which should have been exercised. How many similar cases may there have been which have not been discovered?

A Change in the Methods of Teaching Physiology in Public Schools, is necessary and indeed imminent, according to many of our best educators. The present method is usually a bad mixture of bad anatomy, physiology, hygiene, and biology. As to human anatomy and physiology the younger pupils can learn little of any great value, and this little can be better learned by the biologic route at a later time in the course, say in the high school. When it comes to this time the new plan is to give the biologic teaching by laboratory methods. The day of teaching any biologic branch by textbook and didactic methods is, we trust, forever past. Moreover, in teaching hygiene, which is

at last the chief object of public school work in physiology, the practical method should be preferred. There is no reason why a short elementary course in practical bacteriology should not prove an instructive and interesting part of hygienic study in high-school work.

To Encourage the Endowment of Medical Journals, the publishing company should be incorporated and should have as its principal object the establishment of a professional organ, the profits of which shall go to its purification and perfection, and to progress in general professional concerns. We frankly state that it is our aim to make of AMERICAN MEDICINE such an endowed journal. We have already secured the promise of a small endowment of about \$100,000 upon the death of two persons now living, upon certain conditions. We ask every physician in making his will to consider seriously that the profoundest need of the profession today is a medical journal placed permanently and absolutely beyond commercial temptations and dangers. Nothing else can free us from many abuses that now cripple and disunite us. Nothing else can bring the united power of the whole profession to bear upon the problems of city, state and national legislation and sanitation. To a journal thus founded endowments may be made under the conditions desired by the giver, such, for example, as the elimination of criticised advertisements, the support of reforms, the prevention of disease, the payment of commissions to investigate and abrogate abuses, to aid good and to prevent bad legislation, etc., etc. We shall be glad to correspond concerning endowments and to consult with those having the future welfare of the profession at heart.

Hipjoint Amputation, to which unfortunately recourse must be had in some cases of traumatism, malignant and other diseases, technically considered is usually a matter of comparative ease. In some cases, however, the conditions are such that it is impossible to follow the ordinary and desirable methods of procedure, and resort must be had to various devices that do not meet the unqualified approval of the surgeon. A case of this sort is reported by DaCosta (*American Journal of the Medical Sciences*, March, 1901). The patient was a girl, aged 15 years, who suffered from an ulcerated sarcoma of the thigh from which blood oozed constantly in such quantity as to give rise to the fear of a sudden furious hemorrhage. Such was the situation of the ulcerating mass that it was necessary to take the flap from the posterior aspect of the thigh. The patient made a good operative recovery, but the involvement of the tissues by the sarcoma was so extensive that more could not be expected. The making of this posterior flap was looked upon as an unfortunate necessity, being attended by positive disadvantages—the flap being heavy and tending to tear open the wound. DaCosta states that were he obliged again to perform such an operation, he would make the flap devoid of muscle and he would use at least four button sutures to give support.

The Association of Medical Librarians is an agency of incalculable possible good to the entire medical profession of America. Its object is to encourage the for-

mation of permanent and useful public medical libraries in medical centers, and to render more efficient those already established. The *Exchange* of the Association is designed to act as a sort of literary clearing-house for all its associate members, whereby may be utilized perhaps a million volumes of books and periodicals at present wasted because no mechanism has heretofore existed to act as the intermediary of the distribution. The *Exchange* is now in active working order, under the charge of Miss M. C. Noyes, the zealous and capable Librarian of the Library of the Medical and Chirurgical Faculty of Maryland, located at 847 North Eutaw street, Baltimore, Md. The Association has already secured for its members gifts of periodicals and books which are worth many times more than the annual dues of \$5. Many of the membership-libraries also subscribe in addition \$25, and all so doing secure contributions through the *Exchange* of greater value than the contribution, although the institution is really as yet but in its infancy. Correspondence as to joining the association should be addressed to Mr. C. Perry Fisher, Library of the College of Physicians, Philadelphia. All business concerning the gift or the distribution of books and periodicals should be addressed to Miss Noyes.

“Prescribing Drugs and Medicines” is defined by Judge Elliott, of New York, as necessary to the practice of medicine. Those who do not do these things are not liable to legal damages for practising medicine without a license. So when little Irma Grossenbach died after being prayed over by the unchristian unscientist, then the unchristian unscientist was not to blame because she was not “practising medicine.” If this is to be the law and such is to be its interpretation one of two things is needed:

1. The law should be amended by some one with a grain of common sense, and made so explicit that the silliest pseudopath can understand it, that modern medicine has neither necessarily nor even generally anything to do with drug-giving.

2. Or, if medicine-prescribing is required to constitute one a legal practitioner, then a new law is demanded to the effect that those who practise pseudopathy without giving medicine are criminals. To kill a child by not giving drugs is as much criminal malpractice as to kill it by wrong drugs, or by too much drugging.

Postinfluenzal Melancholia.—There is a strange mystery about the peculiar and overwhelming depression of mind following the grip in many cases. Either in his own person or in his patients, every physician has been startled by the illogical malignancy of this psychic insult. The distressing death of Dr. William N. Guernsey last week in New York, followed close upon the suicide of a leading Brooklyn physician from the same cause. The last death was, it is said, only a few days after the physician had argued long and seriously with a patient suffering from influenzal melancholia, against the suicide he felt compelled to commit. The impulsion is, frequently, doubtless almost irresistible, and terribly insistent. One, at other times most optimistic and life-loving, will acknowledge the illogicality, even the stu-

pidity of his pessimism, and yet he overcome with the utter worthlessness of life, and even be filled with a loathing for it. We come here face to face with one of the horrid mysteries of personality, and are shocked and paralyzed to see how dependent is mental poise and control upon disease. With all our professional recognition of the serious nature of the malady, it is still true that we must attack the problem of the etiology and therapeutics of this frightful affection with the greatest scientific resolution.

The Midwife Evil.—The obstetrician often has a graver responsibility than either the medical or surgical practitioner; for he has charge of two lives at the same time instead of one; and must often decide the most serious questions in casuistry, involving the life of one individual, while directing his efforts toward saving both. While legislation is being directed toward the suppression of illegal practitioners and the enactment of laws regulating medical practice and the qualifications of students, the untrained, unskilled, unclean midwife is permitted to flourish unmolested. The fact that four cases of puerperal infection occurred within four weeks in the hands of one Italian midwife and that three of these unfortunate women died, and that recently an infant was permitted to strangle because the midwife became panic stricken, are forcible arguments against allowing these ignorant, presumptuous individuals to continue jeopardizing the lives of parturient women. Midwives will rarely give up a patient, or call in a regular practitioner until she is nearly moribund, or all chance for effectual aid has been lost. Indeed, such a mass of evidence could be collected against midwives as would convince a "Committee of husbands who can count coincidences and draw conclusions as well as a synod of accoucheurs," and might even influence a body of legislators, if properly presented before them. Midwives are indeed a relic of medieval medical barbarism and by no means a necessary evil; for it would be far better to trust these patients to trained medical students working under the immediate supervision of instructors in obstetrics—earnest, trained men—than to leave them to the mercies of these ignorant women.

A Plea for General Biologic Training in Medical Schools.—A recent discussion by Dr. Ch. Wardell Stiles of the frequent misuse of generic and specific names by physicians, and an article on the "Teaching of Bacteriology in Medical Schools," which appeared in a late journal, are indications of the feeling among more thoroughly trained physicians, especially those who have had advantages of foreign study, for the necessity of bringing into the curriculum of American medical colleges some instruction in botany and zoology.

Recent discoveries in the etiology of infectious diseases, and in the phenomena of fertilization emphasizes very strongly the need of some systematic teaching along these lines.

For a time many of our colleges offered courses in general biology preparatory to medicine, wherein students were made familiar with the nomenclature, systematic relationships and life histories of at least selected types of

lower organisms, organisms which in increasing instances are found to act as the exciting causes of infectious diseases, or through their relations as parasites to produce severe disturbances of the circulatory and nervous systems. Such instruction has, however, of late been largely replaced by courses in morphology and ecology, and the study of general biology by means of types is for the present considerably neglected.

While the crowded courses of our medical schools will not permit of special courses in zoology and botany, nor in most cases even of systematic training in bacteriology and parasitology, it is becoming more and more essential that some course should be established in which the student may be made familiar with the life phases of simple organisms.

Not every one is able to supplement his medical training by working under such masters as Leuckart or Blanchard; but there is no reason why American medical students should not receive at least some of the advantages, which are now offered only by European medical schools along the lines indicated.

Why not revive the course in general biology so largely abandoned and bring it into the medical curriculum. The wisdom of Huxley in the establishment of a general course of training of this character is more than ever apparent, and though it may have failed to meet the needs of the botanist, the zoologist, the embryologist or the morphologist and to have trespassed to too great an extent on these special domains; yet it might be made to include, in medical colleges, those subjects for which there seems at present to be no place, and to furnish a foundation of biologic facts and a sufficient knowledge of the relationships of lower organisms among themselves, and, in their developmental phases, with the higher organisms, to form a valuable introduction to many of the most interesting phenomena of clinical medicine.

The Red Blood Corpusele—the Erythrocyte.—A Shanghai correspondent of the *British Medical Journal* laments the fact that the "little physiological orphan," the red blood corpusele, is without a proper cognomen. Doubtless therefore in China, though numerically superior, circulating with its fellow the leukocyte, it feels the degradation of unappreciated importance. In consequence, the correspondent suggests the term "xanthocyte," as "expressing the yellow-red color of the corpusele and at the same time placing it on a footing of equality with the leukocyte which has for so long been treated with proper ceremony by medical authors." We would suggest that the term "erythrocyte" is sufficiently dignified and expressive, and it has assuredly been employed in this country at least quite long enough for the knowledge to have percolated even to Shanghai.

A Warning as to Certain Emergency Cases was the lesson derived from a recent experience in private practice. A patient was suspected of an attempt at suicide, and there was much doubt as to the drug which may have been taken. Naturally, the condition of the pupils was carefully and repeatedly observed, and conclusions drawn therefrom. But in this case the conclusions were, in a double sense, omissions, and were

subsequently proved erroneous, because the patient had a chronic iritis, with the irises bound to the capsules of the lenses by old adhesions. It occurs to us that such an error may have frequently occurred, or may any day lead to incorrect inferences in the practices of hospital surgeons in emergency cases generally, and even in some nervous diseases. It follows that whenever the pupillary reactions are studied the examining surgeon should be able to detect occlusion of the pupil if it exists, and should be on his guard against assumptions drawn from their nonreaction to light or darkness. Doubtless a somewhat large proportion of alcoholics have had iritis.

“**The College of Fine Forces,**” or to use its extended title, *The California Institute of Suggestive Therapeutics and College of Fine Forces*, according to local newspapers, has “found the elysium of its founder’s dreams” in Santa Barbara, California. The Dean of the College, and a Ph.D., LL.D., of course, says his institute is “established for the treatment, by suggestion, of all Human Diseases, and Functional Disorders,” and that “instruction will be given to Physicians and Students, with practical work in Psycho-Therapeutics.” He cures astigmatism by hypnosis, although “formerly it was believed by the most skilled oculists [*sic!*] that the only relief was the use of properly selected glasses.” What a pity it is that as a people we are fast losing our sense of humor. If Mark Twain should live a few years longer he would hardly be able to find an appreciative public. Fun has no effect either upon the fool, the fooler, or the fanatic.

Pierie Acid as a Local Remedy in Affections of the Skin.—During the last two or three years many writers have testified to the value of pierie acid as an anti-septic, sedative and keratoplastic agent in various inflammatory affections of the skin. It has proved especially valuable in superficial burns, acute eczema and herpes zoster. The strength of the solution employed is usually 1%. Compresses are wrung out of this, applied to the part, covered with a thick layer of cotton, and retained by a gauze bandage. Redressing is not necessary for two or three days. For a few minutes there is some smarting, but this soon gives way to a sense of relief. The advantages claimed for this treatment in burns are simplicity, painlessness, rapidity of healing, minimum of suppuration, and a smoother cicatrix than is obtained with other methods. It should not be employed in old, deep or suppurating burns. Like certain other local remedies, pierie acid seems capable in some instances of causing a generalized cutaneous eruption, as in a case reported by Aehard and Clere (*Gaz. Hebdomadaire de Med. et de Chirurg.*, October 11, 1900) in which the application of the acid to a small burn on the face induced a universal scarlatiniform and vesicular eruption with edema and well-marked eosinophilia.

The New Cancer Parasite.—It has been the misfortune of editors in all centuries to criticize, at times wrongly but according to their light, those who rise up and proclaim their discovery of some great new thing—

some boon to mankind or some shattering blow to his cherished convictions. Still it is not clear that even such eriticism has ever obliterated the truth and it may be as well that they should continue. Dr. Gaylord, of Buffalo, whose discovery of the parasite of cancer has been so bravely heralded abroad by the daily papers, presented the results of his work with his preparation before the Johns Hopkins Hospital Medical Society April 15.

Parasites were practically constantly found in cancers and could be observed under the microscope to pass through a cycle of development, many of the forms of which could be found in scrapings from the tumor. Of these the youngest form resembled a coccus—then came a larger form like an oil droplet, but not soluble in ether and not stained by osmic acid—then a form indistinguishable from a polymorphous clear leukocyte—finally one seen only post mortem forming the spore sac and difficult to distinguish from an infected epithelial cell. In this cycle the young forms are said to arise in the spore sac or perhaps to begin in the leukocyte-like stage as granules which grow larger in the next stage. The first two stages show an evidence of the presence of a nucleus except in taking a general stain with anilin dyes; the third has a well defined nucleus like a leukocyte, and protoplasmic granules, and the spore sac has a nucleus or the remains of one—an unusual phenomenon in the sporozoa to which group these organisms are referred and in which the nucleus of the mother-cell goes to form the nucleus of the spores. Here however the spores apparently arise in the protoplasm, perhaps in the third stage in the presence of a well formed nucleus, or in the fourth or spore-sac stage, leaving the disintegrating nucleus quite visible. Such variations from the analogies of related organisms require at least a zoological explanation.

The results of inoculation varied; in most cases peculiar changes not of the nature of tumor-formations were found in the tissues, explained as the result of overwhelming the animal with the organism. In one or two animals tumor-like formations appeared, but the most definite of these had been inoculated, not with the cancer parasites, but with a yeast. Nevertheless it was thought not to have been infected with the yeast but rather to have been accidentally infected afterward with the cancer parasite.

These bodies which are identical with “Plummer’s bodies” and Russell’s “fuchsin bodies” are also found in other tumors of the most various kinds; indeed it occasions no surprise to find them in any sort of other lesion the etiology of which is obscure—syphilis, the various exanthemata, Hodgkin’s disease, primitive splenomegaly, etc., etc. This might seem to detract from their character for specificity in cancer, were it not explained that all these other diseases of which we do not know the cause are the result of a protozoan infection.

Thus we have an “organism” occurring indiscriminately in cancer and in the most various other conditions (the different species characteristic of each disease to be distinguished at a later date), said to be culturable or at least to change its form in a culture medium, passing through a cycle of development which departs in

many respects from that of analogous organisms, producing an inoculation into animals' various lesions, but not as yet definite tumors in any convincing numbers.

Taken all in all, although there is no doubt of the occurrence of peculiar cell-inclusions in carcinoma, the resemblance of the various stages of this parasite to other familiar anatomic elements, the anomalies of their cycles, the indiscriminate distribution of the parasites, and the results of the inoculation, lead us to the view that while possibly the cause of cancer is laid before us it is not convincingly proved.

Home Study for School-children has most wisely, as we believe, been prohibited by the legislature of California. To test the wisdom of the prohibition, experiments were conducted in three San Francisco schools, and in all cases the teachers were satisfied that the work of the no-home-study classes and their percentages were equal or superior to that of the classes in which home-study was kept up. Improved deportment was also noticed. Upon the celebration of the conclusion of her fiftieth year as a teacher in the Philadelphia public schools, Miss Anna Lyle said that nowadays "we have too many studies, and give too much attention to the higher branches." Is there any physician who has not, almost daily, little patients brought to him whose health has been injured or positively broken by school-studies and overpressure? We do not say it is the teacher's fault, and sometimes it is not directly due to the great grinding system, but to be charged to parental pride or to the pupil's ambition. But it is at least all permitted or made possible by the school system. Before all other things the health of the child and his normal physical development is to be assured. All education that forgets that is false education, and there can be little doubt that our pedagogs have often come far too near to forgetting it.

Cross-education is the name given by Professor Scripture of Yale to the results upon the organs of the opposite side of the body from exercise of a limb or organ. The simplest instance is that a gain of 70% in strength of the right hand from exercising it alone secures a gain of 50% in the unexercised left hand. The law holds not only as regards strength but also in other qualities. The fact helps to explain why in right-handed people, for instance, the left retains so much strength and expertness. The question also arises if other organs than corresponding ones may not be influenced, for example, the left foot by means of exercise of the right hand. (Why are right-handed soldiers required to step off with the left foot first?) Finally the development in the defective classes of mental and moral characteristics by systematized physical instruction which teaches order, rhythm, accuracy, judgment, etc., is explained and put upon a rational basis. The claims of the manual training advocates are justified and made clear. The experiments at the Elmira Reformatory thus elicit the greatest interest. How far it may be possible to educate into something like normality the weak-minded, criminally inclined, and even the idiotic, becomes an important study. Professor Scripture calls this "the principle of character-building by motor activity."

Marriage of the Unfit.—In a recent number of *Lestie's Weekly*, Bishop Doane had contended that in order to suppress vice in our cities conscience must be appealed to, offers made of the means of grace, hating the sin and loving the sinner, and behind all, the patience of God. In reply Dr. William Lee Howard, of Baltimore, emphasizes the role played in the continuance and increase of vice by marriage of the unfit, about which the Church has been too little concerned. It is, he rightly says, by preventing the propagation of the vicious, that we shall stop vice, not by reclaiming them; and such prevention can be best effected by forbidding marriage of the diseased, alcoholics, criminals, the semi-insane, the defectives, etc. We think this is true, and just because it is true we hesitate to mention a modifying factor, fearing it may serve to prevent the acceptance by some of the greater truth. Nevertheless it is a lesser truth that stringency in the preventive measure rightly urged by Dr. Howard would undoubtedly to some extent increase prostitution and illegitimacy. The thing to be aimed at is the application of the known laws of biology and stirpiculture to human social life. In enacting our laws not the Church alone, but all institutions and professions have been guilty of indifference to and ignorance of this duty is beyond dispute.

The Journal of Hygiene, the new quarterly periodical edited by Drs. G. H. F. Nuttall, John Haldane and Arthur Newsholme, and issued by the Cambridge (England) University Press, nobly illustrates the scientific spirit of its founders. It is designed to serve as the medium of publication of original work on which all genuine hygiene is based. We commend it in every way and trust it may secure the professional support it deserves.

The Success of American Medicine, and of the ideals it strives to realize, depends upon the efforts and zeal of its founders, stockholders and subscribers. So far there is only the possibility and the probability of success. So far only the opportunity is presented. Here is the well-planned, and as we believe, the perfectly builded machine, awaiting only the energy, the living steam, of professional life and cooperation. When this shall fill and drive it, a great mechanism will have been created to help on our professional progress and unification. (It comes practically to this, of securing for us new subscribers and endowment.) This is your journal, and it is dependent upon your help. For the sake of its future, and also for the interest of the subscribers, our *Life-endowment* offer is the best of the several propositions made. We beg you to commend it to your friends. We trust that every present subscriber will secure for us three, two, or at least one, additional name, according to one of the offers made, within the next month. This would more than place AMERICAN MEDICINE on a self-supporting basis. Commercial medical journals do not require looking after. The more genuinely professional our journals seek to become the more spontaneous and insistent must be the help of every physician who loves his guild, and its function in the world's life.

BOOK REVIEWS

Diseases of the Nose and Throat.—By D. BRADEN KYLE, M.D., Clinical Professor of Laryngology and Rhinology, Jefferson Medical College, Philadelphia; Consulting Laryngologist, Rhinologist, and Otologist, St. Agnes' Hospital. Second Edition, Revised. Octavo, 646 pages; over 150 illustrations and 6 lithographic plates. Philadelphia and London: W. B. Saunders & Co., 1901. Cloth, \$4.00 net.

Anyone who has carefully perused this work cannot be otherwise than impressed with the thought that the author has mastered his subject and has set it forth in this book in such a way that his views of the subject matter may be understood by the student or general practitioner and at the same time be sufficiently thorough and complete for the specialist. Dr. Kyle's vast clinical experience in his specialty gives him the necessary confidence and makes his writings have the ring of authority about them.

One would gather that it was the author's object to lay particular stress upon the pathology of the disease under consideration. We believe that is as it should be, especially when accompanied by colored illustrations of sections which so clearly show the existing conditions as seen through a microscope. The cuts are mostly original and illustrative of the points made, and are one of the best features of the work, and show a great breadth of knowledge and skill in the author as a pathologist. It is our opinion, however, that looking at it from the standpoint of the average man who needs a work of this class that the author has given too much space to histologic pathology, as comparatively few physicians now practicing can appreciate what Dr. Kyle sees through his microscope. They must have his trained eye to do that. The classification is systematic and complete and leaves nothing to be desired in that direction.

A Text-book of the Diseases of Women. By HENRY J. GARRIGUES, A.M., M.D., Gynecologist to St. Mark's Hospital in New York City, etc., with 367 illustrations. Third Edition, thoroughly revised. Price, \$4.50 net in cloth, and \$5.50 net in sheep or half morocco. Philadelphia: W. B. Saunders & Co., 1900.

The appearance of a third edition of this work after so short a period of time is a measure of success indicating its substantial worth. In the preface to the first edition Dr. Garrigues stated that he had endeavored to make his work a practical one. How well he succeeded is evident by the continued demand for it. The material is so simply arranged that we are scarcely aware that any art has been used at all. From embryology, the beginning of things, we are led on through anatomy to physiology, and so throughout the book, from general to special, each subject preparing the way for that which follows. The chapter on embryology is set forth almost completely in pictorial form and by reason of this graphic method will be correspondingly useful to the student. The space devoted to anatomy is quite large and it might be objected that such information could be secured from general works on that subject; but even the anatomy of the female pelvis must be approached from the gynecologist's viewpoint in order that its problems may be best understood. The histology of the uterine mucosa and menstrual changes therein are wisely left without dogmatic assertions. Many of the illustrations of this chapter are unusually good. The several divisions of physiology are admirably handled. Just a short, clear statement of the essential facts of each. The subject of "Etiology in General" covers only 4 pages, but is well handled and full of good ideas. Under "Treatment in General" are taken up the various procedures usually employed in this department of medical practice. The subject of curettage has not been as prominently set forth as its gravity demands, in view of the large place it has assumed in the hands of even the general practitioner. A little more than one-third of the book is devoted to preliminary and general topics, while the remainder is occupied by special chapters on each portion of the tract in order, from the vulva to the ovaries. The treatment of perineal lacerations is perhaps the weakest chapter. Its illustrations are not equal to those in other sections of the book. A subsequent chapter is added,

which treats of pelvic conditions not classified under any of the preceding heads. Finally, there is an appendix which contains an admirable reference to some methods of intestinal surgery. The operative procedures advocated throughout the book are, as a rule, well described, and a very judicious selection of methods is apparent. The pathology of the various conditions is thoroughly treated. The indexing is well done, which adds materially to the usefulness of the book. As a whole, it is a reliable guide to the subject of gynecology, and will prove a useful addition to any medical library.

The Hygiene of Transmissible Diseases: Their Causation, Modes of Dissemination and Methods of Prevention. By A. C. ABBOTT, M.D., Professor of Hygiene and Bacteriology, University of Pennsylvania. Octavo, 311 pages. Numerous illustrations. W. B. Saunders, Philadelphia, 1899. Cloth, \$2.00 net.

In this volume, just as the author says, there is no effort to present the subject of hygiene in the broad, comprehensive sense usually implied by the word. The purpose is rather, by dealing with that phase of hygiene embracing a knowledge of preventible specific diseases, to impress the student with the various factors bearing upon the suppression of such diseases. In this way the author emphasizes general sanitary importance. Much has been written on this topic that is too glitteringly general to avail the student or practitioner anything. What has been needed is specific information as to the detailed management of transmissible diseases, and to this—the weightiest aspect of hygiene—Dr. Abbott has devoted his book with conspicuous success. While not overtechnical in its method, the volume is scientific enough to satisfy the most exacting, and it carries the student as far as the present state of our sanitary knowledge permits. The book is thoroughly characteristic of the author in its clearness of statement, its thoroughness of method and its soundness of teaching throughout. It certainly deserves to be widely and carefully read by both student and practitioner.

Retinoscopy (or Shadow Test) in the Determination of Refraction at one Meter Distance, with the Plane Mirror. By JAMES THORNTON, A.M., M.D., author of "Refraction and How to Refract," Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine, etc. Fourth edition, revised and enlarged; 51 illustrations. Philadelphia: P. Blakiston's Son & Co.

That this volume has reached a fourth edition in so short a time and is demanded in French and German, speaks for itself. One element of its popularity is the author's clearness in presenting his subject, making it possible to acquire this invaluable method of refraction without further instruction. New illustrations and other additions give the volume increased value.

Diet and Food.—Third edition. By Alexander Haig, M.A., M.D., F.R.C.P. Philadelphia: P. Blakiston's Son & Co. 1901. Price, \$1.00.

In the third edition of this monograph, the author further emphasizes his well-known conviction that most organic disease is the result of excessive uric acid and the poisonous xanthins, derived from improper alimentation. The essence of the work is a plea for a "diet free from all animal flesh, tea coffee, and similar alkaloid-containing vegetable substances."

A Laboratory Guide in Elementary Bacteriology.—By William Dodge Frost, instructor in bacteriology, University of Wisconsin. Illustrated; 1901. Published by the author. Madison, Wis.

This work, as its name implies, is designed to aid the student of this subject in classifying and preserving the results of his laboratory experiments. It is an octavo volume of 205 pages. Only the alternate pages, however, are printed leaving the others for notes. The paper is of excellent quality permitting the use of ink in note taking. It sets forth a model laboratory technique for each procedure in bacteriology. The adoption of such a systematic plan in all our teaching laboratories would soon turn out a body of trained observers to "leaven the whole lump" of the medical profession.

AMERICAN NEWS AND NOTES

GENERAL.

Pneumonia in the Klondike is reported as very prevalent and a number of deaths have occurred.

Plague.—Rio de Janeiro city and port were declared, on March 9, free from plague, no case having occurred there for 20 days.

Ration for Philippine Soldiers.—It is reported that pickled pigs' feet and tomatoes are to be added to the list of rations for the soldiers in the Philippines.

Nonimmunes from Cuba.—Assistant Secretary Spaulding, of the Treasury Department, has issued a circular extending until May 1, 1901, the provisions of department circulars issued March 22, 1901, permitting travel from Cuba to nonimmunes after their inspection at port of departure and necessary disinfection of effects, including northern ports.

Yellow Fever.—The news of the appearance of a case of yellow fever at Port Simon, Costa Rica, has been cabled to the Surgeon of the Marine Hospital. A suspected case of yellow fever was removed from the transport Rawlins at Key West en route from Havana to New York. Two cases of yellow fever and 1 death are reported April 10 at Port Royal at the entrance to Kingston Harbor, Jamaica.

Tuberculosis in Hawaiian Islands.—In view of the decision of the authorities of Honolulu and the Hawaiian Islands that the increased death-rate from tuberculosis during the past year is due to the importation of the disease a bill has been framed and will be brought before the Territorial Legislature prohibiting the landing at any port in those islands of any person suffering from tuberculosis or any other contagious disease. Any person who aids or abets the landing of such persons will be considered guilty of misdemeanor.

Mosquito Theory Accepted by Surgeon-General Sternberg.—Surgeon-General Sternberg has just given his approval, without reservation, to the report of the Special Medical Board, composed of Surgeons Reed, Carroll, and Agramonte, upon the "Etiology of Yellow Fever," in which the conclusion was reached that the mosquito is responsible for the transmission of this disease. Moreover, the medical department of the army is moving energetically to put into practical operation the methods of treatment to prevent yellow fever, involving a radical reversal of existing methods.

A Petition from Porto Rico.—Senor Santiago Iglesias, delegate of the Federation of Labor of Porto Rico, brings word of a terrible condition of affairs among the workingmen of that place. He is the bearer of a petition having 6,000 signatures in which the Porto Ricans say: "Misery, with all its horrible consequences, is spreading in our homes with wonderful rapidity. It has already reached such an extreme that many workers are starving to death, while others, who have not the courage to see their mothers, wives, sisters and children perish by hunger, commit suicide by drowning themselves in the rivers or hanging themselves from branches of trees."

Obituary.—HENRY MANCHESTER of Pittsburg, April 8, aged 75.—WILLIAM JAY YOUMANS, for many years editor of *Popular Science Monthly*, at Mt. Vernon, N. Y., aged 62.—FRANK WAYLAND ABBOTT of Buffalo, April 9.—A. E. HERNERT of Quebec, April 7.—SETH W. WEBB of Houlton, Maine, April 5, aged 35.—J. C. HOFFER at Columbia, Pa., March 22.—REUBEN B. NISBET of Eatonton, Ga., April 11, aged 71.—J. P. DILLARD of Martinsville, Va., April 10.—EDWIN C. BALDWIN at Dover, N. J., March 25, aged 87.—JOHN POWELL HUNTER of West Chester, Pa., March 27, aged 35.—JOHN S. SCOFIELD of Hillsboro, Texas, March 23, aged 74.—JOSEPH S. MCCORD of Iowa City, Iowa, March 30, aged 51.—HENRY C. MARTIN of Harper, Kansas, March 26, aged 70.—CHARLES E. COATES of Abilene, Texas, March 25, aged 73.—JOHN M. GLASGOW of Omaha, Neb., March 30, aged 65.—HENRY A. ROBERTS of Wakefield Corner, N. H., January 19, aged 35.—E. F. MEACHEM of Nashville, Tenn., March 24, aged 49.—THOMAS COUTURIER ROBERTSON of Columbia, S. C., March 21.—JAMES DATON GALLAGHER of Steubenville, Ohio, April 1, aged 27.—JAMES R. NELAN of Pittsburg, Pa., March 28, aged 50.—WILLIAM McCLELLAND of Denver, Colorado, April 13, aged 80. He was the first physician to make a study of the climatic influences of the mountain regions upon pulmonary diseases.—H. M. HOUSER of New Albany, Miss., April 9.—THOMAS A. O'CALLAGHAN of Worcester, Mass., April 13, aged 45.—GEORGE W. CARMAN of Brooklyn, April 11, aged 50.—CHARLES KELLY GARDINER of Huntingdon, W. Va., April 14.—DR. BLOCK, of San Francisco, in Berlin, Germany, April 12.—GEORGE W. SHILLING of Sharon, Pa., April 12, aged 58.—N. D. GADDY of Seymour, Ind., April 12, aged 72.—J. ARCHER WATSON of Montreal, Canada, April 11, aged 45.—H. B. BELL of Athens, Ga., April 12.—JOHN A. MEYERS in San Francisco, April 11, aged 50.—C. G. ADAMS of Portland, Me., April 12, aged 70.

EASTERN STATES.

Insane Hospital.—In 2 months the new hospital for the insane at Bangor, Me., will be furnished and in readiness to receive patients. About 150 patients will be transferred from Augusta to the new hospital. After these patients are gone the old buildings at Augusta will be thoroughly renovated.

Forest Preservation.—A Society for the Protection of New Hampshire Forests has been organizing and is endeavoring to obtain the support and cooperation of lumbermen, railroad authorities, hotel owners, farmers, manufacturers, summer residents and State officials, that they may work together to conserve their own rights without injury to any.

Veterinary School to be Closed.—Harvard University, on finding that no satisfactory work could be carried on in its Veterinary department without endowment, and that such is not forthcoming, has decided to close this department. Some who have gone there to study and who expected to have the benefit of clinical work feel themselves wronged. The department will be continued until those who are in it have been graduated. Surprise is expressed that some one has not suitably endowed this department.

NEW YORK.

Gastrectomy for cancer of the stomach was performed on a citizen of Newark, 59 years of age, on March 30 last. He died April 12 from weakness of the heart.

To Parole Prisoners.—A bill has been passed providing for the creation of a board of parole, by which prisoners confined in the State prisons and in the Eastern Reformatory at Elmira may be paroled.

Roof-gardens for Public Schools.—In connection with the vacation schools of New York there is a proposition to teach the children practical gardening, and for this end to remodel some of the roofs of the public school buildings into gardens.

Home for Incurables.—The Trustees of Albany, N. Y., Home for Incurables have secured a bill authorizing the city to grant a license to "Albany Home for Incurables" to erect such buildings upon a certain property described as are adapted for their purpose.

Inebriates' Home.—A bill to incorporate the Inebriates' Home for New York City has been introduced by Senator Trainor. The bill provides that the city shall maintain the home by the payment of a sum not exceeding 5% of the annual revenues of the liquor-tax law, for the support of habitual inebriates committed to it by any magistrate. The home may receive private patients at private rates, but the cost of their care is not to be charged to the city.

Vaccination.—The Assistant Sanitary Superintendent of New York, F. H. Dillingham, laments the indifference of the public to the smallpox situation and fears that unless people awake to a realizing sense of the importance of vaccination the smallpox will continue through the summer, as official reports show that there has been no actual advance made in decreasing the number of cases. The totals of cases reported to the Health Department for the various months since the discovery of the disease are: November, 35; December, 68; January, 78; February, 142; March, 194; April (to date), 73. Three deaths were reported for the period from November 5 to January 1. The records for the succeeding months show 8 deaths in January, 34 deaths in February, 37 deaths in March, and 7 deaths for April to date. In the Girls' High School in Brooklyn an order issued very recently by the principal that no pupil who failed to show a certificate of having been vaccinated within the last year would be allowed to attend the school, was met by such a storm of excited protest on the part of the 2,000 pupils, in many cases upheld by their parents, that the order was revoked.

PHILADELPHIA, PENNSYLVANIA, ETC.

Marriage of First Cousins will be illegal in the State of Pennsylvania on and after January 1, 1901, and all such marriages contracted in the State after that date will be declared void.

Crime and Capital Punishment.—In the House at Harrisburg a resolution was offered on April 8 appointing a commission to inquire into the subject of capital punishment, with a view to ascertaining its effect on the repression of crime.

Communion Cups.—The Huntingdon County Medical Society, at a late meeting, passed a resolution recommending all the churches of the different denominations in the county to use the individual communion cup, for sanitary reasons.

A Strange Endemic which puzzles the physicians, is reported as scourging the town of North Bellevue, Westmoreland county, Pa. The disease is marked by vomiting and yellowing of the skin and after spasms of hiccoughs and coma the first patient died; 6 other victims within a radius of 100 yards are similarly affected and no hopes are entertained of their recovery. The public schools have been closed in consequence and active measures are afoot to fathom the causation.

Vital Statistics of Philadelphia for the week ended April 13, 1901:

	Cases.	Deaths.
Total mortality		469
Apoplexy 13, paralysis 7,		20
Brain—congestion 2, disease 2, dropsy of, 2, hemorrhage 1, inflammation 20, softening 1, sarcoma of, 2, surgical shock 1		31
Convulsions 14, puerperal 1		15
Diphtheria	59	6
Heart—diseases of, 29, fatty degeneration 1, neuralgia 4		34
Kidneys—Bright's disease 12, uremia 11, inflammation 24, dropsy 1, diabetes 2		50
Inanition 10, debility 5, teething 2		17
Liver—cirrhosis 8, carcinoma 1		9
Lungs—congestion 4, inflammation 68, edema 21, pleurisy 2, tuberculosis 44		139
Scarlet fever	77	6
Typhoid fever	37	5
Old age		23
Stomach and bowels—inflammation 11, peritonitis 9, indigestion 1, carcinoma 6, dysentery 3, diarrhea 2, obstruction 1		33
Marasmus		18
Abortion 1, alcoholism 1, asthma 3, atheroma 2, burns and scalds 4, carcinoma of tongue 1, carcinoma of uterus 1, casualties 7, cellulitis 1, childbirth 1, membranous croup, 1, cyanosis 5, spinal disease 8, drowned 1, erysipelas 1, puerperal fever 1, goiter 1, senile gangrene 1, hernia 2, influenza 4, cystitis 1, bronchitis 3, laryngitis 1, jaundice 1, rheumatism 3, septicemia 3, suffocation 1, suicide 8, coroner's case 2, whooping cough 6.		

SOUTHERN STATES.

Cigaret Law.—At the twenty-seventh session of the Texas Legislature a bill was passed prohibiting the sale of cigars in that State.

The Medical College of South Carolina has graduated 2 young women physicians, the first in the history of the medical profession of that State.

New Hospital for Atlanta.—On April 2, a board of trustees was elected and the plan of work outlined for the Presbyterian Hospital, to be erected in Atlanta. The proposed hospital will be nonsectarian, and will be modeled after similar institutions conducted by the Presbyterian Church in New York, Philadelphia and Baltimore.

The Tennessee State Board of Medical Examiners, at a meeting held April 4, urged the passage of the bill now before the State Legislature, which provides that no one shall practise medicine in the State until he has passed an examination before the State Board of Medical Examiners. Reports show that there are 2,120 medical students in Tennessee.

WESTERN STATES.

Christian Scientists are not practising medicine while engaged in their calling, therefore are not amenable to medical regulations, was maintained by a recent decision of the Supreme Court of Minnesota.

The Colorado Medical Library Association at its eighth annual meeting, held recently, elected Dr. C. D. Spivak president and Dr. Edward Jackson secretary-treasurer. The Denver and Arapahoe Medical Society donated to the association the sum of \$150.

The Samaritan Hospital of Chicago keeps a record of each case treated and gives each patient, on leaving the institution, a metal tag bearing the inscription: "In case of accident telephone this number to Samaritan Hospital, Chicago. They will notify my friends and give you instructions."

Pure Food Legislation.—A new law to be strictly enforced in the State of Washington provides that all compound articles must have their ingredients designated on their labels. Retailers are authorized to demand from wholesalers a guarantee of the purity of each article.

CANADA.

Cremation.—Sir William Macdonald is interested in a movement to educate the poorer classes of Montreal to a less ostentatious display in disposing of the dead. He is the originator of a proposal to endow the crematory with \$50,000, or an amount to enable their making incinerations at a nominal price, say \$5.00, or in deserving cases free. He is not likely to win French Canadians to sanction this method, as their Church does not approve it, but he depends on the force of example to lessen the extravagance of their ceremonials.

FOREIGN NEWS AND NOTES

GENERAL.

State Lunatic Asylums in India.—The Secretary of State for India has sanctioned a plan for 5 large central asylums for the insane in India where hitherto there has been only a number of small asylums under the care of the local civil surgeons. It is hoped that men skilled in psychologic medicine will have the superintendence of these asylums and the special rates of pay offered, indicate that it is the intention of the government to attract such candidates. The salaries will range from 600 to 1400 rupees per month—about 50% higher than full regimental pay in the Indian Medical Service, with a house provided and leave to conduct a private consulting practice. The appointments which are open to the officers of the Indian Medical Service are not restricted to them.

Obituary.—RICHARD MARTIN DANE of Millbrook, Southampton, England, March 27, aged 87.—JOHN LAWRENCE GROWSE, at Bildeston, England, March 30, aged 69.—THOMAS MORRIS of Hayes, Kent, March 27, aged 82.—WILLIAM SKENE of Buckley, Cheshire, March 24, aged 55.—WILLIAM RICHARD ROGERS of London, aged 84.—ARTHUR K. F. McCUTCHEON of Dublin, March 27, aged 43.—RICHARD JEFFREYS OWEN of Slandover, England, aged 42.—DR. OLAVIDE of Madrid, a distinguished dermatologist. RUFINO FERRANDO FENOLL, of the University of Valencia aged 70.—ALBERT GAMBA of Turin. ALBRUCHT BERGER of Munich, aged 54.—JOSEF V. FODOR of Budapest, aged 58.—JOHN DUDGEON of Glasgow, Scotland, at Peking, China.—LEO E. F. NELL of Sydney, Australia.

GREAT BRITAIN.

Vaccination Fees.—At a meeting of the Chippenham Board of Guardians lately, J. P. Martin declined by letter the appointment of public vaccinator for that parish at the fee of 5 shillings per case.

Smallpox in Glasgow.—During the week ended March 29, there were 54 new cases reported, 104 patients were dismissed recovered, and 11 deaths were recorded. Over 319 patients remained under treatment.

Sir William MacCormac, for many years consulting surgeon to the Italian Hospital in London, has been promoted by the King of Italy to the degree of Grand Officer of the Order of the Crown of that country. This is the second grade of that order, the first being the Grand Cordon.

Annuities for the Blind.—Under the will of Dr. George Seale, who retired from practice in 1872 on account of blindness, the Corporation of Portsmouth, England, has received recently a sum of £20,000 to provide annuities for the blind. The applicants must be necessitous and over 30 years of age; the amount of each annuity is fixed at £30.

CONTINENTAL EUROPE.

Influenza in Turkey.—Influenza was quite unknown to the physicians of Turkey before 1890. Since that time the disease has raged epidemically in spring, summer, fall and winter.

X-Ray Burn.—In a suit before the Paris lower court recently a physician was fined 5000 francs damages and expenses on account of a burn caused by 3 long x-ray exposures in the course of 3 weeks.

The Department of Public Instruction in France has made an official reaffirmation that the diploma of a technical school is not an open sesame to the university courses of law, literature or medicine.

The Vrach.—It is announced that this well-known Russian medical journal, according to the expressed wish of Professor Manassein, its recently-deceased editor, will close its course at the end of the current year.

A Portuguese Medical Expedition.—The Portuguese Government has appointed a Commission to study the sleeping sickness in the Province of Angola, and also to investigate the etiology and transmission of malaria.

Malaria.—A commission of 5 has been appointed by the *Sociedade das Sciencias Medicas*, of Lisbon, to study prophylactic measures against malaria in Portugal, as that disease is said to decimate the population of that country.

German Physicians Demand Higher Pay.—The municipal physicians of Leipzig, following the example of those of Munich, have struck for higher pay and better treatment. The Munich physicians have declared themselves in sympathy with the movement.

Pasteur Monument.—A statue of Pasteur in bronze, mounted on a pedestal 8 meters high, the work of Antonin Carlès, is to be erected in the town of Dôle, Department of Jura, the birthplace of Pasteur, during the present year. He is represented in a meditative attitude; at the base of the monument Humanity is represented, holding out 2 children to Pasteur, while Science offers him a palm.

SOCIETY REPORTS

College of Physicians of Philadelphia.—A regular meeting was held April 3 with the President, Dr. W. W. KEEN, in the chair.

Dr. JAMES TYSON read a memorial of the late Dr. William Pepper.

Dr. S. ORMOND GOLDAN, of New York, was the guest of the evening, and read a paper on **Nitrous Oxid and Oxygen as a Surgical Anesthetic**; description of a new apparatus for administering these gases; report of 100 operations, the narcosis lasting half an hour and upward; remarks regarding the use of nitrous oxid as a preliminary to ether in general anesthesia. The sole effect of nitrous oxid is not to cause asphyxia, its anesthetic power being proven by the fact that it will anesthetize when oxygen is also given. The latter must be below 30%, better 10%. Anesthesia is caused in from 1 to 2 minutes. The 100 cases reported included almost all major operations, the longest being 2 hours and 40 minutes. The respirations and pulse remain practically normal. Nausea and vomiting or headache occur in some cases, but they are generally not severe. The quantity of the gases used make this the most expensive method in use. The general sentiment of the college was that the method seemed good, but that it was not applicable to hospitals where short term residents were the anesthetizers, as a specialist was needed to manipulate the apparatus.

A paper by Dr. ORVILLE HORWITZ, entitled **Hydrocele—its treatment**; summary of 338 operations; description of a new method by Doyen for the radical treatment of hydrocele of tunica vaginalis testis, was read by title.

Section of General Medicine.—College of Physicians of Philadelphia.—At the meeting of April 8, Dr. HARE exhibited a case of **aneurysm of the right carotid artery**. The aneurysm can be pushed about in a remarkable manner, being saccular.

Dr. J. A. SCOTT exhibited a case of **endocarditis resulting from typhoid fever**. The diagnosis was based upon the occurrence of pain, cardiac symptoms, leukocytosis, and the appearance of a murmur which persists and increases.

Dr. A. O. J. KELLY reported a case of **enlargement of the spleen and liver** accompanied by no obvious symptoms.

Dr. S. McC. HAMILL reported a case of **thoracic aneurysm** of 13 years' standing in a patient recently operated upon for an enormous intraligamentary cyst. No untoward symptoms developed because of a dilation of the ventricle.

Dr. J. M. SAILER detailed a case of **aortic regurgitation with Flin's murmur**. The cause of this murmur was discussed, the theory advanced being that it was due to a relative stenosis caused by a dilation of the ventricle.

Dr. D. J. MILTON MILLER showed specimens of a **multiple thrombosis of the innominate, external and internal jugular, and axillary veins** from a case of aortic and mitral disease.

The New York Academy of Medicine.—A stated meeting was held April 4, 1901. Papers were read on the subject, "The Duty of the Public to the Medical Profession," by D. B. St. John Roosa and W. H. Thomson.

Section on Surgery held a meeting April 8, 1901. A paper was read by J. P. Tuttle on **Cancer of the Rectum**, with Demonstration of New Methods of Examination; this was preceded by presentation of patients who had undergone successful operations for cancer.

Section on Otolaryngology held a meeting April 10, 1901. Presentation of cases was followed by the presentation of specimens of tuberculosis of the ear with the history of the case by H. L. Swain and a paper on **Tinnitus Aurium** by Thos. J. Harris and one on **Tympanic Vertigo**, due to obstruction in the eustachian tube, by Wm. P. Brandegee.

New York Academy of Medicine.—At a meeting on April 4, Dr. D. B. St. JOHN ROOSA introduced a discussion upon the **duty of the public to the medical profession**. He began by referring to an article which had appeared in one of the lay press ridiculing a proposal that the State should endow a chair of electrical engineering. The writer of the article referred to objected to the proposal on the ground that it savored too much of paternalism, and incidentally he remarked that medicine, horseshoeing and landscape painting might be regarded as equally desirable subjects for the patronage of the State. This, remarked Dr. Roosa, was in keeping with what they must always expect from the laity as to the value of medical education. He was not there, however, to make any argument for the endowment of medicine by the State. He wanted rather to show what the public as individuals owed to medicine. Every provision should be made in order that the education of medical men should be of the highest order. The national Government made adequate provision for the education of medical officers who were to look after the well-being of the army and navy. Christian scientists and osteopaths had no chance of obtaining recognition there. Few State governments were equally careful to see that aspirants to the medical profession were subjected to a proper examination. The theory seemed to be that any one might be tried as a doctor, just as if

he were a mechanic or a tradesman. Now, it required a large investment of money, and a considerable amount of time, to make a qualified doctor.

Formerly it was sufficient, after a young man had got a very ordinary education, for him to spend a few years in **desultory work with a medical practitioner**. Then he was supposed to be qualified to practise. Now it was necessary for him to go through a 4 years' course at one of the universities, and then to spend a few more years in attendance at the hospitals. The general result was that a medical graduate had to reach the age of 30 or thereabouts before he began to earn a moderate living. For his hospital work the young medical man must look for reward to what he might acquire in the way of renown and to the satisfaction of his conscience. Dr. Roosa then asked what the medical profession had achieved to deserve the confidence of the public, and by way of answer quoted the articles by Dr. Osler and Dr. Keen on the progress of medicine and surgery during the last century. All things considered, he contended, the public ought to take a greater interest in the progress of medical science and extend a more generous treatment to the medical profession, with a view to the bringing about of the millennium spoken of by one of the prophets when the people should no longer have to complain that they were sick, and when human ingenuity and skill, foresight and care should be used to the end that no accidents should occur and no epidemics should prevail, and human beings should not die prematurely.

Dr. WILLIAM H. THOMSON said there were some reasons why the public failed to appreciate the services of the medical profession. First, there was the conception of the profession as a trade. That it was anything else than the means of getting a livelihood was seldom thought of. Besides there existed the impression that the medical profession was a particularly close corporation, that it was very jealous of all competitors, and that it was hostile to all innovation. Even the code, which was designed to regulate their conduct to one another and to the public, was looked upon as purely a trades-union protective measure. As a consequence the profession was powerless to do anything for the exposure of quackery. If they moved at all in this direction, it was regarded as persecution, and the result was to give new life to the persons or bodies proceeded against. Physicians were not regarded as having a **monopoly of knowledge** in regard to disease. As life was a mystery, so was disease, and the door was opened to the believers in occult influences, the disciples of Mrs. Eddy, the osteopaths and others. Apart from these classes, there would be found to be a widely spread belief that doctors did not know so much more than other people. They lived in a world of male and female eritics. These evils were the result of ignorance, and nothing but ignorance.

The most intelligent man in town was likely to come in with his **diagnosis already made**: "Doctor, there is something wrong with my liver," or the like. Very few even among the intelligent classes had any reasonable conception of matters pertaining to medicine. It did not matter that all the professional men of America and Europe, as well as of some outlying countries like Japan, were working with all the appliances of modern science to discover the causes of disease and the possible remedies, nor yet that the discoveries made in the last century in the domains of medicine and surgery had done more as regarded the welfare of the human race than the inventions in any other branch of science, say the steam engine or the telegraph. Theories and speculations were swept aside with contempt and only strict scientific results paid heed to in the investigations of medical men of the present day. There was no living man who knew one-fourth of what was known by the profession as a whole about the human body and disease. Physicians knew that they were not capable of dealing with every class of disease, and this surely showed the absurdity of ignoramuses claiming to be able to treat any disease. The public would not put inexperienced men in charge of a locomotive or a dynamo; yet so great was its ignorance in regard to the human body and disease that it did not hesitate to trust their ailments to persons who had had no training for the practice of medicine. He thought it was the duty of the profession to take concerted action to counteract this great evil. One means by which they could do this was by teaching anatomy and physiology in the high schools devoted to both sexes. Surely it was as important that people should know something about themselves as it was that they should know about grammar, *belles lettres* and the dead languages. He did not advocate the teaching of medicine as such, but only the imparting of sufficient elementary knowledge to prevent them being duped by quackery, just as they were taught enough about astronomy to make it impossible for them to place credence in astrology.

Dr. ANDREW H. SMITH remarked on the singularity of the coexistence at the beginning of the century of **2 opposing facts**—one, that the last 2 decades had witnessed an unexampled advance in the science and practice of medicine and surgery, amounting almost to a revolution, and the other, that the popular mind was daily growing more and more prone to return to old superstitions in medicine, or to invent new ones even more absurd. He suggested as a remedy for this the education of the public through the lay press and the schools, not in medicine but in the elementary facts in regard to their bodies about which there was such lamentable ignorance.

Dr. F. R. STUNGIS contended that the medical profession was itself to blame for the want of confidence the public had in

it, because even it did not attach sufficient importance to sound medical education. There were too many medical schools and too much cut-throat competition among them, which was sufficient to account for the fact that so many of them were not able to support themselves. He questioned the value of much of the gratuitous medical service. Physicians who had large clinics had not time to study their cases properly, and the public was pauperized without having its ailments adequately treated.

Dr. A. JACOBI said the existence of jealousies in the profession and the sight commonly seen of experts swearing against one another in courts of law had something to do with the want of confidence shown by the public. No doubt it was to be desired that the public should be educated, but he objected to the method by which the lay press usually wished to do it—by sending reporters to interview medical men and wanting them to tell all they knew about a subject off-hand.

The Chairman (Dr. GEORGE L. PEABODY) said he thought the public got a great deal more from the medical profession than it showed that it wanted or cared to pay for. It was more to the interest of the public than the profession that quackery should be stamped out, but there was always the danger that if doctors moved in matters of this kind it was thought it was because they were concerned about their own interests. Were it not for the harm done the public the Christian scientists and other bodies of the same sort might be looked on with tolerance as people who added to the gaiety of nations.

Dr. ROOSA, in replying on the debate, said that although there might be objectionable medical men here and there, there was no class that more conscientiously did its work, and he believed the public would be willing to give them more support if it only knew what they were doing.

New Hampshire Surgical Club.—The regular meeting was held at Concord April 9, with a good attendance of members from various parts of the State. An interesting case of fracture of the skull was reported by Dr. G. P. CONN, of Concord. Dr. FRED. B. LUND, of the Boston City Hospital, read a paper on The Surgical Treatment of Ulcer of the Stomach, with report of several cases. The report of a case of dermoid cyst, with operation and recovery, was read by Dr. S. A. TOLMAN, of Dover.

Pediatric Society of Philadelphia.—At the meeting of April 9, the guest of honor was Dr. L. EMMETT HOLT, of New York, who addressed the society on some forms of indigestion in infants and young children, with especial reference to their dietetic treatment. Dr. Holt stated that direct inheritance of indigestion is questionable. As his experience increases he is more and more impressed with the sensitiveness of infantile digestive apparatus. This is deranged as frequently by bad nursing as by bad feeding. Obstetricians in general have but little knowledge of the management of infants. If Dr. Holt is to look after the feeding of a child he wants it from the first and not at the end of a month. Infants become used to cow's milk only after a most careful training. The Walker-Gordon Laboratory milk is preferred to any other infant food. An initial formula often used is 1% fat, 6% sugar, .5 proteids. The comfort of the child is the guide to the modification to be used. Constipation should not cause alarm as it disappears when the food is made stronger. If the child is entirely comfortable the lack of gain in weight and constipation should occasion no concern.

The symptoms of indigestion belong to one of 2 groups, those where the stomach is at fault and those in which the intestines are involved. Indigestion is rarely caused by gastric dilation. The organic acids formed from the fat of high percentage milk is the most frequent cause of vomiting. In such cases milk and water instead of milk and cream must be used. Stomach washing or irrigation may be used in some cases. When mucus is causing the vomiting stomach washing is the only efficient remedy. Acute indigestion is often dangerous. A number of cases were cited. This condition may be caused by an exceedingly small quantity of cow's milk. Infection from the milk is generally said to be the cause, but other things may cause the same condition. The trouble may not lie in the milk but in the child. If there be a previous history of indigestion from the use of cow's milk do not begin it at once. An immense amount of harm may be done by nursing infants when they should not be fed in this way. Satisfactory results are not obtained from the analysis of breast milk in cases of indigestion. The correct test is the effect of the milk upon the child. Persistent indigestion with no gain in weight marks the case as hopeless and nursing should be stopped. Change in diet is often of great importance. Less milk with higher percentages and water between meals may prove a valuable expedient.

Some of Dr. Holt's conclusions were as follows: (1) The comfort of the child should be the guide as to the kind of feeding employed; (2) no mother should nurse a child that has persistent indigestion and no gain in weight. If there is a gain the indigestion may be overcome; (3) a change in diet is of great importance in cases of indigestion; (4) symptoms of inanition should be carefully studied, as they may demand the employment of a wet-nurse; (5) vomiting is generally due to too high fat percentage, hence the fat should not be increased too rapidly; (6) too much attention should not be paid to traditional opinion regarding the amount of fat and proteids in

a formula. Dr. Holt's paper was discussed by Drs. Griffith, Graham, Packard, Stengel, Miller, Westcott and Taylor.

Philadelphia County Medical Society.—A stated meeting of the society was held April 10, at which Dr. JAY F. SCHAMBERG exhibited a case of **dermographism**.

Dr. J. MADISON TAYLOR read a report of the committee on the Jay Hospital for Contagious Diseases. Attempts are being made to interest physicians in the project. Two pavilions are planned, 1 for scarlet fever and 1 for diphtheria. A third is needed for emergency cases.

Dr. JOHN B. ROBERTS read a paper on the Doctor's Fee—a plea for honorable dealing.

Dr. RICHARD F. WOODS reported the results in 212 cases of **ventrosuspension of the uterus**. They were from the practice of Drs. Penrose and Beyea and were especially valuable in that some of them dated back 8 years. Of the 212 cases, 129 were entirely cured and 53 greatly improved. Hernia had not followed in any case.

Philadelphia Pathological Society.—The first paper at the meeting of April 11 was by Dr. H. F. HARRIS on 1. **Experimental Dysentery in Dogs**. 2. **A new Method of Staining Elastic Tissue with Hematein**. Various organisms, including amebas and Bacillus dysenteriae were used. Bouillon cultures which were first employed caused no pyogenic infection. Fresh feces of cases of dysentery were used, and dysentery was induced in puppies, but not in old dogs or cats. The conclusion reached was that the ameba was the cause of dysentery.

Dr. FLEXNER said that there was no pathologic anatomy nor symptom-complex in dysentery. It is possible to separate the acute from the chronic. Shiga's bacillus has a good claim to being the cause of the former. Experiments have been unsatisfactory but there is probably a bacterial dysentery as well as that form due to the ameba. The latter may be grafted upon the acute form.

Dr. HARRIS said that amebic dysentery seemed to be a disease of cities while the so-called bloody flux was found in the country. He looks upon Shiga's bacillus with suspicion until further proof is obtained.

Drs. E. W. ROBINSON and D. J. MCCARTHY exhibited a **brain weighing 52 ounces from a child 6 years of age**. The brain was remarkable not only for its size but because of the great irregularity of the fissures. These distorted the normal lobes and marked out various new ones.

Dr. RANDLE C. ROSENBERGER reported the results of a **bacteriologic examination of clinical thermometers**. Cultures made from thermometers used in various diseases were made, and in every instance a number of colonies grew. These were found to consist of staphylococci, sarcinae, etc. Cultures made from thermometers cleaned in an antiseptic fluid were sterile. The time which elapsed from the use of the thermometer in the former set of experiments was as high as 56 days. The use of an antiseptic fluid as is done in hospitals is to be commended. If this cannot be obtained each individual should have a thermometer.

Dr. GEO. B. WOOD exhibited an **endothelioma of the cheek**.

Dr. W. E. ROBINSON exhibited a **cyclopaen monster**.

Wills' Hospital (Philadelphia) Ophthalmic Society.—At a meeting held March 25, Dr. CONRAD BERENS presented a case illustrating the secondary stage of **primary sarcoma of the iris**. The patient, a young man, who was free from any symptoms and obtainable history of syphilis or tuberculosis, first noticed the affection some 3 years previously. Imbedded in a partially degenerate and comparatively uninfamed iris-tissue were 5 irregular tumor-masses, over and through which some fine vessel ramifications could be plainly seen. The plane of the iris was pushed forward. The pupillary area, which was slightly distorted, contained some meshes of glistening lymph. The crystalline lens occupied its normal position. No view of the fundus could be obtained. Intraocular tension was increased to plus 2. There was not any ciliary tenderness.

Dr. FRANK FISHER exhibited a series of water-color sketches of several stages of a case of **embolism of the central retinal artery**. The patient, a young subject with a mitral murmur, gave the usual history of sudden blindness. Besides the characteristic eyeground of the affection, all of the main retinal blood currents, both arterial and venous, were found to be interruptedly flowing in their proper directions, the curious fact being that the venous currents were traveling with twice the rapidity of the arterial.

Dr. SCHWENK showed a man of 45 from whom he had successfully removed a piece of manganese steel from the left lens, the form of steel which was imbedded in the lens substance was but feebly attracted by the magnet, and much of the lens matter which had appeared transparent at the time of the removal of the foreign body afterwards became opaque and greatly swollen.

Dr. OLIVER exhibited a Hungarian boy of 9, from whom he had successfully removed 2 **congenitally opaque lenses** by free dissection, obtaining a corrected vision of normal in each eye. The case was of interest as showing the good effect of diametrically opposed forms of treatment in the 2 eyes, necessitated by an attack of secondary glaucoma from stoppage

of lymph flow caused by a blocking of the pupillary area. He did not consider such a complication of any great moment in the young otherwise healthy eye as it rapidly subsided under appropriate treatment without any damage to the organ. Dr. SCHWENK presented a case of congenital cataract in a white male of 30 years of age, 3 brothers being similarly affected, while 3 sisters had normal eyes.

Dr. OLIVER showed the immediate results of a Mules' operation in a case of panophthalmitis. The patient was a sailor aged 23, who had lost his eye about a year previously from gonorrhoeal infection. In less than 5 days' time without any reaction, the conjunctival sac was clean and the eyeball was freely mobile. He had employed pressure bandages instead of the usual iced compresses.

New York County Medical Association.—The annual meeting of this association, the first under its new charter, was held April 15. Dr. WILLIAM S. GOTTHEIL presented 2 cases showing respectively sarcoma cutis in its early stage and naevus uncus lateralis. He also exhibited drawings of a case of adenoma sebaceum of the scalp.

Dr. AUGUSTIN H. GOELET read a paper: **The Diagnosis and Surgical Treatment of Prolapsed Kidney**, with a demonstration of a simple method for its detection. He said his observations led him to believe that prolapsed or movable kidney was much more common, especially in women, than was supposed, and one reason why it was frequently not suspected was that it did not always give rise to symptoms directly referable to the kidney. Chronic digestive disturbances with distension of abdomen was among the commonest indications of prolapsed kidney. Examinations should be made with the patient in a standing position, and it was important that more than one examination should be made, as a full colon or other internal conditions might prevent its discovery the first time or the patient might be nervous which would cause rigidity of the abdominal muscles. It was by no means easy except for experts to make a diagnosis. His experience convinced him that operative interference was desirable in a large number of cases, and the operation was not so serious that patients need shrink from it.

Dr. GEORGE TUCKER HARRISON took exception to a statement which seemed to imply that traumatism was a frequent cause of prolapsed kidney; if that were so, it would be more common in men than in women, whereas the reverse was well known to be the case. While agreeing to some extent with Dr. Goelet's method of examination, he said there were many cases in which it would be found impossible to make a satisfactory diagnosis without producing a state of narcosis by the use of chloroform or some other medicine. He had seen a great many cases of movable kidney which existed only in the mind of the diagnostician. It was necessary to guard against being misled by their enthusiasm, especially if they had a fondness for surgery. In regard to the operation itself, he had no faith in sandbags or other material aids for holding the kidney in place. The hand of a competent assistant surpassed all mechanical contrivances.

Dr. HEINRICH STERN thought a movable kidney was only an indication of the general prolapse of the enteric organs. Therefore he was opposed to operative interference, especially as one-third of the operations were failures. They could accomplish quite as much, in his opinion, by bandages and general treatment.

Dr. J. RIDDLE GOFFE discussed the technic of the operation. In replying on the discussion Dr. GOELET said that out of 100 women examined in his clinic 20 were found to have prolapsed kidneys, and half of these he put down as requiring operation.

The ballot for new office-bearers resulted as follows: President, Dr. Parker Linns (relected); first vice-president, Dr. Alex. Lambert; second vice-president, Dr. Francis W. Murray; secretary, Dr. Ogden C. Ludlow (relected); corresponding secretary, Dr. M. L. Maduro; treasurer, Dr. Charles E. Denison (relected).

A Novel Petition.—A man from New Boston, Michigan, has petitioned Congress to grant him a pension for injuries received before he was born. It seems a brother, 20 years older than the applicant, was engaged in the war, and after one of the battles was reported dead. This report was afterward contradicted but at the time the shock was so serious to the mother that her next child was born a cripple, and claims that the war and the act of the Government in reporting his brother dead are responsible for his injuries.

Child-Labor.—According to the report of the State Factory Inspector of Illinois, the child-labor laws are only partly successful. They have succeeded in excluding children under 14 years of age from employment in certain occupations, but in the protection of children over that age they have been a total failure. The factory inspectors have again and again insisted that children must leave work and return to school, but each time they have been circumvented in some clever manner by the parent or guardian of the child. In some cases even marriage has been resorted to, the parents knowing that a married woman must be adjudged of legal age.

CORRESPONDENCE

THE ANATOMY ACT OF 1883.

BY

W. S. FORBES, M.D.,

of Philadelphia.

To the Editor of AMERICAN MEDICINE:—In view of Bill Number 61, House of Representatives, Harrisburg, now pending before the Senate and tending to destroy the Humane Anatomy Act of 1883, I desire to place before your readers the speech of Macaulay, the historian, delivered before the House of Commons advocating the passage of the Anatomy Act, known as the Warburton Bill, which is kindred to our Anatomy Act of 1883. This speech of Macaulay is so forcible and carried such conviction that in medicine and surgery England is what she is today.

Let us hope that the thoughts of this great and good man and sincere patriot may assist us today to defeat this House Bill, No. 61, so destructive in its intent. For, to disturb the Anatomy Act of 1883 will be to go backward and do great injustice to the poor and the afflicted suffering from accident and disease.

A SPEECH DELIVERED IN THE HOUSE OF COMMONS, FEBRUARY 27, 1832, ON THE WARBURTON ANATOMICAL BILL, BY THOMAS BABINGTON MACAULAY.

"Sir, I cannot, even at this late hour of the night, refrain from saying two or three words. Most of the observations of the honorable Member for Preston I pass by, as undeserving of any answer before an audience like this. But on one part of his speech I must make a few remarks. We are, he says, making a law to benefit the rich at the expense of the poor. Sir, the fact is the direct reverse. This is a bill which tends especially to the benefit of the poor. What are the evils against which we are attempting to make provision? Two especially; that is to say, the practice of Burking, and bad surgery. Now to both these the poor alone are exposed. What man, in our rank of life, runs the smallest risk of being Burked? That a man has property, that he has connections, that he is likely to be missed and sought for, are circumstances which secure him against the Burker. It is curious to observe the difference between murders of this kind and other murders. An ordinary murderer hides the body and disposes of the property. Bishop and Williams dig holes and bury the property, and expose the body to sale. The more wretched, the more lonely, any human being may be, the more desirable prey is he to these wretches. It is the man, the mere naked man, that they pursue. Again, as to had surgery; this is, of all evils, the evil by which the rich suffer least, and the poor most. If we could do all that in the opinion of the Member for Preston ought to be done, if we could prevent disinterment, if we could prevent dissection, if we could destroy the English school of Anatomy, if we could force every student of medical science to go to the expense of a foreign education, on whom would the bad consequences fall? On the rich? Not at all. As long as there is in France, in Italy, in Germany, a single surgeon of eminent skill, a single surgeon who is, to use the phrase of the Member for Preston, addicted to dissection, that surgeon will be in attendance whenever an English nobleman is to be cut for the stone. The higher orders in England will always be able to procure the best medical assistance. Who suffers by the bad state of the Russian school of surgery? The Emperor Nicholas? By no means. The whole evil falls on the peasantry. If the education of a surgeon should become very expensive, if the fees of surgeons should consequently rise, if the supply of regular surgeons should diminish, the sufferers would be, not the rich, but the poor in our country villages, who would again be left to mountebanks, and barbers, and old women, and charms, and quack medicines. The honorable gentleman talks of sacrificing the interests of humanity to the interests of science, as if this were a question about the squaring of the circle, or the transit of Venus. This is not a mere question of science; it is not the unprofitable exercise of an ingenious mind; it is a question between health and sickness, between ease and torment, between life and death. Does the honorable gentleman know from what cruel sufferings the improvement of surgical science has rescued our species? I will tell him one story, the first that comes into my head. He may have heard of Leopold, Duke of Austria, the same who imprisoned our Rlehard Coeur-de-Lion. Leopold's horse fell under him and crushed his leg. The surgeons said that the limb must be amputated; but none of them knew how to amputate it. Leopold, in his agony, laid a halchet on his thigh, and ordered his servant to strike with a mallet. The leg was cut off, and the Duke died of the gush of blood. Such was the end of that powerful prince. Why, there is not now a bricklayer who

falls from a ladder in England, who cannot obtain surgical assistance infinitely superior to that which the sovereign of Austria could command in the twelfth century. I think this is a bill which tends to the good of the people, and which tends especially to the good of the poor. Therefore I support it. If it is unpopular, I am sorry for it. But I shall cheerfully take my share of its unpopularity. For such, I am convinced, ought to be the conduct of one whose object it is not to flatter the people, but to serve them."

The noble heart from which sprung these thoughts and many others that have elevated our race, has long since been at rest. Let us hope that his spirit still animates the English-speaking people to dare to do that which is right and good for the whole body politic.

THE CLINICAL VALUE OF TRACHEAL TUGGING AS A SIGN OF ANEURYSM OR MEDIASTINAL TUMOR.

BY

GEORGE W. NORRIS, A.B., M.D.,

of Philadelphia.

To the Editor of AMERICAN MEDICINE:—The following case which was seen at the Pennsylvania Hospital within the last month has seemed worth recording:

G. H., a negro, aged 42, was admitted to the medical ward in a condition of anasarca, with ascites and intense dyspnea. He admitted having used alcohol to excess, and said that he had been in good health and able to perform his duties as janitor up until within 5 weeks. About this time his feet began swell and he was troubled with shortness of breath.

Physical Examination. Pupils equal; radial arteries sclerotic; the right radial pulse synchronous with the left but perceptibly smaller in volume. The lungs were markedly congested; and following notes were made upon the heart: Cardiac impulse feeble and diffuse, felt in sixth interspace in the anterior axillary line. A distinct, rather coarse presystolic thrill was felt over the whole precordium. Dulness begins at right border of sternum and upper border of third rib. At the apex a soft low-pitched systolic murmur is heard, which completely replaced the first sound, and was transmitted to the axilla and angle of the scapula. At the aortic area a loud, high-pitched musical double murmur is heard, the systolic and diastolic elements of which were transmitted into vessels of neck and down the sternum respectively. Traube's murmur was present. Distinct forcible tracheal tugging synchronous with the cardiac rhythm was felt. The patient improved under treatment, but died suddenly and without warning 6 days after admission.

Necropsy showed moderate bilateral pleural effusion, with marked congestion of the lungs. The heart was markedly hypertrophied and dilated. There was moderate thickening of the aortic leaflets. The aorta was slightly atheromatous, but there was no aneurysm of any of the vessels or other abnormality of the mediastinal tissues.

PURPURA IN TYPHOID FEVER.

BY

DR. W. L. GRANT,

of St. Thomas, N. D.

This condition in typhoid is extremely rare, mention of it seldom being made in the standard works on practice. Anders, in his late work, says: "Out of 250 cases of typhoid fever among the soldiers in the Spanish-American war treated in the Medico-Chirurgical hospital, 2 manifested purpuric spots." But he gives no hint as to prognosis or treatment.

Mrs. J. G. B., aged 37, was of good family and personal history, except that she was a subject of chronic constipation. The family had but lately moved into a house newly painted, and as the weather was cold, it being in December, there was not much ventilation and the air was laden with turpentine fumes. The father and 3 older children who spent much time out of doors were not affected thereby, but the mother and girl of 5 who were confined to the house were taken with nausea, vomiting and severe headache. This continued for a week or more, neither of them developing any rise of temperature and as the smell of turpentine disappeared the symptoms improved. The child recovered perfectly but the mother failed to gain strength and a week later developed signs of beginning typhoid. The case ran an ordinary course except that the headache was uncommonly severe, requiring morphin or codain to keep it in control. Then too, the stomach rejected milk, which later caused a great

deal of gaseous eructation and tympanites aside from the vomiting. For the first 2 weeks she was fed almost entirely on Wyeth's beef, milk and gluten, which was well borne and caused no eructation. After that peptonized milk was taken with the other food.

At the end of the third week small, bright purpuric spots began to appear upon the neck beneath the band of the gown. They increased but little in size, but fresh ones appearing in close proximity merged themselves into the older spots until they were the size of a split pea, ranging from this down to that of a mere pin point. They gradually increased in numbers covering the breast, abdomen, back, arms and face until the whole surface had the appearance of being sprinkled with fresh blood from the vigorous shaking of a whisk broom dipped into it. At no time was there any bleeding from the bowels or bladder, but all the visible mucous membranes of the lips, mouth, tongue, and the conjunctivas, were spotted with the same minute hemorrhages. In the left eye they were so numerous and pronounced that the whole marginal looped plexus (the circle of vascular loops about the cornea) was apparently broken down and all nourishment shut off from the cornea so that it became soft and cloudy and the vision entirely destroyed. This eye was the only point from which blood flowed at any time, and here for 4 days it oozed a little.

There was mild delirium for the full period of purpura, but no more pronounced than is often seen in uncomplicated cases of typhoid. But during the night of the twelfth day of purpura the stupor was deeper than it had been previously, and the cheeks were puffed out with each expiration, as in a hemiplegic attack. Also the tongue was protruded laterally, leading me to suspect a small cerebral hemorrhage. The stertorous respiration and dribbling from the mouth lasted for 36 hours, and the slight paralysis of the tongue not quite so long. These signs reappeared a few days later, lasting for about the same length of time.

The temperature was but little above normal when the purpura made its appearance, but it rose with each fresh crop of spots, making a very irregular record, varying from 96.8° to 105°, and at times running the whole gamut in 12 hours. The pulse varied from 112 to 160 during the purpuric period, strychnin and whiskey with digitalin or nitroglycerin being administered at frequent intervals.

After consultation the patient was put on aromatic sulfuric acid in very small doses, with the only result of disturbing the stomach and producing a good deal of vomiting with consequent weakness. Then ergotin was tried hypodermically, with no results as far as the purpura was concerned. As soon as the stomach would retain it I put her on tincture of chlorid of iron, beginning with minimum doses every hour and increasing as rapidly as possible until she was getting a dram and a half in the 24 hours. After a few days of the iron treatment the spots began to fade and no new ones made their appearance, but the disease had produced such asthenia that death supervened at the end of the sixth week of illness and the third of the purpura.

Should I have the care of such another case I would begin the administration of tincture ferric chlorid at the beginning, irrespective of temperature, and push it to the point of toleration on the part of the stomach.

As no necropsy was made, I can give no particulars as to the condition of brain and internal organs, but I should have expected to see the same small hemorrhages in all the tissues.

THE OYSTER AS A CARRIER OF TYPHOID.

By DR. A. B. FARNHAM,

of Milwaukee, Wis.

To the Editor of AMERICAN MEDICINE:—Last December a family of 7, 6 women, 4 between the ages of 18 and 24, received a present of shell oysters from Baltimore. Two of the younger women partook freely of raw oysters. The others avoided them uncooked. The two young women who ate the oysters raw were attacked by the premonitory symptoms of typhoid fever some 5 days after eating them. They have not yet recovered. The others were not attacked. The surroundings were such as to exclude with a good show of probability other sources of infection. I know the weak points in the case. What is the fuller bill of indictment against the oyster?

Hospital Closed.—Mercy Hospital, known as the Emergency Hospital of Iron Mountain, Mich., was closed April 3, by order of Bishop Eis, and the nuns were ordered to leave the diocese. Last January a novitiate of the hospital was arrested on a charge of insanity preferred by the Mother Superior. The Probate Court judged her sane. After being released from custody she brought severe charges against the Mother Superior, one being drunkenness. An investigation resulted in the order to close the institution.

HOW TO DEAL WITH THE VERMIFORM APPENDIX. SOME FORMS OF COMPLICATED APPENDICITIS.

BY

HOWARD A. KELLY, M.D.,
of Baltimore, Md.,

Professor of Gynecology in the Johns Hopkins University.

The removal of an appendix, in which the organ is still free, or in which it is but lightly adherent to the surrounding structures, may now be considered a fairly routine procedure which presents but few difficulties, and in consequence has become one of the safest of all major surgical operations.

The case is, however, quite different when the appendix is found densely adherent, or when it opens into an

all avoidable injury to the coats of the adherent intestines.

I have long since found, in common with other operators, that when the appendix is diseased and densely

adherent at its tip, the best plan often is first to seek out and expose its base, which I detach and divide so as to free the appendix from the cecum. The distal freed portion is now wrapped for protection in a bit of gauze, while the opening into the bowel is sewed up by whatever plan

abscess, or when there exists a more or less general peritonitis. Under such circumstances there is wide room for the exercise of good judgment and the special features of the case demand careful attention in order to adopt just the right course of action.

Success will often crown the right move, while a failure to realize the individual difficulty frequently results in a mishandling of the tissues and the death of the patient, or at best a protracted convalescence.

The operator who is most successful in dealing with complicated cases of appendicitis dreads two things, firstly, all avoidable contamination of the surrounding tissues with any part of the appendiceal abscess, and secondly,

An ovarian cyst with omental adhesions above on the left and an adherent vermiform appendix below.

the operator likes best. Then as a final step the severed appendix is dealt with and dissected out of its bed with much greater facility than was possible with both ends anchored, one to the cecum and one to the adhesions.

This plan of procedure applies especially in the gynecological field when the vermiform appendix is attached to a pyosalpinx, or an ovarian or a fibroid tumor; in these cases, after severing it from the bowel, it is then enucleated with the tumor or with the pelvic abscess.

When the appendix lies imbedded in strong old adhesions there is often considerable risk run in sewing the adhesions, either of tearing the subjacent structure or of exciting hemorrhage from numerous small vessels which are difficult to control in the matted tissues. I have found in such cases, in the absence of an abscess and perforation, that an excellent plan of dealing with the adherent organ is to detach its base, in the way just described. I then catch the free end with a pair of artery forceps and lift it up, and circumsise it just below the forceps, cutting through the peritoneal and the external muscular coats; a longitudinal incision, still including only these two coats, may also be carried on down the dorsum of the appendix as far as it is visible. The appendix is now stripped out of its bed by pulling it toward the end, or pulling it straight out; if it begins to break, it is grasped afresh with the forceps and the stripping continued.

In this way the entire mucosa is removed with the circular muscular coat, while the longitudinal muscular coat is left behind. There is often no bleeding at all, but if any occurs it is more easily dealt with than when the entire organ is dissected out.

I have often had recourse to this plan since I first adopted and reported it to the Johns Hopkins Medical Society some two years ago. The same procedure has also been found useful by Dr. Mixter, of Boston, who, on the occasion of a recent visit to his clinic, gave me the specimen here figured, which shows how perfectly even an unusually long appendix may be skinned out in this way.

Another plan of treatment is advisable when the end of the appendix enters an abscess-cavity surrounded by adherent intestines which cannot be stripped off with safety. In such a case, recently, after freeing the base of the appendix from the cecum, I traced it up until it entered an abscess-cavity under the ascending colon. I could not separate the adhesions without injuring the bowel, so I grasped the appendix close to the abscess with a pair of forceps on either side. I then split the appendix open and followed its lumen as a guide by using a groove director and a pair of open scissors with one blade in the appendix. I was thus enabled with certainty to enter the very middle of the abscess-cavity, to lay it open and clean it out and sterilize it without doing any damage to the colon. I followed the cleansing of the cavity by drainage and the patient recovered without any interruption.

Dr. Mixter's Case.

THE GOOD AND BAD EFFECTS OBTAINABLE FROM DIGITALIS USED AS A THERAPEUTIC AGENT.*

BY

WILLIAM HENRY PORTER, M.D.,
of New York City.

The further study of so old and well tried a remedy as digitalis might at first seem uncalled for, yet as one follows the current literature upon this subject, it is quite apparent that its action upon the system is not fully understood. Therefore a review of its physiological action and therapeutic possibilities may not be without profit.

Thoroughly to comprehend the action of any drug, its chemical composition must be fully understood. At the same time the laws that govern the action of all chemical compounds introduced into the system must be accurately apprehended, and correctly applied to those that are introduced as medicinal agents. When this is accurately done much new light is let in upon the action of our remedial agents. In this manner many a drug, so called, has been taken from the speculative and empirical class and transferred to the exact or truly scientific, thus raising the whole field of therapeutics to a higher standard.

With digitalis there still appears to be considerable doubt and difference of opinion prevailing in regard to its mode of action, and also as to the therapeutic utility of this drug and its various preparations; some praising it highly, while others vociferously condemn it.

Digitalis like many other vegetable substances appears to develop in its anabolic growth numerous chemical compounds, all of which are composed of the atomic elements carbon, hydrogen, and oxygen, in varying proportions. This particular group of compounds has been classed as glucosids, in contradistinction of those containing nitrogen, and which are, in consequence, known as alkaloids.

The glucosids which have thus far been isolated and identified in connection with digitalis are digitalein $C_{25}-H_{40}-O_{15}$, digitoxin $C_{21}-H_{32}-O_7$, digitonin $C_{31}-H_{52}-O_{17}$, digitalin $C_5-H_8-O_2$, digitin $(C_4-H_9-O_2)_n$.

Exception is taken however to digitoxin as a glucosid; still its atomic construction is very similar to the other 4 which are classed as true glucosids. Why the digitoxin is excepted is not clearly stated, but it is probably due to the fact that when boiled with dilute acid it does not yield glucose, which is the critical test for those substances designated as glucosids. Be it a glucosid or otherwise makes little difference so far as the chemical problem is concerned, for they are all composed of the same class of atomic elements and being composed of the same class of chemical elements they are all amenable to the same chemical laws; all are oxidizable substances and they all yield the same products as the result of their oxidation reduction, to wit, heat, carbon dioxide, and water.

Owing to the varying proportion of these atomic elements, the amount of oxygen required to reduce each one will vary; likewise the amount of heat generated

*Read before the Litchfield County Medical Society of Connecticut, January 8, 1901.

will vary, both in amount and in the intensity of its action upon the various portions of the nervous mechanism. The following table illustrates at a glance the possible chemical products of the oxidation-reduction of the principles contained in digitalis, while they all yield at the same time a heat equivalent :

Digitalein $C_{25}-H_{40}-O_{15}+55(O)=25(CO_2)+20(H_2O)$.

Digitoxin $C_{21}-H_{32}-O_7+57(O)=21(CO_2)+16(H_2O)$.

Digitalin $C_5-H_8-O_2+12(O)=5(CO_2)+4(H_2O)$.

Digitonin $C_{31}-H_{52}-O_{17}+71(O)=31(CO_2)+26(H_2O)$.

Digitin $2(C_4-H_9-O_2)_n+21(O)=8(CO_2)+9(H_2O)$.

Thus it becomes apparent in the very beginning that the problem before us is not a simple one, but one that is very complex and difficult to elucidate.

Of the 5 medical compounds contained in digitalis 4 are said to influence the animal economy actively while 1, digitin, appears to be absolutely inert. Of the remaining 4, 3 have actions in common, while the fourth absolutely antagonizes the other 3.

Beginning our study of the action of digitalis with the powder, which is the simplest preparation to use, and one which does not involve the question of varying solubilities of the contained, active ingredients, its action can be pretty closely analyzed. When this preparation is used there is introduced into the animal economy a substance containing chemical compounds capable of being oxydized, and as a whole, has a decided tendency to paralyze all the muscles.

So far as the nervous system is concerned, it is generally conceded that none of the active principles, have any pronounced primary effects, yet, on the other hand, acting through the nervous mechanism, or directly upon the heart itself, the contained active principles do produce profound changes in the action of the heart and circulation.

Acting directly upon the heart, or through its nervous mechanism, the 3 active principles, which have a similar action, cause a more intense and shorter systolic contraction with a prolonged diastolic period. Synchronous with this effect upon the heart there is a marked contraction of the arterioles and a very pronounced rise in the blood-pressure. Following immediately upon these effects there is at first a marked decrease in the number of cardiac pulsations to the minute, which by some are said to be due to the direct depressing effect upon the spinal accessory fibers distributed to the heart. A better explanation for the reduced speed of the heart is to attribute it to the increased resistance to the blood stream in the arteries. This, coupled with the depressing effect of the digitonin upon the muscle fibers, easily explains the decreasing number of pulsations to the minute. If the digitalis is continued the pulsations become more frequent and feeble, which is readily explained by the toxic effect of all the active principles of digitalis upon all the involuntary muscles. The continued high tension in the arterial system tends also to deprive the cardiac muscles of their requisite nutrition. Thus, we find that at first the heart is called upon to do more work, by the action of a substance that is all the time poisoning the muscle fibers, and at the same time its nutrition is being progressively cut off by the increasing high tension in the arterial system.

A little later the toxic effects of the active principles of the digitalis begin to be felt in the muscle fibres of the arterioles; the tension relaxes, the heart becomes more feeble and irregular, and death ensues in diastole. While a very large dose of digitalis may cause a complete cessation of the heart's action in profound systole, the usual mode of death is as above described.

The mechanical effects of the changes in the cardiac rhythm are, that with the slower action and prolonged diastole, the cardiac cavities are more nearly filled; this tends to relieve any venous engorgement, both in the pulmonary circuit and throughout the whole venous system. The increased ventricular contraction tends to overflow the arteries and arterioles.

This forced contraction of the left ventricle tends to close quickly and more completely the left auriculo-ventricular orifice; thus preventing the escape of blood back into the auricle, and forcing the full complement into the aorta.

While the general arterial system is in a state of high tension that of the *splenic* arcade remains normal or is slightly lowered, unless an enormous dose has been administered, then the latter, as well as the former, becomes contracted. This, however, is a very rare occurrence.

This, then, briefly stated, is the sum of the effects that can be produced upon the heart and circulation by the internal administration of digitalis and its varying preparations. If its use is continued for any length of time, provided the preparation has any virtue left in it, death must speedily ensue, from what may be called internal or intrinsic starvation, the high tension of the bloodvessels preventing the requisite amount of nutritive pabulum from reaching the various tissues.

With the liquid preparations these statements have to be somewhat modified. Especially is this true with the infusion, for the simple reason that 2 of the active principles, digitoxin and digitalin, are slightly, if at all, soluble in water, hence the infusion contains only digitalein and digitonin. The one directly antagonizes the action of the other, yet both are, in a measure, toxic to the involuntary muscle fiber. In this respect the infusion becomes of comparatively little value and less damaging in its effect upon the system than the powder.

With the tincture still another condition obtains. The digitoxin and digitalin are freely soluble in alcohol, while the digitalein is but slightly so, and the digitonin is soluble both in alcohol and water. Thus we find that each preparation of digitalis differs from the other and cannot be directly compared with it. The fluid extract more closely resembles the powder, being transmutable to either by the action of the alcohol and water. This, however, is, in a measure, a very uncertain preparation, for there is no practical method of determining how much of the soluble elements in the water and in the alcohol may be dissolved or precipitated by the presence of the soluble and insoluble menstrum.

With this knowledge of the chemical composition of digitalis and its contained active principles; and the variation in the composition of its preparations, its therapeutic possibilities can easily be worked out.

While digitalis is often spoken of as a cardiac tonic,

there is little or nothing known in relation to its action upon the system that will justify such an assumption.

Digitalis can be made to slow the action of the heart, but to do this the cardiac muscle is stimulated to do more work, at the same time the intrinsic muscle fibers are being steadily poisoned, and the nutritive supply steadily diminished by the increasing high tension. Hence, the recommendation that digitalis must be interrupted every few days to avoid sudden and fatal syncope.

At this point it may be well to consider the so-called and much talked about accumulative action of digitalis. Careful scrutiny of the standard works upon materia medica and therapeutics throws but little definite light upon its method of action. One of the latest explanations, which, however, does not explain, was that of Joseph W. England, who attributed it to the unduly slow absorption of the drug. Still the *modus operandi* of this emulative phenomena has certainly been far from being satisfactorily elucidated.

Little or no evidence is produced to prove that the drug has been stored up in the system in the form of 1 or more of its active principles, and then suddenly eliminated in large quantities; following which, all the bad effects are suddenly dispelled as quickly as they were produced.

On the contrary, the weight of evidence, as already noted, establishes the fact that the active principles of the drug are rapidly decomposed within the system into carbon dioxid, and water, with the production of heat; and that they are never found in their original form in the excretions of the body.

Therefore, the assumption of a quiet accumulation of a large quantity of the drug within the system, which is finally let loose upon the heart, is hardly tenable and a more logical explanation must be sought, and one that accords more closely with known physiological laws.

By some, it is assumed that a high tension of the renal arteries is established, which produces a condition synonymous with suppression of the urine. Then, to this sudden, or so-called "uremic poisoning," thus induced, the symptoms commonly classed as those of the "cumulative action of digitalis" are ascribed.

Here again, while symptoms simulating digitalis poisoning can be produced thus, experimentally, in healthy subjects when the drug is pushed rapidly to its full limit—this method of action does not appear to hold true in ordinary clinical experience. For it rarely happens that the renal functions are suspended to this extent in ordinary cases of digitalis poisoning, even in those instances in which death finally results.

The cumulative action of digitalis appears to be more directly exerted upon the heart, the kidneys often acting freely even in the presence of the depressed action of the heart, and death comes on quickly, often without any warning, by a sudden arrest of the heart's action. How then can this so-called cumulative effect of the digitalis be rationally explained is the important question to decide? By keeping closely to the well known actions of digitalis and combining these actions with the physiological laws that govern the nutritive processes of the body, a perfectly rational solution of these so-called cumulative symptoms is developed.

Digitalis, as we have already observed, increases primarily the motor force of the heart, the muscular contraction is more intense, the expenditure of cardiac energy is increased, and the isomeric or kalabolic transformation of the muscular elements augmented.

This, in itself, would deteriorate the muscular strength; but digitalis taken as a whole is further classed as a direct muscle poison, and this is doubly so of the contained digitonin.

Digitalis, therefore, at first apparently increases the working power of the heart muscle, and all the cardiac symptoms are, for the time being, ameliorated. At the same time the digitalis also increases the arterial tension, and by this change in the vascular pressure, greatly increases the resistance offered in front of the heart, which is now acting as a mechanical pump. This fact alone increases the work to be accomplished by the cardiac muscle, and, as a necessary sequence, the rapidity of the heart muscle is slowed down, to increase its working capacity. Up to this point the heart has suffered no material damage from the action of the drug and its contained constituents; and its working capacity has been enhanced. But physiology teaches that the high arterial tension increases the speed of the blood-current in the arterial and capillary system, and most positively cuts down the time for nutritive interchange between the blood and the protoplasmic tissue in the intravascular protoplasmic spaces.

Applying this same undisputed law in connection with the digitalis upon the heart muscle, the result is that the drug by its action upon the arterial system is slowly but persistently cutting down the nutritive supply to the cardiac muscle fibers; this being considered, in addition to the increased work imposed upon the heart muscle, and the fact that digitalis *per se* is a decided muscle poison, the 3 factors causing the symptoms of digitalis poisoning are clearly apparent; and furnish the first logical explanation for the so-called cumulative action of digitalis.

The working capacity of the heart is augmented, the cardiac muscle is poisoned, and at the same time the relative quantity of nutrition distributed to the organ is positively diminished. But one thing can follow, degeneration of the muscular fibers constituting the ventricular and auricular walls, particularly the former. At first the heart's action is slowed to meet the increasing demands, but soon like every other degenerated heart, it becomes rapid and feeble in action, then irregular, or stops in diastole at some slight exertion, like sitting up in bed, or rising to pass urine. If the drug is administered in homeopathic doses no perceptible deterioration of the heart will be apparent, but where a thoroughly reliable preparation of digitalis is used and the drug is exhibited continuously up to the full physiological limit, the heart is invariably damaged. This explains the oft repeated remark that digitalis proves unsatisfactory in permanently alleviating cardiac affections.

Viewed from the purely mechanical standpoint, digitalis and its various preparations might be used in the temporary management of lesions of the mitral valve. In both insufficiency and in stenosis of the left auriculo-ventricular orifice digitalis improves the condition

temporarily; in the former instance by more quickly and effectually closing the incompetent orifice. It also intensifies the systolic contraction and more nearly empties the contents of the ventricular cavity into the aorta. This accomplished, the mechanical action of the heart is improved.

In a similar manner, in mitral stenosis, the prolonged diastole, with an intensified contraction of the auricle, enables the latter to more completely fill the ventricle. This, coupled with the more intense systolic contraction, drives a larger volume of blood into the aorta. Thus in both lesions of the mitral orifice the pulmonary congestion is overcome and the dyspnea consequent upon the pulmonary engorgement is removed. If this were the only and the complete action of digitalis it would be an exceedingly valuable remedy. While this improvement in the mechanical action of the heart is being effected, the action of the digitalis is to increase the intrinsic work of the cardiac muscle. It further augments the work imposed upon the heart by heightening the arterial tension and thus increases the resistance in front of the heart; or in other words the intrinsic work of the organ is augmented. Of course this argument in reference to the vessels does not apply at first, when there is abnormally low arterial tension together with general venous engorgement.

Up to the point of overcoming the decreased arterial tension and the removal of the venous engorgement, the physiological function of the circulation, as well as the mechanical action of the heart, is greatly improved. Once the normal tension has been reached and passed, the action of the digitalis is detrimental to all the physiological functions of the body, because it increases the work of the cardiac muscles, poisons the muscle fibers, and progressively decreases the nutritive supply distributed to the organ.

In aortic lesions, either incompetence or stenosis, there seems to be no good reason for using digitalis at any stage. Certain it is that in aortic regurgitation, the increased systolic stroke cannot fully compensate for the prolonged diastolic period and longer time during which regurgitation can take place, added to this is the increasing arterial tension, with its greater resistance in front of the heart and the progressive cutting down of the nutritive supply to the heart muscles, both of which, or either alone, would be sufficient to counterindicate the use of digitalis in aortic insufficiency. In aortic stenosis the augmented cardiac systole might, for a time, force a larger volume of blood into the aorta, thus temporarily improving the condition, but the increased work of the cardiac muscle, together with the poisoning effects of the digitalis upon the muscle fibers, and the progressively diminishing nutrition, will soon be followed by a deterioration of the cardiac muscle and an aggravation instead of an amelioration of the symptoms.

In fatty degeneration, or any enfeebled condition of the heart muscles, digitalis is contraindicated.

In hypertrophy of the heart digitalis might theoretically be useful in cutting down the nutritive supply, thus lessening the tendency to further hypertrophy, even if the hypertrophic condition could not be completely removed. Even in this instance digitalis is too dan-

gerous a remedy to use for such purposes, for clinical experience has shown that the continued use of digitalis, even for a comparatively short space of time, will cause so much degeneration of the muscle fibers, that acute dilation has been observed to follow its use, death being averted only by the withdrawal of the digitalis, and the administration of more lively remedies.

Thus it is apparent, that digitalis is of service only for a few days at the longest. It should only be given to influence the heart and circulation when the arteries are very much relaxed, and the pulmonary or systemic veins overfilled with blood. In such instances as these it will tighten up the vessels and by augmenting the power of the systole will force a larger volume of blood into the arterial system.

In this manner the surplus of blood can be pumped, as it were, from the venous system, into the arterial. This accomplished, the digitalis should at once be stopped and more reliable remedies used to maintain the heart and circulation, remedies that will accomplish the desired result without damaging the cardiac muscle or interrupting the physiological nutritive functions of the animal economy. To use digitalis outside of these narrow confines when there are so many other, safer, and more reliable remedies is, to say the least, extremely poor therapeutics.

Some argue that by giving a sufficient amount of nitroglycerin in conjunction with the digitalis, the damaging effects of the digitalis can be obviated. In a measure, this is true, but it does not altogether diminish the increased work forced upon the heart muscle, neither does it antidote the general toxic effects of digitalis upon the general muscular system. While this is a wiser therapeutic measure than the use of digitalis alone, it is not the best for the patient; and nothing short of the best should be the aim of the truly scientific and practical therapist.

Up to this point we have been dealing simply with the action of the digitalis upon the heart and circulation. Its action as a diuretic next deserves attention. Before this can be studied intelligently, however, we must first attain a clear conception of the normal functions of the kidneys, then it is easy to understand how the excretory functions of the renal glands can be influenced by the introduction of medicinal agents into the system. The functional activities of the renal glands are best divided into two grand series; the first comprising the changes effected through the action of the glomeruli; the second, the changes brought about through the agency of the epithelial cells lining the uriniferous tubules. Athwart the walls of the bloodvessels constituting the Malpighian tufts is filtered the water, with the inorganic salts held in solution.

Through the agency of the epithelial cells lining the uriniferous tubules, the fully utilized proteid constituents are drawn into the protoplasmic substances with active oxygen, and are there, by a process of oxidation-reduction, converted into urea, uric acid, creatin, carbon dioxide and water, and discharged into the lumina of the renal tubules, with the exception of the CO₂, which flows back into the blood stream, thus forming the normal products of proteid oxidation found in the urine.

Also, in the various abnormal conditions of the system, by a less perfect oxidation of the proteid constituents in these renal cells, the various byproducts of the proteid oxidation are eliminated by the action of the epithelial cells. Most common among the abnormal excretory products are albumin, glucose, indican, oxalic acid, lactic acid, hippuric acid, and the various leucomaines, ptomaines and toxins. The albumin cannot, strictly speaking, be classed as an oxidation-reduction product like the others enumerated; still it results from imperfect oxidation of the proteid constituents in the renal cells. Its elimination, however, can be credited to the epithelial cells of the uriniferous tubules, which, when not able to oxidize the proteid into some one of the simpler reduction products, either normal or abnormal, have the power to transform isomerically the proteid constituents, drawn into their substance from the blood, and excrete it into the lumina of the renal tubules as some one of the many forms of derived albumin (which is often toxic in nature) that are found in the urine.

The functions of the glomerule is comparatively simple, being entirely, although indirectly, under the control of the vasomotor system of nerves. Experiments have shown that a division of the spinal cord below the medulla oblongata greatly diminishes the flow of urine. The explanation of this phenomena is, that large vascular areas are cut off from their communication with the medullary vasomotor center, and this, together with the general shock to the spinal cord, destroys the innervating impulses distributed to the muscular walls of the blood-vessels throughout the body. Their lumens expand, and a great fall in the general blood-pressure is the final result.

With this general relaxation, comprising also the renal artery, it might be expected that a large volume of blood would pass to the kidney and that an augmented flow of urine would follow; but the great fall in the general blood-pressure overbalances the effect produced upon the renal circulation; hence the actual hydraulic pressure in the glomeruli is decreased, and the flow of urine is, in consequence, less than normal.

Stimulating the spinal cord below the medulla, affects the cord in an opposite manner from division, but produces the same diminution in the quantity of urine excreted.

This is explained by the renal artery becoming so much contracted by the increased innervation distributed to its muscular wall, that the blood is largely shut out from entrance into the kidney, similarly as in ligation of the renal artery. This sudden reduction of the renal circulation overbalances the good effects which might have come from the general rise in blood-pressure. Therefore, it is clear that directly opposite actions upon the cord will not produce opposite results upon either the renal circulation or its excretory function, but may produce a similar effect upon both the secretion and function.

These physiological effects clearly explain how, under opposite circumstances, drugs possessing entirely different properties may produce clinical phenomena almost identically parallel.

Section of the renal nerves produces a marked relaxation of the renal artery. This greatly augments the

volume of blood distributed to the kidneys, thus increasing greatly the blood pressure in the capillary vessels which constitute the Malpighian tufts. This augments the flow of urine because the general blood pressure remains nearly normal.

Section of the spinal cord after division of the renal nerves arrests the polyuria by suddenly dilating the arteries and increasing the general vascular capacity outside of the kidney, thus reducing general blood pressure and in this way withdrawing the high volumeric pressure from the glomeruli. Stimulation of the spinal cord after division of the renal nerves still further increases the flow of urine by contracting the general arterial capacity outside the kidney, thus raising the volumeric blood pressure in the glomeruli to a still higher degree.

The same kind of results are obtained by division of the splanchnic nerves, but the action of the kidneys is less positively marked because the whole splanchnic arcade responds simultaneously to the impulses causing a rise or fall in the blood-pressure.

From these facts it is clear that the quantity of water discharged from the kidney is dependent upon the relation of the hydraulic pressure within the glomeruli, on the one hand, and the tension in the arterial system throughout the body, on the other hand.

The function of the epithelial cells lining the uriniferous tubules *per se*, is a much more complex process.

The epithelial cells of the kidneys have, for their special function, the property of taking up from the blood into their protoplasmic substance the fully utilized proteids that have served their isomeric purpose to the animal economy. At the same time that the proteid is taken into the cells a certain quantity of active oxygen is drawn in with the proteid element. Once within the protoplasmic substance of the cell, the active oxygen attacks the proteid molecules and, if the kidneys are acting normally, produces by this process of oxidation reduction, urea, uric acid, creatinin carbon dioxide, and water. When there is a surplus of albumin in the blood, either utilized or otherwise, over and above the complement of oxygen for its complete reduction, instead of the perfect products of oxidation in their normal proportions, an excess of the lower products will be formed at expense of the higher, or still lower products will be formed, those which are absolutely abnormal to the system and its excretions, such as lactic acid, oxalic acid, glucose, and a host of others such as leucomaines, ptomaines, toxins, etc. Some of which have been isolated and identified, while many more are still without clear identification.

When the functions of the system are still more profoundly disturbed by the introduction of microbic or toxic substances, or other causes such as a still greater reduction in the complement of oxygen, a certain proportion of the fully utilized proteid or the excess of non-utilized proteids, when drawn into the protoplasm of the renal cells, cannot be oxidized and reduced even to the lower products of imperfect oxidation. Under these circumstances, either from the lack of oxygen or from the deteriorated condition of the protoplasm of the renal cells, and their inability to excite oxidation reduction, the cells become swollen and tend to undergo retrograde

changes as the result of this excess of unoxidized proteid matter in their substance. Now, as if to relieve themselves of this excess of proteid material, the contained proteids within the cells are isomerically transformed and eliminated directly from the cells into the lumina of the uriniferous tubules under one of the many isomeric forms of the proteid molecule found in the urine. In this manner is produced the condition commonly classed as albuminuria, and said to be due to an escape of so-called "serum-albumin" from the blood through the walls of the bloodvessels.

The exact condition, however, is the elimination of the various isomeric forms of proteid material from the cells themselves. Thus, albumin in the urine becomes a direct excrementitious product from the cells and not the transudation of "serum-albumin," so-called through a non-diffusible membrane. Another ground upon which the so-called "serum-albumin" theory of albumin (albuminuria) in the urine is untenable is, that no "serum-albumin" exists in the blood as a single substance. That which was once supposed to be a simple and single substance and named "serum-albumin," is now absolutely known to be composed of at least 3 isomeric forms of the proteid molecule. While 3 forms have been absolutely identified, there is much evidence that proves that there are more isomeric forms of the proteid molecule to be found in the substance that once was known as simple "serum-albumin."

Assuming that "serum-albumin" is a single and simple proteid, the albumin, as found in the urine, does not conform to the tests employed for identifying the so-called "serum-albumin," which is further and positive chemical proof that the albumin found in the urine is not in the same isomeric form that is commonly found in the blood-stream and known by the name of "serum-albumin."

Still further, there is chemical proof that the albumin which finds its way as an isomeric excrementitious product from the epithelial cells of the kidney into the urine is composed of many isomeric forms of proteids. This is strongly evidenced by the varying behavior of the proteid constituents of the urine when brought into contact with heat and chemical reagents. Those in the urine are found to differ widely when compared with those found in the blood stream. The same is true in different cases, when the albumin of the urine is carefully studied; all this proves that we are not dealing with a single proteid in the blood and one of the same character in the urine, but in both instances there are many isomeric forms.

[TO BE CONCLUDED.]

Gout Versus Tuberculosis.—Dr. Henry Harper, an English physician, through study of tuberculosis has been led to an interesting theory and experiment which may be of great value. He first noted that despite favorable conditions many of his cases were from the country. He also noted that herbivorous animals were more liable to the disease than carnivorous. Again, he noted that gouty or rheumatic families were rarely affected with tuberculosis, and that there are cases on record in which the disease had been arrested as cured by a severe attack of gout. This led to the theory that the superabundance of urea, which is the supposed cause of gout, acts as an antitoxin to the tubercle bacilli. This is in accord with the treatment of tuberculosis in sanatoriums where meat is given to patients in abundance.

CONGENITAL DEFORMITY OF WRIST; OSTEOTOMY OF RADIUS.

BY
DEFOREST WILLARD, M.D.,
of Philadelphia.

Clinical Professor Orthopedic Surgery, University of Pennsylvania, Philadelphia; Surgeon Presbyterian Hospital, etc.

The subject of the accompanying skiagraphic representations was a girl of 14, whose carpus was thrown, by the arched condition of the radius, so far out of the nor-

Fig. 1.—Congenital dislocation of wrist. Carpus unconnected with ulna from arching of radii.

mal line anteriorly that it entirely failed to articulate with the ulna, and was joined very faultily with the radius. The resulting disability was so great that she

Fig. 2.—Congenital dislocation of wrist. Carpus unconnected with ulna from arching of radii.

was unable to perform the simplest exertions with any comfort. The weakness and difficulty in using her hands, which had existed from birth, was becoming greater every year. The mother had the same deformity

in both wrists, but to a less degree; enough, however, to decidedly weaken her arms; otherwise there were no deformities in either mother or daughter. As will be seen in the skiagraphs (Figs. 1 and 2) the styloid process of the ulna on each side lies entirely free from the carpus, and the distortion of the second row of carpal bones in their relation to the first row is very marked.

The arch in the radius caused its articulating surface to look almost at right angles to its normal position, while the semilunar and scaphoid lay with their sides against the joint surface instead of upon their normal faces.

An osteotomy of the radius $1\frac{1}{2}$ inches above the wristjoint, with forcible straightening and fixation for 5 weeks in a corrected position with plaster-of-paris,

Fig. 3.—Congenital dislocation of wrist from arched radii. Result after osteotomy of both radii.

gave a greatly improved result, both as to appearance and strength. A skiagraph taken 4 months after operation showed the result, as per Fig. 3. The carpus is still out of its proper relation with the ulna, but the obliteration of the curve in the radius has brought the hand into much better line with the arm, and has thereby greatly lessened the deformity, and has also added largely to the muscular power and strength of the member.

Although the girl has not the full normal strength of hands, she is able to accomplish all ordinary movements of the wrist.

This form of congenital deformity is exceedingly rare. Hoffman¹ states that he was unable to find any report of a case uncomplicated with clubhand. Congenital dislocations of any of the articulations of the upper extremity are much more infrequent than are those of hip or knee.

THE LOGIC OF HYDROCHLORIC ACID THERAPY, RESTORATION OF LOST GASTRIC HCL SECRETION BY MEDICAL AND SURGICAL METHODS.

BY

JOHN C. HEMMETER, M.D., PHIL. D., ETC.,

of Baltimore, Md.,

Professor in the Medical Department of the University of Maryland,
and Director of the Clinical Laboratory.

Soon after Prout first discovered, in 1828, that the normal acid of the gastric juice was hydrochloric acid, this chemical substance gradually became the panacea for all digestive disorders. From this extreme view we have in recent years drifted to the opposite extreme, according to which HCl as a therapeutic remedy is entirely dispensable. This acid should never be given except when the analysis of test-meals shows the absence of free HCl. Furthermore, it is not sufficient to test with the phloroglucin-vanillin, resorcin, Congo paper or dimethylamidobenzol, but the amount of the HCl deficit, i.e., the amount of decinormal HCl solution that must be added until the reaction of the chyme shows free HCl, must be determined, in order that one may know how much beneath the normal the secretion may be. The HCl deficit should be determined when the reactions for free HCl prove negative. In one case the deficit may be very slight, in another very considerable. Slight deficits generally yield readily to treatment by diet and lavage, often without administration of HCl; large deficits may be a sign of atrophy and never yield to HCl therapy, no matter how much is given.

The purposes for which HCl is given in the absence or diminution of the normal secretion are: (1) To supplement gastric proteolysis; (2) to act as an antiseptic; (3) to act as a tonic and stomachic.

To these effects that we have in mind in supplying HCl, may be added its influence as a stimulant to gastric peristalsis, and the fact that it brings the insoluble calcium and magnesium salts of the ingesta into solution; in fact, all of the objects and functions that are recognized as physiologic to the HCl may be at least partially accomplished by supplying it in sufficient quantity. But the question arises: Can it be supplied in sufficient quantity? Positive reaction on Congo paper and phloroglucin-vanillin after test-meals indicates, it is true, that HCl is secreted in excess of what is required to combine with the food. In healthy digestion it is always found that this excess amounts on the average to 30 cc. of a decinormal solution of NaOH after an Ewald test-meal (in Baltimore); and it seems to be what is necessary or

¹Trans. Amer. Orth. Asso., Vol. XIII, 1900, p. 96.

advantageous, not for digestive purposes (for even with a large excess of HCl it is not the rule for all the proteid matter to be digested in the stomach), but for destroying the exuberance of microorganisms swallowed with the food and for bringing about a proper reaction for the best digestive secretion of the pancreas. The cases frequently noted in patients without any gastric secretion whatever who succeed in maintaining their nitrogen equilibrium (and we have seen many such), and the experiment on the dog (Kaiser and Czerny), and the weight of which was kept up, although the largest portion of the stomach was removed, and Brigham's and Schlatter's total extirpations of the stomach, constitute but a weak argument against the therapy of HCl. For although such patients and animals manage to get along fairly well for a time, it is only under the most careful and scientific supervision that their health is maintained. Permanent and perfect health with total absence of gastric secretion is rarely observed, except in those who are able to rest much and have their food prepared with great care.

These facts must not be overlooked in considering the work of von Noorden,¹ which demonstrated that absolute and permanent deficiency of gastric juice may be accompanied by perfect health. This health is perfect under the conditions mentioned, but when such patients are taxed by work or the diet is not the usual one, in my experience suffering invariably becomes manifest. If achylia gastrica could really exist without any subjective or objective disturbances, how is it that so many of these patients consult the stomach specialists and are reported by them in literature? When we must work for our living and cannot have the benefit of the dietetic kitchen at all times, we must have an active gastric juice to at least partially disinfect and dissolve our food, and a person who secretes no gastric juice is or soon becomes a patient.

In a recent article on achylia gastrica, by F. Martius and O. Lubarsch², the authors arrive at the conclusion that neither simple achylia nor that dependent upon atrophy of the mucosa (anadenia) can bring about severe anemic or cachectic conditions, unless motor insufficiency, atrophy of the intestinal mucosa, or general diseases (tuberculosis, lues, infections, etc.), are added. Even if this is true, generally speaking, it does not disprove the statement that absence of HCl in the gastric secretion compels the individual to lead the life of a patient, for dyspepsia and dystrypsia may exist and become severe without the anatomic changes spoken of by Martius and Lubarsch. But, over and beyond this, Flint, Fenwick³, Quincke⁴, Nothnagel⁵, Osler⁶, Kinnicut⁷, also Rosenheim and G. Meyer⁸, have described cases of pernicious anemia in which atrophy of the gastric mucosa was, at the autopsy, found to be the only organic disease existing. It is conceivable that the intestine can not persistently digest an amount of proteid sufficient to maintain the nitrogen-equilibrium during work; that it depends upon a certain part of this proteolysis to be performed by the stomach; that the acid gastric chyme is necessary for the stimulation of the duodenal secretions. Pawlow⁹ has proved experimentally that the gastric HCl is an important stimulant to the secretion of pan-

creatic juice. It is probable that digestion in the duodenum is not perfect without the acid proteids, which, as we know, cause increased diastasic action of the pancreatic juice.¹⁰ So that we are justified in concluding on experimental and clinical grounds that in the absence of secretion of HCl in the stomach the entire duodenal digestion is abnormal.

Therefore, we take the ground that the supplementing of HCl is rational, even if we cannot supply the deficit, because the amount necessary thereto could not expediently be administered. If we cannot always add sufficient HCl to make the chyme distinctly acid, we can at least add enough to exert a disinfecting influence and free it from a part, the surplus, of its germs, and perhaps produce some of the preliminary stages to peptone. For the acid albumins (syntonin) and propeptones are absorbable, and those not absorbed,¹¹ we believe, are of some further utility in duodenal digestion. This conclusion is based upon quantitative analyses of human duodenal contents, drawn by my method¹² of duodenal intubation from cases of achylia gastrica, and from normal individuals. In some cases, however, we are enabled to add enough to give the reaction of free HCl to the chyme.

According to Honigmann and von Noorden,¹³ 1 part by weight of pure HCl is able to saturate 18 parts by weight of egg-albumen; 100 drops of dilute hydrochloric acid, containing 0.8 grams of absolute HCl, will suffice to digest 15 gm., or 825 grains, or 13.75 drams, of pure egg-albumen. Riegel cites this statement evidently to show how inefficacious 100 drops of a 12.5% solution of HCl is as a digestive. (The dilute hydrochloric acid of the U. S. Pharmacopeia is a 10% solution.)

The conclusions of Honigmann and von Noorden, however, are, in my opinion, not calculated to inspire therapeutic skepticism; an amount of proteids equal to 13.75 drams of dried egg-albumen is a considerable quantity to be relieved of, and it cannot fail to ease gastric digestion to give the acid, even if it can do no more work than this. But then it is practicable to give more than 100 drops of dilute HCl if necessary. Furthermore, the albumin molecule need not be saturated in order to become absorbable, as we shall see. Not nearly so much HCl is required for the formation of acid albumin as for that of hemialbumose or peptone. Riegel himself succeeded in causing a resumption of secretion of HCl in a patient who had not shown any for months, after he had taken 1.5 gm. of hydrochloric acid daily for 14 days. He believes, however, that diet and lavage may have had much to do with the recovery. Reichmann and Mintz¹⁴ report several cases in which free HCl could be again demonstrated after it had been missing for a prolonged time; the resumption of HCl secretion was attributed by them to a prolonged dosage with the same acid. This condition may depend on a number of very different factors. Sometimes there is no evidence of pathologic change in the mucosa, and naturally these may readily recover (neuroses), even without HCl treatment.

In December, 1898, I had under treatment a well-known Baltimore physician afflicted with an immense atonic dilation of the stomach. The greater curvature extended into the pelvis. Every morning, before break-

fast, stagnating food masses could be washed out of the stomach. I analyzed his stomach-contents after several of the double test-meals recommended in my book¹⁵, but could never detect free nor combined HCl. The ferments, pepsin and chymosin, were still active in their precursory stages; i. e., pepsinogen and chymosin-zymogen. He also suffered from a floating right kidney which could be moved about in his abdomen *ad libitum*. His was perhaps at one time a case of enteroptosis, and in a period far back in his history, his stomach presented most likely a "ptosis" or prolapsus, and from this the gastrectasia developed gradually. He did not present the floating tenth rib, to which Stiller has called attention. This clinician asserted that he found the tenth rib mobile like the eleventh and twelfth, and not attached by cartilage to the costal arch, but perfectly free or only very slightly attached by ligamentous fibers to the costal arch. Stiller¹⁶ claims to have been able to detect this floating tenth rib in a large majority of cases of emaciated nervous dyspeptics afflicted simultaneously with floating kidney and dilated stomach.

After 6 months of medical treatment by carefully selected diet, electricity, daily lavage, rest, and internal administration of dilute HCl and strychnin, no lasting improvement was effected. I then advised my patient to undergo the operation of gastroplication. This operation and that of nephrorrhaphy was successfully performed by my colleague, Professor Randolph Winslow, in June, 1899. The patient, 64 years of age, made a splendid recovery. Five months after this operation, I made 2 careful examinations, and to my surprise and that of the patient, free HCl was detected after the test-meals, the amount in 10 cc. of gastric filtrate being equal to 10 cc. one-tenth normal NaOH.

This return of HCl secretion in the patient was an evidence that the glandular layer had not been destroyed by disease, but that the peptic cells had simply been exhausted by the constant presence of food in the immensely dilated stomach, which could at no time empty itself entirely. The presence of food acted as a constant stimulus to secretion, and the oxyntic or acid cells, as well as the central or ferment cells in the peptic ducts, became exhausted. But with restoration of the normal motor functions, as the food was regularly expelled into the duodenum, they became rested, and resumed their normal secretion.

[TO BE CONCLUDED.]

Inexact Topography—A daily paper in speaking of a recent medicolegal case spoke of the lesion as located in the "Aisle of Ryle."

METATARSAL FRACTURE.

BY

CARL BECK, M.D.,

of New York City.

It is generally accepted that the superficial location of the metatarsal bones makes recognition of their fractures easy. Still, while this may be true of the first and fifth metatarsi on account of their accessibility, the dense tendinous and ligamentous tissues overlying the second, third and fourth metatarsi are apt to veil the fracture-signs within their tract. The difficulty of differentiation is much greater, when, as is the rule, the fracture is associated with injuries of the soft tissues, which cause edema and swelling.

If the fracture is located near the tarsometatarsal joint, crepitus can but rarely be elicited. Pain and tenderness cannot be relied upon as characteristic fracture-

Fig. 1.

signs, since they would be present in simple contusion of the foot, and in equal intensity.

How often metatarsal fracture has been overlooked can be best estimated by the fact, that in the pre-Röntgenian era most cases of fracture of the second or third metatarsus used to be taken for a pathologic change in the soft tissues—in the German army known as "foot-edema." It was reserved for the Röntgen rays to disclose that this much dreaded condition was a fracture pure and simple, and that it was produced by overburdening the marching soldier.

Many cases of so-called neuralgia, metatarsalgia, neuritis, etc., belong to the same category. The small bony enlargements of the foot, its broadening, and sometimes the callosities following metatarsal fracture, were observed in former years; but they were misinterpreted in the majority of cases, since they were due to the badly united fracture only. Union in a displaced position, especially in lateral displacement, must necessarily lead to compression of the digital nerves. It is evident that treatment

of such cases of "peripheral neuritis" can consist only in reducing the fragments to their proper position by osteotomy.

Pain induced by walking points to dorsal or plantar displacement, while metatarsalgia, coming on in a paroxysmal manner, is generally due to lateral displacement. Metatarsalgia is somewhat analogous to coccyodynia, which, as I have had the opportunity to prove (see Appendix to my "Textbook on Fractures," page 288), was produced by fracture in most cases, the fragments also having united in a deformed position.

If only one or two metatarsal bones are broken, but little tendency to displacement is present, which explains why the symptoms of this fracture are, as a rule, not at all pronounced. The other metatarsal bones serving, to a certain extent, as lateral splints, it is natural that the final results in these cases are nearly always good, no matter what special kind of treatment was employed. In the event of displacement, however, the result would be somewhat different.

The textbooks treat metatarsal fracture as a step-child, most of them saying that it would neither require detailed description nor any special mode of treatment. A few say that if there would be any displacement it would be toward the dorsum of the foot. Only Hoffa alludes to the possibility of plantar displacement also. But nowhere is reference made to the lateral displacement, which I regard as of no infrequent occurrence, and also as an important complication, since it is always followed by considerable functional disturbance. The fact that the lateral displacement was never recognized before explains fully why efforts of reduction have neither been made nor advised; consequently, the fragments, left to themselves, whether in a general immobilizing dressing or not, unite in a deformed position, and bony enlargements, as well as functional disturbances, have been the result. The edematous feet of persons who have to work hard, or to march, or to stand on their feet during the whole day, furnish a striking illustration of the consequences of badly united metatarsal fractures, as they are disclosed nowadays by the Röntgen rays.

It is obvious that the more accurate and various diagnoses they enable us to make must also inspire different plans of treatment.

1. If there is no displacement present in fracture of any of the second, third or fourth metatarsal bones, a simple and short plaster-of-paris dressing fulfills all requirements. During the first week the patient is best kept in bed. During the following two weeks he should carefully try to walk in an ambulatory dressing, made by applying a solid plaster-of-paris dressing, after the skin is well oiled. The dressing reaches from the toes up to the lower third of the leg. The support is furnished by the malleoli. The sole of the dressing is fortified by inlaying with strips of tin, zinc or wood.

2. If the first or fifth metatarsus is broken, and no displacement is noticeable, a small strip of mossboard, slightly moistened, is placed alongside of the outer or inner margin of the foot, before the plaster-of-paris dressing is applied. The ambulatory dressing should not be chosen for this type before two weeks.

3. If there is displacement of the second, third or fourth metatarsal bone, either in the dorsal or the plantar direction, pressure will easily reduce the fragments. They are then kept in place by coaptation-splints, preferably also consisting of mossboard and protected by a plaster-of-paris dressing. The after-treatment is conducted on the same principles as that of the former type.

But if the displacement is sideways, reduction is somewhat more difficult. It is accomplished best by grasping the fragments as firmly as possible near their epiphyseal ends and alternately turning and shifting them until reposition is perfect. Sometimes a consider-

Fig. 2

able degree of counterpressure is necessary. To hold the fragments in place is a still more complicated task; for, as shown by the Röntgen rays, the displacement will recur even if a plaster-of-paris dressing is applied at once. If the lateral displacement is such that the metatarsal fragment (as is evident, for instance, from Fig. 1) is pressed against its neighbor, consolidation may take place between the two metatarsi; and this would naturally be followed by functional impairment, as well as by disturbances of a sensory nature.

Previous experiments have showed me that metacarpal fragments are invariably held in place by elastic

pressure.¹ The same principles obviously apply to metatarsal fracture.

For fracture of a displaced metatarsal bone, two rubber drainage-tubes of moderate size are chosen, and lightly pressed into the adjoining interosseous spaces at the dorsum, so that they fill them up to a certain extent. (Fig. 2.) If two metatarsi are fractured, three drainage-tubes are necessary, and so on. The tubes are kept in situ by adhesive plaster strips; thus the recurrence of the displacement is absolutely prohibited. The dorsum is surrounded then by a moss-splint, a material which, after being dipped in cold water, adapts itself to the contours of the foot like a cast. The whole is protected by a plaster-of-paris dressing, which reaches from the toes up to the lower third of the leg. The patient remains in bed for about 10 days. Then an ambulatory dressing is applied after the principles elucidated above.

When skiagraphed through the plaster-of-paris dressing, the formerly displaced fragments must be found in exact apposition. If not, the dressing must be reapplied in the corrected position. There is no doubt that in pursuing these therapeutic principles, which are based upon a correct anatomic diagnosis, metatarsalgia and its companions will become a very rare affection.

Fig. 1 represents the case of a man of 31 years, who sustained a fracture of the lower epiphyseal ends of the third and fourth, and a fissure of the second metatarsus. While smoothing the asphalt pavement on the street, holding an iron bar of 40 pounds in his hands, he was knocked down by a street-engine coming from behind, so that he fell forward. While the second metatarsus shows only a slight sideward bending, the dentated fragment of the third metatarsus is markedly displaced outwardly. The lower fragment of the fourth metatarsus is not only displaced, but its external portion is also tightly pressed against the fifth metatarsophalangeal joint. Fig. 2 shows the rubber tubes in apposition. The patient was able to walk in one week in an ambulatory dressing, and made an uneventful recovery.

SOME REMARKS ON INGUINAL COLOSTOMY.

BY

WILLIAM J. MAYO, A.M., M.D.,
of Rochester, Minn.,
Surgeon to St. Mary's Hospital.

Several years ago I received a marked copy of a newspaper printed in a neighboring state in which it said, in substance, that Mr. — had just died in great misery as the result of an unnecessary operation performed upon him in the hospital with which I am connected. I recollected the case well. The man had an inoperable carcinoma of the rectum. I had made an inguinal colostomy as a palliation, and he lived about 4 months after leaving my care. The article seemed to me to be wholly malicious, but after some reflection I am not sure that it was entirely unjust. The operation certainly did not cause his suffering, but was the relief obtained sufficient to warrant the pain of an operation, with its expense and the separation from his family during several weeks? It is an open question.

Ten years ago, excision of the rectum was in great disfavor, the immediate mortality was high, the percentage of permanent cures near the vanishing point. Colostomy gave relief in cases in which obstruction was a prominent symptom, and was deservedly popular. The ease of performance and the small mortality of the operation itself, led to its indiscriminate employment, merely because the patient had a cancer of the rectum. It has been claimed that by deflecting the fecal movements and giving the rectum absolute rest, partial atrophy of the unused portion of the bowel is one result, and that the diminished blood-supply and avoidance of irritation checked the growth of the malignant process or greatly retarded its progress, and experience has shown that to a certain extent this is true. It should not be forgotten, however, that carcinoma of the upper rectum is often, if not usually, a slow process, and much of the supposed prolongation of life is the natural evolution of the disease. High carcinoma of the rectum, in my experience, is not infrequently found in the comparatively young. I had one patient but 14 years of age and several under 30. Vast improvement in the results of excision of the rectum followed the impetus given this operation by Kraske, to whom much credit is due, although there is a great tendency to radical departures from the technic he popularized. The results, both immediate and remote, of radical operations in this locality are relatively good, and compare favorably with those for carcinoma of the breast or uterus.

This at once removes a large number of cases from the list in which colostomy has been the resource. In advanced cases without obstruction the operation is not indicated, and surgery is discredited by its performance, but in selected cases colostomy is of great benefit to the victims of hopeless disease.

In making a permanent artificial anus, the suggestion of Wyeth that all of the movable sigmoid should be pushed upward, making the opening as near the rectum as possible, is of great importance. The sigmoid flexure of the colon is the natural reservoir of fecal accumulation, and by placing it to the proximal side the ability to retain the feces is much better than after the method of Allingham and Cripps, in which, to prevent prolapse of the mucous membrane of the upper colon, it is advised that as much of the bowel as will readily pass to the distal side of the artificial anus should be so placed. The formation of a spur is best accomplished by suturing the proximal and distal limbs of the colon to each other and the advice of Kelsey, that the margins of the incision be well fastened to the colon, to prevent wound-separation under sudden strain, is sound. Kelsey had 2 cases in which the small bowel escaped alongside of the colon during a fit of sneezing or coughing, 24 to 48 hours after operation.

The most annoying feature of the average artificial anus is the difficulty of controlling the escape of feces and gas at inopportune times. Bailey suggested and carried out a plan for colostomy on the principle of the gastrostomy of Ssbanajew-Frank. This operation is especially recommended by Tuttle. An intermuscular separation of the usual colostomy incision is made, through which the loop of sigmoid is drawn out and a

¹New York Medical Journal, August 4, 1900.

spur formed. The knuckle of bowel is firmly anchored in the deeper wound, with sufficient projection of the apex to enable the anus to be formed at a separate skin incision 2 inches below, in the direction of the internal ring. The superficial incision at the point of egress of the bowel from the abdominal cavity is now closed. The loop of colon lying between the skin and muscular wall of the abdomen is easily compressed against the firm aponeurosis of the external oblique muscle by an elastic truss with a water pad. The appendices epiploicae, which may be exposed on the open surface of the bowel, should be ligated at their base and cut away, as they slough and separate slowly, adding considerable unnecessary odor. The exposed bowel should be covered with some protective dressing, such as rubber tissue, to prevent the granulations which firmly unite the gauze to the colon and cause great difficulty in getting it loose. Witzel makes colostomy after the same general plan as Bailey's, except that the colon is divided and the distal end inverted and permanently closed, the proximal end being carried over the iliac crest. It sometimes happens that the mesentery of the sigmoid is too short to allow of its being sufficiently drawn forth for the formation of the colostomy as described. Under such circumstances, the operation of Maydl will usually be fairly satisfactory. Grieg Smith endeavored to obtain better muscular control by separation of the muscular layers in their natural lines and not suturing the parietal peritoneum to the skin, as has been so commonly practised, allowing the knuckles of colon to become attached directly to the muscle fibers. I have found this advice excellent. To those interested in the subject of artificial anus, the scholarly article of Robert F. Weir¹ will be of great value.

Colostomy as a preliminary step to excision of the rectum has been largely practised, but as the newer operations almost invariably permit of a restoration of the continuity of the bowel, the danger of wound infection from fecal contamination is greatly reduced and as it requires an independent operation for its performance, as well as closure, it is probable that the combined risks are greater than a well planned complete primary excision. If a preliminary colostomy is made, it should be located as high on the bowel wall as possible, giving the greatest amount of sigmoid below the artificial anus for future manipulation during the excision. As a preliminary step to an extirpation of rectal carcinoma, I have made a colostomy 4 times. My first case was lost as a result of tension on the sigmoid causing gangrene. The artificial anus firmly anchored the colon, and after the resection of the rectum there was not enough sigmoid to reach to the proper site of attachment without undue strain.

While the field of colostomy has greatly narrowed in malignant disease, for nonmalignant affections of the rectum it has an increasing usefulness. Tuberculous and other forms of ulceration of the rectum which are essentially chronic or incurable in their nature, as well as some nonmalignant strictures are best treated by temporary or permanent artificial anus. In deciding upon colostomy, it should be ascertained if possible, beforehand, that the diseased condition does not extend above the point at

which the artificial anus is to be situated. Some 6 years ago I had a case of multiple polypi of the rectum. There were profuse and foul smelling discharges of mucous, pus and blood. The man was in miserable condition. It was thought, after such examination as could be made, that the disease was confined to the rectum. A left inguinal colostomy was performed with a result of greatly aggravating his already deplorable condition. Before the operation he was able to control his discharges but nothing would prevent their escape from the artificial anus and he became a burden to himself and everyone with whom he was brought in contact, and later the opening was closed by another surgeon. I have since encountered 4 of these cases of multiple rectal polypi, and have been able to satisfy myself that the disease extended throughout the entire colon, as in my above related unfortunate experience. In doubtful cases since that, I have exposed the sigmoid in the inguinal region before doing a colostomy to make sure that such an opening would be above the seat of disease. In this way the lumen of the bowel can be explored in the same manner as the rectum, and in 2 instances I found the disease had extended to a point above the proposed site of the colostomy thus rendering the intended operation useless. A few sutures close safely the exploratory incision in the bowel itself.

From my own experience I would urge that this be more frequently done, and the point of exploration need not necessarily correspond with the intended artificial anus, and if desired the delay in the opening of the colon to secure safe adhesions may be postponed a few days without regard to the sutured intestinal opening. I will merely call attention to right sided colostomy for the relief of chronic diseases of the entire colon. Temporary right artificial anus has been performed by Barbat and Sullivan for the cure of amebic dysentery. Keith recommended and carried out this procedure for the cure of chronic membranous colitis. White and Golding-Bird, Lawrie, and others also report cures of this troublesome form of colitis in a similar manner. Right-sided colostomy does not offer the mechanical conditions requisite for a satisfactory anus; the discharges are more liquid and the inability to lift the ascending colon out of the wound precludes the possibility of an adequate spur or perfect control. However, as the pathologic conditions calling for right-sided colostomy are in themselves so serious a disability, the relief from pain and the prospects of cure may compensate for the annoyance. For temporary purposes the colon should be opened longitudinally and the retraction will usually be sufficient to enable one to close the opening by an incision about the margin of the artificial anus, and after trimming away the skin, a few provisional sutures will prevent leakage during the further steps of the operation, which is completed by opening into the free peritoneal cavity, loosening up the sigmoid and with a second row of sutures turning in the first row.

On a recent visit to Krause's clinic at the Altona General Hospital, Germany, he exhibited several cases in which he had passed a specially devised clamp, one jaw into each limb of the open lumen of the bowel, and by slowly closing the instrument the opposing surfaces

¹ *Medical Record*, April 21, 1900.

were compressed, and by necrosis, a communication between was established. The instrument was made of aluminum to prevent weight-pressure of the handles on the wound, and was left in position a week. The external opening closed spontaneously after the anastomosis was established. The instrument is so constructed as to exert its pressure at a point beginning 2 inches below the external opening and the communication established is $2\frac{1}{2}$ inches long by $\frac{3}{4}$ inch wide. In elderly or debilitated subjects this contrivance, to avoid the necessity of a secondary operation, might be of value. I brought 1 of the instruments home with me, but have hesitated to use it. Krause's results were good, but the essential principle is the same as the old and rightly abandoned operation of Dupuytren.

In conclusion it may be said:

1. Colostomy is not now a rival of excision of the rectum for malignant disease, and should only be employed in hopeless cases presenting obstructive phenomena.
2. For a permanent colostomy, the combination of Wyeth and Bailey's methods gives a satisfactory result.
3. Colostomy preliminary to excision of the rectum should be located high on the colon to give sufficient length of sigmoid to permit restoration of the continuity of the bowel.
4. For ulceration and other conditions in which the upper limit of the disease is not definitely known, the interior of the bowel should be explored through the inguinal incision in order to determine the proper site of the opening.
5. Right-sided colostomy has an increasing field of usefulness, as in amebic dysentery, chronic colitis, etc.

THE PREVALENCE OF STREPTOCOCCI IN COW'S MILK.

BY

D. H. BERGEY, M.D.,
of Philadelphia.

First Assistant, Laboratory of Hygiene, University of Pennsylvania.
(From the Laboratory of Hygiene, Univ. of Penna.)

Last spring I was requested to make a bacteriologic examination of some milk which had presumably been the cause of sickness in an infant fed upon this milk, which was derived from one of our best dairies. The examination revealed the presence of enormous numbers of streptococci. This result led to the employment of milk obtained from other first class dairies and the examination of each yielded the same results, viz., the presence of large numbers of streptococci. These samples of milk, as they reached the laboratory, were in the form of separate feedings which had been kept warm for some hours, in short, each sample submitted was prepared in the same manner as the several feedings required during a night. It is probable, therefore, that the treatment of the milk was responsible for the large numbers of streptococci found, but was not accountable for their presence.

The following questions presented: To what extent are streptococci found in the milk of healthy cows?

Are they more prevalent in herds kept under bad sanitary conditions than in those kept under the most approved conditions? What is the significance of the presence of streptococci in cow's milk?

Very little light could be gained from the literature of the subject. Archibald R. Ward¹ had shown that "certain species of bacteria normally persist in particular quarters of the udder for considerable periods of time." This statement is based upon the results of the bacteriologic examination of the udders of 19 cows immediately after death. Dr. G. Leslie Eastes² found streptococci in 75.2% of the samples of milk examined. Dr. Max Beck³ made an examination of 56 samples of Berlin market milk. A definite portion of each sample of milk was injected into the peritoneal cavity of a guineapig, and in this manner it was found that 62.3% of the samples contained streptococci. These streptococci produced purulent peritonitis, causing the death of the animal in 3 or 4 days. All the experiments of Beck, with pure cultures of these streptococci, indicate that they were probably identical with the ordinary *Streptococcus pyogenes*.

During the past summer a number of samples of milk, collected from individual cows, were examined for the presence of streptococci, and they were found to be present in the milk of some cows and absent from that of others. They were found somewhat more frequently in the milk of cows kept under unfavorable conditions than in that of cows kept under the best hygienic conditions, though the differences were not very marked, probably on account of the season of the year at which the examination was made. The examinations were made by centrifuging 10 cc. of the milk and then examining stained films prepared from the sediment.

Of 40 samples of market milk examined in this manner 90% were found to contain micrococci, while in 50% of the samples streptococci were definitely found. It is also most probable that most of the other samples containing micrococci contained streptococci, but no definite chains of cocci were found in these.

Of 16 samples of mixed milk collected from one of our best dairies only 12.5% contained micrococci, while only 6.25% contained streptococci. Of 28 samples collected from another of our best dairies only 17.8% contained micrococci, and no streptococci were found. In another first class dairy, of 7 samples of mixed milk examined, 85.71% contained micrococci, and 28.57% contained streptococci. In still another first class dairy, of 8 samples examined, 62.5% contained micrococci, while none contained streptococci.

Cultures of streptococci were isolated from the milk of several individual cows and inoculated into the skin of the ears of rabbits, but, aside from slight edematous inflammation at the point of inoculation, no results were obtained. Eight samples of milk derived from individual cows belonging to first class dairies were injected into the peritoneal cavities of guineapigs but only 3 of the animals died and *Staphylococcus pyogenes aureus* was isolated from the peritoneal cavity and organs of these animals; no streptococci were found. While streptococci had been found in limited numbers in these samples of milk by cultural methods none had been

found by examination of the sediment of the centrifugized milk.

Nothing definite can, as yet, be stated with regard to the significance of the presence of streptococci in the milk of healthy cows. Beck believes that they are closely related with the streptococci which Escherich found in infantile enteritis, and states that Romme also believes that they are the cause of severe forms of colitis in children. Judging from the results of Beck's experiments, it is most probable that these organisms are not infrequently the cause of serious gastrointestinal disorders in infants. The effects noted in the infant whose illness led up to the present investigation, indicate that this source of infection should always be taken into consideration where the cause of the sickness is not at once apparent.

In the light of the results obtained from this examination, and those of Ward, Eastes and Beck, the labors of the Pediatric Society of Philadelphia, in the direction of securing a satisfactory milk supply for infant feeding, are most praiseworthy. The most important phase of their labors consequently is not so much the securing of milk of low bacterial content, but the systematic examination of the herds and dairies from which the milk is derived. While no inflammatory conditions of the udders were noted in the cows whose milk was examined, it is probable that repeated examination of herds by competent veterinarians will tend to the detection of any such conditions should they exist in any herd. The extreme cleanliness which is necessary in order to produce milk containing less than 10,000 bacteria per cubic centimeter will also tend to the exclusion of extraneous bacteria from milk. In this respect herdsmen should be cautioned regarding the danger to the milk from the hands of milkers having even slight lesions. The entrance of such bacteria into a milk poor in bacteria would be followed by enormous multiplication under favorable conditions of temperature.

CASE OF CONGENITAL FORM OF HERNIA OF THE APPENDIX VERMIFORMIS IN CONJUNCTION WITH A CYST OF THE CANAL.

BY

G. CHILDS MACDONALD, M.D.,
 of San Francisco, Cal.

Brux, [Hon. F.R.C.S., Ed., M.R.C.S., Eng., Fellow Med. Chir. Soc., London, Visiting Surgeon to St. Mary's Hospital.

W. A. F., a mariner, aged 16, and a native of Liverpool, England, was admitted to St. Mary's Hospital, January 16, 1901, complaining of pain and swelling in the right iliac region.

His previous history was good, but in 1891 he had enteric fever. Two months prior to his admission to St. Mary's he experienced pain in right iliac area. This was aggravated by going aloft on his ship and by straining at stool. His bowels were regular, but on 3 different occasions he vomited. About this time a swelling appeared at the external abdominal ring which lasted for 3 weeks, disappearing when a cold compress was applied.

The patient was a well developed and well nourished young man, about 5 feet 7 inches in height, the abdomen was normal in outline, save a slight fullness in the right inguinal canal.

There was a tenderness over the whole right iliac fossa, which was most marked on pressure at a point midway between the anterior superior iliac spine and the umbilicus, the bowels were irregular. He was kept under observation for 14 days. The pain in area above noted varied from day to day, at times being severe, at others absent. The part was, however, always sensitive to touch. Vomiting occurred on several occasions.

The treatment pursued was palliative, consisting of hot fomentations to the painful region, and mild aperients, as castor oil, the diet was restricted to peptonized milk; but as there was no improvement, I determined to open the abdomen.

The patient being prepared, and the usual aseptic precautions having been taken, the operation was performed on January 26, 1901. The line of incision extended along the outer border of the rectus, about 3 inches in length, so that its center corresponded to a point midway between the anterior superior iliac spine and the umbilicus. On opening the cavity of the peritoneum the following conditions presented: The internal abdominal ring was patulous, and lying just inside it was the appendix, which measured $3\frac{1}{2}$ inches, and had a long mesentery at its upper third, the remainder being free. The entire organ was somewhat hypertrophied and evidently contained some semifluid material.

On passing the forefinger into the internal abdominal ring, it caught on a fine cord descending along the inguinal canal. This, on being withdrawn, was seen to consist of a filament of white fibrous tissue about $3\frac{1}{2}$ inches in length, ending in a cyst about the size of 2 lima beans. The cyst wall was of very delicate structure, containing a clear straw-colored fluid. The finger could now be passed down the canal to the testicle, which was below and behind. The upper, lower and anterior surfaces of the organ could be well made out, proving the condition to be congenital. The pedicle of the cyst was found to spring from the distal portion of the cecum and was, no doubt, a cystic degeneration of one of the appendices epiploicæ. This was removed with the appendix in the usual manner.

It now remained to close the internal ring, which was accomplished the more readily by reason of the extreme looseness and redundancy of the peritoneum, the peritoneal lining of the canal could be drawn out of the canal like an invaginated finger of a glove at its base. This portion was sutured across with catgut and the whole lower segment brought up into the inferior angle of the wound and there firmly sutured; thus the upper end of the canal was obliterated. The orifice was covered by a smooth continuous portion of the peritoneum, leaving no hole or depression for future trouble. The abdomen was closed with one row of interrupted silk worm gut sutures.

The patient made an uninterrupted recovery; the wound not being dressed until the eighth day, when it was found to have healed by first intention; the sutures were removed on the tenth day, the cicatrix was solid, presenting a straight linear scar. The patient sat up on the lounge on the fourteenth day. He said, "the pain and discomfort have left." He is now on light diet. The bowels have acted regularly since the second day of the operation. The temperature has been normal and the pulse has averaged between 60 and 64.

I have never, up to the present time, seen or heard of a case quite like the above. Probably there have been such but I have failed to run across their reports.

The Fabrication of Antiplague Serum in the laboratory established recently at Manguinhos, was placed under the control of the Federal Government on May 24, 1900. Since then it has been under the charge of the general board of health, by which its name was changed to "Institute Serotherapico Federal."

The Bacteriologic Laboratory at Rio Janeiro for the examination of suspected cases of diphtheria and distribution of the respective serum, is connected with the vaccination institute. During the year 1900 there were distributed 806 bottles of serum, received from the Pasteur Institute; there being 559 bottles of antidiphtheric serum, 185 of antistreptococcal serum and 62 of antitetanic serum.

PRACTICAL THERAPEUTICS

Under the charge of
A. A. STEVENS,
Assisted by
L. F. APPELMAN.

Phosphorus in Rachitis.—Monti (*Wiener klin. Woch.*, January 17, 1901) states that phosphorus does not cause the slightest improvement in cases of rachitis. He believes that a specific action has not been demonstrated experimentally or clinically. [Jacobi holds a favorable opinion of phosphorus not only in rachitis, but also in purpura, scurvy and in similar processes. He has obtained the best results from its use in craniotabes. He recommends from 6 to 15 minims 3 times daily of the official elixir of phosphorus.]

Ichthyoforn and its Use in Practical Therapeutics.—Polacco (*Treatment*, February, 1901), records the following results of the use of this drug, which is a combination of formaldehyd with ichthyol: Ichthyoforn is both energetic and innocuous when used as an intestinal antiseptic. It has no untoward effects upon the heart or upon the kidneys. In that most intractable form of diarrhea due to intestinal tuberculosis its action is very successful, and it may be used with good effect in the diarrhea of typhoid fever, and also in dysentery. The drug appears to combine the analgesic and astringent action of ichthyol with the exceedingly energetic influence of formic aldehyd. The average dose to adults is 15 to 30 grains in 24 hours, although in some cases much larger quantities have been taken.

Treatment of Acute Nephritis.—Perrier (*Merck's Archives*, March, 1901) aids elimination and relieves vascular engorgement of the kidneys by placing the patient in bed between blankets, in order to promote the free action of the skin and induce sweating. Profuse diaphoresis is produced by giving hot drinks freely. The bowels should be moved freely every day by the use of saline cathartics in hot, concentrated solution. The diet should be light and at first confined to bland, nutritious liquids. In severe cases the use of the hot-air bath may be necessary. When the urine is scanty or if suppression exists, hot linseed-meal poultices, containing a tablespoonful of mustard, applied to the loins and changed at intervals of 4 hours are generally successful, leeches or cupping over the loins never having been necessary in the author's experience. In the nephritis of scarlatina, when uremia is threatened or has occurred, the hot pack is most valuable with administration of pilocarpine to promote sweating if the heart is strong and the pulse full. In the uremia of acute nephritis, when all other means fail, resort should be had to the subcutaneous injection of normal salt-solution, of which 1 quart should be given and repeated every 6 to 12 hours until relief is obtained. High enemas of the same solution may be substituted but are not nearly so effective. Croton oil in $\frac{1}{2}$ -drop doses every hour until the bowels have moved freely aids in elimination, or elaterium may be given for the same purpose. The free use of natural lithia waters should be continued for some months after convalescence is established. The diet should be gradually extended; farinaceous foods may be given freely but no meat should be allowed until albumin has disappeared from the urine.

Suprarenal Capsule in Diseases of the Lower Air-Passages; a Preliminary Report.—Floersheim (*Medical Record*, November 17, 1900), concludes: The suprarenal powder is indicated in acute and chronic bronchitis, bronchiectasis, asthma, congestion and edema of the lungs, hemoptysis, and in some cases of pulmonary tuberculosis, especially in those associated with hemoptysis. The suprarenal powder should be administered in the form of 3-grain capsules on account of their convenience. The powder should be chewed without water, and then swallowed in a few moments. The action becomes apparent in from 2 to 15 minutes. In some cases the action of the suprarenal powder was permanent, while in the majority of cases the action was temporary, continuing from 10 minutes to 6 hours.

Gastric Hemorrhage and Surgical Treatment.—A. Mayo Robson (*Scottish Medical Journal*, March, 1901) draws the following conclusions for the treatment of gastric ulcer: (1) All cases of acute uncomplicated gastric ulcer should be submitted to thorough medical treatment in the shape of long-continued rest and attention to diet, the patient not being allowed to get up or to resume solid food until at least a fortnight after all disappearance of pain; (2) when the ulceration persists and proves intractable to medical treatment, or when relapses occur, gastroenterostomy should be performed, so as to secure physiologic rest and relieve the hyperacidity of the gastric juice nearly always found in such cases; (3) perforation demands immediate surgical treatment; (4) the complications of disabling adhesions around the stomach and pylorus, pyloric contraction and hour-glass contraction due to chronic ulcers leading to pain, dilation, loss of flesh, and general impairment of health, and now often treated as chronic indigestion, should be treated surgically; (5) in recurring, or so-called chronic hematemesis from chronic ulcer, surgical treatment is decidedly called for; (6) in acute hematemesis, further accuracy in diagnosis as to the size of the bleeding vessels is urgently needed; and the cooperation of the physician and surgeon is advisable in all cases of hematemesis, so that if relief be not obtained by medical and general treatment, surgical means may be adopted if the bleeding is believed to occur from a large vessel; but seeing that capillary hemorrhage is capable of relief by medical means alone, medical should always precede surgical treatment.

Intravenous Injections of Cinnamic Acid in Tuberculosis.—Hödlmoser (*Zeitschrift für Heilkunde*, 1900, No. xi) reports 18 cases of tuberculosis treated with intravenous injections of cinnamic acid. The injections were given daily for from 1 to 6 months. Sixteen of the cases had pulmonary tuberculosis; 1 had tuberculous peritonitis, and 1, tuberculosis of the lungs and joints. Of the whole number 22% improved. How far improvement is to be attributed to the cinnamic acid is still an open question. Under this treatment Fraenkel reported 90% improved, and Weismayr, 74% improved. Hödlmoser believes with Ewald that the treatment is worthy of further study.

The Treatment of Whooping-cough.—Goodson (*Treatment*, February, 1901) says that the method of treatment he has found most satisfactory is the following: Begin at once with the continuous inhalation of creasote. Clear the lungs of bronchitis as much as possible before using any special internal antispasmodic remedies. In bronchopneumonia, however, belladonna appears at once to do good. In all cases, when the chest is fairly clear and the circulation good, antipyrin may be given in suitable doses. Expectorants should be combined with the antipyrin. Good air, warm clothing, light and wholesome food are necessary in all cases. He has followed these rules for the last 6 years, and am quite satisfied with the results. The average length of time required for cure in a variety of cases last year was 19.8 days, but these figures in no way represent the benefit derived from the creasote treatment. In every case the diminution in the number of paroxysms was so immediate that the patients willingly put up with the inconvenience of the smell of the drug for the sake of its manifest advantage. This in itself is a sufficient testimonial to the remedy to warrant its more extensive employment.

The Treatment of Burns in Infancy and Childhood.—C. W. Allen (*Pediatrics*, March 15, 1901) states that he knows of no better local remedy for burns of the first and second degree than picric acid. Applied in a 1% watery solution it has the effect of giving almost immediate relief from pain, and healing takes place rapidly under its use. After the burned area has been coated once or twice with the solution a thin layer of absorbent cotton may be applied dry, over this a layer of impervious tissue, then as much cotton as is required, and over this a loose bandage. At subsequent dressings all may be removed excepting the dressing next to the skin which may be made wet with the picric acid solution and the dressings be applied as before. The pain of erythematous areas may be greatly relieved

by local baths containing potassium nitrate or sodium bicarbonate in saturated solution. In deeper and extensive burns a permanent bath offers one of the best means of securing comfort and warding off a fatal issue. A narrow tub may be improvised for this purpose. The permanent bath for the entire body, as employed for burns with excellent results in the Vienna Hospital, can be initiated in the severe burns of infancy. Exuberant granulations may be treated by brushing over the surface a strong solution of silver nitrate or passing over the granulations with the solid stick of silver nitrate. As a soothing remedy the author has found carron oil (lime-water and olive oil) useful. He incorporates with it boric acid (5%), thymol (1 to 1,000), carbolic acid (1 to 500), or orthoform (1%). He emphasizes the importance in redressing of allowing the last layer of gauze or cotton to remain on the wound, and applying the solution, oil or ointment over and through it.

Formalin in Pulmonary Tuberculosis.—Hoffner (*Therapeutische Monatshefte*, February, 1901) reports 10 cases of tuberculosis in which he used formalin inhalations with unfavorable results. On the other hand Beerwald (*ibid.*) believes that the inhalations lessen the cough and secretion, sharpen the appetite and promote sleep.

Infantile Scurvy.—J. P. C. Griffith (*Phila. Med. Journal*, February 2, 1901) reports 16 cases of infantile scurvy, and calls attention to the fact that the disease is often mistaken for rheumatism, as pain in legs or arms is often the first symptom. He states that hematuria may be the sole symptom, and that redness and swelling of the gums may be absent, especially if no teeth have appeared. With or without an alteration of the diet a cure usually follows the administration of fresh fruit juice (orange juice). Since in many cases a change of diet is not necessary to effect a cure, he warns us against too quickly altering the food which for certain reasons has been deemed best, simply on the ground that scurvy has developed, a curable scurvy being much to be preferred to a possibly fatal diarrhea or gastritis, the result of a diet which may precipitate these. When raw milk can be used safely it is to be preferred.

The Treatment of the Later Phases of Heart Disease.—Heffron (*Boston Medical and Surgical Journal*, January 31, 1901) states that when compensation has failed it is important to lessen the work of heart by keeping the patient at rest, and by diminishing the volume of blood to be propelled. For the latter purpose he recommends hydragog cathartics in the following order: Elixerium, calomel and salines. The distressing nervousness which increases the irritability of the heart is best controlled by ice-bags locally, and by codein or morphin internally. Heroin he believes is a modern fraud. In cases in which the restlessness was not extreme he has found cannabis indica very efficacious. The diet, of course, must be controlled. When there is dropsy, mechanical means are often necessary before drugs will act. The author advocates the use of the hot-air cabinet and the administration of digitalis, squill or potassium acetate to increase the flow of urine. He believes the oxygen-inhalations are of great value in completing the metamorphosis of waste matter. While strophanthus, spartein, adonis vernalis and eactus are useful, digitalis is the most reliable heart stimulant. In sudden heart failure, quickly acting stimulants—nitroglycerin, ammonia, alcohol and strychnin should be used.

The Action of Iron in Anemia.—Müller (*Deutsche Med. Woch.*, December 20, 1900) concludes from a series of experiments upon young pups that inorganic iron salts act by stimulating the activity of the blood-making organs. In support of this conclusion he found that iron caused a marked increase in the number of nucleated red blood-cells, and an increase in the number of mitoses. He believes that nothing is gained by using complicated preparations of organic iron. On the other hand caustic preparations, like the tincture of chlorid, should be avoided because their action on the gastric mucous membrane interferes materially with absorption. He states a preference for the oxytartrate of iron and for Blaud's pills.

Treatment of Gonorrhoea.—Balch (*Boston Medical and Surgical Journal*, February 7, 1901) states that it is best to treat cases of acute gonorrhoea twice daily for the first week or 10 days, and subsequently to allow the patient to use an injection 2 or 3 times a day for 2 or 3 weeks longer. As abortive remedies he prefers silver nitrate, potassium permanganate and protargol. He uses silver nitrate in a solution of 1 grain to the ounce, or, if the inflammation is not very active, in a solution of 2 grains to the ounce; protargol in $\frac{1}{2}$ % solution, weaker if there is much scalding; and potassium permanganate in a solution of 1 to 4000 in large quantities rather than a less amount of a stronger solution. It is often necessary to give mild astringent injections with any of the above solutions to remove the gluing together of the lips of the meatus in the morning. If the patient is first seen after the disease is well developed, injections, if used at all, should be very mild. It is best to rely on medicines, such as the citrate or acetate of potassium, which make the patient thirsty. The same result is secured by drinking large quantities of water. Compound salol capsules are efficacious, and should be taken after meals and before going to bed. In obstinate cases it is occasionally surprising to see how promptly the discharge subsides when all treatment is suspended.

Sodium Salicylate in Diabetes Mellitus.—Williamson (*British Medical Journal*, March 30, 1901) states that recently he has prescribed sodium salicylate in a number of consecutive cases of diabetes and glycosuria, and in 20 of these he has been able to keep records of the sugar excretion. He does not regard the drug as a specific for diabetes. It does not usually produce any marked diminution of the sugar excretion in the severe forms of the disease; also it has little influence in some of the mild cases. But in certain mild cases of diabetes or persistent glycosuria it has a decided action in very markedly diminishing the sugar excretion. The drug is not suitable for all cases. It must be watched, and fairly large doses are necessary to secure decided results. The author prefers the natural sodium salicylate to the artificial preparation. Ten grains should be given 3 and then 4 times a day, and this amount steadily increased to 15 grains 4 or 5 times a day. Even in severe forms of diabetes, while the sugar excretion is not diminished, patients sometimes gain in weight and improve in general condition under the salicylic treatment.

Treatment of Senile Pruritus.—Jaenecke (*Treatment*, March, 1901) observed that the regions affected in these cases were dry, glazed and ill-nourished, and that a quantity of degenerated epithelial cells could be separated by brushing. He recommends regular friction with a soft brush continued for from 10 to 20 minutes 3 times daily, then twice a day, and finally once every second day, which should be kept up. This removes the degenerated cells and increases the nutrition of the part. At first there may be no observable change either in the irritation or nutrition of the skin; but in a short time the patient experiences marked relief, and in many instances is entirely freed from suffering. No water should be applied to the affected area, as it counteracts the effect of the brushing, and produces only temporary alleviation itself. Patients frequently brush with so much vigor that the skin is abraded, and the itching may be at first increased in intensity. Lanolin inunctions are useful in the intervals.

The Treatment of Typhoid Fever.—Stengel (*Therapeutie Gazette*, November, 1900) recommends camphor as a cardiac stimulant in certain cases of typhoid fever when the maximum of stimulation is required to combat the depression resulting from diarrhea, tympany or other causes. Camphorated oil, consisting of 1 grain of camphor dissolved in 15 minims of sterilized olive oil may be injected under the skin without pain, and with rarely any unpleasant consequences, such as indurations or abscesses. The oil is quickly absorbed and the stimulation is prompt and continuous, at the same time quieting the nervous system. Injections of 1 or 2 grains may be given every 2 hours, although as a rule 4 hours should elapse before the dose is repeated.

The Therapeutic Use of the X-Rays.—H. P. Towle (*Boston Medical and Surgical Journal*, April 11, 1901), reviewing the literature of the therapeutic use of the x-rays, draws the following conclusions: That the real nature of the x-rays is not yet determined definitely, nor whether the therapeutic action following their use is due to the action of the rays themselves, or of something of electrical origin accompanying them; that the treatment is not without danger, unless the greatest care is used; that the effects of the x-rays remain for a long time, and recovery is very slow; that whatever may be the exact origin of the effects produced, a definite reaction is caused in the skin by the use of the x-rays; that the changes induced in the skin are similar histologically to those seen in ordinary inflammation; that the x-rays are not proved to have any bactericidal power; that their therapeutic effect is probably due to the inflammation existing; that hair can be removed by their use, and that lupus and several other diseases can be healed over; that in a few reported cases we may fairly assume that a permanent cure has been effected, but that in a majority of the reported cases too little time has elapsed to rule out the possibility of return of the disease; that the effect of exposure to the x-rays is so extraordinarily slow in disappearing that months should elapse before an absolute cure is assumed; that while the permanency of the cure effected may perhaps be doubtful as yet, it is certainly desirable to experiment further.

Superheated Dry Air in the Treatment of Sciatica, Arthritis Deformans and Scleroderma.—Neumann (*Lancet*, March 30, 1901) states that in upwards of 2,000 applications of superheated dry air at the Landesbad, Baden-Baden, there has not been a single case of scalding. He has not found the immediate remission in the symptoms of arthritis and sciatica, claimed by English writers, but has found that in many cases curative action continues after treatment. In the course of the year he has applied the treatment in 70 cases of lumbago and sciatica, 35 of arthritis deformans, a number of cases of chronic rheumatism, badly mended fractures, severe sprains, painful cicatrices, inflamed flatfoot, 3 cases of scleroderma and 1 of myxedema. No result was obtained in 3 cases of sciatica, in 1 of sciatica and lumbago with special involvement of the ileo-inguinal nerve, and in 1 of ankylosis of the kneejoint. Unequal results were obtained in 2 cases of arthritis deformans, the hands being improved while the knees remained unaffected. Unimproved also were 2 cases of old fracture of the neck of the femur, 1 of inflamed flatfoot, and 1 of scleroderma. All the remaining cases were either substantially improved or completely cured. In a case of scleroderma, almost universal and well-advanced, the results were remarkable.

Surgical Treatment of Ascites Due to Cirrhosis of the Liver.—Packard (*American Journal of the Medical Sciences*, March, 1901) reports 2 cases of cirrhosis of the liver in which an operation was performed with the view of establishing a collateral circulation through peritoneal adhesions. In neither instance was the operation successful. Of 14 uncomplicated cases collected from the literature, 7.1% died immediately, 7.1% died ultimately, and 7.1% were unimproved, 14.3% were improved, and 64.3% recovered. The author's conclusions are as follows: *A priori* cases of cirrhosis of the liver stand injury badly, and therefore are poor subjects for operation. The resistance of their tissues is presumably much less than in health. Without operation these patients as a class are doomed to a life of perpetual invalidism, requiring constant treatment and repeated tappings to make life bearable. It is our opinion that when the diagnosis of portal cirrhosis can be made, and when persistent well-directed medical treatment is productive of insignificant results, the operation should be strongly recommended. On the other hand it would seem that the operation is scarcely indicated in cases of ascites associated with other kinds of cirrhosis (Hanot's syphilitic, mixed, etc.), or with chronic peritonitis.

Treatment of Pneumonia.—T. R. Brown (*Maryland Medical Journal*, January, 1901) states that results of the anti-toxin treatment of pneumonia have been problematical, but that they give encouragement. As to the advances along the

line of symptomatic treatment the author believes that the best results are obtained by careful nursing, diet, hygiene, and by the systematic use of hydrotherapeutic measures during the entire course of the disease, cold sponging and cold packs being more practical than the full tub. Saline infusions are to be employed when the heart-sounds are faint and the pulse is weak. Inhalations of oxygen or medicated oxygen vapors are valuable in extreme cases. Morphin for pain, alcohol and strychnin for stimulation, are the most reliable drugs. The author also calls attention to the importance of disinfecting the sputum.

Treatment of Lupus with Permanganate.—Butte (*Merck's Archives*, March, 1901) recommends the following method of treatment as very efficacious: The entire locality affected with lupus is carefully washed either with ichthyol soap or with the following antiseptic emulsion:

R	
Corrosive sublimate	5 grains
Tincture of benzoin	75 minims
Tincture of soap	1½ ounces
Distilled water	7 ounces.

After applying this, follow with a compress saturated with a warm 2% solution of potassium permanganate, to be kept on for 12 or 15 minutes. This treatment is repeated every day. In about 10 days the tubercles are covered with a blackish coating and are flatter; to the touch they no longer give the sense of elevation, but are atrophied and what is left of them is of a soft consistence. After the first 10 days, the treatment is to be applied only every other day, but must be continued for a period of 2 or 3 months. At the end of this time no more tubercles are to be seen, and the skin presents a smooth appearance; though it is red and cicatricial in character, the process seems to be arrested. Should any new tubercles reappear, a few applications of permanganate causes them to disappear. Of 16 cases treated, only 1 required a full year's treatment. In the rest the above-described results were obtained in from 2 to 3 months.

Poisoning by Chronic Acid Locally Applied.—Shaw (*Merck's Archives*, March, 1901), reports a case of a young woman, who had a mass of vegetations covering the vulva, extending upward toward the pubes and downward to the anus. A solution of chromic acid, 100 grains to the ounce, was applied to cauterize the mass; about a half ounce being used in the process. After coming from under the influence of the anesthetic, the patient complained of great pain in the vulva; about 6 hours later the author was called, and found her with a rapid pulse, nausea and great thirst. This condition was ascribed to the ether, but when called to see the patient early the next morning she was very restless, and frequently called for water, which was immediately vomited: her face was pale, extremities cold, skin covered with profuse perspiration and she expressed fear of approaching death. Consciousness was preserved. Recognizing chronic-acid poisoning, the dressings were removed, and the vagina douched, for fear some of the acid solution might have entered in spite of care, but the mucous membranes showed no evidence of this. At the same time very active stimulating treatment was resorted to internally. The patient remained in this extreme condition for about 36 hours, after which she gradually returned to her normal state and after 2 weeks was able to leave her room.

Fecal Accumulations.—Brunton (*Lectures on the Action of Medicines*) recommends when the impaction is rather high up in the bowel a copious enema of thin starch mucilage, to which has been added about an ounce of castor oil. The thin starch seems to emulsify the oil better than soap and water, and it is easier to give. Another excellent purgative enema, he states, is official in the British Pharmacopoeia; its composition is as follows:

R	
Magnesium sulfate	1 ounce.
Olive oil	1 ounce.
Mucilage of starch	15 ounces.

1.—Barrs, in an address on some clinical aspects of chronic Bright's disease, states that the distinctions that pathologists draw between the different forms of chronic Bright's disease are of little clinical value. He believes that acute nephritis ends in recovery or death, and but rarely does it eventuate in chronic nephritis. The nature of chronic nephritis suggests a slow infection; lead may be a cause in some cases, but alcoholism has little to do with the disease. It is believed that renal disease is more properly the cause than the result of gout. As regards the diagnosis, it is stated that when chronic Bright's disease gives rise to symptoms it gives rise to albuminuria; otherwise we cannot recognize it clinically. The idea of chronic Bright's disease without albuminuria is based largely, if not entirely, upon necropsy experience. To diagnose Bright's disease, it is maintained that albuminuria must be present persistently, more or less, but the quantity of albumin and the amount of urea excreted are of no consequence. Urine of low specific gravity without albumin is believed to be an unreliable indication of nephritis, and urine without albumin need not be searched for casts. The association of cardiovascular changes with nephritis is said to be of infrequent occurrence, arteriosclerosis altogether independent of Bright's disease, being a far more common cause of cardiac hypertrophy and also of cerebral hemorrhage, than is nephritis. If the patient's bowels are acting freely, Barrs permits him such mixed diet, including meat, as he has appetite for and can digest. Patients who are confined to bed and suffering from uremic vomiting or diarrhea cannot, of course, have any appetite and the difficulty is to contrive food of any kind for them. In the treatment, beyond the systematic use of purgatives, no drugs are necessary except for the treating of special symptoms as they arise. [A.O.J.K.]

2.—Ward, discussing generalized infection in gonorrhoea, states his position as follows: The gonococcus in its process of growth in the human body produces an irritating toxin. This toxin is the direct cause of all the symptoms of the disease. In all cases it is absorbed into the system, where its presence causes systemic degenerations of varying degrees of severity. Gonorrhoea is thus a general toxic affection; but the microbes that form the toxin are generally localized on or around a mucous tract. The microbial invasion may extend to the organs communicating with the infected tract, or it may penetrate into the tissues, either by direct extension, as in the invasion of the

peritoneum through the uterus and the fallopian tubes, or by a process of growth through the mucous membrane affected. Thence the infection may invade the cellular tissues, the lymphatics and glands, and the vascular system. This invasion is rendered possible by the action of the absorbed toxin upon the leukocytes, which is of a paralyzing nature, and prevents the encapsulation of the microbes by these cells. Having reached the circulation the gonococci may invade the heart and endocardium, or may be carried to the peripheral capillaries. In these they become stranded and grow, producing more toxin, which sets up local inflammation. The microbes invade the joints, and are found in the synovial sacs, and also in the pleura and pericardium. They are probably present in the analogous inflammations of the tendons and periosteum. The invasion of the organism is favored by all too energetic measures directed to the local infection, since they depress the local powers of resistance, and by abrading or lacerating the mucus surface, may directly open the door to invasion. General treatment must vary according to the general conditions, and will differ when these are referred to toxemia alone, or to toxemia complicated by metastases. Local treatment is always required, and should always be free from instrumental, mechanic, or chemic violence. [A.O.J.K.]

3.—Rolleston and Hayne report a case of congenital hepatic cirrhosis with obliterative cholangitis (congenital obliteration of the bile-ducts) in a male child, aged 6 months. The child had been jaundiced since birth, but the jaundice was not extreme. The liver and spleen were much enlarged, but there was no ascites. At the necropsy the liver weighed nearly twice its normal weight and it was the seat of mixed monolobular and multilobular cirrhosis. The common bile-duct was obliterated. Sections of the common bile-duct near its obliteration showed very considerable fibrous thickening of its walls with complete alteration of its normal epithelial lining. Discussing the hypotheses held to account for the condition, it is concluded that the disease is primarily started by poisons derived from the mother and conveyed to the liver of the fetus, and that a mixed cirrhosis and cholangitis is thus set up. The cholangitis accounts for the jaundice, and by descending to the larger extrahepatic bile-ducts induces an obliterative cholangitis. In some cases, especially those fatal in early life, the latter change has not been effected, and cirrhosis alone is found. Possibly in some instances this change never occurs, and in this way some of the cases of cirrhosis in very early life are accounted for. Again, in exceptional cases, the obliterative cholangitis might possibly be delayed and come on much later. It is possible that there are several conditions at present included under the title congenital obliteration of the bile-ducts, and that some are due to constriction of the duct by localized peritonitis, and deserve the title more than those cases which are intimately associated with cirrhosis. [A.O.J.K.]

4.—See Therapeutic department.

5.—Fergus describes a new operation for congenital ptosis which consists in making a horizontal incision along the whole extent of the eyebrow separating the skin from the underlying structure for about 2 inches above this incision and to almost the edge of the eyelid below. A vertical band of the occipitofrontalis tendon, about $\frac{1}{2}$ of an inch broad and 2 inches long, is then dissected free, so that its only attachment is to the occipitofrontalis. This band is then drawn down into the upper eyelid and secured by catgut sutures as near the edge of the lid as possible. The incision is then closed. [J.W.M.]

6.—Thomson, in a note of the peculiar nystagmus of spasmus nutans in infants, points out that in spasmus nutans the horizontal nystagmus is convergent as contrasted with the conjugate character of the ordinary horizontal nystagmus, and that in the rotatory nystagmus of head-shaking the eye movements are more of the nature of circumduction than pure rotation. In addition, the nystagmus of spasmus nutans is often unilateral, instead of being very rarely so; and it is often vertical or rotatory, instead of being nearly always horizontal. The direction of the movements, also, is occasionally different in the 2 eyes—that is, vertical or rotatory in one eye, and horizontal (at the same time) in the other. Lastly it is invariably recovered from in a certain number of months. [A.O.J.K.]

7.—McCaw reports a case of *tetanus neonatorum* successfully treated with antitetanus serum, administered subcutaneously. The diagnosis was confirmed by bacteriologic investigations. [W.K.]

8.—Gordon speaking of the *kneejerk* in chorea, states that with the patient recumbent, if one raises the knee allowing the heel to rest on the couch making sure that all the muscles of the limbs are relaxed for the time being, and if one then tests the *kneejerk* in the usual way, the foot is found to raise more or less smartly; but instead of falling back immediately, it remains suspended for a variable time—hung as it were—and then slowly sinks back to its initial position. This peculiarity of the *kneejerk* is thought to shed some light on the nature of chorea and to be of diagnostic value. [A.O.J.K.]

9.—Blackadder reports a case of congenital hypertrophy with stenosis of the pylorus, occurring in an infant, aged 8 weeks. The diagnosis is said to be simple when a tumor can be felt. Constant vomiting, especially when it assumes the character peculiar to the vomiting of dilated stomach, and when associated with obstinate constipation from birth, is said to be very suggestive of pyloric hypertrophy. [A.O.J.K.]

10.—Savory, from his observations on seasickness, concludes that it is due to irritation of the 2 terminal branches of the auditory nerve going to the cochlea and semicircular canals. [A.O.J.K.]

11.—Sykes reports a case of vasomotor neurosis in varying regions of the same patient, a woman, aged 32 years. She was of hysteric habit and had had ailments accompanied by excessive fluid secretion from different regions—diarrhea, perspiration, and bronchial mucorrhoea with asthma—all of which were referred to vasomotor dilation. The case is believed to support the view that asthma is a vasomotor neurosis. [A.O.J.K.]

12.—Cooper reports a case of lobar pneumonia with empyema during the last month of pregnancy, in which a portion of the seventh rib was removed in order to evacuate the pus. This was followed by the birth of a living child and the complete recovery of the patient. [W.K.]

13.—Smith has a brief note on the occurrence of influenza or mumps in several members of the same household. [A.O.J.K.]

14.—Jardine reports the birth of a living child only 13 inches long and weighing 2 pounds, the gestation having lasted not more than 6½ months. It was kept in an incubator at a temperature of 95°, and at the end of a fortnight had lost ¼ pound in weight; it then remained the same for 2 weeks; but at the time of writing again weighed 2 pounds and was quite lively, kicking vigorously when washed. This case is an exception to the rule that infants weighing less than 3 pounds rarely survive. [W.K.]

15.—Chester reports a case of prolonged melancholic stupor (more than 2½ years), occurring in an adult man, and treated with thyroid extract (almost 600 5-grain tablets), with partial recovery. [A.O.J.K.]

12. A Successful Case of Excision of the Cecum, Vermiform Appendix, and Portion of the Ileum for Carcinoma. GEORGE HEATON.

1.—Addison, in his second Hunterian Lecture on the topographic anatomy of the abdominal viscera, discusses lateral displacements of the pylorus; movements of the stomach; the influence of the stomach upon the shape and position of the parts behind it; the duodenum with reference to variation in its position and its shape; the small intestine; the peritoneum with reference to prolapse of the mesentery and other structures; and the lower end of the ileum. The lecture, which is of much value, does not lend itself to abstracting. [A.O.J.K.]

2.—Hewitt discusses recent advancements in the administration of anesthetics and describes the use of an inhaler for the administration of nitrous oxid and ether in succession which is a modification of the Clover inhaler. It has a larger base permitting a freer exchange of gas. He also describes a modification of the Junker's inhaler for the consecutive administration of nitrous oxid, ether and chloroform, and a chloroform prop which serves as a mouth-gag to which is attached a metal tube which transmits chloroform from a Junker inhaler. It is used in operations on the mouth and nose. [J.W.M.]

3.—Bucknall details 6 cases of epiphyseal separation. This may occur without any displacement, when its recognition is particularly important. When displacement occurs it must be determined by careful measurements on the uninjured side. The treatment consists in the application of a molded fixation dressing, or, if necessary, wiring, followed on the tenth day by passive motion to prevent the formation of adhesions following the effusion into the synovial cavity of the proximal joint. [J.W.M.]

4.—Walsham describes an operation for the relief of collapse of the ala nasi, which consists in dissecting up from the inner wall of the vestibule a thick strip of mucous membrane denuded of epithelium about ¼ of an inch wide and leaving it attached above. The surface of the pit at the angle of the bending of the lower lateral cartilage is then denuded of epithelium. The strip of tissue is rolled up as a bandage and applied to the denuded pit, where it is retained by a suture passing into the other nostril and back. Union occurs and this mass of tissue serves to prevent the ala from falling in contact with the septum during inspiration. [J.W.M.]

5.—See the department of Practical Therapeutics.

6.—Jakins describes a successful operation for temporosphenoïdal abscess following suppurative middle ear disease in a young man of distinct tuberculous tendency. For 2 years he had a discharge from his ear which was not improved by the removal of a polypus 5 months before he came under observation when he suffered from pain all over the side of the head, with excessive tenderness over the mastoid, giddiness, nausea, drowsiness, and emaciation, with temperature 99.4°, pulse 64. The antrum was opened and cureted, granulation-tissue and cholesteatoma being removed. The bone over the temporal region was trephined but in the absence of bulging of the dura it was not opened. For 3 days he did well, when he complained of severe occipital pain, became drowsy, comatose and developed hemiplegia. On operation the dura, which was bulging through the trephine opening, was incised, a trocar and canula inserted into the brain substance and 2 ounces of pus evacuated. Drainage was established, the wound packed, and the patient gradually progressed to complete recovery. Two points, are emphasized: (1) The presence of a polypus or granulation-tissue is indicative of antrum or attic trouble or both; (2) suppuration from the middle ear which does not yield promptly to treatment should be subjected to surgical interference. [J.W.M.]

7.—Tunncliffe and Rosenheim, reverting to the subject of selenium compounds as factors in the recent beer-poisoning epidemic, reaffirm their previous observations that selenium compounds have played a definite role in the recent beer-poisoning epidemic, their part being, however, subsidiary to that of arsenic. They discuss certain of the chemic tests for the detection of arsenic and selenium, with reference to the recent article of Willcox (AMERICAN MEDICINE, page 41). [A.O.J.K.]

8.—Thornton, in an article on the management of home

military hospitals, details the general conduct of the military hospitals in England and points out instances of defects that he believes could be remedied. [A.O.J.K.]

9.—Stewart reports a remarkable case of malformation in a child. It had a double harelip with a double cleft palate, bilateral corneal ulceration and supernumerary auricles. The right ear was represented by an enlarged lobule and a portion of the tragus. No meatus could be found. By removal of a portion of the maxillary bone both clefts were successfully closed. The child died afterward. No autopsy. [J.W.M.]

10.—Rose reports a case of Landry's paralysis in a youth, aged 18 years. The patient was suddenly affected with a sensation of coldness, pain in the back and right side, and immediate loss of power in his legs. When examined 3 hours after the onset of symptoms, paralysis of motion and sensation in the legs was complete, the reflexes were abolished, and no response to the electric current could be obtained. A strong faradic current elicited only a sluggish response from the muscles of the arm. The mind was quite clear. At the end of 12 hours more the patient was much worse, the heart was failing, the respiration was frequent and labored, and there was little or no response to the electric current from the muscles of the arm. He died within 24 hours of the onset and was conscious to the end. At the necropsy the brain and spinal cord appeared quite healthy. The case is noteworthy on account of the sudden onset without premonitory symptoms, the very rapid course, and the absence of sensation over the paralyzed area. The course of the disease suggests the operation of some infective toxin. [A.O.J.K.]

11.—Hodgson reports a case of pemphigus neonatorum in an infant 3 days old. The bullas appeared first over the eyes (on the third day); later others developed on the abdomen near the umbilicus, the fold of the groin, the outer part of the thigh, and the nape and sides of the neck. At the end of 3 weeks the child had entirely recovered. The opinion is expressed that the condition was not due to syphilis. [A.O.J.K.]

12.—Heaton reports a case of intestinal resection for carcinoma of the cecum. The mass was delivered from the abdomen and about 3 inches each of the ileum and ascending colon excised with it. Lateral anastomosis was done by the use of Murphy's button. Complete recovery followed. [J.W.M.]

1.—The address deals with the relations of science to clinical medicine. The practice of medicine without being well grounded on the sciences leads to charlatanism. A knowledge of physics and mechanics is necessary to appreciate the causes and the repair of fractures, deformities, hernias, etc.; of physiology and chemistry in understanding the problems of internal medicine. To be a good diagnostician and rational therapist one must know pathology, not only the macroscopic and microscopic appearance of morbid tissues and organs, but

the natural history of disease. Only so can the physician discriminate between disease processes and detect the insidious onset of certain chronic diseases. In etiology, research has given satisfactory evidence of the bacterial origin of anthrax, tuberculosis, relapsing fever, leprosy, actinomycosis, glanders, gonorrhoea, typhoid and Malta fever, diphtheria, cholera, lupus, tetanus, influenza, plague, erysipelas, dysentery, pneumonia, cerebrospinal meningitis, various septic infections, meat poisons, etc., while to the lower forms of animal life have been traced filariasis, malaria and some varieties of dysentery, recent investigation showing other varieties to be of vegetable origin. The most noteworthy of recent discoveries are those of the role of the mosquito in propagating malaria and probably yellow fever. With the knowledge of the cause of diseases has come a better understanding of the problems of resistance. To the method of physical exploration in aiding diagnosis, introduced at the beginning of the century, has been added of late years laboratory methods. No one alive to his responsibilities can neglect these aids and a knowledge of them can be mastered by any one having the inclination. Much light has been thrown on disease problems by the discovery of the elaboration of toxins and their selective action, and the establishment of the doctrine of internal secretions. Modern sanitary science is founded upon these advances in pathologic knowledge. It has promoted the welfare of the community, prolonged life and prevented many epidemics. To it is due the crusade against tuberculosis. To the scientific spirit is due the fact that the physiologic action of each drug has been carefully worked out, and when our treatment must be symptomatic it is at least intelligent. The crowning glory lies, however, in serum-therapy, so markedly successful in diphtheria and relapsing fever and promising so much in other fields. [H.M.]

2.—Laminectomy for Pott's disease is applicable to less than 50% of all cases, but is destined to more therapeutic importance than heretofore. In Lloyd's list of cases (15) there was no death from operation, it occurring later from advance of the tuberculosis. Two operations were ultimately successful. Success would be greater if patients could be seen earlier, especially when the lesion is restricted to the posterior part of the spine. The operation is also indicated when mechanical treatment fails, and extension of the disease threatens, and also when degeneration of the cord begins. Cases of posterior spinal involvement with paraplegia should be operated on as the lesion is easily reached. The cervical region is the least satisfactory, the dorsal the next, and the lumbar and sacral regions the best for operation as regards mortality. If care was taken to protect the vertebral artery and origin of the phrenic nerves results in the cervical region would compare much more favorably with those of the dorsal region. One hundred and fifty-four cases are tabulated. The article will be continued. [H.M.]

3.—A large proportion of cases of joint tuberculosis are not recognized until actual destruction has taken place. At the beginning cure is perfectly feasible. Constitutional symptoms, swelling, redness and pain are absent. Muscular rigidity is pathognomonic. For diagnosis the patient should be stripped and comparison of positions and motions made. The majority of cases are treated for rheumatism which never occurs in a single joint in children. Proper treatment includes rest, relief from weight bearing, fresh air, good food. The particular splint employed is of no consequence. [H.M.]

4.—Permanent catheterization fell into disrepute before the advent of asepsis. Eastman's cases show that the danger of mechanical urethritis and cystitis is perhaps overestimated. Tolerance is more marked when a large instrument is used and it is more easily retained. The possibility of friction is restricted and spasm is relieved much as in dilation of an irritable sphincter ani. The lumen increases in size from absorption of tissue. Salol and eystogen are administered during retention, and in some cases antiseptic injections are used. [H.M.]

5.—Syphilitic deformities are (1) those in which alar columella, or other parts of the external nose have ulcerated away; (2) those in which the supports of the cartilaginous nose have been destroyed, causing depression below the nasal bones; (3) those in which (2) has been followed by cleatricular invagination of the alar or end of the nose. Perforation of the hard

palate, loss of part of the alveolar process, cicatrix from ulceration of the soft palate and loss of nasal tissue may complicate. Cases of the first class are improved by **plastic operations**. Alas are constructed from cheek flaps, columella from the upper lip. Trimming and modelling follow after healing is complete. In the second class a transverse incision is made in the sunken area, the lobule is carried downward until the openings of the nostril are brought from the vertical into the normal horizontal plane, and the space between the lobule and nasal bones is filled with flaps from cheeks and forehead large enough to allow for retraction in healing, and rigid enough to maintain a straight line along the dorsum. Six or 12 months may be required to complete the reconstruction, in order to allow between each step for cicatricial contraction. An opening in the hard palate must be closed by an obturator. A lever may be attached, with spring joint and narrow pad, to act as ridge-pole to the nasal roof. When much new tissue is needed, a large flap from abdomen or thigh may be attached to the hand and afterwards transferred to the face. Scars become scarcely perceptible in time. After active syphilitic processes have ceased, wounds heal as quickly as in healthy persons. [H.M.]

6.—Shattuck advises for **peptic ulcer**, rectal feeding for 2 weeks. If discomfort persists or hunger is importunate, morphin—gr. $\frac{1}{2}$ to $\frac{1}{4}$ —is given twice daily. After a daily cleansing enema, from 6 ounces to a pint of milk with egg may be given every 6 hours. Statistics show very favorable results when rectal feeding is persisted in for more than 10 days. [H.M.]

7.—**Lavage of the stomach** relieves habitual constipation. This is attributed to excitation of peristalsis. The best results follow the use of cold water, or cold and hot alternately 1 hour before breakfast for 3 weeks, and at greater intervals later. [H.M.]

8.—Opium, cinchona and nux vomica are the only things which have an established standard of alkaloidal strength in the United States pharmacopeia. In the case of some powerful drugs the pharmacist depends upon his eyes, nose and judgment as to the strength of the article he is buying, and is often deceived. In other cases manufacturers have assayed and standardized their own products, but what is needed is a **national standard** in order that **physicians** may depend upon getting uniform results. When this is demanded by physicians it will be established by the Revision Committee in the following edition of the Pharmacopeia, except in cases in which the chemistry of drugs is not sufficiently known. All that is needed is the encouragement and cooperation of the medical fraternity. [H.M.]

9.—Following a description of the **hospital** and its management is a review of the clinical features of the nodular and nervous forms of **leprosy**, with a history of typical cases illustrated by photographs. [H.M.]

10.—Banniske reports 32 cases known by himself and 34 by Bridge, of Los Angeles, of **tuberculosis in husband or wife**. Out of the total there are only 5 cases of possible communication from one to the other, these all being from the wife to the husband, supporting the theory of lesser predisposition in females. The family histories obtained indicate much greater personal risk so far as danger of acquiring the disease is concerned from a tuberculous parent than from a husband or wife so affected. [H.M.]

11.—The pathology and treatment of **keloid** are described and 4 cases following **burns** are reported. [H.M.]

12.—After a brief description of the chief theories of **immunity** including phagocytosis, alexins, antitoxin, that associated with race and heredity and that conferred by previous attack, age, prolonged residence and temperament, Class presents his theory as to how this immunity, aside from all description of its chemie nature, may be acquired. The majority of persons acquire it through the agency of the specific germs themselves. These enter the body in quantities too small or of insufficient virulence to produce a typical attack of the disease but in sufficient numbers and virulence to form an antitoxin which protects against further invasion. This theory explains the escape of the vast majority from smallpox before the days of vaccination when all were exposed, and also the susceptibility of new arrivals in the tropics to yellow fever and the epidemics of

measles in certain South Sea islands, in which not a single inhabitant escapes the before unknown disease. The finding of Sanarelli's and the Kiebs-Löffler bacillus and **Diplococcus scarlatina** in healthy individuals, or those who have died from some other cause, further supports the theory. It does not explain the immunity of the young. Infection in childhood usually occurs through the nasopharynx, and in very young infants the crypts and lymphoid tissue of the tonsils are developed very slightly, and the bacteria are deprived of a suitable breeding place. [H.M.]

13.—Finlay believes the **enlex mosquito** is the agent of **yellow fever transmission** in Havana but it is possible that in other centers other species may assume the role. The discovery that a mosquito may be contaminated by a single bite opens the way to great improvement in Finlay's former method of preventive inoculation. Fomites do not carry infection except as a possible hiding place for the live mosquito. Precautions should be taken against the importation of eggs lest the brood hatched increase the difficulty in controlling the spread of the disease from a case accidentally introduced. A case cited shows that contamination of the mosquito may occur as late as the fifth day of the disease, and that as early as 2 days after contamination the bite will cause a mild attack in the nonimmune. [H.M.]

14.—Stout sutures passed near the lid margins may be used as retractors in cases in which ordinary ones are useless. When the eyeball is ruptured suturing and distending with salt solution or paraffin makes **enucleation** easier. [H.M.]

Boston Medical and Surgical Journal.

April 11, 1901. [Vol. CXLIV, No. 15.]

1. A Review of the Literature of the Therapeutic Use of the X-Rays. HARVEY P. TOWLE.
2. Pathology of the Newborn as Illustrated in the Practice of the Writer. FREDERIC W. TAYLOR.
3. Oblique Subtrochanteric Osteotomy for the Lengthening of the Femur, and Correction of the Deformity of Flexion Resulting from Hipjoint Disease. E. G. ABBOTT.
4. A Case of Chin Left Posterior. H. T. SWAIN.

1.—See Therapeutic department.

2.—In 654 deliveries Taylor found 64 of the children presenting **pathologic conditions**—almost 10%. None was less than 7 months' development, and 23 were stillborn, 9 of them being forceps deliveries. Many causes for death are assigned in the various cases, but not all were explainable. Twenty-two died shortly after birth; asthenia is the cause of death assigned for 8, which is the largest group. One had an occlusion of the esophagus. Delayed respiration occurred in 10 cases, and it took 1½ hours to fully restore 1 child; vigorous slapping successively over all parts of the body seemed to be the most effectual remedy in this case. Mild ophthalmia occurred in 3; melena in 2; cleft palate, nevus, fracture of the clavicle, depression of the skull, facial paralysis, each affected 1. The paper aims to stimulate more careful recording in this field. [J.W.H.]

3.—Abbott reports a case of **oblique subtrochanteric osteotomy for lengthening the femur and correcting the flexion deformity resulting from hipjoint disease**. The operation is as follows: The femur is divided obliquely at an angle of 30° about 4 inches below the great trochanter. The section is partly made by the use of an osteotome and completed by fracture. A Buck's extension-apparatus is then applied to secure relaxation of the muscles. The length and position are thus regulated, and a splint is firmly applied to retain it in the corrected position for about 8 weeks, when all apparatus is removed and the patient is permitted to go about on crutches. In the case reported the result was excellent. The making of a radiograph before operation is advised, as the size of the femur is thus determined as well as the point at which the osteotome must be entered to sever the attachment of the iliopsoas muscle from the lesser trochanter. [J.W.M.]

4.—In this case of **face presentation** no abnormal point of infringement could be found, and yet all efforts to cause flexion and rotation were unavailing, even under full anesthesia. The head was finally pushed up above the inlet and podalic version accomplished, and delivery by the half breech method. [J.W.H.]

Medical Record.

April 13, 1901. [Vol. 59, No. 15.]

1. Remarks on Enteroptosis. MAX EINHORN.
2. Small Hospitals and their Administration. LOUIS N. LANEHART.
3. X-Ray Photography. EUGENE R. CORSON.
4. Some Facts of Responsibility in Spirit and Drug Takers. T. D. CROTHERS.
5. An Unusual Case of Partial Recovery from Embolism of the Arteria Centralis Retinae. EDGAR S. THOMSON.

1.—Einhorn uses the word **enteroptosis** to signify a general tendency to prolapse of the abdominal organs. In etiology the corset is important; belts may also cause dislocation of organs. Constitutional weakness explains some cases. These frequently show a floating tenth rib. A weakened abdominal wall from whatever cause is a primary factor. Given this condition, coughing or vomiting may produce prolapse. The frequency can be gauged only by clinicians well versed in examination for these anomalies. Einhorn examined 1,912 patients consecutively, and out of 1,080 males found 70 cases of ptoses of abdominal viscera, including 20 of enteroptosis. In 832 females there were 277 ptoses, including 240 of enteroptosis. Subjective symptoms may be absent, but are generally present and are frequently a faint feeling after rising; fatigue after slight exertion, especially walking, combined in women with backache; a feeling of weight in the lower abdomen and a dragging in the epigastrium; flatulence; constipation in most cases and frequent micturition in many. Complicating disorders of digestion do not yield easily to the usual remedies. Prolonged cases lead to anemia and in consequence to neurasthenia. The objective symptoms are thinness; flaccid abdominal walls too commodious for their contents; protrusion of the abdomen beginning at the navel with a caved-in epigastrium, found principally in females, and occasional diastases of the recti muscles. Gastroptosis is a significant sign, and can be demonstrated by gas inflation, gastrodigraphy and splashing sounds. The latter can be elicited by tapping above and below the navel. In this condition the sounds are absent immediately below the ribs. A strongly pulsating aorta, due to partial uncovering, is frequent. A ribbon-like transverse colon, suggesting enterostenosis, can be palpated above the navel. One or both kidneys may be movable; the liver wholly or partly descended. Prolapsus uteri is frequent. The diagnosis is easy if one has the condition in mind, and it is aided by the belt test, in which the physician, standing behind the patient, encircles the lower part of the abdomen, supporting and lifting it. If this gives relief, it points toward enteroptosis. A perfect cure is possible. The treatment is a well-fitting abdominal supporter, of which cuts are given, including that of the writer; ample nutrition, exceeding that necessary for maintaining the balance of the body, and including bread, butter and milk between meals; out-of-door exercise; electricity intragastrically in functional disturbances of the stomach; iron and arsenic for anemia, and bromids for nervousness. Massage is contraindicated in advanced anemia or considerable prolapse, as it causes irritation or even inflammation. [H.M.]

2.—Lanehart knows of no instance in which physicians and community have not been made better by the presence of rural hospitals. They are educational centers. Suggestions are made as to the best methods of organization and administration. [H.M.]

3.—Corson in discussing x-ray photography, states that the most important consideration is the securing of an apparatus which generates powerful rays, for it is both camera and sunlight. This being secured the rest of the process is comparatively easy. But unless the apparatus is powerful enough to penetrate the bone itself it is impossible to secure fine details and the picture will be unsatisfactory however great the care in developing. Contrary to common notion the best results will not be secured from the use of a long spark coil but from one of perhaps 8 or 10 inches, with a wire that will pass heavy currents. This secures a negative of great brilliancy and fine detail. The time of exposure and development are both shortened by the use of a wire of greater current. Absolute immobility of the part skiaographed may be secured by binding

it to the plate and the pulsation movement prevented by placing a heavy weight upon it. The best developer is hydrochinon. It gives a deeper, denser and more brilliant negative, while the detail is equal to the metal. There is a field of usefulness for x-rays that has not yet been marked, that is the study of normal osteology by means of these plates. Enlarged skiagraphs will prove most valuable in the lecture room or laboratory for giving the outline of the internal bony structure, and most important of all in their exact spacings and relationships. [J.W.M.]

4.—Inebriety is a disease in which there is brain and nerve paralysis, congestion and impaired activities varying in degree with the excess of alcohol habitually indulged in. The highest activities of the brain are the first impaired, hence loss of power to discriminate between right and wrong, and loss of volition. Apparently malicious and brutish acts indicate merely suppression of the higher coordinating centres. Habits formed before the use of alcohol give the appearance of normality to the ordinary routine of life, but when an emergency has thrown him out of the automatic range of action the real condition of the alcoholic is revealed. The present legal theory that inebriety is a development of the moral depravity innate in every life, and that the remedy should be punishment involving pain is unscientific, and in its application increases the very condition it aims to check. That there was no excessive use of spirits just before or during the commission of an illegal act has no bearing on the question of moral responsibility. [H.M.]

5.—The case was unusual in the extent of recovery. The day after the embolism occurred vision was reduced to fingers at 2 feet in the supero-temporal periphery, increasing in 17 days to 20-200. When first seen by Thomson 2½ years later, the entire upper field to within 10° of the macula was restored, vision being 20-40. A row of 6 large arteries sprang from the lower disc edge. The fact that vision was primarily reduced in the area they supplied shows conclusively that they were not branches of the circle of Zinn but of the central artery. The latter probably bifurcated in the nerve, and the embolus was dislodged in a day or two and driven on into the superior branch before atrophy had occurred in the lower part of the retina. [H.M.]

Medical News.

April 13, 1901. [Vol. LXXVIII, No. 15.]

1. The Immediate and Remote Results in 100 Conservative Operations on the Ovaries and Tubes; with Brief Reports of 4 Cases. W. L. BURRAGE.
2. Tropaeocain Hydrochlorate. A Substitute for Cocain Hydrochlorate in Spinal Anesthesia. WILLY MEYER.
3. A Study of Cases Presenting Symptoms of Asthenopia and Anomalies of the Ocular Muscles in which Ablation of the Middle Turbinal Was Effective Treatment. HEBER NELSON HOOPLE.
4. Acute Traumatic Malignancy. WILLIAM B. COLEY.
5. The Akouphone and Its Limitations. J. A. KENEFICK.
6. Perforating Gunshot Wound of the Chest with Fracture of Both Bones of the Left Leg and Lacerated Wound of the Right Thigh—Recovery. VICTOR COX PEDERSEN.

1.—Among the immediate results of conservative operations upon ovaries and tubes, noted by Burrage, are swelling and pain in the resected ovary, which was probably due to hemorrhage into the organ and pelvic inflammatory exudate following resection of a closed tube; death in 2 cases. Remote results were symptomatic cure in 73%, failure in the remaining 27% being probably due to previous neurasthenic condition; anatomic cure in 64%, some enlargement or prolapse being present in the others. Pregnancy ensued in 32%; but never when resection of both tubes was necessary. Only 64% of those previously sterile became pregnant. Subsequent operation was required in 9%, and in 7% of cases a remaining ovary was found enlarged but producing no symptoms. Portions of ovary remaining decrease symptoms of menopause. No relation exists between the amount of stroma and menstrual functions nor sexual desire and gratification. The longer time required for these operations necessitates dispatch. The patients unfavorable for such work are neurasthenics and those affected with long-standing gonorrhoea. [J.W.M.]

2.—Meyer, in discussing the value of **tropacocain hydrochlorate as a substitute for cocaine in spinal anesthesia**, asserts that it is not attended with the unpleasant effects of the latter, such as pallor, perspiration, nausea, vomiting, headache, dizziness and rise of temperature. He has found $\frac{1}{2}$ of a grain dissolved in 50 minims of distilled water sufficient to produce anesthesia lasting an hour. It is less toxic and less depressing than cocaine. Meyer uses it with great satisfaction in urinary surgery. [J.W.M.]

3.—Four cases are presented with refraction errors of varying degree and **imbalance of the lateral muscles** and a history of severe headaches and other **asthenopic symptoms**, in which permanent relief was directly traceable to ablation of the **middle turbinal** or removal of a spur pressing upon it. The irregularities of the muscles and consequent symptoms arise from disturbances of innervation by irritation of a particular area of nerve distribution in the nasal mucosa. [H.M.]

5.—Kenefick discusses the **akonphone and its limitations**. It consists of an electric storage battery of 6 volts which is carried in some convenient place about the body, a transmitter fitted with a series of funnel-shaped resonators for the concentration of sound waves, and a receiver constructed so that all sounds carried to it are intensified producing a sonorous and penetrating wave. Its greatest field of usefulness is in the case of deaf mutes who are by its use taught articulate speech. Its practical value is, however, yet limited owing to its imperfection. [J.W.M.]

6.—Pedersen reports a case of attempted suicide in which the patient inflicted upon himself a **perforating gunshot wound of the chest, a fracture of both bones of the left leg, and a lacerated wound of the right thigh**. His recovery is attributed to the fact that for 8 days he was kept in a semicomatose condition by the administration of morphin, while he was also actively stimulated. The point emphasized is the securing of rest following such an injury, the wounds being only temporarily dressed to avoid disturbing the patient during the shock. [J.W.M.]

8. A Clavicle Crutch. CARTER S. COLE.
9. A New Tenaclum. R. C. COFFEY.

1.—After commenting on the frequency of **venereal diseases** and their terrible ravages on guilty and innocent alike, Morrow takes up the question of their **prophylaxis**. He condemns the government control of prostitution because of its injustice to the female offender, its inquisitorial character, and because it tends to scatter vice by making it more clandestine and elusive and hence less susceptible of real control. He advocates what has been termed the **prophylaxis by treatment** which includes the hospitalization and free treatment of as many sources of contagion as possible, the abandonment of forced detention and the founding of more dispensaries. At the same time an energetic campaign of education should be inaugurated. "Patients should be enlightened not only as to their individual risks but the risks they convey to others and the necessity of prolonged treatment. The same plan that is employed in many foreign clinics should be adopted, viz., each syphilitic patient should be handed a printed slip, stating in plain language the nature of the disease, the modes of

contagion, the risks of personal contact from erosions or mucous patches, the possible contamination of household articles, towels, spoons, drinking utensils, etc., the risks of hereditary transmission, and also emphasize the necessity of thorough treatment. The gonorrhoeal patients should be instructed as to the details of the technic to be employed in local treatment, the possible gravity of the disease, the danger of contagion even when the discharge may have apparently ceased, the significance of shreds in the urine as an indication that the disease, though latent, is still uncured, etc. Physicians should never sanction marriage until all possible danger of infection is passed. The medical profession should be better equipped for this prophylactic work by a more thorough knowledge of venereology. This campaign of education should be extended to the high schools and colleges for young men. There is no reason why young men should not be forewarned of the pitfalls and dangers which beset their pathway—dangers into which they often ignorantly and unconsciously rush. They should also be taught that self-restraint, personal purity and respect for women are among the surest foundations of character. Finally, the public should be educated to a recognition of the fact that the prostitute is largely the product of her environment. The vast majority of fallen women become so—not from choice or from innate depravity—but because of the hard and unjust social laws which force many of them into this life. Society should deal with them as unfortunates rather than as criminals." [H.U.C.]

2.—Dana of New York holds that **insomnia** should be treated with drugs but temporarily, if at all; even maintains if only half or two-thirds of the regular sleep be secured, an individual can very well do with this amount if 10 or 12 hours of rest be spent in bed each night. Morning insomnia is frequently produced by worry, ill health, or arterial degeneration, and may often be benefited by administering small doses of trional or bromid; general tonic treatment; heart tonics; arterial sedatives, as potassium iodid, strophanthus or glonoin. A sudden awakening with a start or jump, known as motor shock, is usually indicative of nervous irritability or fatigue. Rest is usually all that is required for this condition, with perhaps small doses of bromid and potassium iodid for some time. The condition of the liver should also be investigated. Migrainous seizures in sleep, a condition in which a patient is suddenly awakened with nausea and an intense pain in the head, are closely allied to nocturnal epilepsy, and should be correspondingly treated. Insomnia in early life is often due to irritations below the diaphragm, and later from affections of either the lungs, heart, or bloodvessels. In the chronic disorders of sleep, hypnotics should if possible be avoided, the patient placed under favorable hygienic rules, securing plenty of fresh air, moderate exercise, with as little worry as possible. Heart and general tonics, arterial sedatives, and small doses of the bromids employed continuously for a long period if necessary, may be resorted to where medicine is positively indicated. [H.U.C.]

3.—Edsall, in a discussion of general metabolism in **diabetes mellitus**, concludes that it is an error to hold that the waste of fatty tissue in diabetics is due to an excessive protein metabolism, but this waste is due to the fact that large amounts of food are excreted practically unchanged, so that there remains for the repair of the body waste an insufficient quantity. To make up for this loss more carbohydrates and fats should be given. Experiments recently carried out would tend to either one of the two following theories as regards the disturbance in mechanism producing diabetes: (1) loss of normal power of destroying sugars, or; (2) lack of the normal power of producing glycogen, and of controlling thereby the amount of sugar supplied to the blood. [H.U.C.]

4.—The study of the **brains of eminent men** has been necessarily so limited as to create more than passing interest when such cases are reported. From the College of Physicians and Surgeons in New York comes a description and the measurements by E. A. Spitzka of the brains of two eminent physicians, father and son, Drs. Edouard and Edward C. Seguin. [H.U.C.]

5.—Major L. C. Carr, chief surgeon, Department of Eastern

Cuba, compiles statistics showing the **extremely filthy and unhealthful condition** of the two cities Santiago de Cuba and Santos, Brazil, during the years 1888-1897 inclusive, with a progressive death rate per thousand of 26.37 in 1888 to 99.93 in 1897. Tuberculosis and yellow fever were the cause of $\frac{1}{2}$ of the deaths during this period. For the years 1898, 1899, and 1900, the annual death rate has been respectively per thousand 133.71, 30.73 and 28.30, the number of deaths from yellow fever being as follows: 1898-20; 1899-53; 1900-0. Tuberculosis, 1898-415; 1899-173; 1900-85. If the theory that yellow fever is more prevalent under conditions of heat and moisture be accepted, the figures for 1900 should have shown an increase rather than a decrease in mortality, that year having been one of more than ordinary warmth and moisture, thus showing the effect which American methods have produced upon the mortality. The tables given would also tend to indicate a certain degree of fallacy in the theory above referred to, as there was present a much greater amount of heat and moisture at Santiago during the 6 months from May to October, 1900, than during the same length of time in 1899, while the mortality from yellow fever in 1900 was decidedly lower. The following will show what steps were taken to prevent an outbreak: (1) Work furnished for tramps, and arrest if refusal to work; (2) disinfection of foci with mercury bichlorid solution with salt, by the aid of force pumps, swabs and scrub brushes; (3) attempts made to prevent the throwing of filth into the streets; (4) cleaning out latrines; (5) pumping out and disinfecting man-holes every day. [I.I.C.]

6.—In an article on the **propagation of yellow fever** with special reference to the theory of its conveyance by *Culex fasciatus*, Carter correlates a number of facts well established and generally admitted by the profession: (1) Yellow fever is not transmitted directly from the sick to the well, but is propagated from the patient by his infecting his environment, from which it is contracted by others exposed thereto; (2) certain conditions of environment are necessary for it to become infected; (3) infection may apparently be retained a long time by an environment without a reinfection; (4) that the infection of yellow fever is conveyed by fabrics, clothing, and bedding especially; (5) according to New Orleans physicians certain precautions of cleanliness will prevent the infection of his environment by the patient. These precautions take no account of the mosquito, save in the general selection of an upper room for treatment; (6) the theory of conveyance by a mosquito is entirely consistent with the general belief that yellow fever occasionally hibernates in the States north of the Gulf, as well as with the belief that it does not do so in the extreme southern part of the United States, mosquitoes habitually hibernating in the first region and not in the second. The deduction that the disease is not propagated by material conveyed directly from the sick to the well, and that some material after leaving the body of the patient undergoes some change outside the body, and often this change produces yellow fever, may be based upon (1) a change in physical condition of the excretion containing the microorganism rendering it able to reach the proper atrium for the infection of others; (2) the injection of a host, by which host (or its offspring) the microorganism is transmitted; (3) a change in the microorganism itself (outside of the human body). [I.I.C.]

7.—Boyce outlines a method of preventing both primary and secondary **hemorrhage** from operative interference within the **nose**. Three different tampons of cotton are used and each is left in the nose for 10 minutes: (1) The tampon is soaked in a 5% solution of cocaine; (2) in addition to the cocaine the tampon is covered with dry **suprarenal capsule**; (3) a tampon like the first. The results are claimed to justify the expenditure of time necessary. [A.G.E.]

8.—The **clavicle crutch** recommended by Cole consists of hard rubber supports applied to the clavicle and an adjustable steel band which furnishes a false clavicle. [A.G.E.]

9.—Coffey illustrates and describes an **improved tenaculum**. It consists of a tube, near the end of which are fangs resembling a cat's claw. These fangs are protruded by a rod which carries them and works within the tube. Single, double, or quadruple fangs may be employed. The instrument is used for holding membranes in position for a continuous suture, as

a guide and tenaculum in repairing cervixes, in vaginal hysterectomies, etc. [A.G.E.]

April 13, 1901. [Vol. 7, No. 15.]

1. Ligation of the Carotid Artery as an Operation Preliminary to Resection of the Superior Maxilla. CARL SCHLATTER.
2. Thoughts on the Treatment of Diabetes Mellitus. JAMES TYSON.
3. The Medical Relations of the Prevailing Forms of Food Adulteration. HENRY LEFFMANN.
4. Ruptured Traumatic Aneurysm of the Femoral Artery Due to Gunshot Wound; with Report of a Case. WALLACE NEFF.
5. Multiple Tumor of the Sciatic Nerve. JOHN B. ROBERTS.
6. Venous Angioma of the Flexor Muscles of the Fingers. JOHN B. ROBERTS.
7. Diabetes Mellitus as a Cellular Fault. THOMAS C. ELY.

1.—Schlatter discusses at length **ligation of the carotid artery preliminary to resection of the superior maxilla**, and summarizes his observations as follows: (1) By the application of a preliminary ligature, the hemorrhage, as well as the danger from blood aspiration, are markedly diminished. (2) This ligation is highly recommendable in all anemic individuals, and in those whose vitality has been lowered from cachexia and hemorrhages, provided they do not suffer from diseases of the bloodvessels, particularly arteriosclerosis. Exposing the bifurcation of the carotid in advanced cases is in itself indicated for the purpose of extirpating the lymphatic glands, which in this region, are generally the first attacked by metastasis. (3) In by far the most cases, ligation of the external carotid alone will suffice; the latter should be a permanent ligation. Conducted antiseptically, the procedure is without danger. The ligature may be applied by enlarging above the incision which has been made for exposing the bifurcation. (4) In exceptional cases it becomes imperative to ligate the common carotid; this seems to be less dangerous if done temporarily than permanently. After resection the dental work is very important in securing the best results. An obturator divides the nasal and oral cavities, enables the patient to articulate distinctly, supports the eyeball and preserves the contour of the face. [J.W.M.]

2.—While admitting that the dietetic **treatment of diabetes mellitus** is of decided importance—more especially in the milder forms of the disease—since by this means the carbohydrates giving rise to at least a portion of the glucose are withheld from the body—economy, Tyson suggests that more attention be paid to remedies which stimulate oxidation and thus result in the appropriation by the body-tissues of the glucose which would otherwise be eliminated unused and unoxidized. Arsenic and iron in small and long continued doses, massage, exercise, frequent bathing, warm flannels, perchlorid of iron, chlorate of potash, potassium iodid, and the bromids, the derivatives of opium and of petroleum in nervous diabetes are mentioned as remedies. [I.I.C.]

4.—Neff discusses **ruptured traumatic aneurysm of the femoral artery** due to gunshot-wound and reports a case. The variety of aneurysm following an injury depends on the character and extent of such injury; and its gravity depends on the size and location of the artery, and the general condition of the patient. The diagnosis depends on the history of an injury, the presence of a tumor, pain and limit. An aspirating needle may be necessary to differentiate between an aneurysm and an abscess. Many methods of treatment employed with good results in other aneurysms are contraindicated here. Ligation is the proper treatment, and may be proximal, or both proximal and distal, with excision of the sac, which diminishes the possibility of gangrene. A case is reported in which complete recovery followed proximal ligation of a traumatic femoral aneurysm. Statistics of the War of the Rebellion show that of 20 cases of traumatic aneurysm, 16 of which were treated, only 5 recovered. [J.W.M.]

5.—Roberts reports a case of "**multiple tumors of the sciatic nerve**" in a man aged 39, who had suffered for 14 years with pain in the popliteal region, where, on examination, a small sensitive tumor was felt. It was increasing in size; there was weakness of the leg, with numbness, and sweating of the

foot. A 15-inch incision was made, exposing the sciatic nerve with its internal and external popliteal branches, all of which were found to be studded with tumors, varying from $\frac{1}{2}$ to $1\frac{1}{2}$ inches in diameter. They were removed by separating the nerve fibers and splitting the capsule of the tumors. Microscopic examination showed them to be fibrous. [J.W.M.]

6.—A case of painful venous angioma of the flexor surface of the forearm is reported, which, according to the patient's statement, followed injury. It involved the superficial and deep muscles, in which the venous channels were developed and surrounded by abundant fibrous tissue. As its removal would necessitate irreparable damage to the flexor muscles, it was not attempted. Incision into the mass was followed by profuse hemorrhage, which was controlled by ligation, pressure and elevation. [J.W.M.]

7.—Ely claims that there are 5 general reasons for considering diabetes mellitus to be a fault of cellular protoplasm: (1) A biologic reason. The glucose, after being produced by certain cells in the body, is not capable of further elaboration (oxidation) by the cells which it normally nourishes—in other words, a condition of faulty metabolism is present. (2) A hereditary reason. From $\frac{1}{4}$ to $\frac{1}{2}$ of all cases of diabetes are hereditary, showing that the state of faulty metabolism may be inherited. (3) A reason by exclusion. While the glucose producing cells and the nerve centers controlling glucose production may be perfectly normal in their functions, glycosuria still may be present—a state of affairs indicating (by a process of exclusion) that the fault lies with the protoplasm of the cells which should oxidize the glucose. (4) A reason of associate diseases. In diabetes, concomitant, intercurrent and associate diseases point to metabolic disturbances as the basic cause. Its frequent occurrence when metabolism is weakest—after and during febrile attacks and acute diseases, gout, rheumatism, obesity, uric acid diathesis, alcoholism, etc., are significant. (5) A therapeutic reason. The only drugs which benefit diabetes, arsenic and codein, may be called cellular drugs, having, as they do, a well recognized action upon general body cells. Arsenic, as an alternative, reconstructs, builds up weak cells. Opium conserves tissue, retards and prevents waste. Again, the fact that diabetes is most fatal in the young, may be explained by this cellular theory as the survival of the fittest in cell life. [H.H.C.]

1. Can Interstitial Keratitis be prevented in the Offspring of Syphilitics? PETER A. CALLAN.
2. Two Interesting Cases. CHARLES P. NOBLE.
3. A Case of Pseudo-Ileus, following Instrumental Delivery and Adherent Placenta. JOSEPH M. RECTOR.
4. The Relation of Appendicitis to Diseases of the Uterine Appendages. ALBERT L. BEAHAN.
5. Cholemia and Hemorrhage. D. TOD GILLIAM.
6. Seventeen Years of Congenital Nocturnal Incontinence of Urine cured by Operation. GEORGE H. NOBLE.
7. The Cure of Complete Prolapsus Uteri by Plastic Surgery. JOHN DUNCAN EMMET.

1.—Callan assumes that the majority of the cases of interstitial keratitis are due to inherited syphilis. He has found Hutchinson's teeth more frequently than any of the other diagnostic signs. The majority of his cases occurred between the eighth and twelfth years, and the next in order of frequency, between the seventeenth and twenty-first years. Offspring of syphilitics show the evidences of the inherited taint in only a slight percentage of the cases; that is, if we except children that die under 5 years. Only a slight percentage of such children develop interstitial keratitis. When the disease attacks one eye, all treatment seems powerless to prevent its development in the fellow eye. The outbreak of interstitial keratitis in certain cases may possibly be delayed, but not prevented. [F. C. H.]

2.—The two cases reported by Noble are: Multiple sinuses in the perineum resulting from infection and the failure to remove sutures, and pelvic abscess resulting from attempted abortion in an unimpregnated uterus. [F.C.H.]

3.—Rector details the history of a patient in whom it was necessary during her first labor to make a high forceps application. Two years later, during her second labor, it was necessary to apply axis-traction forceps. The placenta was adherent over its entirety, and was removed by enucleation. Three hours subsequent to the last labor she was found in a state of collapse, the condition simulating ileus. The abdomen continued to distend for 8 hours, when the bowels were freely moved. Within 24 hours she was convalescent and fully recovered. [F.C.H.]

4.—Beahan recapitulates the relation of appendicitis to diseases of the uterine appendages as follows: A febrile disturbance during menstruation, with a swollen, tender appendix, obstinate constipation and gas-formation in bowel; painful, retarded menses, pain in lower segment of abdomen, especially in right side; loss of flesh, pallor, or muddy complexion, peculiar nervous symptoms, as irritability and exhaustion occurring in a more exaggerated form than is peculiar to the individual, make the probability of disease of the appendix certain and its removal imperative. [F.C.H.]

5.—Gilliam thinks we should reconsider the teaching that cholemia tends to diminish the coagulability of the blood thus leading to intractable and oftentimes uncontrollable hemorrhage. It can be shown that the hemorrhage of cholemia is not so much due to a blood-change, *per se* as to a structural change in the mucosa of the gallbladder, usually associated with cholangitis. The treatment consists of swabbing the interior of the gallbladder with strong carbolic acid, and packing with iodoform gauze. There is no fear of systemic intoxication from absorption, because of the immediate and powerful escharotic effect, which not only blocks absorption, but produces a nonpoisonous organic combination. [F.C.H.]

6.—The rarity and intractability of congenital incontinence of urine, makes this case interesting. The patient, a girl of 17, has continued the habit of bedwetting all her life. No physical defect of the urinary apparatus could be found, the urine was normal, and the medical treatment has been unsuccessful. Cystoscopic examination revealed a normal mucous membrane. No malformations were discernible. An inflamed and thickened hymen having a very intimate connection with the meatus appeared to be the probable source of trouble, which is explained as follows: It was her habit to sleep on her face, a posture which doubtless contributed to an accumulation of bodily heat about the external genitals, resulting in stimulation of the sensitive and irritable hymen, which becoming more or less erectile, irritated the meatus; this in turn stimulated the circular muscles at the neck of the bladder and trigonum, resulting in involuntary micturition. The operation consisted in cutting through the hymen on either side of the meatus and dissecting the urethra free from its attachment for about half its length. Separation of the urethra from its attachments severed all nerve-connection with the meatus, cutting off all possible reflexes from the inflamed hymen. Sutures were introduced through the attached portion of the hymen, on either side, and fastening them to the pubic arch, making a sling or support for the urethra. This with a little moral treatment has resulted in a perfect cure. [F.C.H.]

7.—Emmett lays stress on the mechanism of prolapsus uteri, and the anatomy of the parts involved. He then describes the operations on the cervix, anterior and posterior vaginal walls. He prefers to keep his patients in bed 4 weeks prior to operation, with the foot of the bed elevated in order to reduce the size of the subinvolved uterus. [F.C.H.]

January, 1901. [Vol. XXXIII, No. 1.]

1. Ventral Hernia following Abdominal Section. B. BRINDLEY EADS.
2. On Traumatic Keloid of the Median Nerve, with observations upon the Absorption of Silk Sutures. OTTO G. T. KILIANT.
3. An Intestine Holder. Devised for Facilitating the End-to-End Suture of Intestine. EDWARD H. LEE.
4. Laryngectomy under Eucain Anesthesia, with Remarks on the Technic of the Operation. GWILYM G. DAVIS.

5. Double Ureter. Report of a Nephrectomy done upon a Young Child with this Condition Present. JOHN EDWARD SUMMERS, JR.

1.—Eads believes that 15% of all patients upon whom celiotomy has been performed if examined 5 years later will be found suffering from ventral hernia. In discussing the causes of hernia he lays great stress on injury to nerve-supply of muscles in incisions. A long incision does not necessarily predispose to hernia and it lessens the mortality by providing ample space for operation and by diminishing the time required for the operation and the duration of the anesthesia. Hence it is important to make the incisions long enough to provide every facility for thorough work. Muscle fibers and nerves should be separated rather than divided. In operating for such hernias he believes that it is important to close the wound by bringing as much muscle fiber together as possible. Fascia he considers quite useless in the repair of hernia. In closing abdominal incisions he advises the layer suture, closing the peritoneum with continuous fine catgut and the muscles with silkworm-gut. [M. B. T.]

2.—A woman, 21 years old, cut her median nerve by falling into glass. This was followed by loss of motion and sensation. Secondary nerve-suture with silk was undertaken 4 weeks after the accident with resection of a small neuroma on the distal and central ends of the nerve. There was no complete primary union. Six weeks later a good sized neurofibroma was found which interrupted completely the conduction of the nerve. The tumor was again extirpated; the ends were joined with catgut and primary union resulted. There was immediate restoration of sensation and soon after that of motion. Three months after this operation a small tumor had recurred, while the skin showed a keloid. The keloid disappeared under symptomatic treatment and the patient now has good use of the hand and fingers. Another interesting feature in the report of this case is that Kiliani reports that microscopic examination shows that absorption of single fibers of silk had set in in the neuroma which was excised after the first operation. He believes that it is possible that had some time elapsed before extirpation the sutures might have been entirely absorbed. [M. B. T.]

4. Davis reports excision of the larynx for carcinoma under local anesthesia with eucain B solution. The removal was found comparatively easy, the dissection being carried from below upward on 1 side, then across at the hyoid bone and down on the other side. A general anesthetic was considered contraindicated because of the danger of suffocative symptoms. Davis believes that preliminary tracheotomy is an advantage, though it is unnecessary to leave an esophageal tube projecting from the wound. The wound need not be tamponed but can be closed from the upper end of the trachea to the hyoid bone. [M. B. T.]

5.—Summers reports a successful nephrectomy for removal of a tuberculous kidney from a female child 2½ years old. A double ureter was found on the affected left side. The wound healed by first intention and the child has remained in good condition since the operation. [M. B. T.]

February, 1901. [Vol. xxxiii, No. 2.]

2. Sarcoma of the Uterus. VAN BUREN KNOTT.
3. Contribution to the Surgery of Multilocular Renal Cyst. CARL BECK.
4. Cleatrical Stricture of Pharynx cured by Plastic Operation. B. FARQUHAR CURTIS.
5. The Improved Technic in the Operative Surgery of Carcinoma of the Stomach. WILLIS G. MACDONALD.
6. Cases of Compound or Complicated Fracture Illustrating the Value of Operative Interference in the Treatment of these Injuries. HENRY R. WHARTON.
7. A Method of Performing Anastomosis of Hollow Viscera by a New Instrument. M. O'HARA.
8. I. An Improved Brace for Head Extension. II. A Hard Rubber Spring Brace for Lateral Curvature. JOSEPH M. SPELLISSY.

1.—From a study of gunshot-wounds, which have come under his care in the Philippine-American war, Robinson draws the following conclusions: Modern gunshot-wounds are generally aseptic. This is due chiefly to the character of the bullet,

early application of first-aid dressings and possibly in slight degree to the velocity of the projectile. Primary hemorrhage is rare, the bloodvessels being displaced rather than cut. The explosive effect is much less common than recent military literature would indicate. Gunshot-wounds of the chest are rarely infected; simple antiseptic treatment with aspiration of the pleura in cases of severe hemorrhage is all that is necessary. Gunshot-wounds of the kneejoint are usually aseptic, but if infected, demand immediate amputation to save life. Excision of the elbow is always justifiable in severe shattering or infection of that joint. Resection of other joints is rarely necessary, erosion or amputation being preferable. Injuries of nerves from gunshot-wounds can often be benefited by operative intervention or by resection. In modern military surgery, abdominal section for gunshot-wounds is not justifiable. The patient's best chance of recovery lies in conservative treatment without operation. [M. B. T.]

2.—A case of sarcoma of the uterus is reported, occurring in a woman of 43. Her symptoms had begun with menorrhagia 9 months previously. She had lost no flesh, there were no signs of cachexia; there was constipation and frequent urination. On opening the abdomen a large, irregular liver-colored tumor was found filling the lower abdomen and pelvis and crowding the intestines upward. There was no hemorrhage during the operation, but the shock following was pronounced. The patient made a good recovery. On abdominal examination, the growth was reported to be a spindle-celled sarcoma. [M. B. T.]

3.—Transperitoneal nephrectomy is reported for a multilocular renal cyst occurring in a woman of 55. Death resulted from uremia 11 days after the operation. [M. B. T.]

5.—From a study of the literature, Macdonald has found 43 cases in which pylorotomy was done for carcinoma of the stomach, in which the patients were living without recurrence 3 years after the operation. Some of these patients were alive 10 years after the primary operations. This group of cases is collected from 527 pylorotomies. The average operative mortality is about 30.4%, but individual operators have reduced it to as low as 8.7%. Macdonald emphasizes the importance of earlier surgical intervention and a wider extirpation of the disease. [M. B. T.]

6.—Wharton reports several compound or complicated fractures in which operative treatment was undertaken. Among these was a fracture of the lower end of the fibula and internal malleolus of the tibia with decided and persistent deformity. Tenotomy of the tendo-achillis was performed with a good result, and this procedure is recommended in such cases. In a case of comminuted fracture of the upper end of the humerus, excision of the shoulder was undertaken, with a useful arm resulting. Excision of the shoulderjoint was also performed for an extensive gunshot injury. [M. B. T.]

7.—O'Hara describes a simple instrument by means of which intestinal anastomosis of the hollow viscera can be readily performed. The instrument consists of 2 pairs of straight forceps, the jaws of which are slender and about 2½ inches long for ordinary work. Instead of being roughened as are ordinary hemostatic forceps they are grooved down the center of 1 blade and into this groove fits a ridge from the opposite blade. The forceps are held together by means of an adaptation of the serrefine. In performing resection followed by end-to-end anastomosis the serrefine clamp is removed and 1 forceps is placed transversely across the bowel at the point selected for the upper border of the resection and locked. The other forceps is placed in a similar manner at the lower part of the resection. The tips are in exact line with the mesenteric attachment. The forceps are placed upon the ends of the intervening portion of the intestine to prevent leakage. The bowel is then cut close to the forceps; the incision also removes a wedge-shaped piece of the mesentery but avoids wounding important vessels. The forceps are then brought together and held by means of the serrefine clamp. Sutures are introduced starting nearest the lock and carrying them down to the tips where care should be exercised to get accurate apposition at the mesenteric attachment. The sutures are then tied, the forceps are turned over and sutures placed on the other side in the same manner. The forceps are now unclamped; one pair is removed by unhooking

and drawing out in a straight line, the other is unlocked and passed above and below the line of suturing within the lumen of the gut to insure that both walls of the gut have not been included in any of the sutures. They are then withdrawn and the remaining opening closed by one stitch. If desired a second row of sutures may be placed to reinforce the first. The mesentery is closed in the usual manner. For a satisfactory understanding of this method of anastomosis the cuts of the original article are necessary. The method seems to be one of the simplest that has thus far been introduced. [M. B. T.]

1. Clinical and Pathologic Contributions to the Diagnosis and Treatment of Brain Tumors. MINGAZZINI.
2. The Disturbances of Growth Associated with Infantile Cerebral Palsy. KOENIG.
3. Hysterie Position of the Hip with Scoliosis. SALOMONSON.

1.—Mingazzini reports a series of cases of brain tumors and other conditions of the brain for the purpose of throwing light upon certain mooted questions in the diagnosis of cerebral new-growths. Case I was a man aged 20, who complained of intense, left-sided headache, occurring chiefly at night but later spreading to the right side and persisting during the day. Examination revealed very little of moment. There was a slight tendency to lateral swaying, the patellar reflexes were much diminished, and the upper tendon reflexes in the upper extremities were abolished. There was tenderness on the left side of the skull on percussion. The internal and external recti muscles were somewhat insufficient, and tinnitus existed in the left ear. The head-pains were spasmodic and extremely severe. Psychically nothing was noted except slowness in answering questions. Ophthalmoscopic examination, during which the patient had an attack of unconsciousness, showed marked choked disc. After this attack of intense headache occurred, with acceleration of breathing. The left side of the face was redder and hotter than the right, and the muscles supplied by the left facial nerve were contracted. After lumbar puncture had been performed the attacks became still more frequent. On the day following the puncture the patient died in collapse. At the autopsy the convolution of the left parietal lobe were found flattened, and the second and third occipital convolutions and the annectant parietooccipital gyri were replaced by a tense-walled, echinococcus cyst. In discussing this case the author points out the absence of all symptoms indicating homonymous hemianopsia. There was nothing in the history to suggest disease of the occipital lobe; on the contrary, the symptoms pointed to cerebellar growth. In favor of this also was the sudden death, which is not rare in cases of cerebellar tumor. The fact that the patient became much worse after lumbar puncture leads the author to caution against this procedure in tumor of the occipital lobe, cerebellum, and oblongata. Case II was a man of 32, who had been subject to epilepsy since his fourth year. He showed asymmetric development of the halves of the body, restricted movement of the right eye outward, disturbance of the facial muscles, atrophy of the right arm, pes varoquinus of the left foot, spasmodic gait with dragging of the left leg, active patellar reflexes, and normal tactile, thermal, and muscle senses. Psychically the patient was apathetic, and answered questions slowly and in monosyllables. The epileptic attacks were accompanied by complete unconsciousness and discharge of urine and feces. There appeared to be no aura, and there was no premonitory cry. The clinical diagnosis was polioencephalitis dating back to childhood. At the autopsy a solitary tubercle was found, occupying the right precornu and the right striatum. The clinical diagnosis was therefore wrong. In view of the tumor, the absence of vertigo, vomiting, and choked disc was interesting. Moreover, the attacks of epilepsy, lasting almost 30 years, would hardly turn the thought to tumor. It is true that some of the symptoms were against the view that the epilepsy was the result of polioencephalitis, as in that condition unconscious discharge of urine and feces, biting of the tongue, and frothing at the mouth, present in the patient, are absent. Case III concerns a woman of 38 who had been subject to epilepsy

for 3 or 4 years. There were marked signs of mental impairment and only the simplest questions could be answered. Memory was poor, and she seemed unconscious of her surroundings, but was good-natured and very religious. Sensation and the organs of special sense presented nothing abnormal of note. The epileptic attacks had the typical characteristics. The patient died of a diffuse bronchial catarrh. Autopsy showed sarcoma of the mesial and anterior part of the prefrontal lobes, chronic atrophy of the kidneys, arteriosclerosis, and bilateral bronchopneumonia. The tumor was unsuspected, and the clinical diagnosis had been diffuse arteriosclerosis with kidney disease. All of the symptoms could be explained on the latter basis. It should also be noted that there was no disturbance in the patient's character or disposition, such disturbances being ordinarily present in prefrontal tumors. Case IV was a woman of 30, who, during the 4 months previous to her entrance into the asylum, had shown signs of progressive weakness and had become totally blind. Intelligence was diminished. There was left-sided hemiparesis and flaccid hemiplegia, with participation of the upper part of the facial nerve and the external rectus; epileptic convulsions; disturbed, nasal speech; dysphagia; and gray atrophy of the optic nerves. Three conditions were considered possible: tumor of the brain, multiple sclerosis, and diffuse sclerosis. The autopsy showed pseudosclerosis of the brain. The brain cortex, microscopically, was transformed into a homogeneous, in part reticulated, tissue containing a variable number of granule-cells. The nerve-cells were in part absorbed, in part they remained as pale, degenerated bodies. Pseudosclerosis (Strümpell) appears between the ages of 9 and 30, in persons who are apparently normal. The principal symptoms are weakness, rarely passing into complete paralysis; increased muscle-tonus; and paretic, spastic gait. Apoplectiform and epileptiform attacks are common; and intention-tremor may also be present. The characteristic speech disturbances consist in a high degree of scanning and bulbar speech with monotonous voice, subject to sudden changes. Sensation is not markedly affected. The psychic symptoms are those of advanced imbecility, with occasional violent outbursts or hallucinations. In all cases there has been a striking development of acne and comedones. The course of the disease is slow— $\frac{1}{2}$ to 10 years. Macroscopic examination usually shows a decided increase in the consistence of the medullary substance of the brain. The differential diagnosis from diffuse sclerosis is difficult; also from multiple sclerosis. Case V was a woman of 46, of neurotic ancestry. From infancy she had been subject to attacks of headache with vomiting. Four years before this examination she began to have epileptic seizures, affecting primarily the right hand. Eventually a right-sided hemiparesis developed, but it subsequently disappeared. There was dysarthria, and impaired intelligence; irritability, and objectionable behavior. The optic nerve showed gray atrophy, secondary to choked disc. At the autopsy a sarcoma of the lateral portion of the left frontal lobe was found. The tumor had involved the lower left frontal convolution, together with the operculum. As the patient was right-handed, it is noteworthy that aphasia was absent. The author explains in detail why in right-handed persons lesions of Broca's center sometimes do not produce aphasia. He believes that the right-sided, as well as the left-sided, glossosfacial center, is capable of transmitting impulses from Broca's region. Case VI concerns a man of 51, who, during an alcoholic debauch, fell down a stairway and struck the right parietal region of the head. A few months later, left-sided Jacksonian epilepsy developed. An operation was performed, and proved fatal. At the autopsy a spindle-cell sarcoma of the right insula and striatum was found. The tumor had not been suspected; and in the belief that the epilepsy was due to the injury to the skull, the eye-examination had been overlooked. An interesting point was that the patient had complained of pain in the limbs of the left side. Pain in cerebral tumors has been noticed before, and has been attributed to interference with the sensory fibers in the thalamus. In the author's case these were compressed by the growth. The case is also interesting from a medicolegal aspect. Case VII concerns a woman of 38, whose first symptom was tingling in the right side of the lips. Afterwards this became associated with

fornication in some of the fingers of the right hand. Convulsive twitchings and paralysis developed in the right arm. There was deafness, but not choked disc. When the patient withdrew her eyes from her right hand, she could not make any purposive movements with that member. She was operated upon, and **amyxomatous papilloma**, springing from the pia, was found in the lower lower part of the left prerolandic gyrus. Numerous nervous symptoms followed its removal—among others, loss of the pressure sense, diminution of the tactile sense and stereognosis in the right hand. In Case VIII., a man of 40, there was an **endothelioma in the left paracentral convolution**, which was removed with good result. Cranial percussion was painful on the left side. There were no paresthesias. The kneejerks were increased, more on the right side than on the left. The epigastric reflex was weak, particularly on the left side. Ophthalmoscopic examination showed bilateral choked disc. Radiographic examination was negative. The pressure-sense in the right hand was entirely lost, while the stereognostic sense, pain and heat sense, and touch, were present. Regarding the value of **percussion of the skull**, it would seem that when there is much pain on percussion, the tumor is probably situated near the dura or the bone. The percussion-tone may vary from a cracked-pot sound to a most marked dulness, depending upon whether the tumor has produced thinning or thickening of the overlying skull. [D. R.]

2.—A study of 41 cases of different types of **infantile cerebral palsy**, with a view to determine the existence of **defective growth**, leads the author to the following conclusions: (1) For the disturbances in growth occurring in infantile cerebral palsy, the term **hypoplasia** is preferable to that of atrophy. (2) The hypoplasia may affect the circumference, as well as the length of the limbs. (3) The hypoplasias, according to their location, are divisible into 5 groups: (a) Cases in which there is a hemihypoplasia of the body. (b) Cases in which in addition to both extremities, more or less isolated parts of the corresponding half of the body (as the mamma or the scapula) are affected. (c) Cases with exclusive involvement of the 2 extremities. (d) Cases with involvement of 1 extremity, or parts of it. (e) Hypoplasia of the entire body. (4) Unilateral hypoplasias occur chiefly in the hemiplegias or the transitions between hypoplegia and diplegia. (5) Bilateral hypoplasia occurs not only in the diplegias, but also in the hemiplegic transitional forms. (6) Hypoplasia is more frequent in the early cases than in the later ones, but the hypoplasia is not necessarily dependent upon the period of development of the disease or upon its duration. Hypoplasia may be absent in congenital cases. There is no constant relation between the hypoplasia and the gravity of the clinical condition; although high degrees of hypoplasias are most common in the severe, spasmodic paralyzes. Hypoplasia may be the dominant and sometimes even the only focal symptom. (7) Whether the reaction of degeneration occurs in the hypoplastic muscles has not been definitely determined. (8) (a) Hypoplasia can occur with a microscopically intact spinal cord and a macroscopically intact brain. (b) It may be absent in disease of the entire postcentral convolution. (c) Hypoplasia may correspond to a reduced size of the opposite hemisphere, but the latter can exist without producing a hypoplasia of the entire opposite half of the body. (d) Up to the present, microscopic results have thrown no light upon the variability of the clinical picture of unilateral hypoplasia. (e) Total hypoplasia of the body can exist with a macroscopically intact brain. [D. R.]

3.—**Hysterical scoliosis** has been repeatedly described as a primary affection. In 2 cases observed by Salomonson, however, the scoliosis was **secondary to a hysterical contracture of the hip**. He believes that the peculiar position in which the hip is held in these cases is due to a **subluxation of the femur**. As in both patients recovery was sudden, and was attended by a sensation of something cracking in the hip, this view would seem a reasonable one. [D. R.]

1. The subject of the **coagulation of the blood** is still an unsolved problem, but much more is known concerning its morphologic than its chemie features. According to Schwalbe, a pupil of Arnold's, the red corpuscles show the most marked changes in the process of coagulation. The clotting process occurs in 2 types; either after that of the so-called **crystallization**, or after that of the so-called **stroma fibrin**, the former being the more frequent. The red corpuscles undergo peculiar form changes, with the constricting off of small particles that become blood—platelets and granules. Schwalbe inclines to the view that the **formation of these platelets and granules is the morphologic characteristic of clotting**. When it is prevented, by means of salt-solution, clotting does not occur. Salt-solutions have a peculiar effect upon the blood, which wanes according to their concentration. Sodium chlorid and sodium fluorid were especially tested in this respect. Isotonic solutions, i. e., those of the same concentration as the salts in the blood, produced no change; hyperisotonic solutions accelerated clotting, and in such solutions the red corpuscles showed most strikingly the development of blood-plates. Hypoisotonic solutions produced a solution of the blood-corpuscles. Hyperisotonic sodium chlorid solutions, i. e., solutions of 2% or 3% strength, differ markedly in their action from concentrated solutions (30% strength). In the former, as already stated, there is shrinking of the corpuscles, with active platelet formation and clotting; in the latter these are absent, and clotting does not occur. In solutions of **calcium chlorid**, which hastens clotting, the disintegration of the corpuscles into blood-plates is very intense. It is difficult to say what relation the platelet formation bears to clotting. It may be that in the disintegration of the red blood-corpuscles a ferment is set free. It is known that the red corpuscles do contain a ferment. It is not impossible that the leukocytes, as well as other cells, may have the power of liberating ferments. Ferment-formation is probably a widely disseminated cell-property. [D. R.]

2.—**Clubbing of the fingers and toes** occurs (1) in diseases characterized by purulent or putrefactive processes, as pulmonary tuberculosis with cavity-formation, bronchiectasis, empyema, cystopyelonephritis, and dysentery; (2) in infectious diseases and chronic intoxications, as pneumonia, pleurisy, syphilis, alcohol (?) and chronic jaundice; (3) in valvular lesions, especially the congenital; (4) in malignant tumors; (5) in diseases of the nervous system, as syringomyelia and neuritis (?). Dennig also adds to these an instance of clubbed fingers, due to **dilation of the stomach** and fermentation of the food, the result of pyloric obstruction from cicatricial contraction. Radiographic examination of the fingers in a number of cases showed practically no change, except in one case. The enlargement appears to affect only the soft tissues. In rare instances there is an ossifying periostitis. [D. R.]

3.—Krause reports a fatal case of **parenchymatous nephritis complicating chickenpox**. The renal tissue was free from bacteria, both on culture and on staining. [D. R.]

4.—**Hedonal** is a urethan derivative, which in doses of from 2 to 3 grams (30 to 45 grains) is a **harmless hypnotic** in mild grades of insomnia. Secondary effects are not uncommon, but are not serious. [D. R.]

Deutsche Medicinische Wochenschrift.

March 7, 1901. [27 Jahrg. No. 10.]

1. The Value of the Arloing-Courmont Serum-reaction in Tuberculosis. A. BECK and L. RAHINOWITZSCH.
2. A Remarkable and Unexplained Condition Found by Auscultation in an Infant. K. GREGOR.
3. Radical Operation in Infantile Hernia. H. MAASS.

4. An Apparatus for Diagnosis of Incipient Scoliosis (Thread Scoliosg-nost). K. TANTZ.
5. A New Method for Certain Detection of Diacetic Acid in the Urine. L. LIPLIAWSKY.
6. The Treatment of Gangrenous Hernias (Conclusion). W. PETERSEN
7. The Treatment of Pathologic Fixation of the Uterus. STEFFECK.

1.—As a result of 75 original experiments with the **Arloing-Courmont serum-reaction** on cattle, Beek and Rabinowitsch reach the conclusion that this test is not diagnostically conclusive of the presence of tuberculosis.

3.—After discussing the various indications and contra-indications to the **radical operation in congenital infantile hernia**, Maass describes his method of procedure and reports 2 of his cases. He concludes that the radical operation for congenital inguinal hernia is, although not entirely without danger, it is much less so than in the case of the adult. The same method of treatment is also applicable in the case of umbilical hernia, although not so certain in its results. [H.H.C.]

4.—In order to detect any slight asymmetry in **incipient scoliosis** Tantz has constructed an apparatus which is not only much simpler in construction than the larger scoliosimeters but much easier of application. The apparatus consists of a metal plate attached between the shoulder-blades by means of 2 straps. In the center of the plate is a hole into which a horizontal rod is screwed, from which 2 threads, a red and a green, hang downward. The red or proximal thread is drawn down between the nates, while the green or distal thread supports a weight, thus acting as a plumb-line. The angle formed by the 2 threads when viewed from a distance indicated the degree of scoliotic deviation. [H.H.C.]

5.—Liplawsky uses a **modification of Arnold's test** which he claims to be much more sensitive. Two solutions are used: (1) A 1% solution of paramidoacetophenon, and (2) a 1% solution of potassium nitrate. Six cc. of 1 and 3 cc. of 2 are added to an equal volume of urine containing 1 drop of ammonia, and the whole well shaken till brick-red color appears. Ten drops to 2 cc. of this mixture are then added to 15-20 cc. of concentrated HCl., 3 cc. of chloroform and 2-4 drops of ferric chlorid solution. After gently shaking this mixture (avoid emulsifying the chloroform) for $\frac{1}{2}$ -1 minute a beautiful and very characteristic violet tinge is the result. [H.H.C.]

6.—Petersen concludes his article on the **treatment of gangrenous hernias**, with statistics showing the greater frequency of operation in such cases at the present day, because, first, more cases of the sort are sent to the hospitals from a distance, and second, because the standard of indication has changed in recent years. With regard to the choice of operative procedure—resection or the creation of anus praternaturalis—Petersen reaches the following conclusions: (1) The Murphy button and local anesthesia, properly used, are 2 important aids in resection and render the operation far less dangerous than formerly; (2) the complete emptying of the gut possible by the use of local anesthesia and the subsequent resection high up into the healthy tissue are of the highest importance; (3) that owing to the great lessening of danger due to the facts just mentioned, resection is *the* method in case of undoubted gangrene of the bowel; (4) reposition is only allowable in cases where the bowel is capable of complete recovery; (5) anus praternaturalis is only a last resort, to be made only in those cases where collapse is imminent or where extensive perihernial abscesses are present. [H.H.C.]

7.—Steffeck considers that the frequent occurrence of **pathologic fixation of the uterus** is ample justification of a consideration of its causes and methods of treatment. Out of 2,400 private patients in Berlin, 140 or 5.8% had a retroflexed or retroverted fixed uterus; and in 3,160 polyclinic patients he found 227 cases of the same disease, or 7.1%. In small cities and states the percentage was decidedly lower. This fact is not accidental. Among the causes of this condition gonorrhoea holds the first place. Characteristic of this gonorrhoeal disease is the frequent return of the so-called abdominal inflammation. The second cause is puerperal infection, but this more generally affects only the perimetrium and often heals spontaneously and only very rarely requires surgical interference. The third and last group

of infectious diseases of the pelvic organs is the result of the intrauterine use of instruments, especially inopportune cauterization or injection. The noninfectious causes of the formation of pathologic adhesions are hemorrhage of tubes or of ovaries, and newgrowths of uterus or adnexa. The symptoms of all these are similar; pain, irregular hemorrhage and sterility; though many give rise to no symptoms. The prognosis is least favorable in cases of gonorrhoeal origin, and a rational treatment requires an exact diagnosis of existing conditions and their cause. Steffeck divides the fixation of the uterus into direct or indirect, according as the adhesions affect the uterus itself or the adnexa and parametrium; a distinction of great importance since a conservative treatment with ichthyol glycerine tampons, vaginal or abdominal pressure, baths, hot douches and rest in bed, will be far more efficient in cases of adherent fixation through inflammation of the adnexa, etc., than in adhesion of the uterus itself. But the basic principle in the treatment of all kinds of uterine fixation is this: An organ which through disease does not endanger life, must not be healed through extirpation but under a retention of the organ. From his experience of years in cases of gonorrhoeal infection, he advises rest in bed for 2 weeks with exclusive treatment with 10% ichthyol tampons renewed every 24 hours, ichthyol being by far the best remedy for gonorrhoea of the vagina. All uterine fixation arising from acute disease demands similar rest in bed with the use of ice and opium suppositories to relieve pain. Local treatment in acute inflammatory processes is a great failure and often directly injurious. In chronic fixation of the uterus accompanied by extreme sensitiveness of uterus and adnexa he advises long rest in bed and pressure per vaginam. For such purpose, rather than shot or quicksilver, he prefers a complete tamponade with pads abundantly saturated with glycerin which should remain 48 hours. At the same time there may be abdominal pressure by means of sacks of sand weighing 3 or 4 lbs., removed occasionally. It is difficult to determine just how this double pressure acts upon the swelling, but it is a fact that inflamed tubes and swollen ovaries, the size of a fist, through continuous pressure have been quickly diminished and remained so. Pyosalpinx is more apt to yield to this treatment than hydrosalpinx; and, whether or not it has been the experience of other gynecologists, in Steffeck's practice it has been true that the persistent hard tubal tumor which demanded operation usually contained, not pus, but a serous fluid. But in old chronic cases the foregoing methods of treatment will not lead to healing in an anatomic sense; freedom from pain and discomfort is all that one can expect to result therefrom. Operative methods for such conditions will be discussed in a future paper. [W.K.]

 - I. The Geographical Distribution of Anopheles in Relation to the Former Distribution of Ague in England. G. H. F. NUTTALL, L. COBBETT and T. STRANGWAYS-PIGG.
 - II. The Structure and Biology of Anopheles. G. H. F. NUTTALL and ARTHUR E. SHIPLEY.
2. Pathogenic Microbes in Milk. E. KLEIN.
3. Industrial Lead Poisoning. Y. M. LEGGE.
4. A Rapid Method of Determining Carbonic Acid in Air. JOHN HALDANE.
5. An experiment on the Effect of Inhalation of Ethylene. J. LORRAIN SMITH and HOSKINS A. PERCY.
6. Artificial Modifications of Toxins with Special Reference to Immunity. JAMES RITCHIE.
7. The Utility of Isolation Hospitals in Diminishing the Spread of Scarlet Fever.

1.—This new quarterly opens with an interesting and timely article in which Grassi's conclusions that the **geographic distribution of the genus Anopheles** would be found to coincide with that of malaria, has no general application, the authors having found Anopheles in many parts of England where there is no record of the previous existence of malaria and where there is certainly no malaria to-day. The article is accom-

panied by notes on the natural history of *Anopheles* and by 3 plates representing its structure and development, and by maps showing the former distribution of ague and the present distribution of *Anopheles* in England. They serve to illustrate regions in which malarial disease seems to have been always endemic and from which in suitable seasons it invaded more extensive areas, probably through the increase in the number of *Anopheles*. The authors conclude: (1) the disappearance of ague from Great Britain does not depend upon the extinction of mosquitoes capable of harboring the parasites of malaria. (2) Three species of *Anopheles* (*A. maculipennis*, *A. bifurcatus*, *A. nigripes*) are to be found in all districts which were formerly malarious, but also in places concerning which there is no record of the former prevalence of ague. (3) The *Anopheles* to-day are most numerous in low-lying land containing many ditches and ponds and corresponding to the districts where ague was formerly prevalent. (4) Since the disappearance of ague does not depend upon the extinction of *Anopheles* it is probably due to several causes operating together: (a) A reduction in the number of these insects in consequence of the drainage of the land. (b) Reduction of the population in infected districts as the result of emigration about the time when ague disappeared from England. This would naturally reduce the number of infected individuals and lessen the chance of the *Anopheles* becoming affected. (c) It is possible that the use of quinin has reduced the chances of infecting the *Anopheles* by arresting the development of the parasites in the blood of subjects affected with ague. Of these, the first mentioned cause seems to have been chiefly operative. The possibility exists of there being another intermediary host besides men capable of harboring the parasite and assuming that this were so, this host may have become extinct in the lowlands where it is known that the fauna and flora have changed. (5.) The coincidence of the geographical distribution of ague and *Anopheles* as claimed by Grassi for Italy, and as probably holding good for other parts of the world, is hereby disproved for England and consequently the generalizations are proved to be premature whereby he excludes other blood-sucking insects from being possible hosts of malarial parasites on the strength of this supposed geographical agreement. (6.) Since the geographical distribution of *Anopheles* in England is wider than the former distribution of ague the conclusion is that it is not a matter of the geographical distribution of *Anopheles* as much as of their numerical distribution. (7.) Having proved the existence of *Anopheles* in nonmalarial districts the occasional occurrence of ague in such places may be explained by the advent of a malarious subject and the subsequent infection of local insects. The authors suggest that *Anopheles* be sought for in nonmalarial as well as in malarial regions. [C.S.D.]

6.—From a comprehensive study of the modifications of toxins, Ritchie arrives at the general conclusions that tetanus toxin under the influence of hydrochloric acid loses with comparative readiness its virulently toxic properties. With less readiness it loses its power of producing immunity and retains it when all trace of toxicity has disappeared. The less poisonous substances produced in the modified toxin are probably of the nature of toxoids. Tetanus toxin is also susceptible to the action of alkalis, such as sodium hydrate and sodium carbonate, under which it again loses its toxicity. Ricin resists the action of hydrochloric acid. It is evident in it also that the capacity of producing immunity remains after the toxicity is destroyed. Abrin and diphtheria toxin are resistant to the action of hydrochloric acid, but relatively susceptible to that of sodium hydrate. Diphtheria toxin which has had its toxicity destroyed by sodium hydrate seems to retain immunizing properties. [C.S.D.]

Revue Neurologique.

February, 28, 1901, [Vol. 1X, No. 4.]

1. Two Cases of Polyneuritis in Gonorrhoeal Patients. RAYMOND and CESTAN.
2. Intramedullary Neuroma in 2 Cases of Syringomyelia with Succulent Hands. BISCHOFSWERDER.

1.—Raymond and Cestan report 2 cases of multiple neuritis, secondary to gonorrhoea. The first occurred in a man aged 30,

who had contracted gonorrhoea, which in its acute stages lasted about 6 weeks. The discharge then ceased. A week later symptoms of multiple neuritis developed, and the discharge returned. There was paralysis of the legs, paresis of the trunk, and marked weakness of the arms, together with numbness and tingling in the affected parts. A diplegia of the face existed. The eyes were not involved. There was marked cutaneous hyperesthesia, but objectively the sensibility was not disturbed. In addition there was some atrophy of the lower limbs and the tendon reflexes were abolished. Reaction of degeneration was only obtained in the muscles of the face. The second patient, a man of 44, who had for a brief period indulged in alcohol, developed pains and weakness in the limbs within a week after contracting gonorrhoea. There was ataxia, the kneejerk was abolished on the right side and scarcely obtainable on the left; the muscles were somewhat atrophic, and the nerves were tender in their course. The arms were intact. There was no disturbance of sensation. The authors believe that in the second patient the neuritis was not due to alcohol, although it may have predisposed the system to be more sensitive to the poison of gonorrhoea than it would otherwise have been. The exact relation which gonorrhoea bears to the development of multiple neuritis cannot at present be definitely stated, nor is it known whether the gonococcus itself or the gonococcus toxin is concerned in the production of the neuritis. [D.R.]

2.—Bischofswerder, in 2 cases, noted the association of intramedullary neuroma and syringomyelia. Both of the cases were characterized by the main succulent (succulent hand). The neuromas were found in the ventral and dorsal portions of the cord, as well as just under the pia, and were to a large extent composed of interlacing nerve-fibers, many of which were myelinated. The neuromas situated near the exits of the ventral roots did not possess bloodvessels, while only a few of those near the dorsal roots were devoid of them. Raymond has explained these neuromas as being on attempt at the regeneration of nerve-fibers, while Schlesinger attributes them to local irritation. The author believes that both views may be correct and may explain the vascularized and the nonvascularized types of neuromas. The former are perhaps due to a local irritation; the latter are the expression of atrophic activity of the nerve-centers. In view of the succulent hands, it was interesting that the neuromas were localized exclusively to the cervical swellings. In the first case, in which there was also disease of the brachial plexus of the right side, the neuromas were almost confined to the cervical region of that side. It would seem as if the condition of the peripheral nerves had something to do with the development of the neuromas, although it does not explain all of the tumors. Since 1895, 5 cases of succulent hands have been reported: 1 by Raymond, with syringomyelia of spasmodic form; 3 by Schlesinger, 2 with tabes and 1 with syringomyelia; and 1 by v. Kahlden, with Pott's disease and spinal-meningitis. The author suggests the possibility that syringomyelia with succulent hand is a peculiar form of the disease, and that neuromas of the cervical swelling, together with a diseased state of the brachial plexus, constitute a special pathologic syndrome of the disease. [D.R.]

THE PUBLIC SERVICE

Changes in the Medical Corps of the U. S. Navy, for the week ended April 13, 1901:

- WAGGENER, Medical Inspector J. R., detached from duty in charge of the naval hospital, Cavite, P. I., and ordered to the naval hospital, Mare Island, Cal., having been condemned by board of medical survey.
- SCHOFIELD, Medical Director W. K., detached from duty in attendance upon officers of the Navy and Marine Corps, April 27, and ordered home and to await order.
- FARWELL, Medical Director W. G., detached from the League Island Navy Yard, April 27, and ordered to duty as relief of Medical Director W. K. Schofield, April 27.
- BIDDLE, Surgeon C., ordered to the League Island Navy Yard, April 27, as relief of Medical Director W. G. Farwell.
- GRIFFITH, Surgeon S. H., detached from the bureau of medicine and surgery, Navy Department, April 25, and ordered to temporary duty in charge of the exhibit of the bureau of medicine and surgery of the Pan-American Exposition, Buffalo, N. Y.

BARTON, Lieutenant Commander J. K., detached from the naval hospital, Yokohama, Japan, and ordered to the Brooklyn.

WILLIAMS, Assistant Surgeon R. B., detached from the Pensacola Navy Yard and ordered to the Key West Naval Station, and thence to temporary duty at Dry Tortugas, Fla., with detachment of marines.

Changes in the Medical Corps of the U. S. Army for the week ended April 13, 1901:

EWING, Major CHARLES B., surgeon, now on duty at Santa Mesa Hospital, Manila, P. I., is detailed as a member of the board of medical officers appointed January 16, 1900, for the purpose of studying tropical diseases as they occur in the Philippine Islands.

FARR, First Lieutenant CHARLES W., assistant surgeon, recently appointed, will proceed from Elmira, N. Y., to Fort Reno, for duty, to relieve Captain Francis M. McCallum, assistant surgeon, who will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

LONGINO, Captain THOMAS C., assistant surgeon, will accompany troops G and H, 10th cavalry, to San Francisco.

HORNE, Acting Assistant Surgeon WILLIS S., will proceed to Fort McIntosh and report to accompany troops E and F, 10th cavalry, to San Francisco.

GARRETT, Acting Assistant Surgeon NEVILL M., will proceed to the detention camp, Angel Island, Col., for duty with companies K and L, 11th infantry.

MORHART, Acting Assistant Surgeon FREDERICK II., having arrived on the transport Logan, and now sick at the Army General Hospital, Presidio, will proceed to his home, Washington, D. C., when able to travel, for annulment of contract.

NEWGARDEN, Captain GEORGE J., assistant surgeon, upon the expiration of leave granted him February 27, will proceed to Fort Mason, for duty.

DE WITT, Lieutenant Colonel CALVIN, D. S. G., is relieved from further duty as chief surgeon, department of Dakota, and will report to the surgeon general of the Army for duty.

Orders of April 5 are so amended as to direct Captain FRANCIS M. McCALLUM, assistant surgeon, upon his relief from duty at Fort Reno, to proceed via Jefferson Barracks to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

Orders of April 1, relating to Captain FREDERICK C. JACKSON, assistant surgeon, are revoked.

JACKSON, Captain FREDERICK C., assistant surgeon, is granted leave for 1 month.

JACKSON, Captain FREDERICK C., assistant surgeon, will upon the expiration of the sick leave granted him April 11, proceed to Columbus Barracks, for temporary duty.

EBER, Captain ALBERT H., assistant surgeon, recently appointed, is granted leave for 1 month.

JOHNSTONE, Captain ERNEST K., assistant surgeon, recently appointed, now in San Francisco, will report for transportation to Manila, P. I., where he will report for assignment to duty.

LAWRASON, Captain GEORGE B., assistant surgeon, recently appointed, will proceed to San Francisco, Cal., for transportation to Manila, P. I., where he will report for assignment to duty.

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine Hospital Service, during the week ended April 12, 1901:

AMERICAN MEDICINE

1321 Walnut Street

Philadelphia

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free: foreign postage, \$2.50. Subscriptions may begin at any time. Volumes begin with the first issue of April and of October.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles, will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is one dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to American-Medicine Publishing Company. Address all correspondence to 1321 Walnut Street, Philadelphia.

PUBLISHED WEEKLY AT 1321 WALNUT STREET, PHILADELPHIA, BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. I, No. 4.

APRIL 27, 1901

\$4.00 PER ANNUM.

The Centralization of Control of Charitable and Educational Institutions proceeds, and all good citizens must hope that it will go on in all the lagging States. The latest instance is that of Minnesota, where there has been an abolition of practically all the separate boards in charge of the charitable and correctional institutions, including the supervisory Boards of Charities and Corrections. For these boards was substituted a central board of three members, which will have financial control not only of all charitable, correctional, and educational institutions of the State, but administrative control of every institution except the university, the normal schools, the schools for the deaf and blind, and the Soldiers' Home.

Concealment of the Plague in California.—We have more than once condemned the crime of concealing the existence of highly infectious diseases in obedience to motives of social or commercial economy. In another column we reproduce the brave words of the *Occidental Medical Times* against the heinousness and stupidity of this sin. In a part of the editorial of the *Times*, not quoted by us, there is an astonishing charge made that the Secretary of the Treasury and Surgeon-General Wyman signed an agreement that the report of the Federal Plague Commission shall not be made public, that all reports of cases of plague shall be suppressed, and that all sources of information as to the plague shall be concealed from the public by the officers of the Marine-Hospital Service. We are authorized by Dr. Wyman to say that "the statement as to an agreement signed for the suppression of plague information is absolutely without foundation."

A Suggestion as to the American Medical Association.—We have, of course, the sincerest desire that the Association may grow more and more powerful, and to that end we would, in the most friendly spirit, offer a suggestion which we believe would have the effect desired. It is that, without losing the democratic or representative control of the business and decisions—the direction and fate of the organization—some plan may be devised whereby a small number of delegates should thresh out all propositions, and decide them according to their combined wisdom and judgment; the general meetings would thus be kept for purely scientific business. If the referendum is instituted, it should be without discussion, by the general body which must vote yea

and nay at once upon presentation of the question of supporting the committee's decisions. When in earlier days the Association was made up of a small number, the town-meeting plan of legislation was possible; now that it has grown so large and will continue to grow still larger a manner of expediting the transaction of business should be instituted. A mob cannot legislate, cannot deliberate dispassionately, and several thousand people even of the best, will be subject to the laws of the psychology of crowds. This representative body might be called the Senate. Each senator should be elected by his State organization and represent a stated large number of members and should devote his entire time, to the exclusion of section work, to the business of the Association.

Philanthropy for Consumptives.—One of the gravest aspects of the problem of caring for consumptive persons is that of the diminished wage-earning capacity of those who suffer from the disease during many years. Not only must a majority of tuberculous patients support themselves during the long struggle against progressive inroads of infection, but in many instances the care of others is also a burden on them. When the semiinvalid is forced to seek a different climate in the hope of cure, he finds himself, even when that hope is to a degree realized, brought into competition with more robust personalities that demand no favoritism in the struggle for a livelihood. Sometimes the consumptive secures work by accepting wages lower than the prevailing scale; thus he becomes at once a disturbing factor in the labor market. The establishment and maintenance of sanatorium settlements where consumptives may become self-supporting in whole or in part without coming into competition with other labor, may prove a partial solution of the difficulty. It may be commended to philanthropists as a charity measure that is practically free from the objection of "pauperizing" the recipients of the aid given.

Pseudopathy as a Warning.—Miracle mongering and medical superstition in the guise of Christian science, faith-cure, etc., should be "held in thought" by physicians as a signal that we may ourselves have gone astray. We should at least never forget the wisdom of the old rule of attending carefully to what your enemy is saying and doing. Certainly the law of rhythm in human affairs, of action and reaction, needed no Spencer to prove

its universality. Classing all the hordes of modern medical superstitions together under the title of pseudopathies, there is one type that glares at us with abundant conviction and unity from the eyes of the morbid pseudopaths—they are in revolt against materialism and fatalism. Is this, it behooves us to ask, to any great extent a reaction against the past deterministic and materialistic attitude of so many scientists and physicians? If so, we are to blame. Every scientist whose opinion is worth consideration has put himself on record against the silliness and unscience of materialism, and every normal human heart believes in freedom. An exaggerated reliance upon drugs, a pathologic pathology, a crass extremism of science-worship, a not infrequent professional bigotry—all these have undoubtedly served to drive too many weak minds into the violent and worse reactionary extreme of pseudopathy. If that extreme is inexcusable, so was ours. Fortunately we have recognized and are fast renouncing our error. But the results of our sins live on after we have repented. These sick minds have yet to be cured. Pseudopathy is real disease.

Political Colonization and Medical Science are constantly increasing their interrelationships. The great problems of statesmen and administrators have constantly to be solved, and are in every detail modified by the aid of data and facts supplied by medical men. What a lesson there is for the world in our universal annexation mania in regard to the interdependence of the highest and lowest, of the farthest removed savage and civilized. Intensely infectious diseases cannot be stamped out in any civilized country unless at the same time they have been stamped out in Central Africa or in Asia. Nothing so well as disease teaches the unity of the human race. Among medical discoveries none is of more importance to expansive governments than that of the disease-carrying powers of the mosquito. Up to now the extension of civilization in almost all new countries has been a terribly expensive or impossible process, owing to malaria, yellow fever, etc. The west coast of Africa today is speedily fatal to Europeans. It is now quite certain that mosquito-curtains and such protective devices, with attention to pure water and proper food, will make it possible to civilize many countries that are now barbaric desolations. The savage protects himself by smearing his skin with filth, or has developed a natural immunization against diseases; for the white man science will make the same safeguards possible by better and quicker methods. There is no money so well invested as the little which civilization spends upon medical science.

An Epidemic of Pharyngitis.—A peculiar form of acute pharyngitis seems to be epidemic in Philadelphia. It has attracted the attention of physicians in general practice, and more strongly that of laryngologists in charge of large hospital dispensaries. It comes on acutely either directly with throat symptoms or first with general manifestations—chilliness, pains, fever—the throat phenomena appearing only after twelve or twenty-four hours. The pharynx is intensely red, and the tonsils

are greatly, but often unequally, swollen. Numerous white points dot the tonsils, but are not confined to them. On careful examination small white patches, round or oval, surrounded by a red inflammatory areola, can be seen on the posterior wall of the pharynx, and frequently also on the halfarches. At times the tiny ulcers are disposed in vertical rows. In some cases the pharyngeal involvement predominates and the tonsillar swelling is but trivial. Pain in the back of the neck and in swallowing is present, together with the other features of a severe tonsillitis. There is, however, not much enlargement of the lymph-glands. The urine is diminished in quantity, is of a dark color, and has a high specific gravity. The severe symptoms persist for two or three days and then subside quickly. Usually the patient is left very prostrated. Both children and adults are attacked; often several members of a family are taken down simultaneously or within a few days of one another. There are no complications, as a rule, but in one case with which the writer is familiar an acute attack of Bright's disease seemed to have no other cause than the pharyngitis here described.

The Toxic Action of Methyl-alcohol in recent times has attracted much attention, and its influence upon the eye and its power to produce blindness have been the subject of many papers and some experimental work. In most of the cases thus far reported the methyl-alcohol has been consumed by men as a substitute for ordinary alcoholic drinks, and has produced with great suddenness amaurosis and optic nerve atrophy. Usually at the end of a spree the patient has wakened up completely blind; a blindness, moreover, which has been permanent except in one instance. In not a few cases death has followed the consumption of this liquid. Not only has methyl-alcohol been so used, but adulterated Jamaica ginger, essence of peppermint and other substances which undoubtedly depend for their activity, as Herbert Harlan has recently demonstrated, upon methyl-alcohol.

In a few instances workmen who are obliged to use wood-spirit have become blind by inhaling its fumes, as has been particularly noticed and reported by Patillo and Casey Wood of Chicago, and quite recently Dr. deSchweinitz has described before the Ophthalmic Section of the College of Physicians of Philadelphia a case of sudden blindness which was probably due to methyl-alcohol and which indicates that varnishers run grave risks when employing this exceedingly potent spirit. The patient for two months prior to his loss of vision was constantly employed in shellacking and was obliged to mix the shellac with methyl-alcohol or columbian spirits which contains about 90% of this liquid, and was therefore during this period of time much exposed to the fumes. Not only this, but he, as well as his fellow-workmen, were in the habit at the close of the day's labor of washing the stains of the shellac from their hands, forearms, and faces with the methyl-spirit. It would seem, therefore, that varnishers who use wood-alcohol should be warned of the grave risks which they run, which are similar to those which are encountered by workers in lead, in carbon bisulfid in the caoutchouc manufactories, and in dinitrobenzol in the roburite

works. The special precautions which the workmen are obliged to employ in these three trades are well known—care in washing the hands, frequent changing of occupation, and, during the period of handling, particularly carbon bisulfid and dinitrobenzol, the use of masks to prevent the noxious fumes from entering the pulmonary tract. In all probability the knowledge of the danger of methyl-alcohol is not nearly so widespread among workers and employers as is the knowledge of the danger of lead, dinitrobenzol and carbon bisulfid, but evidently no time should be lost in making them aware of the serious risks which careless use of this liquid entail.

Nursing School Diploma Mills are springing up with the concealed or avowed purpose of securing diplomas and inclusion in the regularly trained profession before laws shall be passed shutting out such quacks. The nurses of the country should zealously push forward the passage of laws requiring registration and graduation from some genuine training school as conditions of permission to practice. When diplomas (printed in the alluring circulars in double caps), badges, etc., for a certain amount of money may be obtained by correspondence from poor dupes who do not know how to read or write, it is already late for organizing against the shameless humbuggery.

Asthenic Bulbar Palsy.—This somewhat mysterious affection was first brought to the notice of neurologists by Erb, in 1878, although its occurrence had been previously observed by Wilks, and by Wernicke. Oppenheim was chiefly instrumental in establishing it as a clinical entity; and since his original contribution, in 1887, quite a large number of cases have been reported. In this country the condition has been observed by Collins, Wheaton, Berkeley, Sinkler, Burr, and McCarthy.

The chief characteristics of the disease are ptosis and paralysis of the external ocular muscles, and of those of the face, of mastication, and of the tongue, palate, and larynx. Speech and swallowing are greatly impaired, and mastication is difficult. Sometimes the muscles of the neck, trunk, and extremities are paretic. Under voluntary use of the muscles the paresis increases rapidly, and eventuates in complete loss of energy and almost total paralysis. The exhaustion may be so extreme that after a few moments' conversation the patient is unable to utter a word, and that the bolus of food, partially masticated, lodges in the mouth for want of strength to swallow it. The symptoms are subject to rapid changes, and may vary from hour to hour; and as a whole, the disease presents remissions lasting for several weeks or months. Sensory changes, pain, reactions of degeneration, and impairment of the sphincters, are absent. A peculiar electric reaction has been described by Jolly as characteristic of the disease. It is a rapid exhaustion of the muscles under the influence of the faradic current (myasthenic reaction), and is analogous to the fatigue or utter exhaustion that follows voluntary movement of the muscles.

While cures have been reported, the disease is usually fatal. Hitherto the dietum of Oppenheim that the dis-

ease had not an anatomic basis but was a pure neurosis, has been generally accepted, and was corroborated by the results of autopsies, which showed either no changes, or merely unimportant ones. For this reason most authorities ascribe the disease as a neurosis from auto-intoxication. Later, however, Déjerine and Thomas have reported an instance of the disease, typical clinically, in which they found, in addition to trivial cortical changes, a decided atrophy of the pyramidal tracts in the pons and medulla. This they considered as probably a primary degeneration, since it bore no definite relation to the alterations in the cortex. Aside from this, they also noted a high degree of fatty degeneration of the muscles of the larynx, with similar, but milder changes, in the tongue and pharynx. Whether the muscular degeneration was primary or secondary, they were unable to decide, in the absence of knowledge as to the conditions of the muscles of the larynx in cases that have died of hemiplegia or of pseudobulbar palsy. It seemed to them, however, as if the muscular degeneration was more recent than the changes in the pyramids.

These observations of Déjerine and Thomas are an interesting and important contribution to the subject of asthenic bulbar palsy. They suggest the possibility, as the authors properly remark, that the disease is not strictly a morbid entity, but merely a clinical syndrome that may be produced by a variety of conditions.

Pleuritic Urticaria.—Although the occurrence of urticaria during the course of serofibrinous pleuritis has been observed with tolerable frequency, but little general attention has been directed to the subject. The recent report of a case by Gomez (*Riforma Medica*, December 27, 1900), not only brings forward the subject again for consideration, but also suggests some interesting and important practical points. The case reported is that of a girl, aged 17 years, who developed a pleuritis attended with moderate effusion, probably the result of staphylococcal infection. The occurrence of an urticaria that could not be assigned to any dietetic indiscretion was speedily followed by absorption of the exudate. The important practical inference to be drawn from this as well as from other cases is that the urticaria, while it adds temporarily to the patient's discomfort, is of good prognostic import, in that it usually presages the speedy disappearance of the pleural effusion. This is all the more likely to be the case, if the urticaria occurs early in the course of the pleuritis. The point is well worth investigating, and if future observations should confirm our present suspicions, we will have secured a valuable addition to our prognostic knowledge and its accompanying therapeutic indications. The urticaria in these cases manifests itself especially on the trunk, the abdomen, and about the folds of the body, and in the present instance, as well as in the most of the reported cases, it has been attributed to the development of a toxemia, the consequence of absorption of pleural fluid.

The Sufferings of Animals in War.—We wonder if there is any sin deeper and more disgraceful than that of the Antivivisectionists who ignore the horror of the sufferings of horses, mules, and oxen, in war, while

tormenting scientific men with their lies and shriekings. Here are two quotations from English correspondents:

"But of all the pitiful, heart-rending sights I have ever seen none has compared to this view of hundreds upon hundreds of dead and dying horses on this 100 miles of war's promenade. The poor beasts had done no man any harm—in fact, each one had been a man's reliance—and to see them shattered by shell and then ripped open by vultures often before they were dead, was enough to snap the tenderest chords in one's breast. They had not deserved and could not understand their horrible ill-luck. For some reason, hundreds had dragged themselves to the main road, and then had died either in the track of the wagons or by its side. But the worst horror was to come when I approached close upon the last battlefield, only twenty-four hours after the fight at Dreifontein. On this field not nearly all the horses were yet dead. On the contrary, as I came up beside the prestrate body of a beautiful steed it would slowly and painfully lift its head, and turn upon me a pair of the most pleading woe-stricken eyes, full of a hunger to know what I could do for it. All I could do was to drive on, for I had no firearms, even for my own protection, deep in an enemy's country, where we had put no single armed man to guard the route of our supplies and reinforcements. My companion used to turn and look back at these dying horses, only to find that they were still straining their sad eyes after the cart. Then he would say, 'He is looking at us yet; oh, it makes me ill; look, he is staring at us like a guilty conscience. What can we do? I wish we did not see such things.'

"More pathetic than the sight of the dead horses was the sight of the living ones. There were horses that had been bit, horses that had been broken down with overwork and under-feeding, horses with hideous saddle-sores hidden by clustering mounds of flies, horses abandoned for every conceivable defect; some horses for whom death had loosened their riders' control, big English horses, unshod Boer penies, most of them with hip bones that projected so far as to suggest dislocation; they were wandering about helpless, forlorn, abandoned creatures, who looked at you dubiously, as though they feared you were bringing them more of glorious warfare; and then, seeing you pass, turned listlessly away, hanging down their heads."

The cure for such things lies in the organization, or the reorganization of Army Veterinary Departments, the extension of the protection of the terms of the Geneva Convention to those who care for wounded animals, etc. Those who have real kindness of heart instead of egotistic sentimentalism should try to stop pain, instead of screaming at those who are trying to stop it.

Nerve Fibers in the Pia Mater.—In a recent number of the *Revue Neurologique*, Dercum and Spiller report an interesting discovery made in a case of adiposis dolorosa. They found myelinated nerve fibers in the pia mater, over the posterior and, to a less extent, over the lateral columns of the cord. The fibers were most numerous in the sacral, lumbar, and lower thoracic regions; none was found in the cervical portion of the cord. They had an irregular course, and in a few places it was evident that they came from the posterior roots. After entering the pia, they ascended for a considerable distance, and then seemed to pass into the posterior columns. As there was no degeneration of the posterior columns or of the posterior roots, the presence of these fibers could not be explained on the basis of a compensatory growth—an hypothesis that has been suggested by Saxer and Fickler. Dercum and Spiller offer another and seemingly logical explanation for the presence of the nerves in their own case. On the strength of Ober-

steiner's and Galland's demonstration of the existence of nerve-fibers in the vessels of the cerebral pia, they conclude that the spinal pia must likewise be provided with nerve-filaments. Normally these, like the corresponding fibers in the pia of the brain, are without myelin, but it is possible that, coming as they do from the posterior roots, they may in rare cases retain their sheath and thus be demonstrable by means of the Weigert stain.

The discovery of nerve-fibers in the vessels of the cerebral pia—long foreshadowed by clinical experience—indicates that the circulation in the central nervous system like that in other viscera, is, in part at least, under the local control of the vasomotor system. It was formerly maintained that hyperemia and anemia of the brain occurred only in response to increased or decreased activity of the heart, or as a consequence of purely mechanical conditions favoring or restricting the flow of blood to the brain. Now, as nerve-fibers course in the vessels of the pia, and as these vessels have a muscular coat, it is an unavoidable conclusion that these nerves subserve the same function that falls to them in other parts of the body—namely, to regulate the caliber of the arteries and arterioles.

The knowledge that the brain possesses a vasomotor system of its own throws a flood of light on a number of clinical problems, and will, no doubt, also exert an important influence upon the treatment of cerebral disease.

The demonstration of the presence of nerve-fibers in the spinal pia under normal conditions is still lacking. It would seem that the gold-impregnation method, which gave such good results to Obersteiner, ought to prove equally efficient in the spinal cord.

Reduced Birth-rate.—A French statistician says that in spite of the increase of population in various countries, the rate of increase is steadily diminishing. Austria is really little better than France in this respect, while Germany, which shows the largest increase of European nations, has a declining birth-rate. The United States, with its increase of 14,000,000 in the last decade, has the largest decline of birth-rate and would surely show signs of retrogression but for the steady volume of emigration. It is the old story over again of lessening of increase in accordance with the degree of luxury in civilization.

Homes for Foundlings, according to the committee in New York, are not only easy to find, but there are not enough babies to supply the demand! Many applicants recently had to return to their childless homes when it became known that there were no more little ones to give away. The fact is encouraging, and one may hope that the time will soon come when there shall not be an orphan asylum or an uncared-for child in the civilized world. In Australia and New Zealand there is none such. The "cry of the children" has been a sad one in the world. We are not over-favorable to "grandmotherly government," but we heartily believe in motherly government—of children. Every child has a right to a home and love, and the State should see to it that it gets its rights. Let us have no such abominations as the baby-farming (save the word!) described by Zola in his

powerful novel, *Fécondité*. (Read also the terrible indictment of the monastic orders in the *Contemporary Review* of April, 1900). It is all the more inexcusable when thousands of child-hungry women and men wish to care for waifs. In New York City the number of children who have been legally adopted through the committee's efforts, and who are now in good homes, are as follows:

During the year ending March 31, 1899	3
During the year ending March 31, 1900	18
During the year ending March 31, 1901	32
Total	53

When the committee began its work the death rate among the foundlings in the Infants' Hospital was appalling. Of the 366 infants under six months old admitted in 1896 but twelve were alive on April 15, 1897, a death rate of 96.7%. Since then the death rate has been very materially reduced, as the following figures show:

During the year ending March 31, 1899	55.9%
During the year ending March 31, 1900	31.1%
During the year ending March 31, 1901	18.9%

The Proportion of Doctors Among Men of Genius.—In the recent Dictionary of National Biography which has been issued lately in England, and in which persons of preeminent intellectual ability which Great Britain has thus far produced are considered, there are mentioned some 30,000 persons. Havelock Ellis (*Popular Science Monthly*, February, 1901) has studied the records contained in this dictionary with a view to determining the elements of intellectual ability which have entered into the success of these eminent Britons. He finds that in a large proportion of these persons there is too little recorded upon which to base a judgment and for other reasons he eliminates from his estimates all but 859 men of a high degree of intellectual eminence. The number of doctors included in his list of names is surprisingly small, only 7 being mentioned: Caius, Linaere, Mead, Pott, Sydenham, Cheselden and Cullen. It would have been possible to enlarge the group somewhat by including a certain number of medical men who are not considered by their biographers to have attained a really durable reputation. He believes that just as really able business men are not satisfied with business success, so really able doctors are not satisfied with professional success, but seek a higher success, specially in science. A number of eminent men in science, letters and philosophy have been doctors, but it has not been in medical practice that their reputations have been made. In this class he mentions such names as Harvey, Hunter and Jenner. It is questionable whether it can be truly said that these men did not make their reputations either in medical practice or what is practically the same, in allied medical sciences; and without the experience which these men gained from their medical education and practice, it is questionable whether their intellects would have developed in such a way as to lead them to any pre-eminent success. Among other names which Ellis includes in his lists are those of Locke, Goldsmith, Keats, Livingstone and others who were educated as physicians and some of whom practised medicine but

who cannot be said to have been deeply influenced by their medical training and practice.

This small list of names of doctors shows how little is the reward in the way of fame and public appreciation of service which can be expected even by the most successful medical men. Undoubtedly many of the men included in Ellis' lists were deeply influenced by a medical training. Without this they would never have attained their love for truly scientific study, their thorough understanding of human nature in all phases and the deeper sympathy with people of all conditions which the doctor gains from association with the sick and afflicted of all classes; for truly, suffering makes all men kin, and under the trying circumstances of serious illness men show their true characters as under no other circumstances. While the proportion of men who have themselves a permanent place in the archives of history among the members of the medical profession is not great, there are other rewards which are as great and in many ways more satisfactory. Ellis says that the able doctor is not satisfied with his professional success, but seeks a higher success. Can there be any higher success than the doctor's professional success? The certain knowledge that one has been able to alleviate suffering, and to cure disease is surely worth as much as a place in the Dictionary of National Biography and there are many unknown heroes in the medical profession who have as certainly earned a place in the hearts of their fellows as Ian MacLaren's "Doctor of the Old School."

"Something Unusual to Offer You" in Advertising.—The original of the letter copied below lies before us. If his offer is not so unusual as the writer supposes, it must be remembered that the manufacturer thus solicited not only did not accept, but writes: *We wonder how many of the advertisers in the ——— have been tempted by this most liberal offer?* We shall look out for the future articles of the condescending physician, "able" and "educated," who shrewdly limits his sales to two articles per annum to a single firm.

Gentlemen:—We know that you receive more requests for advertising than is interesting, but we have something unusual to offer you, so we hope you will give this letter your consideration. If you will place a half page or a full page ad. in the ——— one year we will get Dr. ——— to write for the ——— an original article on your preparations. Dr. ——— is an educated man and a very able writer, and in addition to writing some for the medical press, writes for some of the popular magazines. The April ——— has an article on ——— by the Doctor. He does not make a business of writing articles on proprietary preparations, but he has written a few such articles in the past few years for us. He would not recommend any preparation unless he was sure of its value. If you should accept this offer we should expect you to supply the Doctor sufficient of your preparations to try them thoroughly.

We enclose one of the Doctor's articles which will show you some of his work.

In addition to this we will give you each month a notice in the department called ———.

We claim the ——— to be equal to any journal having the same circulation, but some of our advertisers who most accurately and carefully note returns, claim more. We enclose copy of a letter from the ———, ——— St., ———, showing their opinion. This opinion came to us entirely unsolicited.

We should like to start a page in an early number of the ——— for \$75.00 or a half page for \$40.00. Kindly favor us with

a reply whether you take space or not. As we can only get two articles from Dr. ——— this year, we wish to make this proposition to some one else if you should not accept it. We enclose return envelope for reply. We have sent you a March ——— for examination.

Yours truly,

“Youth at the Prow.”—Those who have undertaken any progressive and altruistic work in medicine are likely to be shocked soon by the indifference of the elder and the successful physicians. The leaders do not lead. They often do not follow and, indeed, are prone to pull backwards. There is perhaps a too strong tendency in America for the youngsters to scorn the advice of their fathers and to strike out for new fields and to be regardless of precedent. But in a growing country or a growing science, like ours, it must be admitted that the selfishness and lethargy of the old often give to the young a most exasperating warrant for seizing the helm as well as standing at the prow. It is wise to be governed by wisdom, but age is not always a synonym of wisdom nor of a fine professional spirit. It is a great pity that some physicians are so successful, for success is prone to breed recklessness as to professional abuses. We must look to the young for sympathy with medical reform and advance. Crudeness and impertinence should indeed be avoided, but to those just entering upon their medical life comes the cry, “Take your world, O Youth.”

EDITORIAL ECHOES

The Plague in California.—In the meantime, however, the disease has not been “shut up;” it has relentlessly pursued its deadly course without an effort on the part of any one to stem the tide. Six cases have been verified recently. All have been found dead in the miserable undertaking shops of Chinatown. One contracted the disease in Sacramento, another in Santa Barbara; the rest belong to San Francisco. We are fairly well convinced that the disease exists or has existed in Stockton, Fresno, and Bakersfield. A report, not verified by inoculation experiments or bacteriology, of two cases, from the last-named town, one dying in San Francisco, a man, ill for three days, with a large carbuncular mass involving the scrotum and inguino-femoral region, becoming rapidly comatose; the other, a case of supposed pneumonia, dying within a short period of illness, showing post mortem absolutely no pneumonic condition, but presenting enlarged glands in the femoral region, with hemorrhagic tissues surrounding bloody effusions in the peritoneal and pleural cavities, and those of the brain, presents a fairly typical picture of plague. The supposed cases of pneumonia in this town have been rapidly fatal, of a type puzzling the physicians, and presenting symptoms not in keeping with the history of pneumonia. In other words, the condition of affairs in California stands an awful menace to the health of its own people and those of the United States, especially when, through the falsehoods and instability of the Governor and people, absolutely nothing has been done for protection. It should be remembered by the officials of this State, great and small, that the commission has warned them personally of the solemn duty they owe their country in this crisis. They should recall the warning of Dr. Barker, when he stated that it was his belief that the disease existed from San Diego to Vancouver, B. C. They should recall the fact that, when they asked what should be done with Chinatown, they were told that it should be depopulated, that a

detention hospital should be established, and that in the end, to eradicate the disease, it in all probability must be destroyed. And yet our people hearken not! They still cry, “No plague,” stand idly by, while the disease continues its slow and threatening march, picking off a man here and there in dreadful warning. Woe betide this community if it ever invades the homes of the rich or of those who have outraged all honor and the truth in their false groveling to mammon and preferment!—*[Occidental Medical Times.]*

The Extermination of Rats.—“Some English statesman or other was described as a man who ‘looked like a rat that had seen a cat.’ The whole rat tribe may well be supposed to wear that air of mingled slyness and fear as soon as it hears of the formal proposal of the Japanese that the civilized world join forces for the purpose of exterminating rats. This is no affair for the Pied Piper of Hamelin. ‘Yankees of the Orient,’ as the Japanese have been called, it is no mere Yankee notion, this idea of theirs that the world should be rid of rats. It breathes, rather, the spirit of pure science. Rats are, next to mosquitos, the great germ-bearers and infection-carriers, and we should not wait till they get the world into the condition of a sinking ship, when, of course, they would leave it, if ye have writ your proverbs true, but should make haste to fling them overboard before they infect the whole crew with cholera and the plague. Ways and means are not yet described; and the skeptical will wonder how the job could be done in a country like India, where rats swarm and animal life is sacred. But if aimless and wanton hunting has exterminated more than one species of fauna during the past hundred years, a scientific campaign might avail even against rats. At any rate, life can never be quite the same to them again. They have seen the Japanese cat.”—*[The Evening Post, New York.]*

The Growth of the American Medical Association.—A decided reduction of the number of delegates, the proportion for each constituent body remaining the same, would, it seems to us, enhance the scientific work done in the sections and give time for a greater number of formal addresses, papers of general interest, and demonstrations. There need be no limit to the number of non-voting members so that the attendance at the meetings would go on increasing as it has done up to the present time. In short, we can see no objection to a decided curtailment of the representative element, and we believe that it would prove advantageous. Such a move, we are quite aware, would involve practically a reorganization of the association; if our ground is well taken, however, why should not a reorganization be effected?—*[N. Y. Med. Jour.]*

May a Hospital Steal Cases?—When our hospitals, whose staffs usually are made up of some of the leading physicians in the community, set the example of stealing cases from brother physicians under the guise of impersonal “rules of the institution,” it is time for medical societies to take a hand; and it is not to be wondered at that the younger men in the profession say the code operates chiefly to enable the older men to steal cases from those less well established, while preventing the contrary from being done. It is a terrible example to set the young men in the profession, and the institutions which are doing these things are doing more real damage to the *morale* of our profession than all other causes combined. The wrong is a deep one; and if we are to save ourselves from complete degradation to the methods of the charlatan, either those physicians who happen to be members of hospital staffs must see to it that these things do not occur, or else the medical societies

must take a hand and ostracise those members who tacitly permit case-stealing to be carried on by the institutions they guide and serve.—[*Cleveland Journal of Medicine.*]

Responsibility for Medical Attendance in a Divided Family, according to the *New York Medical Journal* has been settled by recent and old decisions, which makes the husband liable for the physician's services although the man and wife are not living together, and he is paying her a fixed amount monthly for her support. The father under similar circumstances is liable for the support of the children. "The physician's claim stands on an altogether different basis from a trade claim. Many instances in which the physician is summoned are such as involve matters of life and death, and common humanity in such cases demands that the physician should not lose time before rendering his services in taking steps to protect himself, as the tradesman would and should do, before allowing indebtedness to be incurred."

Executive Value of Medical Training.—Such a neglect of the medical profession in public affairs is nowhere found, excepting in this country. In France, Italy and Germany, a large number of physicians are found in the legislature and in many administrative positions. Some of the leading statesmen and politicians of the continent have had medical educations or have achieved signal distinction as medical teachers or practitioners. In this respect the profession in England is less prominent than that of the continent, but even in England the role played by the medical profession in the control of affairs is greater than in this country. One would think that a republic would be a place where all occupations would be represented in government; and yet it is a singular fact that almost the sole avenue to political preferment is through the legal profession. Nearly nine-tenths of our legislators and a large proportion of those who hold executive positions are drawn from the law, with the result that in the conduct of public affairs the commercial and other interests of the country are practically unrepresented. We believe that there are more lawyers engaged in governing in this country than in all the balance of the world beside, so that it has literally become a government of lawyers, by lawyers, and for lawyers. In France and Germany just the opposite conditions prevail. The sentiment of these countries is to the effect that a legal education does not especially fit one as a legislator.—[*Medicine.*]

Fees and Commissions—A Remedy.—The *Cleveland Journal of Medicine*, in order to stop the division of fees behind the patient's back, recommends that the medical societies shall arrange a fee bill for medical cases, not as now on the principle of the number of visits made, but "for services rendered," according to the disease, its severity, complications, etc. A provision could be inserted in this fee-bill, e. g., "For sharing the responsibility of urging surgical intervention, 25% in addition to the fee charged by the surgeon." This charge would be explained beforehand to the patient and his friends as having been agreed upon by all physicians. In each case then the surgeon and the physician could regulate their charges to accord with the gravity of the case, the difficulties to be encountered, and the ability of the people to pay. It would not be a commission paid clandestinely, but a regular fee for a definite service. By this plan the demand for commissions would pass away by the complete relief of the difficulties that seems to demand them.

The Widal test is by no means simply a positive or negative answer to the question, Is typhoid fever present? It may prove to be a valuable prognostic measure that will point out the failure of immunization and the con-

sequent danger of relapse. Its practical importance from this standpoint can be scarcely exaggerated. A delayed Widal reaction will be the indication for exercise of the greatest care in the resumption of ordinary diet. Relapses will not come as the surprise they have been heretofore, and the practitioner will realize during the course of the first attack the necessity for the conservation of the patient's strength.—[*The Medical News.*]

Dyspeptic Glycosuria.—The *Bulletin* of the French Academy of Medicine contains an interesting communication from M. Albert Robin upon the relations of glycosuria and diabetes to dyspepsia and stomach disorders. Although the writer is mistaken in supposing that this relation had not been previously observed, he carries the subject a step forward by connecting it definitely with hyperchlorhydria or that condition in which there is an excessive secretion of hydrochloric acid by the stomach. He points out that there is entire failure of the ordinary symptoms of diabetes, the quantity of sugar being small and its presence irregular; it appears during digestion, and is absent at other times. Albuminuria is frequently present. The quantity of urine is slightly increased; its density varies from 1,022 to 1,032, and there is excess of urea, phosphoric acid, and uric acid. The liver is swollen, the stomach distended, and in addition to dyspeptic troubles there may be neurasthenia, with vertigo, phosphaturia, skin troubles, cardiac disturbance, profuse sweating, etc., but none of these symptoms have any special significance. This mild and comparatively unimportant glycosuria occasionally becomes transformed into what the author calls dyspeptic diabetes with all its classical symptoms—namely, thirst, polyuria, and wasting. For the treatment of dyspeptic glycosuria, M. Robin recommends the use of remedies calculated to control the hyperchlorhydria, such as absolute milk diet, with magnesia, bicarbonate of soda, chalk, Vichy water, etc. When dyspeptic diabetes supervenes, regular antidiabetic treatment must be commenced.—[*Brit. Med. Jour.*]

Regulation of Marriage.—The *Medical Record*, in speaking of the Chilton Bill, which has passed the Minnesota Senate and is expected to become a law, says the bill is not only intended to restrict the marriage of persons afflicted with physical or mental disorders, but will affect all wishing to marry, as every candidate for matrimony must undergo a physical examination by a competent medical practitioner. "Even if its provisions, in many instances, should be covertly violated, every attempt at enforcing the law would prove a valuable educational measure, and carry with it a proper deterrent effect."

The Oleomargarin Bill and Substitution.—The argument is advanced that oleomargarin is an excellent food and a good substitute for butter. We shall not attempt to argue this question, for even if we admit that oleomargarine is a wholesome and palatable food, there is still no reason why it should be sold as butter. If wholesome and nutritious, it can easily rest upon its own merits as a food, but there is no reason why it should masquerade as butter; those who want the latter article should have it, and those who wish a substitute should be able to obtain it to a certainty. The public should not be asked to buy a mixture of lard, tallow, cottonseed oil and 1.5% of butter fat as pure butter. We question that the food value of this mixture is equal to pure butter fat, and the substitution of one for the other is a fraud with which the medical profession has had abundant experience in the matter of drugs. The bill now before Congress aims simply to prevent the coloring of oleomargarin in imitation of butter, and as such it is to be hoped that it will pass, as it will lessen in so much substitution and adulteration.—[*Medicine.*]

AMERICAN NEWS AND NOTES

GENERAL.

Blackleg.—The vaccine sent out by the Department of Agriculture for treating blackleg among cattle is in great request.

Smallpox in the United States.—The total number of cases for 1901, as officially reported, is 16,748, and for the same period in 1900, 8,013.

Rinderpest is reported from Manila as spreading in the provinces of Tayabas and Pangasinan and more remote districts. Military physicians have been sent to inspect the localities where the disease prevails.

Sanitary Condition of Havana.—The tabulated report of the vital statistics of Havana for March is accompanied by a letter from Major W. C. Gorgas, Chief Sanitary Officer there, calling attention to the fact that the death-rate (26.28) is lower than that of any March since 1889. There were only 4 cases and 1 death from yellow fever. He attributed this to the systematic and extensive destruction of mosquitos, and also to the quickened ability of physicians to recognize the milder types of the fever, consequently cases formerly overlooked are now promptly recognized and reported. The smallpox situation is equally satisfactory.

Increase in Drunkenness among the private soldiers of the army is reported to the War Department from every part of the country where troops are stationed. This is regarded as the result of the abolition of the sale of beer in the post canteens as there has been an increase in the number of saloons in the villages adjoining the military reservations dispensing cheap whisky and other heavy liquors, and the soldiers are led into vices which are excluded from the limits of a military post. In Manila the effect has been the same where "bino" is drunk instead of beer. It is stated that $\frac{1}{3}$ of the men who have deserted to the enemy or have gone home sick or insane are "bino" fiends.

Obituary.—H. S. SCRUGGS, JR. of Memphis, Tenn., April 17. CHARLES M. COVERNTON of Toronto, Canada, April 14, aged 88. THOMAS PHILLIPS GRAHAM of Pittsburg, April 14, aged 61. HENRY AUGUSTUS ROWLAND, renowned physicist of Johns Hopkins University, April 16, aged 53. ALERIO HERMANSE of Brooklyn, April 16, aged 66. JOHN WANLESS of Toronto, April 14, aged 88. B. F. HILL of Bardstown, Ky., April 16, aged 45. JOHN P. ROBB of Fredericksburg, Va., April 17, aged 80. J. G. MCCRARY of Macon, Ga., April 15, aged 81. WILSON A. SMITH of Middlebourne, W. Va., March 23. CHARLES H. DANA at Bartow, Fla., March 25. LOUIS T. DAWSON of Club Run, Ky., March 29, aged 36. W. B. HARLAN of Danville, Ky., April 6, aged 72. ALBERT E. KELLEY at Newark, N. J., April 2. COLON C. WATSON of Crystal Lake, Ill., March 20, aged 45. MERRITT H. CHANDLER of Woodstock, Vt., April 6, aged 56. THOMAS HEPBURN BUCKLER of Baltimore, April 20, aged 90. LEWIS R. KIRK of Rising Sun, Md., April 19, aged 69. GEORGE W. COX of Germantown, Pa., April 19, aged 60. EDWARD M. SCHIAEFFER of Baltimore, April 21. WALTER W. MEDILL of Denver, March 14. ASHLEY N. DENTON of Austin, Texas, March 4. SHERMAN A. YULE in Philippine Islands, March 4, aged 33. GEORGE COGSWELL in Haverhill, Mass., April 21, aged 93.

Smallpox.—In New York City 9 new cases were reported April 10 from scattered localities, and in Albany it has broken out in the Lathrop Memorial Home.—It is reported in a malignant form from Union Hill, N. Y., and in Jersey City and Paterson, N. J.—In Steelton, Pa., 40 cases are reported in the borough, and to prevent its spread an order has been issued to stop all public meetings in Steelton, Enhaut, New Benton, and Oberlin, Pa. New cases are reported in Pittsburg and Sharon, Pa. At Bradford, Pa., a mob burned a schoolhouse that had been fitted up for a pesthouse, and at McKeesport the authorities find any plan to establish a pesthouse frustrated by the adjacent property owners.—From Laurel, Del., it is reported that nearly all the schools in the western part of the State are closed on account of smallpox. In Sussex county of that State the State Board of Health reports the enjoined regulations are being faithfully carried out and the people are using their utmost endeavors to stamp out the disease by quarantining, disinfection and vaccination.—At Guthrie and Springfield, Tenn., the smallpox situation is considered serious, but at the State lines it is improved; 31 patients reported discharged from quarantine and 25 still under medical care.—In Hartselle, Ala., it is reported prevalent, and as existing extensively in a mild form about Batesville and Subline, Texas.—At Springfield, Ill., 5 fully developed cases were found April 13 at the Salvation Army hotel. At Metropolis, Ill., an outbreak is feared on account of the infection of some of the clothing sold at a church rummage sale which has already resulted in 1 case.—Official information received by the United States Marine Hospital Service states that at Merida, Mexico, smallpox has an

endemic form, over 500 deaths having occurred since last April. There are now about 600 cases of the disease in the place (Merida) and the deaths average about 8 per day. Cases have occurred in almost every house. Progreso is situated about 42 miles from Merida and is a little place with a half dozen warehouses and with a population of about 500. Twenty-five cases have occurred in Progreso, with a few deaths. Private advices report its presence in Panama. Smallpox is officially reported from Kentville, 70 miles from Halifax, Nova Scotia and compulsory vaccination has been instituted there. In Philadelphia 8 cases have been reported in the Twenty-fourth ward April 22, and it is also increasing in Chicago. It has been discovered in the Western Reserve Academy in Hudson, Ohio. At Anna, Illinois, there has been a crusade against the cats of the town, the physicians having discovered that these animals were suffering from the disease and spreading it. The schools and churches are closed on account of its prevalence. On board the transport Lawton which left Manila, March 16, a case of smallpox occurred and the patient was left at the U. S. Hospital at Nagasaki. Two other cases occurred later and the patients were landed at Honolulu.

EASTERN STATES.

New Hospital for Boston.—Provisions to this end are made in the will of George L. Thorndike, of East Boston, who has directed that after the death of the last legatee under the will, and when the estate exceeds \$200,000 it shall be used to found a hospital. He has also bequeathed to the city \$10,000 in trust, the income of which is to be expended in the distribution of coal among the indigent widows of East Boston.

Hospitals for Tuberculosis.—Connecticut will probably have a hospital for tuberculosis capable of caring for 200 patients in the incipient stages of the disease if the bill now pending passes the Legislature. The bill carries with it \$150,000 for building and equipment. As a result of the action taken by the Trenton Board of Health against the spread of tuberculosis, Senator Hutchinson will introduce a bill into the New Jersey Legislature asking for an appropriation of \$50,000 for the establishment of a hospital for cases of tuberculosis. Bills have been introduced in the Michigan Legislature providing for the establishment of a hospital for sufferers from tuberculosis. Chicago will have a hospital for tuberculous patients under the management of the Sisters of St. Elizabeth Hospital. The fund now aggregates \$20,067.

American Climatological Association.—The eighteenth annual meeting will be held at the Cataract House, Niagara Falls, on May 30, 31, and June 1, 1901. The following papers will be read and discussed: President's Address, Dr. R. H. Babcock; Puerto Rico: Its Climate and its Diseases, Charles H. Alden; Nantucket and the Ocean Climate, Harold Williams; paper by R. G. Curtin; The Association of Tuberculosis and Syphilis, F. I. Knight; A Case of Mechanical Obstruction of a Bronchus Simulating Rapid Phthisis, J. B. Walker; The Selection of Favorable Cases of Pulmonary Tuberculosis for Sanatorium Treatment, E. R. Baldwin; The Carrying Out of the Hygienic Treatment of Pulmonary Tuberculosis Outside of Sanatoriums, Charles L. Minor; Devitalized-air Toxemia a Prime Cause of Tuberculosis, Charles Denison; Cases on which Tuberculin Test Seemed Justified and Decisive, W. E. Casselberry; The Home Treatment of Tuberculosis, Irwin H. Hance; Discussion on the Home Treatment of Tuberculosis vs. The Climatic Treatment, opened by A. C. Klebs; The Relation of Sunshine to the Prevalence of Influenza, Howard S. Anders; A Case of Pulmonary Osteoarthropathy, R. C. Newton; Physiologic Influence of Climate on Nervous Diseases, F. Savary Pearce; The Use of Strychnia in Diseases of the Heart, Abraham Jacobi; The Etiology, Pathology and Clinical Aspects of the Bovine Heart, Leonard Weber; The Hygienic Treatment of Heart Disease, Boardman Reed. Titles to receive a place on the final program must reach the secretary not later than May 1. They should be accompanied by abstracts to facilitate discussion. A favorable arrangement by which the papers read at the last meeting have been printed in the *Journal of Bacteriology and Climatology* (British) has delayed the appearance of the *Transactions*, but in other respects has been of advantage to the association.

NEW YORK.

Diphtheria.—The Public School in Highbridge has been closed on account of an epidemic of diphtheria which prevails in that region.

Asked to Resign.—Dr. Van Gieson, director of the Pathological Institute of New York State Hospitals, has been notified that the State Lunacy Commission will dispense with his services after the first of May. The 7 members on the staff of the Institute threaten to resign if Dr. Van Gieson is forced out.

Tenement Legislation.—Four laws passed at the present session of the New York Legislature regulating the building of tenements have been signed by Governor Odell and are now operative. They provided for the abolition of dark interior rooms, for proper sanitary appliances for every family, protection against fire and efficient enforcement of existing tenement house laws.

Common-law Marriage.—The bill to prohibit common-law marriages has been signed by Governor Odell. It provides that after January 1, 1902, there shall be no common-law marriage recognized in the State of New York except the parties thereto shall have signed a contract in the presence of witnesses and filed it with the clerk of the town, village or city in which the contract was made.

Nonunionists.—The Unchristian Unscientists of New York are gravely contending that in obedience to prayer the lettering on the cornerstone of their temple was changed according to the Mother's orders. The *New York Times* says that this should be brought to the attention of the Stonecutters' Union every one of whose rules was violated by the employment of non-unionists to do the work of alteration.

Scarlet Fever.—The town of Norwich, N. Y., has an epidemic of scarlet fever, and 65 houses are quarantined. About 60 of these families purchased milk of a milkman in whose family there had been a mild case. A young lad assisted in milking during the time his hands were desquamating. The disease is running a mild course and no fatalities have been reported.—A number of cases of scarlet fever have appeared in the Borough of the Bronx and some deaths are reported.

The State Prison at Sing Sing has been condemned as unfit for use because of its very unsanitary condition and a concurrent resolution has been introduced by Assemblyman Morgan Bryan, as chairman of the Prison Committee of the Assembly, providing for a commission to consider the necessary steps for the transfer of the prisoners confined there and to examine and report upon a suitable site for the reconstruction of the prison buildings and to report to the Legislature not later than January 20, 1902.

PHILADELPHIA, PENNSYLVANIA, ETC.

The Pennsylvania Board of Pharmacy continues the prosecution of Pennsylvania druggists. Last month 26 indictments were returned by the grand jury against 19 druggists in Pittsburg on the charge of adulteration.

An **Obstetrical Amphitheater** will be added before the close of the present year to the University Hospital. The new building will be known as the Scott Amphitheater, in memory of Mrs. Thomas A. Scott, the mother of Mrs. C. B. Newbold, who has donated \$25,000 for its erection. It will be built adjoining the west wing of the present Maternity Pavilion, with the entrance on Hamilton walk. The building will be of brick, 50 feet square, and will accommodate 150 students. A complete sterilizing plant for instruments and bandages will be an important feature. A system of piping will also be introduced, to be used for flooding the operating department after each operation.

Pay Hospital for Contagious Diseases.—The committee appointed by the Philadelphia County Medical Society to investigate ways and means for such an establishment reported April 10 to the effect that in response to circulars sent out replies were received from 561 physicians endorsing the measure. Of this number 63 were homeopaths. The object is first to get the medical profession interested, and then appeal to the public for money. The municipality can be expected to assist, as it is a supplement to the Municipal Hospital. The plan provides for only 2 pavilions, 1 for scarlet fever and 1 for diphtheria; another is deemed advisable for other contagious diseases. A tract of 5 acres in the northwest section of the city has been purchased as a site.

Philadelphia Polyclinic.—The Board of Trustees has accepted the resignation of Dr. Samuel D. Risley, and has elected him emeritus professor. Dr. William Campbell Posey has been elected professor of diseases of the eye, to succeed Dr. Risley. Dr. Ralph W. Seiss has resigned his chair of diseases of the ear, and the board has elected Dr. Francis R. Packard to succeed him. The resignation of Dr. Packard as Dean has been accepted, and Dr. B. M. Randolph, of Richmond, Va., has been elected Dean and also director of the laboratories, succeeding the late Dr. Thomas S. Kirkbride, Jr., who died in July last. Dr. Randolph at present holds the post of adjunct professor of pathology in the Richmond Medical College. He will spend this summer in Germany and Austria doing advanced pathologic work, and will assume his new duties at the Polyclinic about September 1.

The Pennsylvania Society for the Prevention of Tuberculosis held its annual meeting in Philadelphia. It was reported that its influence aided in securing the new rule of the Bureau of Health by which cases of tuberculosis are to be registered in Philadelphia. It has published a leaflet on the subject of Registration. Its publications have been sent all over the United States in response to many requests. Its officers have endorsed and assisted the Free Hospital for Poor Consumptives of Philadelphia and have gone to the New Jersey Legislature to assist in pleading for a State Hospital for consumptives in that State. The society has made strong efforts to show the need of a State hospital for tuberculosis.

SOUTHERN STATES.

Resident Physicians Elected.—Dr. Thomas H. Magness of Baltimore and Dr. Joseph T. Devine, of New York, have been elected resident physician and assistant resident physician, respectively, of the Baltimore University Hospital.

Medical Training and Christian Science.—Judge Lumpkin of the Georgia Legislature handed down a decision to the effect that Christian Scientists cannot practise in that State without having graduated in medicine or passed the Medical Examining Board.

Heart-suture.—H. L. Nietert, superintendent of the St. Louis City Hospital, sutured a stab-wound $\frac{3}{4}$ of an inch long in the heart of a young man brought to him in a semi-conscious condition. It was necessary to resort to artificial respiration several times during the operation. He died 25 hours later. A paper by Dr. Nietert on this subject will appear in a future number of *AMERICAN MEDICINE*.

Hygiene and Sanitation of the Public Schools.—The fact that the School Board of New Orleans contends that the Board of Health has no power in connection with the hygiene and sanitation of the schools except to fumigate them at their request, has excited considerable comment. It would seem that if the Board of Health has power to enter and inspect private properties, the schoolhouses would certainly be under their jurisdiction in all matters pertaining to sanitation and hygiene.

The North Carolina State Board of Medical Examiners' regular annual session will be held in Durham, N. C., beginning May 16, 1901. Applicants desiring examination will carry with them a diploma from a college of medicine requiring not less than 3 years' attendance, evidences of clinical instruction, and certificates of character. The license fee is \$10. The president of the board is Dr. E. C. Register, Charlotte, N. C.; secretary-treasurer Dr. J. Howell Way, Waynesville, N. C.

Georgia Pasteur Institute.—The Board of Governors of the Georgia Pasteur Institute and Laboratory met in Atlanta April 12, 1901, and received the first semiannual reports of the physician, James N. Brawner, and the pathologist, Claude C. Smith, in charge. Since December 1, 1900, 11 cases have been treated and dismissed as cured. Of these, 8 were bitten by rabid dogs, as proved by inoculation of rabbits. A number of applicants were not treated as there was no evidence that the animal inflicting the wound was rabid.

WESTERN STATES.

Ann Arbor Medical Department is so overcrowded that to relieve this condition a building is to be erected near the present one during the coming summer which will accommodate the bacteriologic and histologic laboratories. It is to cost \$100,000.

Tuberculosis.—The State Health Commission of Colorado has promulgated the rule that when tuberculosis is known to be in a family, a certificate declaring no danger of contagion must be presented by any child applying for admission to the public schools of the State. All teachers or children afflicted with that disease are excluded.

Pure Food Bill.—Because he has been charged with scratching out the words "or bitartrate of potassium" from an Indiana "pure-food bill," prohibiting the use of formaldehyd, arsenic and bitartrate of potassium, in food or food products, the Secretary of the Senate has been arrested and must stand trial. Had the bill gone through without mutilation it would have barred the sale in Indiana of any food or food product containing cream of tartar.

Amendment to Medical Bill Killed.—On April 12, the amendment to the medical bill which provided a special examining board for osteopaths was killed by the Wisconsin Legislature. It is stated that both sides have made concessions which will result in a substitute bill allowing the osteopaths to practice in certain cases and giving the osteopaths one member on the regular examining board. The bill prohibiting marriages between whites and blacks was also quashed.

Christian Science.—Judge Eugene S. Elliott rendered recently a decision in the Wisconsin Circuit Court that Christian Scientists are not liable to prosecution under the State medical law and that they can no more be held for practising medicine when their means for healing is by prayer than a minister who prays at the sickbed and receives therefor a fee. The case was that of the State against Crecentia Arris and Emma Nichols, Christian Scientists who treated a child named Gosenbach, afflicted with diphtheria, and who died from the disease.

National Sanatorium for Consumptives.—The establishment of a National Sanatorium in Colorado for the treatment of consumptives has been officially announced. Physicians of Denver, and other professional men and women are its founders. It will be conducted as an industrial colony—the labor of the patients being utilized in the carrying on of remunerative industries, as well as in doing the work of the institution. In

this way patients in moderate circumstances can avail themselves of a change of climate during the incipient stage of the disease.

Typhoid fever has been prevalent in Milwaukee for 2 years, and its presence is now being traced to the ice supply. In fact, the Health Commissioner has been conducting a microscopic examination of all the ice delivered to consumers. Ice is harvested from the river above the dam, where a large amount of sewage gets into it, and, as freezing does not destroy bacteria, contagion is probably frequently caused in this way. The city has been under great expense to insure a pure water supply, and it is certainly against all ideas of good government to permit ice-dealers to deliver disease-laden ice to customers; consequently, the people are asking for a law prohibiting the cutting of ice on the impure water, except solely for the use of brewers and shippers for cooling purposes alone.

Mortality of Michigan during March, 1901.—The total number of deaths reported to the Secretary of State for the month of March was 3,488, corresponding to a death-rate of 17.2 per thousand population. This is an increase of 343 over the number for the preceding month, and of 355 over the number returned for March, 1900. There were 673 deaths of infants under 1 year of age, 203 of children aged 1 to 4 years, and 1,024 deaths of persons aged 65 years and over. Important causes of deaths were as follows: Pulmonary tuberculosis, 217; other forms of tuberculosis, 34; typhoid fever, 45; diphtheria and croup, 35; scarlet fever, 44; measles, 7; whooping-cough, 20; pneumonia, 489; influenza, 320; cancer, 112; accidents and violence, 126. There were 3 deaths from smallpox during the month.

Municipal Cleanliness.—The Superintendent of Streets in Chicago has been putting into execution the new ordinance enforcing municipal cleanliness, which requires immediate removal of all street cleanings and provides for the separation of garbage from ashes and other waste, the householder being directed to put ashes in one receptacle and the garbage and waste in another. The ordinance was drawn with the idea of using the ashes for filling and grading, and burning the garbage and other waste. It is purposed to increase the incinerating capacity of one crematory now in operation for over a year, from 25 tons to 100 tons a day and to utilize the heat for light, warmth and power for the institution; another of 25 tons capacity the heat of which is to be utilized is nearly completed in connection with one of the city's electric light stations.

Responsibility for Crime.—In a case tried in California, in which a crime was committed by a person subject to alcoholism, the judge made a ruling that a person of more than ordinary intelligence, with no delusions, good memory, who appreciates the exact nature of a criminal charge and his relations to the proceedings, who is sane as the average person, although his brain may be affected by excessive use of intoxicants so as to change his character that he loses ambition, becomes trifling and aimless, and degenerate so that if at liberty he invariably takes to drinking, and while intoxicated becomes dangerous, he is not insane within the meaning of the statutes which provide for the suspension of proceedings against insane criminals, and if he has been committed to an insane hospital pending the prosecution, he may be returned to the sheriff for trial.

Professional Defense.—A bill prepared by the Legislative Committee of the Medical Association of Missouri asking that no medical college and no diploma not properly registered in the State at the time of the law going into effect be recognized, has become operative. Hereafter all who wish to practise medicine in any branch must pass an examination before the State Board of Health, and if accepted will receive a license to practise. The board has the right to refuse a license to anyone guilty of dishonorable or unprofessional conduct and may revoke a license for like cause after giving the accused opportunity to make a defense. The bill does not prevent Christian Scientists from practising, but does prohibit their charging for services; thus while the public does not receive perfect protection, the measure is an improvement on the former law as it gives the board of health power to proceed against quacks and unlicensed practitioners.

Women in Medicine.—Dr. Victor C. Vaughan, of Ann Arbor, denies having made the statement attributed to him that he had found women superior to men as textbook students in medicine, but that in original work requiring personal judgment they fail in efficiency. He says that during 25 years' connection with the University of Michigan, a coeducational institution, he has found that the women students average quite as high as the male students, and the percent of success among the women graduates has been quite as high as among the male graduates. In delivering a lecture on Mental Hygiene he stated that in his laboratory work he had frequently observed that the women students were less self-reliant, and more frequently applied for advice than the male students; but he went on to state that this was not altogether a fault, and that it would be far better if the male students should more frequently call for advice. A person who heard this statement rushed a story into print that Dr. Vaughan condemned women in medicine.

Rats.—The Board of Health of Denver, Col., taking its cue from health organizations in the Orient, some months ago issued a bulletin declaring rats responsible for much of the contagious disease that existed in that State, and urged the communities that had rats to exterminate them. The Health Board has concluded that drastic measures will have to be adopted to this end, and several plans are under consideration. It is announced that a war of extermination is to be waged against rats and mice by one of the largest manufacturing firms in Chicago, by means of a virus made under the direction of the Pasteur Vaccine Company, and which is harmless to other species of animal life. This virus has been tested officially in France and in this country in the United States Marine Hospital in San Francisco, where the results of the test were indorsed by Dr. Kinyoun, Chief of the Marine-Hospital Service at Washington. The virus is mixed with food, and disposed in the haunts of rats. It produces a fatal disease which spreads rapidly and retains its virulence for some time.

Indiana Mortality and Morbidity in March.—The report of the State Board of Health shows: Total number of deaths 3,272, rate 15.3, corresponding month of 1900—deaths 3,217, rate 15.0. Deaths from important ages: Under 1 year 566; 1 to 5 inclusive 230; 65 years and over 847. Deaths from important causes and rates per annum per 100,000 were: Pulmonary tuberculosis 373, rate 174.9; typhoid fever 44, rate 20.6; diphtheria 29, rate 13.5; scarlet fever 24, rate 11.2; measles 43, rate 20.1; whooping-cough 26, rate 12.1; pneumonia 603, rate 282.7; diarrheal diseases 15, rate 9.0; cerebrospinal meningitis 39, rate 18.2; influenza 174, rate 81.5; cancer 81, rate 37.9; violence 114, rate 53.4. Deaths from smallpox 5. Urban deaths 1,164, rate 16.2, rural deaths 2,108, rate 14.9. Morbidity: There were 472 cases of smallpox reported from the following counties: Marion 22, Steuben 1, Pike 4, Fulton 12, Tipton 6, Fanderburgh 1, Lake 12, Posey 6, Lawrence 101, Vermillion 16, Dekalb 5, Howard 8, Perry 1, Dearborn 4, Wabash 4, Ohio 46, Switzerland 220, Wayne 1, Mobile 2. The smallpox cases are generally mild, but not a few are more or less severe. In all new localities invaded, the uninformed physicians fail to recognize the disease, but what is worse, usually cling to their erroneous diagnosis and so make it hard to apply preventive measures. The diseases which decreased in area of prevalence during March were: bronchitis, influenza, pneumonia, tonsillitis, diphtheria, typhoid fever, inflammation of bowels. Those increasing in area of prevalence were: Rheumatism, measles, intermittent fever, diarrheal troubles, whooping-cough.

CANADA.

The Victoria Cross has just been conferred upon Dr. H. E. M. Douglass, a Canadian, for bravery on the battlefield of Magerfontein, South Africa. He was surgeon to the Gordon Highlanders and although wounded himself crawled to the head of the column where the officers of his regiment were lying dead or wounded. He dressed the wounds of those within reach, made his way back in safety, and being then the senior officer rallied the ranks of the scattered Gordons and led them out to action.

Vaccination.—The City Council and School Board of Halifax, N. S., both passed resolutions recently in disapprobation of the action taken by the Board of Health in ordering a general vaccination in the city as there is no smallpox within 75 miles. The physicians appointed by the Board to vaccinate the poor refuse to accept the fee of 25 cents per case allotted them and are holding out for 50 cents.—The Board of Education of Kingston, Ont., has refused to rescind the resolution making the vaccination of school children compulsory. Until medical certificates are produced 200 children will be debarred from school.

Medical Matriculation in McGill University will have an increased standard to come into effect September, 1902, when a practical knowledge of chemistry and a sound theoretical acquaintance with physics, statics and dynamics will be required of all candidates. The only elective studies after that date will be Greek, German and French, one of which must be taken. Later on the standard will be raised to the degree of requiring that all candidates before matriculating in medicine shall show that they have taken the first year arts course. Recently McGill lengthened its session from 6 to 9 months and established a combined arts and medical course.

Chinese in Canada.—A royal commission appointed by the British Columbia Legislature to investigate the question of Chinese labor as affecting Canadian labor, has been sitting in Victoria, B. C., and summoned the health officer of that place recently to report upon the sanitary conditions of the Chinese quarters. He stated that owing to the erection of new buildings their quarters had been much improved but he considered that they were constantly a slight menace to the public health on account of fresh arrivals from Chinese ports which are always infested with smallpox. Personally, they were eager to be vaccinated. They took every pains to conceal leprosy; he had attended 5 cases of leprosy among them. The Chinese hospital was under the supervision of the medical health officer who made regular visits. The wealthy class called in white physicians when ill.

FOREIGN NEWS AND NOTES

GENERAL.

Opium Smoking.—A law enforcing the penalty of death for opium smoking, it is reported, has been promulgated by the Korean Government.

Famine and Death in India.—The depopulation of India through famine and cholera is assuming alarming proportions. It is estimated that 5,000,000 have died since 1896 from causes directly due to famine. The latest census returns from the central provinces show a decrease of 1,000,000 since 1891, when an increase of 1,500,000 might have been expected. The parts of Western India that have been visited by plague show an even larger percentage of deaths. On the other hand the localities which escaped the plague show a very satisfactory increase.

Women Resident Physicians.—The Royal Free Hospital of London has engaged several women doctors as resident house surgeons and physicians. This is a new experiment, there being no hospital in the kingdom, except those exclusively attended by female doctors, where the resident physicians are women. The young women probably take these positions with a view to gaining experience; it remains to be seen whether the nursing staff, who have been accustomed to act on the orders of a man, will treat them with the proper respect.

Obituary.—MAX RING of Berlin, March 28, aged 84.—V. MARCHERANO in Palermo.—THEODOR WYNEN of Marburg Hygienic Institute.—H. GOSSE, Professor of Forensic Medicine in University of Geneva.—HENRY ERNEST HILL SMITH of London, at Cairo, Egypt, February 22, aged 40.—CHRISTOPHER MERCER DURRANT of Suffolk, April 6, aged 86.—JAMES HOOPER of Bath, England, March 27, aged 95.—ANDREW FLEMING of Edinburgh, March 25.—JAMES POWELL WILLIS at Cork, Ireland, March 27, aged 29.—JOHN SYKES of Doncaster, England, April 1, aged 84.—C. K. D. TANNER at Reading, England, April 21, aged 51.

Leprosy.—The United States Consul, Solomon Berliner, reports officially that on the island of Teneriffe there exist 3 distinct classes of leprosy, *lepra arabum*, *lepra elephantiasis*, *lepra tuberculosis*, and that it is somewhat endemic on account of the people eating a good deal of fish (often putrid) and of their general uncleanliness. Formerly Spain established a colony at Grand Canary for lepers where they were housed but had perfect liberty to wander about with the restriction that they must sleep at the houses built for them. This law became a dead letter in time and gradually they spread over the different islands. Officially it is not recognized that leprosy exists on these islands and it is classed as a scrofulous or skin disease. The provincial government at Teneriffe has taken up the subject and a large building 2 miles out of town from the capital has been provided to segregate them there in 1 wing—the other wing to accommodate the insane. In the island of Grand Canary leprosy is decreasing decidedly, is not in a virulent form and is not believed by the natives to be contagious. In Las Palmas, however, in the lepers' hospital, there are about 59 patients who are not allowed to go beyond the large courtyards and are not allowed to marry. In the whole island there are perhaps about 100 cases of what is there called elephantiasis.

House Rats as Means of Spreading Plague.—The report of the director of the Imperial Institute for Infectious Diseases in Japan, on the epidemic of plague in Kobe and Osaka from November, 1899, to January, 1900, is very interesting as demonstrating the amount of work that has been done to determine the relationship between house rats and the spread of the infection. The municipal authorities at Kobe and Osaka paid 5 sen (about 2½ cents) for rats whether dead or alive, and many other cities not infected followed the same example. A peculiar superstition prevails in Osaka that the house rat is the guardian angel of the empire. During the period of the epidemic 20,000 rats were paid for in Kobe, and 15,000 in Osaka. In Kobe 291 dead rats were found, of which 61 contained *Bacillus pestis*. In Osaka 200 dead rats were found of which 23 were infected with *Bacillus pestis*. There is no doubt that many more were found and disposed of. Fear of the disinfection that followed the finding of a dead rat induced the people to hide them from the authorities. Bacilli very similar to *Bacillus pestis* were often found in the dead rats, and these could readily be mistaken for the true cause of plague, so that cultural and experimental methods in addition to the microscope were used in order to make a diagnosis. The relation of the individual cases to the rats is not fully evident; however, it is proved that the rats take the disease first and afterwards man. This can easily be accounted for in the greater opportunity afforded the rats for contact with infected material.

Malaria in German East Africa.—The Surgeon-General of the United States Hospital Service has received from Joseph B. Greene a report on the result of Koch's study of malaria, carried on in Italy, German East Africa and the East India Islands, from the summer of 1898 until near the end of 1900. Koch confirmed the conclusions of Manson and Ross as regards the propagation of malaria by mosquitos, but Koch holds that not only the genus *Anopheles* is concerned in its transmission

but that *Culex* is also culpable. Every attempt to find plasmodium of malaria in any species of the lower animals was without success so that it is not deemed probable that the parasite can complete its life history in any other organism than the human body. Efforts were unavailing to inoculate other animals such as the monkey and bat with malarial blood from the human subject. Dr. Koch observed in Italy that during the winter months the number of cases of malaria dropped to a minimum and only manifested itself again with the warm spring days. He holds that these early spring cases are relapsing cases either untreated or imperfectly treated and that the malarial parasite exists in a latent form in the human body during the apparent disappearance of the malaria. He considers the free use of quinin the best and most practical method of ridding a community of malaria and that it is of the utmost importance to continue its administration long enough to eradicate the organism from the human body and thus avoid recurrence in the spring. That the free use of quinin alone is capable of ridding a community of malaria is shown by the following statistics from Spandau, a small town in the vicinity of Berlin: Population, 1874, 3,853; 1885, 4,800, and 1891, 5,883. Cases of malaria, 1874, 2,557; 1885, 111, and 1891, 1. The German army is also quoted to show the influence of quinin in eradicating malaria: Cases of malaria, 1869, 13,563 (54.5%); 1896, 230 (0.45%), which is more than 99% decrease in the number of cases. The cheapening of quinin which is now within the reach of the poor, has contributed largely to the eradication of malaria. Although useful, he does not consider mosquito nets so specific as some claim, as on account of heat in the tropics, one cannot always be under the protection of netting. The use of petroleum is in many cases impracticable on account of large marshy areas devoted to the cultivation of rice, and of the number of small cavities capable of receiving the larvae of *Anopheles*, as palm cones, tree trunks, etc. It is stated that the practical disappearance of malaria is not due to better drainage, as *Anopheles* is found in considerable numbers. Dr. Koch found that malaria, existing as an endemic, is distinctly a disease of childhood and among infants under 2 years of age. Dr. Koch found the malarial parasite in the blood of 80% of the cases. Between 2 and 5 years of age it was much less frequently found and later in life it was exceptional to find it at all. He holds that a long attack of malaria confers a certain immunity. As a means of eradicating malaria from the German colonies he recommends sending out young physicians who are trained microscopists and the free distribution of quinin to the natives. In Dutch India more than 2,000 kilograms of quinin are distributed gratis to the natives annually, and to this he attributes their success in diminishing the cases of malaria.

GREAT BRITAIN.

School Hygiene.—In an address before a teachers' conference at the Durham College of Sciences, on the Medical Aspects of Education, Professor Oliver referred to several important considerations—as ventilation, heating, and the physical examination of teachers and pupils. His report of the bacteriologic examination of slates, pencils, and pens used in schools, showing the adherence to them of pyogenic microorganisms, is interesting.

Prevention of Tuberculosis.—At the recent annual meeting of the National Association for the Prevention of Tuberculosis, held in London, there was allusion to the great progress which had been made in Liverpool in relation to the prevention of tuberculosis by the adoption of voluntary notification of it and by the establishment of depots for the supply of sterilized milk. Two sanatoriums for open-air treatment were in course of erection, and one it was hoped would be ready for patients in July. Attention was drawn to the satisfactory result of an experiment made by 3 Liverpool boards of guardians, which had adopted the plan of making it a condition of granting outdoor relief that the family should remove to more wholesome quarters, and they had adopted simple but effectual precautions against infection. They granted relief at a special scale to meet the expense of removal and for better nourishment for the patient.

John W. Garrett International Fellowship of University College, Liverpool, has the following Provisional Regulations: (1) This Fellowship has been founded by William Johnston, Shipowner, of Liverpool, to commemorate the late John W. Garrett, of Baltimore, U. S., and shall be called the John W. Garrett International Fellowship in Pathology and Physiology. (2) This Fellowship shall be open to members of Universities and Medical Schools in the United States, without, however, absolutely precluding members of other foreign schools. (3) The Fellow shall be elected by the Faculty, on the nomination of the Professors of Pathology and Physiology. (4) The Fellow shall be elected for one year, and shall be eligible for reelection. (5) The Fellow shall devote himself to Research in Physiology or Pathology and Bacteriology under the direction of the Professors of Physiology and Pathology. He shall undertake no work which shall in any way interfere with these duties. (6) The work shall be done in the Thompson-Yates Laboratories of University College, but by special permission from the Faculty the Fellow may be allowed to follow his investigations elsewhere. (7) The expenses of any research shall be met out of the funds of the Laboratory, under the direction of the Professors of Physiology and Pathology.

CORRESPONDENCE

HEMORRHAGE IN CHRONIC JAUNDICE.

BY
WILLIAM OSLER, M.D.,
of Baltimore, Md.

In connection with Dr. Deaver's paper on the *Mortality of Operation for Obstructive Jaundice*, I do not see that surgeons can either foresee or avoid an occasional fatality from hemorrhage, and exception may be taken to so strong a statement that "neither consecutive nor secondary hemorrhage should occur, and particularly consecutive hemorrhage." The experience of the past few months in my wards may be of interest, as illustrating how common and how serious is this tendency to bleeding in chronic jaundice:

(1) Mrs. K., admitted January 9, 1901; jaundice of 4 months' duration; recurring attacks of pain; coagulation time, 10 minutes. The condition was very serious, and the pain was so severe that an exploratory operation was performed on January 29. Carcinoma of the gallbladder and of the liver was found. She bled profusely during the night following the operation, and continued to bleed until death, February 1.

(2) Mrs. F., admitted January 30, 1901; jaundice of 4 months' duration, with recurring intermittent fever, associated with stones in the common duct; blood coagulation-time on admission, 8 minutes, gradually reduced by the use of the calcium chlorid to 3½ minutes. Operation, March 5; numerous gallstones in gallbladder and in common duct. Hemorrhage the day after operation, with the formation of hematoma, and March 9, very severe bleeding, with collapse; gradual recovery.

(3) Mrs. C., admitted February 19, with a remarkable jaundice of nearly 10 years' duration; she had recurring attacks of hemorrhage, in 2 of which she nearly died. These had been chiefly from the nose and from the uterus. She was admitted pulseless, and blanched in the third attack. The hemoglobin was 20%, red blood-corpuses 1,600,000. Both she and Mrs. F., the previous patient, had multiple xanthoma. Coagulation-time on admission, 14 minutes; a month later, 4½ minutes, and her blood-corpuses had risen to 4,000,000 per em. On March 22 she had a little nosebleed and a few spots of hemorrhage in the skin. Considering the remarkable tendency to hemorrhage, even when her coagulation-time was at 4 minutes; that her general condition was good, and that she seemed to have got accustomed in an extraordinary way to the persistent jaundice, I did not advise operation.

(4) Mrs. N., admitted February 19, 1901; a stout, healthy-looking woman, with pain, nausea and vomiting, and jaundice of 4 weeks' duration. She had a good deal of vomiting while in the ward, and the blood coagulation-time was 3½ minutes. The nature of the case was doubtful, and she was transferred to the surgical side. The day before the operation she became collapsed, had hematemesis and died. The autopsy showed gallstones, cancer of the neck of the gallbladder, extensive hemorrhage into the lesser peritoneum and about the tail of the pancreas, and hemorrhage into the stomach.

(5) The fifth case was admitted a few days ago. He had been under my care a year before with jaundice of 4 years' duration, and was operated upon on the surgical side by Dr. Finney, I think. On attempting to separate the adhesions about the ducts he bled so profusely that the operation had to be abandoned.

Surgeons must take into consideration the liability to bleeding in chronic jaundice. The calcium chlorid, used as Prof. Wright suggests, in doses of 20 grains 3 times a day, usually increases the blood coagulation-time; for the same purpose the subcutaneous injections of gelatin may be used. But we have had cases in which bleeding has occurred even when the blood coagulation-time was normal. It is to be remembered that hemorrhage from the stomach in these cases cannot always be attributed to the state of the blood, since surgeons have taught us of late that this is by no means an infrequent feature after operation upon the abdominal organs.

The practical points to be emphasized are the importance of study of the blood coagulation-time and the use of calcium chlorid, should it be retarded.

TAIWAN BOZU: EPIDEMIC SYPHILITIC ALOPECIA.

BY
ALBERT S. ASHMEAD, M.D.,
of New York City.

A recent associate press dispatch states that "the dancing girls of Japan are losing their hair from a new disease which is

causing consternation among all the pretty women. The new disease is epidemic in some parts of Japan, and is frightening the people more than the plague. In some villages the hair of all the women in the place has fallen out. The people call the hair plague 'Taiwan Bozu.' The disease has robbed several dancing girls of their beauty. It is said to have been imported from Formosa, and the health authorities have gangs of men at work disinfecting the poor quarters of the towns. The hair plague seems to be spreading over a large area."

Allow me to observe that Taiwan Bozu is not a new disease. The words mean *Formosan Priest*. All Buddhist priests in Japan have the head shaved, and thus one who is completely bald is said to look like a priest, in fact is called "priest." The disease, according to Dr. Kitasto, who writes of the epidemic, in a long letter published in the *Tiji-Shimpo*, February 24, 1901, is supposed to have been brought back by the troops from Formosa; hence the name given to the outbreak, of Taiwan, the Japanese name of the island. It appears suddenly, in one night even, a large field of the scalp will become bare. Some cases are due to disease of the nerves; some to direct infection. Dr. Kitasto says that "it is not the first time the disease has been epidemic in Japan. It does not come from Formosa, although the people think so. It is not very contagious. It is the same disease which occurs all over Europe, etc." Inasmuch as the syphilis of Formosa is fiercer than the syphilis of Japan, and the syphilis of Europe is fiercer than that of Formosa, so *Taiwan Bozu's* ravages differ in different countries. "Regulations by the police of Tokio are being instituted among the barbers to prevent its spread." The itinerant barbers of women, who go from house to house to dress and oil the ladies' hair, are the main carriers of the contagion. Dr. Sasakawa, Professor of Skin Diseases, University of Tokio, in a letter to the *Tiji-Shimpo*, February 25, says that "the disease is of nervous origin," and he says, "when improvement begins, new hair appears as down, of blonde color, which gradually becomes normally black." A peculiarity which he notes in the present epidemic is that old men of yesterday appear like young men today when their hair has returned.

The disease is simply epidemic *Tokuhatz-fizo* (bald disease); Alopecia areata of specific origin (syphilitic), and it is contagious.

I add that in 1867, when the licensing of prostitution went into effect in Japan, the professions for women of "Geisha" dancing, tea-house and archery-gallery keeping, became crowded with prostitutes (more or less syphilitic) to evade the payment of the government tax. Then the hospitals of Tokio had to do with a great number of cases of syphilitic alopecia in no way different from the present outbreak.

REMOVAL OF POWDER GRAINS BY HYDROGEN DIOXID.

BY
FREDERICK K. SMITH, M.D.,
of Warren, Ohio.

I note on page 16 of the first issue of AMERICAN MEDICINE a report of the use of hydrogen dioxid for removal of powder grains, by Dr. J. N. Rhoads. In the *Cleveland Medical Gazette* for January, 1897, Vol. XII, p. 184, you will find a report of the same procedure, presented by Dr. George W. Crile, of Cleveland, at the Cuyahoga County Medical Society, from which it appears that he had used it at that time for several years. I do not think that the method had been previously published, but it is one of those things that would be likely to originate from a number of independent sources. While various discoverers of the same truth or originators of the same method may be entitled to the same credit, we have agreed upon the rule of according to the earliest, usually decided by the date of publication, the principal honor. By this rule Dr. Crile is entitled to the honor in this case, unless further evidence displaces him.

AN ANALYSIS OF MY VAGINAL ABLATIONS IN 181 CASES OF PELVIC INFLAMMATION AND UTERINE FIBROID DEGENERATION.*

BY
W. R. PRYOR,
of New York City.

Professor of Gynecology, New York Polyclinic; Consulting Surgeon, City (Charity) Hospital; Visiting Surgeon, St. Elizabeth Hospital; Founding Member Internat. Gyneec. and Obstet. Society; Fellow American Gynecological Soc; Fellow New York Academy of Medicine; Fellow New York Obstetrical Society, etc., etc.

The vaginal radical operation in this country has had a singularly interesting career. Those who first brought it here seem to have abandoned it almost entirely, while a few have become more and more enthusiastic about it. My own experience with the application of the vaginal method of operating not only in those cases which require the radical procedure, but also in those in which conservatism may be applied, has been such as to convince me that the greater proportion of operations now performed through the abdomen could more easily and with better results be made through the vagina.

An analysis of all my cases of pelvic inflammation and fibroid shows that since 1895 I have been enabled to

cure by the vaginal operation 83% of all those who have applied to me and without mortality. These enviable results are not secured by picking my cases nor by applying the radical operation where conservatism might succeed. Many of these women have been so profoundly septic that intravenous infusion was necessary before I could operate. No one who has seen the illustrations I have published in my book and in the *American Journal of Obstetrics* will deny that no greater difficulties are met in pelvic surgery than have confronted me in my vaginal work. Yet some critics of this method of operating have been so carried away by their affection for the abdominal route and animosity against the new comer as to hint at unfairness on my part in making my report, and selection in my cases.

For the sake, not only of those who have followed me in this line of work but that the claims of this operation to the attention of the surgeon may be substantiated, I have tabulated my cases. I shall not give the names of my patients, but any gentleman who wishes to consult my records in the proper spirit is free to do so. In this first paper I give my results, reserving for a future publication a detailed analysis of the more important points.

* Read before the Medical Society of Tennessee, April 10, 1901.

Date.	Age.	Hospital.	From	Diagnosis.	Operation.	Result.
1. May 2, 1898	44	Private.	Dr. Strauss.	Genital sclerosis multiple adhesions, uterine hypertrophy, constant pain, menorrhagia metrorrhagia.	Vaginal ablation by hemisection.	Cured.
2. Mar., 1896	39	City Hospital.	D. P. P. C.	Left pyosalpinx. A previous vaginal salpingo-oophorectomy for pyosalpinx.	Vaginal ablation <i>en masse</i> . Vaginal ablation.	Cured.
3. Feb., 1901	18	Private.	Office.	Diffuse pelvic suppuration. Profound septicemia. Intravenous infusion.	Vaginal ablation by hemisection. Intravenous infusion.	Cured.
4. Dec. 13, 1897	26	Polyclinic.	Patient of Dr. Mallet. Post-abortion sepsis, 3 curettages, menorrhagia, metrorrhagia. Is bedridden.	Right pyosalpinx, left ovarian cyst. Many old adhesions.	Vaginal ablation by hemisection.	Cured.
5. Jan. 3, 1899	32	Polyclinic.	Repeated attacks of pelvic inflammation abscess discharged by rectum Dec. 23, 1898.	Diffuse pelvic suppuration, broad lig. abscesses, very large	Vaginal ablation by hemisection.	Cured.
6. Feb. 6, 1899	26	Polyclinic.	Postpartum infection. Patient of Dr. Gilday.	Left ovarian abscess, right pyosalpinx, left broad lig. abscess, acute nephritis.	Vaginal ablation by hemisection. May 1, found her at home with right thrombophlebitis and broad lig. abscess, opened abscess above Poupart a lig.	Improved (intravenous infusion.) Cured.
7. Mar. 20, 1899	32		Plastic operation, cervix and laparotomy, Sep., 1896, by Dr. Hanks.	Salpingitis, diffuse pelvic adhesions. Found silver suture in cervix.	Vaginal ablation by hemisection.	Cured.
8. Nov. 16, 1898	28	Polyclinic. Private.	A chronic invalid. Has the morphine habit, has been flowing for 6 weeks.	Left ectopic, right pyosalpinx, syphilitic.	Vaginal ablation by hemisection.	Cured. Subsequently contracted gonorrhoea with vulvo-vaginal abscess.
9. Oct. 10, 1898	31	Polyclinic. Private.	Patient of Dr. Potter, of Newton, N. J.	Salpingo oophoritis, suspected carcinoma of cervix, many adhesions, no cancer found by microscope.	Vaginal ablation <i>en masse</i> in 5 minutes.	Cured. Slight secondary oozing controlled by pressure.
10. Feb. 2, 1899	22	Polyclinic.	Post partum sepsis 6 months ago, pain, fever, flooding.	Right ectopic, left pyosalpinx.	Vaginal ablation by hemisection.	Cured.
11. Apr., 1895		City Hospital.	Laparotomy in French Hospital, Mar. 14, 1895.	Bilateral salpingitis suppurative, specific, infected ligatures.	Vaginal ablation <i>en masse</i> , the previous operation had left half of each tube (at least).	Cured.
12. Dec. 11, 1895	29	Polyclinic.	Dispensary.	Bilateral pyosalpinx, small fibroid, bladder wounded.	Dec. 24 hysterectomy <i>en masse</i> .	Bladder opening not sutured, closed spontaneously.
13. Nov. 1, 1895	47	Polyclinic.	Dispensary.	Pachysalpingitis, multiple adhesions.	Dec. 12 curettage.	Cured.
14. Nov. 16, 1895	25	Polyclinic.	Dispensary.	Multiple adhesions, edematous ovaritis, menstrual epilepsy.	Vaginal hysterectomy <i>en masse</i> .	Cured of pelvic pain, marked improvement in epilepsy.

Date.	Age.	Hospital.	From.	Diagnosis.	Operation.	Result.
15. Oct. 17, 1899	26	Polyclinic.	Dispensary.	Left purulent stump of tube with calcified ligature, right purulent stump of tube, general pelvic peritonitis, 3 previous laparotomies.	Vaginal ablation by hemisection.	Cured.
16. Oct. 2, 1899	25	Polyclinic.	Dispensary.	Septic uterus, fibroids and double pus sacs.	Vaginal ablation by hemisection, intravenous infusion.	Cured.
17. Jan. 3, 1898	26	Polyclinic.	Dispensary.	Right pachysalpingitis, left broad lig. cyst, left ovarian apoplexy, multiple adhesions.	Vaginal ablation by hemisection.	Cured.
18. Apr. 14, 1897	30	St. Elizabeth's.	Patient of Dr. Frank.	Chronic pelvic peritonitis and lymphangitis, very large uterus.	Vaginal ablation, morcellation of uterus, 10 pieces.	Cured.
19. May 24, 1896	21	Polyclinic.	Patient of Dr. Gilday. Operation by Paul Ségond, of Paris.	Double pyosalpinx, granular casts in urine, streptococci in discharge from vagina.	Vaginal ablation by hemisection, subcutaneous infusion repeated.	Cured.
20. June 13, 1896	27	Polyclinic.	Dispensary.	Double pyosalpinx, diffuse pelvic suppuration.	Vaginal ablation greatly adherent. Large woman, small vagina.	Cured.
21. July 12, 1900	24	Polyclinic.	Patient of Dr. Tingley.	Diffuse pelvic suppuration.	Vaginal ablation by hemisection.	Cured.
22. Mar. 7, 1901	26	Polyclinic.	Dispensary.	Bilat. occluded tubes, multiple adhesions, atrophied soft uterus.	Vaginal ablation <i>en masse</i> .	Cured.
23. May 12, 1900	57	Private.	Office.	Fibroids (uterine).	Vaginal ablation.	Cured.
24. Mar. 9, 1898	29	Polyclinic.	Patient of Dr. W. R. Townsend.	Large retro-peritoneal cyst, bilat. tubular pyosalpinx, 3 previous vag. sections. On fourth day appendectomy transfusion.	Vaginal ablation by hemisection. Secondary appendectomy for acute appendicitis.	Cured.
25. Sep. 6, 1898	27	Polyclinic.	Dispensary.	Bilat. hydrosalpinx, many adhesions, small fibroid.	Vaginal ablation by hemisection.	Cured.
26. Jan. 4, 1898	32	Polyclinic.	Patient of Dr. Strauss. Twice cured.	Bilat. pyosalpinx.	Vaginal ablation by hemisection.	Cured.
27. July 11, 1899	39	Private.	Dr. Marvel.	Dif. pelvic suppuration, tuborectal fistula, small fibroids.	Vaginal ablation by hemisection.	Cured.
28. Feb. 16, 1898	28	Private.	Patient of Dr. Frank.	Bilat. pyosalpinx, one very large.	Vaginal ablation by hemisection.	Cured.
29. Oct., 1895	39	City Hospital	D. P. P. C.	Diffuse pelvic suppuration.	Vaginal ablation <i>en masse</i> .	Cured.
30. Apr. 27, 1899	40	Private.	Dr. Kelly.	Uterine fibroids (septic).	Vaginal ablation by morcellation.	Cured.
31. Sep. 15, 1897	24	St. Elizabeth's.	Dr. Davidson.	Left ruptured ectopic pyosalpinx. Has syphilis.	Vaginal ablation by hemisection.	Cured.
32. Mar. 29, 1899	29	Polyclinic.	Dispensary.	Bilateral hydrosalpinx, small ovarian cystoma.	Vaginal ablation by hemisection.	Cured.
33. Mar. 3, 1897	42	St. Elizabeth's.	Dispensary.	Bilateral cystic ovaries, bilateral hydrosalpinx.	Vaginal ablation by hemisection.	Cured.
34. Oct. 13, 1900	27	Polyclinic.	Dispensary.	Bilateral broad lig. cyst. Chr. salpingitis adhesions.	Vaginal ablation by hemisection.	Cured.
35. Aug. 24, 1895	25	Polyclinic.	Dispensary.	Cystic ovaries, bilateral pyosalpinx.	Vaginal ablation <i>en masse</i> .	Cured.
36. July 19, 1898	24	Polyclinic.	Dispensary.	Double pyosalpinx, dif. peritonitis, streptococci, septicemia.	Vaginal ablation by hemisection.	Cured.
37. Jan. 25, 1899	32	Polyclinic.	Dispensary.	Bilat. ovarian apoplexy and tubal sclerosis, multiple adhesions.	Vaginal ablation by hemisection.	Cured.
38. July, 1899	22	Polyclinic.	Dispensary.	Ruptured ectopic peritonitis due to infected clots	Vaginal ablation by hemisection.	Cured.
39. Oct. 29, 1897	28	Polyclinic.	(Dr. Van Arsdale.)	Diffuse suppuration, profoundly septic.	Vaginal ablation by hemisection.	Cured.
40. Nov. 7, 1900	56	Polyclinic.	Dr. Thompson.	Complete prolapse, old pelvic peritonitis, many adhesions, occluded tubes.	Vaginal ablation by hemisection, plastic for prolapse.	Cured.
41. Mar. 31, 1900	35	Polyclinic.	Dispensary.	Dif. pelvic suppuration, abdominal fistula, 6 mos. ago laparotomy in St. Vincent's hospital.	Vaginal ablation by hemisection.	Cured.
42. Sep. 17, 1899	45	Private.	Office.	Fibroids.	Vaginal ablation, large fibroid removed by morcellation.	Cured.
43. Feb. 28, 1895	28	Private.	Dr. Griswold.	Fibro-cyst.	Vaginal ablation by morcellation.	Cured.
44. Dec. 6, 1898	24	Polyclinic.	Dispensary.	Bilat. chr. salpingo-oopharitis, many pelvic adhesions.	Vaginal ablation by hemisection.	Cured.
45. Jan. 25, 1896	23	Polyclinic.	Dispensary.	Bilateral pyosalpinx.	Vaginal ablation by hemisection.	Cured.
46. Jan. 29, 1895	35	Private.	Office.	Adherent retroversion, chr. salpingitis, adherent adnexa.	Vaginal ablation <i>en masse</i> .	Cured.
47. Jan., 1895	34	City Hospital.	D. P. P. C.	Bilateral pyosalpinx.	Vaginal ablation <i>en masse</i> .	Cured.
48. Oct. 16, 1895	16	Polyclinic.	Patient of Dr. Wells. 3 previous vaginal punctures.	Double pyosalpinx.	Vaginal ablation by hemisection.	Cured.

Date.	Age.	Hospital.	From.	Diagnosis.	Operation.	Result.
49. Feb. 12, 1898	39	Private.	Dr. Beers.	Purulent salpingitis, copharitis, small fibroids and uterus large.	Vaginal ablation by hemisection, fecal fistula, plastic operation.	Cured.
50. Mar. 12, 1898	38	Private.	Dr. Tingley.	Ruptured ectopic and left salpingitis, general pelvic peritonitis.	Vaginal ablation by hemisection.	Cured.
51. Dec. 1, 1897	24	Private.	Dr. Griswold.	Dif. pelvic suppuration.	Vaginal ablation by hemisection.	Cured.
52. Sep. 9, 1899	37	Polyclinic.	Dispensary.	General pelvic suppuration.	Vaginal ablation by hemisection.	Cured.
53. May 4, 1900	89	Private.	Dr. Henrotin. A laparotomy in California years ago, septic convalescence.	Dif. pelvic suppuration	Vaginal ablation by hemisection.	Cured.
54. June 6, 1895	34	City Hospital.	D. P. P. C.	Bilat. tuberculous salpingitis.	Vaginal ablation <i>en masse</i> .	Cured.
55. June, 1895	30	City Hospital.	D. P. P. C.	Left pyosalpinx and dif. pelvic peritonitis; laparotomy a year before for right pus tube by Dr. Dudley.	Vaginal ablation by hemisection.	Cured.
56. Jan. 25, 1897	27	St. Elizabeth's.	Dispensary.	Left pyosalpinx, right salpingo-oophoritis, syphilitic.	Vaginal ablation by hemisection.	Cured.
57. Nov. 14, 1897	27	Private.	Dr. Torrens. A previous vaginal section.	Bilat. pyosalpinx.	Vaginal ablation by hemisection.	Cured.
58. Aug. 19, 1899	39	Polyclinic.	Dispensary.	Uterine fibroid.		Cured.
59. Sep. 8, 1898	20	Polyclinic.	Laparotomy at Bellevue Hospital.	Abdominal fecal fistula; ventral hernia; pelvic peritonitis.	Vaginal ablation by hemisection.	Cured.
60. July 20, 1899	33	Polyclinic.	Dr. Torrens.	Bilat. chr. salpingitis.	Vaginal ablation by hemisection.	Cured.
61. Jan. 8, 1898	25	Private.	Office.	Double pyosalpinx, left ovarian abscess.	Vaginal ablation by hemisection.	Cured.
62.	46	Private.	Dr. Frank.	Bilat. pyosalpinx; dif. pelvic suppuration.	Vaginal ablation by hemisection.	Cured.
63. Feb. 15, 1901	46	Polyclinic.	Dispensary.	Bilateral hydrosalpinx, multiple adhesions.	Vaginal ablation by hemisection.	Cured.
64. Jan. 24, 1898	42	Polyclinic.	Office.	Chr. salpingo-oophoritis and carcinoma of cervix.	Vaginal ablation.	Cured.
65. June 29, 1900	51	Polyclinic.	Office.	Uterine fibroids, and secondarily vesico vaginal fistula.	Vaginal ablation for fibroids. Secondarily closing fistula.	Cured.
66. Dec. 15, 1900	31	Private.	Dr. Taylor.	Uterine fibroids.	Vaginal ablation by morcellation.	Cured.
67. Oct. 11, 1899	35	Polyclinic.	Dispensary.	Double pyosalpinx and cystic ovaries.	Vag. ablation by hemisection.	Cured.
68. May 1, 1896	35	Polyclinic.	Dispensary.	Bilateral pyosalpinx, bronchopneumonia.	Vag. ablation by hemisection.	Cured.
69. Apr. 1, 1895	[?]	Polyclinic.	Dispensary.	Bilat. pyosalpinx, secondary hemorrhage, laparotomy, bleeding from ovarians.	Vag. ablation by hemisection.	Cured.
70. Mar., 1896	28	Polyclinic.	Dispensary.	Unruptured tubal pregnancy of right side, chronic salpingitis of left, gonorrhoeic.	Vag. ablation by hemisection.	Cured.
71. Oct. 12, 1900	24	Polyclinic.	Dispensary.	Double pus tubes.	Vag. ablation by hemisection.	Cured.
72. Oct. 7, 1897	30	Polyclinic.	Office. 4 years ago uterus curetted, adhesion between uterus and rectum broken up.	Phthisis pulmonalis, bilateral pyosalpinx.	Vag. ablation.	
73. Oct. 24, 1897	45	St. Elizabeth's.	Office.	Uterine fibroids.	Vag. ablation, morcellation.	Cured.
74. Mar. 14, 1899	37	Polyclinic.	Dr. Brownson.	Uterine fibroids.	Vag. ablation, morcellation.	Cured.
75. Dec. 10, 1897	51	Polyclinic.	Dispensary.	Prolapse of uterus (complete).	Amputation of cervix, curettage.	Cured.
76. Oct. 3, 1896	22	Polyclinic.	Dispensary.	Right ectopic gestation, ovarian apoplexy, left acute salpingitis.	Vag. ablation by hemisection.	Cured.
77. Nov. 10, 1897	35	Private.	Dr. Dawbarn.	Uterine fibrosis, left pyosalpinx and ovarian abscess, right pyosalpinx.	Vag. ablation by hemisection.	Cured.
78. Oct., 1895	29	City Hospital.	Laparotomy at Bellevue.	Gen. pelvic peritonitis due to infected ligatures after celiotomy.	Vag. ablation <i>en masse</i> .	Cured.
79. Apr. 20, 1898	52	Polyclinic.	Dispensary.	Small multiple fibroid and genital fibrosis, uterus 3 times normal size.		
80. Feb. 16, 1899	36	Polyclinic.	Dr. Baldy 2 previous laparotomies.	Fibroid uterus, ventral hernia, multiple broad ligament and sub-peritoneal cysts.	Vag. ablation by hemisection.	Cured.
81. Apr. 1, 1895	23	City Hospital.	D. P. P. C.	Bilat. sup. salpingitis.	Vag. ablation <i>en masse</i> .	Cured.
82. Mar. 13, 1897	28	St. Elizabeth's.	Dr. Davidson.	Septic metritis, retroflex adherent uterus after lap, uterine fibrosis after lap, infected stump and ligatures.	Vag. ablation by hemisection.	Cured.
83. Jan. 5, 1899	49	Private.	Dr. R. Nicholls.	Right ovarian cyst, left pyosalpinx.	Vag. ablation by hemisection.	Cured.

Date	Age.	Hospital.	From.	Diagnosis.	Operation.	Result.
84. Apr. 1, 1899	45	Private.	Dr. Wyeth. Previous curet- tages.	Bilat. salpingo-oophoritis, chr. uterine fibrosis, many adhe- sions.	Vag. ablation by morcellation.	Cured.
85. June 7, 1900	52	Polyclinic.	Dispensary.	Prolapsus uteri, chr. bilateral chr. salpingitis, multiple adhe- sions.	Vag. ablation with ligatures.	Cured.
86. July 19, 1899	25	Polyclinic.	Vaginal puncture for "abscess" of tubes a year ago.	Bilat. hydro. and chr. ovaritis, many adhesions.	Vag. ablation by hemisection.	Cured.
87. Oct. 31, 1899	19	Polyclinic.	Dispensary.	Double pyosalpinx, septic me- tritis, small ovarian cyst.	Vag. ablation by hemisection.	Cured.
88. Oct. 8, 1900	43	Private.	Office.	Sclerosed occluded tubes, scler- osed ovaries, large hard uterus.	Vag. ablation by hemisection.	Cured.
89. Jan. 11, 1901	39	Private.	Dr. Griswold.	Genital sclerosis, retroverted, adherent uterus.	Vag. ablation by hemisection.	Cured.
90. Sep. 6, 1899	35	Private.	Dr. Munde. Vag. removed uterine fibroids. Sepsis.	Bilateral pyosalpinx, septic me- tritis.	Vag. ablation by hemisection, intravenous infusion.	Cured. Was told that she died after an ap- pendectomy performed after she returned home
91. Jan. 1, 1901	36	Polyclinic.	Patient of Dr. Wyeth.	Dif. pelvic suppuration, phthisis, bronchopneumonia.	Vag. ablation by hemisection.	Cured.
92. Sep. 22, 1900	22	Polyclinic.	Dispensary.	Genital sclerosis, old multiple adhesions, 2 previous opera- tions at Bellevue through vagina.	Vag. ablation by hemisection,	Cured.
93. Nov. 9, 1898	44	Polyclinic.	Dr. Liell.	Uterine fibroids.	Vag. ablation, morcellation.	Cured.
94. Mar. 26, 1899	42	Private.	Patient of Dr. Griswold.	Acute sepsis, small fibroids, pelvic peritonitis.	Vag. ablation by hemisection and morcellation.	Cured.
95. Aug., 1899	34	Private.	Dr. S. Strauss.	Large edematous ovaritis and papillomatous cyst on right side. (Chr. bilat. salpingitis).	Vag. ablation by hemisection be- tween 4 prs. of forceps.	Cured.
96. Nov. 20, 1900	28	Polyclinic.	Dispensary.	Bilateral pyosalpinx, intravenous infusion.	Vag. ablation by hemisection.	Cured.
97. Feb., 1901	23	Polyclinic.	Dr. Dillingham.	Many pelvic adhesions, left cyst of ovary and hydrosalpinx, laparotomy 2½ years ago.	Vag. ablation <i>en masse</i> .	Cured.
98. Nov. 3, 1900	28	Dispensary.	Dispensary.	Bilateral pyosalpinx, small fibroids.	Vag. ablation by hemisection.	Cured.
99. Sep. 28, 1898	34	Polyclinic.	Office.	Uterine fibroids.	Vag. ablation, morcellation.	Cured.
100. Dec. 20, 1897	23	Polyclinic.	Patient of Dr. Tucker. Pre- vious curettage.	Right pyosalpinx, left pachysal- pingitis adhesions.	Vag. ablation by hemisection.	Cured.
101. Feb. 7, 1898	44	Polyclinic.	Postabortum infection.	Bilat. pyosalpinx, small uterine fibroid.	Vag. ablation by hemisection.	Cured.
102. Mar. 15, 1898	26	Polyclinic.	Dispensary.	Very large bilat. tubo-ovarian abscess.	Vag. ablation by morcellation.	Cured.
103. Aug. 1, 1898	Polyclinic.	Had been in bed 5 weeks with acute peritonitis.	Right ovarian cyst, acute bi- lateral salpingitis, gen. pelvic peritonitis.	Vag. ablation by hemisection.	Cured.	
104. Mar. 13, 1899	45	Polyclinic.	Dr. Griswold.	Fibroids.	Vag. ablation by morcellation.	Cured.
105. Oct. 28, 1898	46	Polyclinic.	Dr. Griswold.	Fibroids.	Vag. ablation by morcellation.	Cured.
106. Jan. 6, 1899	45	Polyclinic.	Patient of Dr. Goldstein.	Fibroids.	Vag. ablation by morcellation.	Cured.
107. Aug. 12, 1899	21	Polyclinic.	Laparotomy by Dr. Van Ram- dohr 3 months ago.	Pyosalpinx of left side, sup- about ligature of right stump, many adhesions.	Vag. ablation by hemisection.	Cured.
108. Nov. 2, 1899	47	Private.	Dr. Sewell.	Double cystic ovaries adhesions, tubal sclerosis, old lesions.	Vag. ablation by hemisection.	Cured.
109. Nov. 2, 1898	22	Private.	Patient of Dr. W. R. Town- send.	Peritonitis, bilat. pyosalpinx, aortic and mitral lesions.	Vag. ablation by hemisection.	Cured.
110. Feb. 1, 1898	54	Private.	Patient of Dr. Griswold.	Doub. pyosalpinx, left ovarian abscess, acute gonorrhoea.	Vag. ablation by hemisection.	Cured.
111. Aug. 11, 1897	23	St. Elizabeth's.	Dr. Gilday.	Right broad ligt. abscess, left pyosalpinx	Vag. ablation by hemisection.	Cured.
112. May 25, 1899	32	Polyclinic.	Dispensary.	Pyosalpinx right side, ovarian abscess and pyosalpinx of left.	Vag. ablation by morcellation.	Cured.
113. Oct. 12, 1898	22	Polyclinic.	6 previous operations, 3 laparot- omies, 2 nephrorrhaphies. Dr. Tucker.	Pelvic peritonitis after laparot- omy, abdominal sinus, dis- charging feces and urine.	Vag. ablation <i>en masse</i> .	Cured.
114. Mar. 26, 1898	23	Polyclinic.	Dispensary.	Left ectopic gestation, right pyosalpinx.	Vag. ablation <i>en masse</i> .	Cured.
115. May, 1900	39	Private.	Office.	Bilat. pyosalpinx.	Vag. ablation by hemisection.	Cured.
116. Apr., 1901	36	Private.	Office.	Multiple uterine fibroids.	Vag. ablation by morcellation.	Cured.
117. Jan. 11, 1898	27	Polyclinic.	Dispensary.	Ruptured ectopic, left pyosal- pinx, ovarian cyst.	Vag. ablation by hemisection.	Cured.

Date.	Age.	Hospital.	From.	Diagnosis.	Operation.	Result.
118. Oct. 26, 1895	24	City Hospital.	Dr. Outerbridge, laparotomy, Nov., 1894.	Abdominal sinus and dif. pelvic suppuration about infected ligature left after coelotomy, ligature recovered.	Vag. ablation, <i>en masse</i> . Ligatures recovered. Dr. Jacobs of Brussels (present).	Cured.
119. Nov. 1, 1895	21	City Hospital.	D. P. C. C.	Bilat. pyosalpinx.	Vag. ablation <i>en masse</i> .	Cured.
120. Aug. 14, 1897	33	St. Elizabeth's	Office.	Chr. bilat. salpingo-oophoritis, multiple adhesions, fixed retroversion.	Vag. ablation by hemisection.	Cured.
121. Sep. 25, 1898	25	Polyclinic.	Curetage in Russia 4 years ago, ill ever since.	Bilat. pyosalpinx, subperitoneal cyst.	Vag. ablation by hemisection.	Cured.
122. Jan. 24, 1899	30	Polyclinic.	Dispensary.	Bilat. hydrosalpinx multiple adhesions.	Vag. ablation by hemisection.	Cured.
123. Mar. 20, 1895	21	City Hospital.	D. P. C. C.	Bilat. pyosalpinx, dif. pelvic suppuration, large chancroids on vulva.	Vag. ablation <i>en masse</i> .	Cured.
124. June, 1896	22	Polyclinic.	Office.	Ruptured ectopic gestation salpingitis on other side.	Vag. ablation by hemisection, bronchopneumonia.	Cured.
125. Oct. 1, 1899	20	Private.	Dr. Wyeth.	Double pyosalpinx and ectopic gestation, syphilitic.	Vag. ablation by hemisection.	Cured.
126. Oct. 29, 1898	42	Polyclinic.	Office.	Uterine fibroids.	Vag. ablation by morcellation.	Cured.
127. July 8, 1898	38	Polyclinic.	Dispensary.	Retroverted uterus following abortion, dif. pelvic sup.	Vag. section.	Cured.
128. 1897	42	Polyclinic.	Dispensary.	Uterine fibroids.	Vaginal ablation by morcellation.	Cured.
129. Oct. 2, 1895	20	Polyclinic.	Dispensary.	Suppurating salpia. on left side, pachy on right.	Vaginal ablation by hemisection.	Cured.
130. Apr. 5, 1900	38	Polyclinic.	Lap. 3 years ago for pelvic abscess. Lap. 2 years ago, right ovary removed.	Genital sclerosis, multiple adhesions.	Vaginal ablation by hemisection using 3 clamps.	Cured.
131. June 8, 1898	26	Polyclinic.	Dr. Bodine. Ovarian cyst removed by lap. by Dr. Fullerton, of Phil'a, 2 years ago.	Dif. peritonitis, adherent uterus, broad lig. cyst.	Vaginal ablation by hemisection.	Cured.
132. Dec. 20, 1897	36	Private.	Dr. Zitz. Left tube and ovary removed 3 years ago by Dr. Krug, through vagina.	Enormous right ovary, ovarian abscess.	Vaginal ablation by hemisection and morcellation.	Cured.
133. Mar. 17, 1893	33	Polyclinic.	Dr. Munde. Curettag 2 years ago, infection since.	Multiple uterine adhesions, etc.	Vaginal ablation by hemisection.	Cured.
134. Feb. 13, 1898	39	Polyclinic.	Dr. Dawbarn.	Ruptured right tubal gestation, pyosalpinx left.	Vaginal ablation by hemisection.	Cured.
135. Nov. 1, 1897	41	Private.	R. L. Pritchard. Dr. Abbe in consultation.	Multiple adhesions, bilat. occluded tubes, large cystic ovaries. Adhesions more general than I have ever seen them due to puerperal septicemia.	Vaginal ablation by hemisection.	Cured.
136. Feb. 27, 1901	27	Private.	Dr. S. Lewingood.	Chr. salpingo-oophoritis, genital sclerosis, many minor operations.	Vaginal ablation by hemisection.	Cured.
137. Oct. 1, 1900	42	Private.	Dr. Marvel.	Fibroids, old ruptured ectopic, endocarditis, typhoid fever, pneumonia.	Vaginal ablation by morcellation.	Cured.
138. Dec., 1895	35	Polyclinic.	Dispensary.	Pyosalpinx, bilat. cystic ovaries, intraligamentous fibroid.	Vaginal ablation by morcellation.	Cured.
139. Mar., 1901	40	Polyclinic.	Dispensary.	Bilat. hydrosalpinx, multiple adhesions, uterine fibrosis and small fibroid.	Vaginal ablation by morcellation.	Cured.
140. Dec. 29, 1900	30		Dr. Nichols.	Ruptured ectopic, multiple adhesions.	Vaginal ablation by hemisection.	Cured.
141. Dec. 1, 1898	27	Polyclinic.	Dispensary.	Retroversion, adhesions, bilateral hydrosalpinx.	Vaginal ablation.	Cured.
142. May 26, 1900	42	Polyclinic.	Dr. Schaviour, of Stamford, removed fibroid.	Fecal fistula and uterine fibroids.	Vaginal ablation fistula curetted & plugged from above. Fistula did not heal.	
143. July 7, 1899	67	Polyclinic.	Dr. Bodine.	Occluded tubes, many adhesions, prolapse.	Complete hysterectomy.	
144. May 1, 1895	30	City Hospital.	D. P. C. C. Abdom. ovariectomy, Harlem Hospital, 6 months ago.	Bilat. salpingitis, acute peritonitis.	Vaginal ablation <i>en masse</i> .	Cured.
145. Mar. 16, 1896	40	Polyclinic.	Dr. Krug.	Chr. bilat. salpingitis, repeated attacks.	Vaginal ablation by hemisection.	Cured.
146. Apr. 20, 1896	46	Polyclinic.	Dispensary.	Old ectopic which had ruptured into right broad lig. Dif. pelvic suppuration.	Vaginal ablation by hemisection.	Cured.
147. Mar., 1895	44	City Hospital.	D. P. C. C.	Bilat. pyosalpinx.	Vaginal ablation <i>en masse</i> .	Cured.
148. Nov. 27, 1897	24	Polyclinic.	Many attacks gonorrhoea, repeated curettages.	Chr. salpingitis, oophoritis, Chr. metritis. General sclerosis.	Vaginal ablation by hemisection. Very difficult.	Cured.
149. Jan. 31, 1899	37	Private.	Dr. Tingley.	Bilat. pyosalpinx.	Vaginal ablation by hemisection. Intravenous infusion.	Cured.

Date.	Age.	Hospital.	From.	Diagnosis.	Operation.	Result.
150. Feb. 27, 1899	32	Private.	Dr. Griswold.	Left ectopic gestation, right pyosalpinx. Specimen sent to Dr. Williams, Johns Hopkins.	Vaginal ablation by hemisection.	Cured.
151. Mar. 3, 1899	45	Polyclinic.	Dispensary.	Multiple pelvic adhesions, bilat. salpin oophoritis.	Vaginal ablation by hemisection.	Cured.
152. July 10, 1898	39	St. Elizabeth's.	Office.	Specific history. Bilat. sclerosed tubes and ovaries. Many adhesions.	Vaginal ablation by hemisection.	Cured.
153. Sep. 28, 1899	38	Polyclinic.	Jan. 29, 1900, Dr. Wells operated for cure of fistula.	Endometritis, doub. ovarian abscess, doub. pyosalpinx and abscess of left broad lig.	Vaginal ablation by hemisection.	Cured.
154. Aug. 11, 1898	24	Polyclinic.	Dispensary.	Bilat. ovarian cystoma, purulent ovarian abscesses. Chancroid in upper part of left side of vulva. Iliac glands of left side enlarged.	Ablation, vaginal.	Cured.
155. May 16, 1898	23	Polyclinic.	Dr. Rupp curetted 1 year ago. Dr. Polk drained through vagina after.	Right pyosalpinx, left pyosalpinx, uterus large and ante-flexed.	Vaginal ablation by hemisection.	Cured.
156. June 6, 1898	30	Polyclinic.	Dispensary.	Bilat. pyosalpinx.	Vaginal ablation by hemisection.	Cured.
157. Sep. 15, 1898	19	Polyclinic.	Dispensary.	Dif. pelvic suppuration.	Vaginal ablation by hemisection.	Cured.
158. Jan. 5, 1899	22	Polyclinic.	Dispensary.	Bilat. pyosalpinx, acute peritonitis.	Vaginal ablation by hemisection.	Cured.
159. Dec. 31, 1896	30	St. Elizabeth's.	Dr. Gilday.	Bilat. pyosalpinx.	Vaginal ablation by hemisection.	Cured.
160. Nov. 28, 1899	30	Polyclinic.	Dr. McPhee.	Uterine fibrosis, bilat. pyosalpinx, right bystic ovary.	Vaginal ablation, Nov. 30, 1899.	Cured.
161. Nov. 21, 1898	31	Polyclinic.	Dispensary.	Bilat. ovarian apoplexy, multiple adhesions, twisted and occluded tubes.	Vaginal ablation by hemisection. Secondary hemorrhages on 10th & 18th days from right uterin vaginal anastomosis.	Cured.
162. June 28, 1899	22	Private.	Office.	Right lig. abscess, bilat. ovarian apoplexy, left pyosalpinx, syphilitic.	Vaginal ablation by hemisection.	Cured.
163. Jan. 26, 1898	26	Polyclinic.	Dr. Thompson.	Uterine fibroid, bilat. pyosalpinx.	Vaginal ablation by morcellation.	Cured.
164. Sep. 22, 1896	37	Private.	Dr. Hewlett.	Prolapsus uteri, cervix at vulva, large cystic ovaries. Chr. salpingitis, tubes occluded and adherent.	Curettage, later vaginal ablation.	Cured.
165. May 24, 1896	24	Polyclinic.	Operation by Paul Ségond.	Doub. pyosalpinx-hystero-epileptic convolutions.	Vaginal ablation by hemisection iliac.	Cured.
166. Sep. 10, 1898	26	Polyclinic.	Dispensary.	Left ovarian cyst, prosalpinx (right).	Vaginal ablation by hemisection.	Cured.
167. Nov. 3, 1898	22	Polyclinic.	Dr. Nichol.	Left papilloma of tube, right pyosalpinx syphilitic.	Vaginal ablation by hemisection.	Cured.
168. Nov. 22, 1898	28	Polyclinic.	Dispensary.	Left ectopic gestation, right pyosalpinx, profoundly septic.	Vaginal ablation by hemisection. Intravenous infusion.	Cured.
169. Mar. 12, 1899	40	Polyclinic.	Dr. Bodine.	Dif. pelvic suppuration.	Vaginal ablation by hemisection. Bronchopneumonia. Intravenous infusion. Typhoid fever.	Cured.
170. Oct. 9, 1900	58	Private.	Dr. Berkely.	Multiple fibroids.	Vaginal ablation by morcellation.	Cured.
171. Oct. 18, 1899	34	Polyclinic.	Dispensary.	Fibroids of uterus.	Vaginal ablation by morcellation.	Cured.
172. Nov. 16, 1899	29	Polyclinic.	Dispensary.	Genital sclerosis, pelvic adhesions, many infections.	Vaginal ablation by hemisection.	Cured.
173. Sep. 9, 1896	28	Polyclinic.	Dispensary.	Bilat. chr. salpingitis general pelvic adhesions. Many previous minor operations, etc.	Vaginal ablation by hemisection.	Cured.
174. June 22, 1898	38	Private.	Dr. Griswold.	Dif. pelvic suppuration.	Vaginal ablation by hemisection, iliac.	Cured.
175. Jan. 21, 1898	33	Private.	Dr. Griswold.	Left ovarian abscess and right pyosalpinx.	Vaginal ablation by hemisection.	Cured.
176. 1898	3	Private.	Patient of Dr. Gray.	Old chr. salpingitis, multiple adhesions, carcinoma of cervix.	Vaginal ablation <i>en masse</i> .	Cured.
177. Sep. 28, 1900	35	Private.	Dr. Leo.	Gen. pelvic peritonitis, retroversion and adhesions, carcinoma of cervix.	Vaginal ablation by hemisection.	Cured.
178. Nov., 1895	35	City Hospital.	D. P. C. C.	Bilateral pycsalpinx.	Vaginal ablation <i>en masse</i> .	Cured.
179. Oct. 6, 1897	21	Polyclinic.	Dr. Wells.	Ectopic pregnancy and pelvic suppuration.	Vaginal ablation.	Cured.
180. June 1, 1899	36	Private.	Dr. Griswold.	Uterine fibroids.	Vaginal ablation by morcellation.	Cured.
181. Oct. 16, 1899	29	Polyclinic.	Dispensary.	Genital sclerosis, general adhesions.	Vaginal ablation by hemisection.	Cured.
182. Mar. 23, 1901	24	Private.	Dr. Dillingham.	Diffuse pelvic suppuration, preliminary evacuation.	Vaginal ablation by hemisection.	Cured.
183. Mar. 28, 1901	30	Private.	Dr. Gilday.	Bilateral pyosalpinx.	Vaginal ablation by hemisection.	Cured.

THE GOOD AND BAD EFFECTS OBTAINABLE FROM DIGITALIS USED AS A THERAPEUTIC AGENT.*

BY

WILLIAM HENRY PORTER, M.D.,

of New York City.

[Concluded from page 117.]

With this general understanding in relation to the functional activity of the glomeruli and epithelial cells constituting the kidney and our knowledge of the chemistry and physiologic action of digitalis, its therapeutic possibilities in relation to the excretory action of the renal glands, both in health and disease, can be intelligently discussed. Considerable doubt and difference of opinion prevail in regard to both the degree and mode of utility of digitalis and its various preparations in relation to the action of the renal glands—this is true, notwithstanding that this drug has been extensively administered for more than a century, some praising it highly, while others with equal vigor condemn it as worthless. The varying composition of the different preparations would alone easily account for this diversity of opinion; but when to this is added the complex mechanism of the renal function there is little wonder that there is a multiplicity of opinions upon the subject.

Hurchard not many years ago advanced the opinion that digitalis, even when given in large doses, was not hurtful in pathological conditions of the kidney. He claimed, on the contrary, that it was useful in the condition known as parenchymatous metamorphosis or degeneration, because it diminished the amount of albumin excreted with the urine.

Owing to the facts as already detailed, that digitalis contains a number of glucosidal principles, some of which antagonize others, and as the various preparations differ widely in their composition, it is very difficult to secure a uniform preparation for therapeutic use. At the same time one or all of these glucosides must be oxidized and eliminated from the system; when this is being done the animal economy is, in a large measure, uselessly taxed in transmitting those active agents that are foreign bodies in the sense that they are useless and antagonistic to those active principles that alone might be of true therapeutic value. As a natural sequence the oxidation and elimination of these worthless products from the body, must damage the system to greater or less degree, and so far as these principles are concerned, without in the least degree securing the desired physiological action.

Under conditions like these, the therapeutic results from the chemical nature of the drug alone at best become problematic and uncertain which easily explains the abundance of contradictory clinical evidence recorded concerning this drug. If we add to this a misinterpretation of the physiological laws governing the functional activity of the renal glands the uncertainty becomes greatly intensified.

Further than this, it has been ascertained that digitalis is not eliminated from the system by the kidneys in any of the above mentioned glucosidal forms; therefore its diuretic effects upon the system can not be explained

by its elimination, as such, through the kidneys, thus exciting the glands into activity by its irritating properties as it passes through these organs.

As all the active or glucosidal principles are composed of carbon, hydrogen, and oxygen, they are all capable of being oxidized within the system into carbon dioxide and water. While these elements are passing through this transmutation process, they yield heat and energy; and, by acting upon the nervous mechanism, they chiefly yield the physiological action of digitalis. Primarily, the first 3, digitalein, digitoxin and digitalin when oxidized act upon the cardiac-innervating center and the primary or medullary vasomotor centers, thus causing an increase in the number of the cardiac pulsations, and at the same time, they progressively tighten up the entire arterial system outside the splenic arcade. A little later, the cardioinhibitory center feels the stimulating effects, more positively than the cardioinnervating, which fact, together with the heightened arterial tension already produced, naturally increases the peripheral resistance to the heart action.

As a natural sequence, the heart at first beats more rapidly and forcibly against a steadily increasing, peripheral, arterial resistance. Excepting of course the splenic arcade in the domain of which obeying the common law of physiology, the capacity of the bloodvessels is increased and a large volume of blood is moved from the general arterial system and through those of the splenic arcade in a given space of time. At this point the common law of physics comes into play, in this, that the increased resistance in front of the heart, as the result of the augmented arterial tension, greatly augments the task of the heart as a mechanical pump. Consequently, the number of strokes to the minute must be reduced, to increase the power of the heart per stroke, in overcoming the greater resistance placed against it.

If the increased volume capacity in the splenic arcade were equal to the general decrease in the remaining portions of the arterial system, the actual amount of work imposed upon the heart by the contraction of the arteries would not be augmented, but this absolute, equal balance between the 2 systems does not, as a rule, seem to take place. The contraction in the general arterial system is much greater than the expansion in the splenic arcade, which, together with the increased high tension in the coronary arteries, as already elucidated, cuts down the time for the nutritive interchange between the blood in the coronary vessels and the muscular tissue that constitutes the heart wall. As a natural result of this increased work thrown upon the heart, and at the same time of a reduction in nutritive supply, the heart must work slower and ultimately less effectually. Thus it becomes clear that the chief action of digitalis in influencing the renal functions may be explained through its power to change the mechanical workings of the heart and of the circulatory vessels, the combined action of which causes an abnormal distribution of the blood, and therewith an equally abnormal distribution of the nutritive supply.

If digitalis is continuously administered with rapidly increasing dosage, the secondary or spinal vasomotor centers will be actively stimulated as well as the primary vasomotor centers in the medulla, and thus a high ten-

*Read before the Litchfield County Medical Society of Connecticut, January 8, 1901.

sion is produced in the vessels of the splenic arcade as well as in the rest of the arterial system. When this has been produced, almost all nutritive interchange throughout the body is thereby arrested. Owing to the reduction of the lumina in the renal arteries, whatever blood reaches there is driven so rapidly through the kidneys that proper time is not allowed for the epithelial cells to formulate and eliminate the effete material taken from the blood.

If the stimulation of the secondary or spinal vasomotor centers is more intense than can be secured by large doses of digitalis, the contractile effect upon the renal arteries will be still greater, and can be carried to such an extent that the renal arterioles will be so much contracted that the circulation in them is almost if not completely arrested. In either instance a rapidly developing anemic condition of the system is induced in the tissues generally; the functions of the kidneys is practically or absolutely abolished; and the patient finally dies practically with toxic symptoms, commonly classed as uremia.

With this knowledge at hand, and remembering that all renal lesions have for their chief etiological factor an increase in the amount of work imposed upon them at a time when their nutritive supply is below the normal standard, the therapeutic possibilities of digitalis in connection with the renal function can be rationally considered.

Having found in the study of the functions of the kidneys that the quantity of water discharged is largely dependent upon the hydraulic pressure reigning in the glomerule, we shall see that this law is the chief factor in explaining and determining the excretory output of the kidneys.

To summarize, when digitalis is given to a normal individual the general blood tension is increased and the heart's action intensified. This might be expected to increase the hydraulic pressure in the glomerule and augment the flow of urine, but owing to the fact that there is no obstruction to the exit of blood from the kidneys, the blood is simply driven more rapidly through the kidney, and the pressure in the glomerule is not increased above the normal. Consequently the amount of water discharged from the kidney remains about normal; but owing to the greater speed of the blood in passing through the kidneys, less time is allowed for the epithelial cells to take up the fully utilized proteid elements together with active oxygen from the passing blood stream, oxidize and eliminate them as the nitrogenous excreta of the body.

What oxidation does occur is less perfectly effected, and the normal kidney, when the system is under the influence of digitalis naturally excretes more uric acid and less urea. If the system is brought more completely under the influence of digitalis the renal arteries may become so much contracted that the renal function is suspended. This, however, rarely if ever occurs during the ordinary therapeutic use of digitalis. Yet it is clear, that the normal condition of the kidneys, and in many of the lesions of the renal organs, digitalis decreases the elimination of the water and diminishes the perfection and amount of the nitrogenous excre-

mentitious products of these glands. Further than this, the increase in the speed of the blood in its passage through the kidneys also lowers the perfection in the nutritive interchange between the blood and the renal tissue. Therefore, in all kidney lesions, in which there is no marked swelling of the epithelial cells, which when present, compresses the venous capillaries on the efferent side of the Malpighian tufts, and in which the venous exit from the kidneys, so far as the large veins are concerned is impeded, digitalis, as in the normal kidney, simply drives the blood through the renal organs more rapidly, without augmenting the hydraulic pressure in the glomeruli. Consequently, digitalis, in this class of cases, does not produce any diuretic action, but decreases the excretory function of the kidneys, impairs the nutritive function of the renal tissue still more, and practically makes the kidney lesion worse. This arrest in the functional activity may decrease the elimination of the albumin, but proves conclusively, in opposition to Hurchard's opinion, that "digitalis is not hurtful"—that it is very damaging under these circumstances. On the other hand, if there is a general venous engorgement of the system, a passive congestion of the kidney, or an active determination of blood to the renal organs until the circulation therein is impeded, a result entirely different from the one just described is obtained from the use of digitalis. Likewise in all forms of parenchymatitis, metamorphosis, or degeneration of the epithelial cells, when these become swollen and compress the veins outside the Malpighian tufts, and thus prevent the normal and free escape of blood from the efferent vessels of the glomeruli, digitalis improves the nutritive condition as well as the excretory function. In all these instances, when digitalis is first administered, the results will be as follows: the heart's action will be intensified, and the general arterial tension will be greatly increased. At the same time the splenic arcade, which includes the renal system, and which is not thus affected, is, by the general arterial pressure, driven to expand; the volume of blood discharged into the arteries of the kidneys is therefore greatly augmented, and the volumetric blood-pressure in the vessels of the glomeruli rapidly rises. As a result of the obstruction to the venous escape, one of 3 things must follow: The circulation through the kidneys must stop; or the capillaries constituting the Malpighian tufts must burst, and this increased pressure be relieved by an escape of the blood into the tubules; or, what more frequently occurs, the watery constituents of the blood must flow off through the capillaries, constituting the Malpighian tufts, into the uriniferous tubules. When this latter results, there is a rapid increase in the amount of water discharged into the bladder, from which it is finally expelled, thus furnishing typical clinical evidence of the diuretic properties of the drug. With the relief of pressure within the glomeruli, and with the continued steady high pressure upon the engorged venous system in the kidneys from the arterial side, the sluggish circulation through the secondary or venous plexuses of the renal gland is greatly improved, thus allowing a more nearly normal volume of blood to pass through the kidneys in a given space of time than before.

When this stage is reached, a larger volume of the utilized proteid constituents will be drawn into the protoplasm of the renal cells, together with a larger quantity of active oxygen. This will result in a more perfect and more active oxidation reduction of the proteid constituents. As a necessary sequence the amount of albumin discharged from the renal cells will be decreased, the output of uric acid will fall, and the percentage of urea will be proportionately increased. Both the solids, as well as the water, are increased and the true functional activity and the nutrition of the renal tissue is augmented, provided at the same time the patient is properly dieted, and due attention given to improving digestive function.

This is true because too slow a passage of the blood as well as a too quick flow of blood, as already shown, prevents the proper nutritive and functional activity not only of the renal organs, but of every gland in the body. Thus digitalis, in this class of cases, becomes a true diuretic in every sense, while in all other cases its action is the reverse, and often does positive damage.

The improvement in the circulatory activity, which, in this special class of cases, is raised from a low ebb to a normal standard, together with the increased excretory activity of the renal glands, very decidedly tends to enhance the local nutritive activity in the kidney itself, and thus helps to cure the parenchymatous lesion and all lesions of the before described, allied group. Thus fully is sustained the assertion of Huchard in this class of renal lesions. It also shows why the giving of digitalis empirically, and without first determining accurately the true nature of the pathologic changes, will result in failure both in connection with cardiac and renal lesions, quite as often as in success, and in many instances must result in absolute damage to the human economy. Administered as a diuretic when it has no power to act, its therapeutic result must be nil; but given when and where it has the power to act, digitalis is one of the most valuable drugs in the pharmacopia.

The conclusions naturally arrived at from this critical review of digitalis, have been based largely upon a close and extensive observation of the drug and its various preparations in all forms of disease. This study of its action has extended over a period of more than 20 years, both in the hospital wards and in private practice.

The conclusions therefrom are summarized as follows:

1. The composition of digitalis is, chemically speaking, very complex, and some of its active principles antagonize others.
2. That the different preparations differ widely in their composition and action.
3. That its cumulative action is due to its contracting the arterioles, thus shutting off nutrition.
4. That it is both a useful and dangerous remedy; and one that has a very limited range of usefulness.
5. That it is only of use in lesions of the mitral valve, and even then only for a short time.
6. That it should only be used when there is low arterial tension and marked venous engorgements and as soon as these conditions are overcome, its action should be suspended.
7. As a diuretic it is only of value when there is low

arterial tension, venous engorgement and obstruction to the exit of blood from the kidney.

8. Acting upon the normal, and in all diseased conditions in which there is obstruction to the exit of blood from the kidney, it decreases the excretory activity of the renal glands, and impairs their nutritive activity.

9. If pushed to its fullest extent it may completely arrest the functional activity of the renal glands.

THE LOGIC OF HYDROCHLORIC ACID THERAPY, RESTORATION OF LOST GASTRIC HCL SECRETION BY MEDICAL AND SURGICAL METHODS.

BY

JOHN C. HEMMETER, M.D., PHIL. D., ETC.,

of Baltimore, Md.,

Professor in the Medical Department of the University of Maryland,
 and Director of the Clinical Laboratory.

(Concluded from page 130.)

Professor Biedert claims to have used 120 drops of dilute HCl daily, for a number of years, with much benefit¹⁷ to his achylia. Hänni introduced into the stomach 400 cc. of a 2.5 : 1000 solution of HCl, containing also 2 gm. of pepsin, together with an Ewald test-breakfast. So early as 15 minutes afterward, when some of the test-meal was withdrawn, the free HCl had completely disappeared and the digestive power of the sample was equal to zero;¹⁸ and Boas cites this statement to show that the digestive value of HCl therapy is doubtful. To this we might reply that a patient who gets rid of 400 cc. of semi liquid food in 15 minutes has hypermotility; so much could not possibly be absorbed in that short period (the stomach does not absorb dilute HCl solutions). Nor could all of 1 gm. of absolute HCl which 400 cc. of a 2.5 to 1000 solution contains, enter into combination with the proteid of a single roll; for 100 gm. of wheat roll contain only 7 gm. of nitrogenous or HCl-binding materials. We know, however, that 1 gm. of absolute HCl can digest 18 gm. of dried egg-albumen. Therefore the 400 cc. had probably all been rapidly expelled into the duodenum before they could even be thoroughly triturated with the test-breakfast. This does not occur normally, and we are not justified in drawing conclusions from such hyperkinetic cases regarding the value of HCl therapy.

As the amount of absolute HCl introduced in Hänni's experiments equaled 1 gm., and as so much could not enter into combination with the proteid of 1 roll, or 100 gm., of wheat bread, it stands to reason that if the motility had not been so exaggerated, some of the HCl would have been regained. Whenever Hänni¹⁹ succeeded in regaining some of the solution of HCl after it had remained in the stomach 45 to 50 minutes, or even 30 minutes,²⁰ the tests for HCl were positive and fibrin was well digested by the filtrate. The experiments of von Mehring, Moritz, and myself apparently agree in permitting the deduction that 15 minutes is an abnormally rapid time for the expulsion of 400 cc. of semiliquid food (even if it were only water) into the duodenum, and whenever there is a fuller meal given than a simple test-breakfast, this rapid expulsion does not occur, because solid and semisolid food can not be moved out so readily. Again, we must make allowance for a certain unavoidable nervous tension, and for the influence of suggestion, which

takes hold of patients under experimentation, and which, from experience, we know has a decided influence on the rate of peristalsis.

On clinical as well as reliable experimental grounds I feel justified, therefore, in recommending hydrochloric acid, believing in its efficacy in supplementing the digestive work of the stomach in bringing about the normal conditions for duodenal digestion. Whenever it is indicated, I usually give 20 drops of the diluted HCl (U. S. Pharm.) in 2 ounces of water every 15 to 20 minutes, beginning 15 minutes *before* the meal; then 20 drops are taken during the eating, and 20 drops a half-hour after the meal. The medicine should always be taken through a glass tube, and the mouth rinsed with a weak solution of sodium carbonate afterward. Dr. Chas. D. Aaron, of Detroit, has suggested giving the acid in strong, gelatine capsules—a good plan. As a remedy for improving the appetite, HCl is conceded, even by those skeptical of its digestive power, to be of value. For this purpose it is best given in small doses diluted with water (10 to 20 drops in 3 ounces H₂O), on an empty stomach, before meals. With regard to its disinfectant and anti-fermentative effect we entertain serious doubts, since it cannot be given in sufficient quantity to be of much benefit in that direction when given with meals. Whenever there are decided fermentations in the stomach, lavage is the most efficient means of combating it, and for this purpose HCl in the form of a 6:1000 solution may be used.

Hydrochloric acid is contraindicated when the normal gastric secretion is augmented. We have observed cases in which there was no free HCl to be detected on Congo paper or phloroglucin-vanillin, but HCl given by the mouth produced gastric distress and pain; so that there can be no doubt that cases of hyperesthesia toward HCl exist analogous to those described by Talma²² which do not depend upon hyperhilia. One female patient in my private practice could detect whenever 6 drops of the diluted acid were given surreptitiously in the meals or medicine, by the gastralgia caused thereby. This was a highly neuropathic case.

The amount of HCl consumed in the digestion of albumin has been very carefully studied. It takes 0.05 gm. of HCl to transform 1 gm. of egg-albumen into acid albumin. As human beings frequently take in 150 gm. of egg-albumen in 24 hours, it would require 7.5 gm. of pure HCl (or 30 gm. of the 25% solution of the laboratories) to transform this amount into acid albumin. As the gastric juice contains HCl to the amount of 2 per mille, 3½ liters of gastric juice would be required to digest that amount of egg-albumen. Many children consume about one liter of milk daily; this would require 4.5 gm. of pure HCl or 18 gm. of a 25% solution of HCl (100 gm. of cows' milk combined with 0.45 gm. of HCl). These amounts of HCl would bring the ingested albumin only to the stage of acid albumin or syntonin; but as hemialbuminose and peptone would require twice the amount of HCl, the quantity combined with must eventually be increased beyond the figures stated. A portion of the albuminous foods passes over into the intestines, however, and is digested there long before it reaches the stage of hemialbuminose; but when

the transit of the food into the duodenum is obstructed, it is evident that enormous quantities of HCl must be secreted to digest all the albumin that is taken in. For a purely physiologic reason, it is not possible that the glandular layer can secrete the requisite amount. The absence of free HCl in these cases may be due to an invasion of the mucosa by the disease causing the pyloric obstruction. It is not impossible, however, that, even without this invasion, the mucosa has become exhausted, its secretory function being paralyzed. An analogous result has long been known to physiologists in connection with prolonged or overstimulation of the submaxillary (salivary) gland. Stimulation of these gland cells, through the chorda tympani nerve at first causes a secretion rich in ptyalin, but as the stimulation is prolonged for 12 to 16 hours the secreted saliva becomes poorer and poorer in ptyalin and finally contains none whatever. After the stimulation ceases and the gland cells have rested, any renewed secretion will again contain ptyalin.

Whenever the gastric secretion shows an absence of free HCl and it can be concluded that it is not due to an atrophy of the mucosa one of the most efficacious means of restoring the secretion is by lavage with a solution of HCl—3 to 4 parts to 1000 of warm water. As many of these cases require lavage, it is therefore expedient to carry it out with this solution even if there is no stagnation—the lavage is not intended here so much for cleansing the stomach as for stimulating the mucosa.

The diet should consist largely of foods requiring considerable amounts of HCl for digestion as these contain the substances that are the most effective stimulants to the gastric secretion—the extractive substances of beef, finely minced or scraped beef, mutton, fish, soft boiled eggs, etc. Such stomachs require dietetic gymnastics (always precluding dilations, atrophies, neoplasms) and too bland or sparing a diet will simply permit the secreting cells to atrophy from deficiency of work.

Plague.—The United States Consul, Robert M. McWade, at Canton, China, reports that 10,000 deaths from the plague have occurred there during the past 6 weeks, and that 13 cases of smallpox exist on board the United States monitor Monterey. A case of bubonic plague is reported from Alexandria, Egypt. In Capo Colony a steady increase of the plague is indicated in reports received both in London and Paris, there having been 366 cases up to April 10, of which number 85 were Europeans. At Simonstown the rats are reported to be dying from plague. The total mortality from plague for all India during the week ended March 9 is 7,879 deaths, an increase of 952 upon the previous week, which is the highest number of deaths from this disease for any week since its first appearance in India. In Bombay Presidency and Bombay City there is a decline of plague mortality, but in some other parts of India an alarming increase has prevailed. In Bengal, exclusive of the metropolis, 4,525 deaths from plague occurred during the week ended March 9, an increase of 459 deaths in the previous week. In Calcutta, in consequence of the marked recrudescence of plague, inspection of railway passengers at stations has been resumed, and on March 12, 142 fresh cases were reported and 557 plague deaths occurred there during the week ended March 9. It is understood in India that when deaths from plague in large cities number 100 daily a serious epidemic prevails, and this would seem to have been the case during a part of the third week of March. In the northwest provinces there were 417 deaths from plague, and in the Mysore State 169 during the week ended March 9. For the week ended March 28, 2 fatal cases of plague were reported in Mauritius.

HYPERPLASTIC COLITIS: EXTIRPATION OF THE ENTIRE COLON, THE UPPER PORTION OF THE SIGMOID FLEXURE AND FOUR INCHES OF THE ILEUM.

BY

HOWARD LILIENTHAL, M.D.,

of New York City.

Attending Surgeon, Mt. Sinai Hospital.

The following history is a singularly remarkable one not only because of the final recovery after many very dangerous intraabdominal operations, but because of the surgical surprises which were encountered throughout the entire progress of the case. The patient, a girl of 21, was referred to the surgical department of Mt. Sinai Hospital by Dr. Manges, who had observed her for some days in the medical side of the institution. She had for years suffered from diarrhea, accompanied by hemorrhages and the passage of foul mucus, and finally became so weak and anemic that a left inguinal colostomy had to be performed to give rest to the lower portion of the colon and rectum. The surgeon who opened the colon at this time saw that the walls of the viscus were covered with polypoid growths which bled easily even on gentle manipulation. The patient was very much benefited by the operation, the hemorrhages finally ceasing so that it was thought best to close the artificial opening. No sooner had she left the hospital, however, than her old trouble returned in all its severity and the girl became once more profoundly anemic and very weak. She then first came under my care. She had as many as 12 stools a day. There was much abdominal pain and some vomiting. The diarrhea and bleeding were worse after the ingestion of certain articles of food; she could not eat meat at all. On examining the abdomen considerable tympanites was noted, but no distinct mass could be felt. Examination of the rectum disclosed the presence of several small polypoid masses. I determined, on account of the inability of the surgeon to reach the upper limits of the disease with the finger through the original colostomy wound, to open the caput coli through a wound in the right iliac region in order to give the entire colon as thorough functional rest as possible. This operation was performed on December 30, 1899. I found the colon here in much the same condition which had been noted in the descending colon. There was no normal mucous membrane, the entire mucosa being covered by large and small papilloma-like excrescences. One of these was removed for examination and proved to be an hypertrophied solitary follicle (examination by Dr. F. S. Mandelbaum, pathologist). Incidentally the vermiform appendix was removed at this time. Its mucosa was hyperplastic. I will not go into the details of the treatment but will simply say that everything, which in my mind promised success, was tried—nitrate of silver injections and irrigations, saline irrigations, etc. The patient rapidly improved in her general condition. The hemorrhages almost entirely ceased, but it was evident that the closure of the right colostomy wound would surely be followed by the recurrence of her trouble since the condition of the visible mucous membrane was unchanged. I therefore made up my mind that the exclu-

sion of the entire colon from the alimentary tract promised the greatest relief with the least degree of risk. Accordingly, on March 6, 1900, the operation of end-to-end ileo-sigmoidostomy was performed. Through a median incision the ileum was sought out and divided about 4 inches from the ileocecal valve. The intestine here was observed to be healthy. The lower end of the ileum, that adjoining the ileocecal valve, was closed by invagination with the help of a purse-string suture of silk. The sigmoid flexure was then drawn into the wound, and was in turn divided somewhere in its lower half, its upper portion being also invaginated by means of a heavy purse-string suture. The lower portion of the sigmoid was then united by Murphy's button with the upper portion of the ileum, so that the intestinal contents would pass directly from the ileum into the lower half of the sigmoid flexure, which was comparatively healthy. A drainage wick was left in the lower angle of the wound, the remainder being closed by sutures. The right iliac colostomy was, of course, not disturbed, because it was understood that a vent for the secretions of the excluded portion would be necessary. The patient was kept quiet with opium, following this operation. Full stimulation was necessary, as there was considerable shock. The urine on March 10 showed the presence of albumin and casts. The patient was then having numer-

ous small involuntary liquid stools. There was a large amount of exceedingly foul discharge from the right iliac wound, and it was necessary to wash out the excluded colon several times a day with a long rubber tube passed as far as possible into the lumen of the gut. On March 19 the Murphy button was extracted from the rectum with forceps. The patient's general condition at this time was greatly improved although she still had 10 or 15 stools a day. On March 26 the number of stools had fallen to about 9 a day.

I was now surprised to learn that the irrigation through the colostomy wound seemed to act as an enema, the patient insisting that the water injected through this wound was passed by the rectum. Irrigations with methylene-blue solutions showed that this indeed was the case. At first I could hardly believe such a thing possible but afterwards came to the conclusion, in the face of the stubborn fact itself, that a tract of suppuration must have formed between the site of the anastomosis and the invaginated end of the sigmoid. It certainly was an example of the wonderful way in which nature tries to reestablish normal conditions.

The patient now rapidly improved. The discharge from the colon became less and less and I was perfectly willing to consider the case ended so far as I was concerned. I had been cauterizing the visible mucous mem-

brane of the colon in the right iliac region, using the Paquelin cautery with the hope of causing the formation of cicatricial tissue so that there would be no annoyance from the wet everted mucous membrane. The patient insisted, however, that she would not be satisfied until the opening was closed. Knowing that the only way which promised success would be the total extirpation of the colon and the stump of the ileum, I hesitated to gratify her wish. Still, on considering the matter, I believed that this operation might, after all, be feasible in view of the fact that the colon was already, so to speak, out of commission. Then too, the mucous membrane had not atrophied and still bled at the lightest touch so that I was obliged to consider the probability that it would become the seat of malignant degeneration. I therefore consented to operate once more.

On June 15, 1900, a median incision at the site of the old sear was once more made. The first point sought out was the region of the anastomosis between the ileum and the sigmoid. I found here a fibrous cord, over an inch long, connecting the invaginated end of the sigmoid with the point of anastomosis. On dividing this a central channel was found which explained the appearance of the methylene-blue solution in the stools after its injection into the colon. This cord was cut off

Fig. 4.

Fig. 5.

Fig. 4 (a.) Invaginated end of ileum. (b) Anastomosis of ileum with sigmoid. (c.) Invaginated end of sigmoid. Fig. 5. The shaded portion was removed in one piece; arrows show direction of traction to evert stump excised at the final operation.

flush with the anastomosis, the place was inverted into the intestine and the opening closed with a few Lembert sutures. The line of the button anastomosis was very perfect and there was no induration. Beginning now at the sigmoid flexure numerous ligatures were passed through the mesocolon, the extirpation coincidentally proceeding. The patient's condition became somewhat critical, and in order to save time I was obliged to take large masses in the grasp of each ligature. At about 2½ inches from the colostomy wound I cut off the colon and removed it from the abdomen. A long forceps was now inserted from without through the colostomy wound, and the end or stump of the colon was grasped and withdrawn thus everting the stump. I tried to treat the stump of ileum, which had shrunk to about 2½ inches in a similar manner, but was unable entirely to evert it. With one hand in the abdomen I guarded against possible protrusion or prolapse of a loop of intestine into the funnel of the everted colon. At the same time I ligated with a heavy piece of silk the entire everted stump, cutting away the external redundancy. The median incision was now closed by sutures, a gauze drain being left in its lower angle and another passed down to the right flank where there had been some bleeding. The patient reacted well after the operation, but on the following

day she developed a pneumonia of the right side at the base. It yielded to treatment. There must have been infection at this operation, for an abscess formed beneath the median wound through which foul-smelling pus and apparently fecal matter but no gas was discharged. On the fourth day I encountered another surprise in the appearance of a distinct fecal discharge from the right iliac wound, the ligature having come away. This I was at a loss to explain. My finger in the abdomen had carefully guarded against prolapse of the intestine at the time the ligature was tightened and yet I could only account for the appearance of feces at this point by assuming the prolapse of a knuckle of intestine which was strangulated by the tightening of the ligature. On June 27 there occurred a spontaneous rupture of a large abscess at the site of the old left colostomy wound and the evacuation of the pus was accompanied by the discharge of a piece of gangrenous mesocolon with 5 or 6 chromicized catgut ligatures still in place upon it.

With varying fortunes all the wounds finally healed with the exception of the fistula in the right side. Realizing that this would not close without another operation I excised the entire cicatrix and fistula on October 6, expecting naturally to come upon the loop of small intestine which it was my intention to excise, anastomosing the ends. What was my astonishment to find a single piece of intestine, *not a loop*, passing directly to the fistula. A large probe passed in at the fistula was seen traversing the lumen of this intestine. The intestines were matted together in many places, but it was possible to explore easily for fully 10 inches along this gut without encountering adhesions. Not wishing to place the patient in further danger for the sake of satisfying my curiosity and knowing that she had passed but a very small portion of the daily quantity of feces through the fistula, I merely cut off this piece of intestine and invaginated it, then closed the wound by suturing, with drainage.

The result has been most gratifying. All the wounds are now closed, and I believe I have finally seen the last of this most interesting but perplexing case. I am absolutely unable to explain the condition of things present at the final operation.

The patient was shown at a meeting of the Section on Surgery of the New York Academy of Medicine on January 14, 1901. At that time there was a pinhole sinus in the right iliac region, but it has now (April 16) closed. The patient is in excellent general health and has 2 movements a day. The stools are usually semi-solid but are sometimes formed.

Malaria.—For a long time many parts of Italy have been infested by the severest forms of malaria. Naturally the scientists of the country are greatly interested in the banishment of the disease, the responsibility of the mosquitos for which is generally conceded and a bill recognizing this fact is now under serious consideration. It provides for the declaration of affected zones and free distribution of quinin to the poor until the extermination of the mosquitos is accomplished. Government departments or contractors responsible for the execution of public works must make free distribution of quinin and must pay indemnity if a person dies or becomes disabled while engaged on such works. Precautions must be taken against the entrance of insects to habitations of public employes within the malarial zone from June to the end of December, and a reward not to exceed \$200 is offered proprietors and manufacturers who do the same for houses of their servants and the peasants.

THE VALUE OF INTESTINAL ANTISEPTICS WITH SIMPLE ASEPTIC PADS IN OBSTETRIC PRACTICE.

BY

HARRIET E. GARRISON, M.D.,

of Dixon, Ill.

That antiseptics are necessary in obstetrics is beyond question, but how they shall be used is still a matter for discussion. Some clinical experiences, which came to me years ago, led me to change my mode of procedure.

CASE I.—On February 6, 1888, I was called to deliver Mrs. F. in her second labor. She belongs to a very intelligent family, and was nursed by her mother. The parturition was unusually easy. At the first indications of labor, the husband came six blocks for me with his horse and sleigh; and I returned with him immediately. When I reached the patient, the head was distending the perineum; and the next uterine contraction delivered the child. The placenta followed in a few minutes. The hips were elevated and the genital tract cleansed with a bichlorid douche, 1 to 3,000. The soiled linen and bedding were replaced by dry and warm. The patient, bright and smiling, was placed in a comfortable posture, and left in as favorable a condition as it has ever been my lot to leave an obstetric case, no shock or exhaustion.

The first two days of the puerperium were uneventful beyond a couple of nervous shocks: the first, produced by her child (aged 2) having been supposed to have swallowed a penny; and the other, by the servant reporting the house to be on fire; also, the weather became exceedingly cold, so that her room was very uncomfortable. She was given every day, as a douche, a quart of warm water containing 1% of carbolic acid. The third day I ordered a saline laxative to be followed by an enema if the laxative did not produce a free evacuation. The fourth day I saw the first unfavorable symptom; the pulse was 90, temperature 100° F. As the patient felt well, and there had been no chill, neither was there any distension or soreness through the abdomen, I attributed the slight febrile action to want of evacuation of the bowels through failure to give the enema as directed. I ordered the patient to be moved into a comfortable room, as she thought she might defecate if she could assume a sitting posture; and if there was not a free movement, to give an enema of turpentine emulsified in soapsuds. On the morning of the fifth day, I arrived just after she had been carried into a comfortable room. The other directions had not been followed. There had been no chill, but the patient said she felt very sick. The temperature was 105° F., pulse 120. There was no distension nor tenderness over the abdomen; the lochia, though scanty, was of good color and free from odor. I asked for a consulting physician and, while waiting, gave a turpentine enema which produced a free evacuation of such material as might be expected from a patient whose bowels had not moved for 5 days. A part of the feces was hard, but the remainder was soft and its appearance showed that the saline laxative had passed through the bowels.

Every day, as is my custom, I had carefully palpated the abdomen and had given gentle massage to the uterus and had found nothing abnormal except, on the fourth day, a distended bladder which was emptied naturally as soon as I called attention to the condition and before I began the massage. My consultant pronounced it a case of septicemia and proceeded to wash out the uterus. To his expressed surprise no debris of any kind was brought away by the return current. After the fresh blood was washed out the water returned as pure as it entered. As the irrigation produced no change in pulse or temperature, my consultant directed antipyrin to be given in 10-grain doses every 4 hours, to be followed in 1 hour by quinia sulf. in 5-grain doses every 4 hours and brandy *pro re nata*. I remained constantly with the patient until a trained nurse could be secured, which was in 36 hours. After the third dose of antipyrin the temperature dropped to 102° F., but before 4 hours, it began rising again. After the fifth dose she sank into a stupor with stertorous breathing from which she was aroused with difficulty, but under free doses of brandy it soon passed.

During the time I was detained, as irrigating the uterus produced no change and the antipyrin only temporary change in temperature, satisfying me that we had not found the source of the irritation which caused the high temperature, I spent a good deal of time in carefully examining the abdomen. As there was no tenderness, this was not disagreeable to the patient. At last I found in the sigmoid flexure, which was back of the uterus, a mass of irregular shaped lumps about 1 inch in diameter. By gentle movements I succeeded in filling the lower rectum with these, and by an enema and digital effort brought away a quart. They proved to be masses of hardened, desiccated feces, and, from their blackened appearance, they must have been there some time. The patient afterward admitted that she had been very careless, and, although repeatedly cautioned, had not had a copious movement of the bowels for several weeks previous to her confinement, but had expelled every day a few hardened lumps. That there was a passage through or beside this mass in the sigmoid flexure is proven by the appearance of the saline laxative in the first evacuation. By repeated efforts and 2 grains of calomel, in 24 hours from the time the mass was discovered, the bowels were free and the emperature soon dropped to normal. In 2 days there was another rise which proved to be due to a small abscess which formed in the cellular tissue to the right of the uterus, which discharged by the vagina in 10 days, and which I thought was due to some of the irrigating fluid having passed through a patulous fallopian tube. The patient soon recovered and has since borne 3 children, one in 20 months after this illness.

This experience caused me to study intestinal antiseptics in its relation to the puerperium. Now, when called to a case of obstetrics, I see that the intestinal tract is rendered aseptic as soon as possible. If you are not sure that the colon, the sigmoid flexure, and the rectum are empty and there is not time to clear them with an antiseptic enema before delivery, then begin to cleanse them as soon as possible after delivery. For this purpose the saline laxatives are preferable on account of their antiseptic action; the best of these is potassium et sodium tartras. Begin with dram doses within 4 hours of delivery and give a dose every 4 hours. The laxative may be aided by an enema if the bowels do not act in 24 hours. If the bowels have moved freely during labor, allow 12 hours to elapse before giving the saline, and if the bowels have not been acted upon freely or the tongue is foul, give a pill, cathartic comp. U. S. P. within 24 hours of the delivery. The pill will relieve the engorgement of the liver which usually accompanies the last weeks of pregnancy. In addition to these precautions, the gastrointestinal tract is further rendered free from danger by giving other antiseptics. So far I have found a 2-grain powder of salol and a 2-grain capsule of quinia sulf., to give the best results. The salol in tablet form is just as good if given so that its antiseptic action begins in the mouth. I begin giving the salol and quinin as soon as labor terminates and give them every 4 hours during the day, for 5 days. The *primæ viæ* being now in good condition we are sure of a supply of pure blood and that this is the best destroyer of virulent germs there is a concurrence of opinion among all authorities.

A free flow of pure blood is nature's way of freeing the genitalia of toxins, therefore, what is now necessary is to maintain a proper flow and prevent it being dammed anywhere internally to form a culture medium for germs. To do this a binder must hold the uterus in proper position so that the cervix does not press anywhere upon the vaginal wall thus allowing the os to

become tamponed with a blood clot; and it must be free from constrictions. To keep the os patulous I use, if there are signs of obstruction or not sufficient flow of clear blood,

R
 Fl. ext. cimicifugae racemosae.
 Tr. gelseminii āā 5ij
 Sig. Two drops every hour until the flow is normal.

All that now remains to be done is to keep the external genitals aseptic. They should be bathed with hot boiled water and covered with a soft cloth made aseptic by being freshly roasted. This is an antiseptic measure so simple that it can be carried out among the most unfavorable surroundings as any cloth can be rendered aseptic by prolonged roasting in an oven or over any fire; even the most smoky kerosene lamp will do. And the most delicate patient enjoys the soothing influence of a hot, freshly roasted napkin. Four of the cases in which this treatment was used are here recorded :

CASE II.—Mrs. S., primipara, aged 32, delivered with forceps December 26, 1892. The labor was tedious from the large size of the child, 13 pounds, and from the short cord, 20 inches, which was wound around the child's neck thus dragging upon the placental attachment at every pain, making the uterine expulsive efforts weak and ineffectual. The broad shoulders of the child tore the perineum through to, but not into, the rectum. A bichlorid douche 1 to 3,000 was given and then 7 stitches were placed so as to restore the perineum. Absorbent cotton dusted over with iodoform was placed over the laceration and over this a pad made aseptic by roasting, these to be changed whenever soiled. My consulting physician agreed with me in directing the nurse not to use the douche unless the lochia became foul, but to confine her attention to the external genitals. While observing the case I noticed that the absorbent cotton became so soon saturated with lochia as to be an undesirable dressing. I then tried various other materials, and finally decided that a very fine brand of ordinary roll cotton, freshly roasted and dusted with iodoform comes the nearest to an ideal dressing of anything yet tried for a newly repaired perineum. It does not absorb the lochia, but if properly applied, obliges the discharge to pass into the pad above the cotton, thus keeping the wound dry. It is an easy matter to instruct a nurse how to prepare and use it. By the advice of my consultant I allowed the stitches to remain 11 days. One stitch caused an abscess which soon healed. The perineal wound had united by first intention and there were no other complications during the puerperium.

CASE III.—Mrs. B., primipara, aged 28; delivered August 27, 1894, with forceps; child, a girl, weighing 11 pounds. Through some mistake when I reached the case, 3 miles from my office, my obstetric bag was destitute of antiseptics and labor too far advanced to wait for them. By the time the bowels were cleansed with an enema, the head was pressing the perineum. It remained in that position so long that, fearing it would injure the body of the perineum, I applied forceps and completed the delivery. Although I had instructed an attendant to make gentle pressure over the contracted uterus, when I was ready to deliver the placenta, I found the fundus uteri above the umbilicus. A little watching, with my hand gently kneading and pressing the uterus, showed me that the longitudinal muscular fibers were not contracting and that the circular fibers were squeezing the placenta into the long, narrow uterus reaching from near the pelvic outlet to above the umbilicus. Not being able to correct this condition by external manipulation, I cleansed my hands with soap and hot water, anointed my right hand with homemade lard, poured brandy over this, and then passed it up to the fundus internally. This was no easy task, as the cavity was so narrow and was filled up by the placenta. The hand had to be formed into a cone as for dilating the cervix, and kept in constant contact with the left uterine wall, allowing the fingers to gently feel their way between the

wall and placenta. After reaching the fundus, the fingers were flexed above the placenta and withdrawn. In this way the whole interior of the uterus was swept clean and the longitudinal fibers stimulated to contract. The parts were then cleansed by a hot douche of solution of sodium bicarbonate, the perineum was repaired with 4 stitches; the favorite dressing applied, and the puerperal regimen laid down in this paper ordered. The perineum united by first intention and in 2 weeks the patient was assisting her mother, in whose house she was staying, in the housework. In a month she returned with her baby daughter to her home in Chicago.

CASE IV.—Mrs. T., delivered January 22, 1895; primipara, child weighed 10½ pounds; perineum ruptured to the second degree, requiring 3 stitches for repair. The only thing noticeable about the case was entire lack of attention to the parts by the nurse after the first day. Every morning, as is my custom (since, in one of my cases, a trained nurse washed out one of the lower stitches, allowing the lochia to form a sinus through the repaired perineum, which was difficult to heal), I see to the cleansing of the parts around the wound, only requiring the nurse to apply fresh dressing whenever it becomes displaced or soiled. When I visited Mrs. T., I never found the wound protected by dressing, and no amount of remonstrance on my part or that of the patient could induce the nurse to replace the dressing when it was removed for urination; and as she was a member of the family I could not dismiss her. But by faithful dressing the first day and keeping the bowels free and cleansed with potass. et sod. tartras, the wound healed by first intention and Mrs. T. convalesced rapidly.

CASE V.—Mrs. B., primipara, aged 19, delivered December 2, 1899, after 14 hours of labor. Mrs. B. was small, weighing 98 pounds, while the child weighed 12 pounds. Slight laceration of cervix, perineum unruptured; was under the influence of chloroform for the last 4 hours, never to complete narcosis. Mrs. B. had been a chlorotic girl and had enlarged lymphatic glands at the time of confinement. As she was very much exhausted, nothing was done but to remove the soiled clothes and make her comfortable. The nurse was directed to apply a binder as soon as she was rested. As I was exceedingly busy in one of the smallpox epidemics, now so common, having 10 cases on my hands when called to attend Mrs. B., I did not see her again for 22 hours. As she had not urinated, I made an examination to ascertain the cause, and found protruding from the vagina a large clot which completely filled it and had pushed the uterus up to the umbilicus. The uterus was enlarged as though it was also distended by a clot. No binder had been used. I cleaned the external genitals, drew 10 ounces of normal urine, applied a binder from the os pubis to above the fundus uteri in such a way that it would steadily press downward on the uterus, and gave quinia and strychnia to stimulate uterine contraction, with Dover's powder to prevent closing the os. In 2 hours the clot was expelled, in 7 hours she urinated, and the next morning the bowels responded freely to the cathartic pill which had been given the previous night. As she was in good condition and I was busy with cases of the epidemic I thought best not to see her again. Continued the saline laxative to be assisted by boiled water enema if necessary to keep the bowels free. Salol and quinia ordered. Lactation well established. Seventy-two hours after delivery she was taken with severe rigor. I responded promptly to the telephone message, to find her livid, with a pulse of 130 and temperature of 105¼° F., lochia scant. Her bowels had not moved since my last visit; enema had not been given. I immediately gave her 5 grains of calomel; ordered a normal salt enema of all the water that could be used, spts. ether. nit. ¼ teaspoonful in water every 2 hours, the vagina to be kept clean by alternate douches of bichlorid 1 to 5000 and permanganate 2% solution every 12 hours. The enema produced free evacuation and the temperature dropped to 102° F. In 12 hours there was free action of the calomel with temperature 99° F. Toward evening there was a slight rise in temperature, but by morning it was normal and remained so throughout convalescence. Lactation was never disturbed. Three weeks after delivery an examination by speculum showed a little endometritis with a shallow laceration in the cervix. A few applications of a 10% solution of ichthyol in glycerin healed both and the patient has since been well.

To conclude: In all obstetric cases have a normal contracted uterus with a patulous os which does not rest against any part of the vaginal wall that pure blood may constantly flow over the endometrium and vagina cleansing them from all bacteria. Bathe the vulva with antiseptics and keep it covered with an aseptic pad. Have a *prima via* free from obstructions and constantly cleansed with antiseptics.

If this regime is carefully carried out 99% of the cases will make an uninterrupted recovery, and vaginal and uterine douches should be omitted until near the close of the puerperium when they will be agreeable to the patient.

GASTROPTOSIS.

BY

ALEXANDER MCPHEDRAN, M.D.

of Toronto, Can.

Professor of Medicine and Clinical Medicine,
University of Toronto.

This condition is so frequently encountered and is in many cases accompanied by such marked discomfort that its consideration is of much importance. With the displacement of the stomach there is also always displacement of some of the other viscera, sometimes of all of them, general splanchnoptosis. It occurs at all ages and in both sexes. In a boy of 7, examined since January 1, 1901, the greater curvature of the stomach was a little below the umbilicus and the right kidney could be easily palpated during inspiration. He was rather anemic, had an irregular appetite, and was not vigorous. In his case the position of the stomach may have been congenital.

In regard to gastroptosis 2 errors are common: first, the opinion that the condition is infrequent; and second, that when it does exist, it must necessarily give rise to grave disturbance, and form part of that medley of symptoms known as Glénard's disease. That the condition is very common any one can verify for himself by careful examination of patients presenting symptoms of malassimilation with or without digestive disturbances. Not infrequently, ptosis of the stomach is met in persons presenting no such symptoms, just as many persons have prolapsed kidney without any discomfort arising therefrom.

The symptoms may be local or general, or, more commonly, both combined. Local symptoms arise from digestive disturbances, especially from gastric motor insufficiency with consequent prolonged lodgment of food in the stomach. In most of these cases there is also excessive secretion of HCl, causing epigastric distress, acidity, flatulence, and general depression. These symptoms may be very slight in degree or they may be severe, at times causing much distress. In these cases relief is obtained by stimulating gastric peristalsis, so that the stomach is emptied before each recurring meal; by suiting the diet both as to quality and quantity to the powers of the stomach; and endeavoring by means of massage, exercises, suitable medicines and hygienic conditions, to restore the stomach, as well as the general physical state, to a normal condition of function. The

following case may be briefly cited to illustrate these statements:

M. E. S., aged 51, 5 feet 8 inches in height, but only weighing 128 pounds, had been ailing for some years with epigastric distress, flatulence, debility, irregular appetite and constipation. Five hours after a light breakfast "splash" was easily demonstrated in the epigastrium. The tube was passed and 5 ounces of grumous material containing pieces of white-of-egg and remains of bread were removed from the stomach. The stomach was inflated and the lesser curvature found to lie below the umbilicus, as shown in Fig. 1. HCl was present but in deficient quantity. The right kidney was easily palpable. The abdomen was almost flat so that an abdominal support would be of little use. His diet was restricted to 1 egg and a piece of toast for breakfast, a glass of warm milk at 11 o'clock, a little tender meat, or fish, and 1 vegetable for luncheon, a cup of soup or fluid beef at 5 o'clock, and a dinner at 7 o'clock similar to the luncheon. The abdomen was well massaged morning and night after the patient drank a glass of hot water. This was followed by systematic exercise of all parts of the body, and especially of the abdomen. Strontium bromid was given before meals and strychnin with some antiseptic such as resorein, bismuth naphtholate, sodium salicylate, etc., after

Fig. 1.

meals. As soon as the epigastric distress was relieved dilute hydrochloric acid was substituted for the bromid. He improved satisfactorily and in a few months his weight was 150 pounds. The lesser curvature of the stomach was raised somewhat above the umbilicus, but care as to diet was necessary to prevent retention of food in the stomach, as shown by the splash.

When constitutional symptoms are marked, the condition is really one of neurasthenia with symptoms of digestive disturbances predominating. In the treatment of these cases the patience of both patient and physician is certain to be taxed. The treatment is that of neurasthenia, plus such measures as are necessary to correct the digestive derangement. The latter can often be overcome and the digestive function restored to a fair degree of efficiency long before the symptoms referred to the stomach are relieved, or the general neurasthenic condition materially improved. The following case is a good illustration of the truth of these statements:

Mrs. P., aged 38, suffered for many years with attacks of neuralgia of the head of great severity, often accompanied by

nausea and vomiting. In the intervals there was always some, often much, epigastric discomfort. She slept badly, the appetite was poor and the bowels were constipated. She is thin, sallow and nervous. She has been married 11 years but has had no children. When she first came under observation considerable residue was found in the stomach several hours after food was taken and always without any trace of free or combined HCl. Test-meals of several kinds were successfully given and the tube passed at varying intervals afterward; in no instance was there any HCl present. The stomach on inflation was found prolapsed, as in the accompanying diagram. The right kidney, as is usual in such cases, was also prolapsed (Fig. 2). She was directed to have systematic exercises short of fatigue, abdominal massage, several hours rest in the fresh air daily and nutritious food of small bulk. On awakening in the morning, and likewise on retiring at night, she was ordered a glass of hot water followed by abdominal massage for a few minutes. Her diet was similar to that of the case already detailed, and with her food she was to take common table salt freely in order to furnish the Cl element of HCl.

Dilute hydrochloric acid before meals to stimulate peristalsis, and after meals to aid digestion, should have been useful,

Fig. 2.

but it caused distress. Most benefit was obtained from strontium bromid with resorcin before meals, to act as a sedative and disinfectant. Strychnin, arsenate of iron and ichthalbin were given after meals with benefit. The digestion improved so that even with the recurrence of neuralgic attacks and epigastric distress, the stomach, on passing the tube, was found to be empty. The general neurasthenic condition improved fairly and she was then sent to the Welland Sanatorium, at St. Catharines, to undergo a course of salt-baths and massage.

Similar cases might be added indefinitely but the foregoing serve to illustrate the object of this short paper.

It is usual to direct a well-fitting abdominal support for such cases; if the abdomen is prominent, in which condition the walls are relaxed, such a support does good and in many, gives a great sense of relief. It supports the abdominal contents and tends to prevent further prolapse. In many cases, however, the abdomen is flat, or even retracted. In these a support is of little, if any, service. In fact, in a number of cases it proves irksome. In all cases, probably massage and suitable exer-

cises of the abdominal muscles constitute the most effective means to relieve the symptoms and restore the stomach to healthy function. By these means the circulation in the abdominal viscera is improved and peristalsis stimulated, consequently renal excretion is increased and the processes of digestion and assimilation improved.

The prognosis in gastroptosis is fairly illustrated by the following case:

J. R., aged 27, a draughtsman. Last autumn he was very neurasthenic from overwork, and was thin, anemic and much depressed. The stomach was prolapsed so that the greater curvature was 3 inches below the umbilicus, as shown both by the gastrodiaaphane and inflation. There was a moderate degree of hyperacidity. The treatment consisted in a regulated diet similar to that directed for M. E. S., massage exercises, out-door life without fatigue, and strychnin with antiseptics after meals. He worked hard all winter supervising the repairs of an electric road. On examination this spring, the stomach was found to be above the umbilicus and its digestive power much improved. His general condition is good, although he remains thin.

The following conclusions may be offered:

1. Gastroptosis frequently exists without giving rise to any discomfort. So long as the functions of the stomach are performed efficiently no symptoms will arise from its abnormal position.

2. The symptoms of gastroptosis are due to the protracted retention and decomposition of food in the stomach with the local irritation and constitutional poisoning resulting therefrom.

3. In the condition known as Glénard's disease the gastroptosis or splanchnoptosis plays only a part, often a minor one, in the production of the symptom-group. In not a few instances the splanchnoptosis is rather the result than the cause of the condition.

PNEUMONIA.—A HISTORICAL REVIEW OF ITS TREATMENT.

BY

WILLIAM CRAWFORD JOHNSON,

of Frederick, Md.

I shall endeavor in this paper to present a summary of the treatment of pneumonia-lung fever, or as Hippocrates called it, peripneumony. As this paper is intended merely to open a discussion as to treatment, I will review very briefly the various modes and medicines suggested by medical writers.

Hippocrates, who lived about B.C. 3450, treated pleurisy and peripneumony in the same manner: by expectorants, errhines and laxatives, not checking the fever until the seventh day, putting the patient in the bath on the fourth and seventh days, anointing with oil on the fifth and sixth days; from the fifth to the eighth the most active expectorants to be used, the food to be of a fatty and saline quality, with wine of a rough character. The actual cautery, cups and elaterium are mentioned as of use in certain conditions.

Galen, who lived to the age of 100 years, and died about A.D. 230, adds nothing to our knowledge except that he maintains the importance of bloodletting, in opposition to Erasistratus, who opposed it violently.

These views have prevailed down to the present time with little variation. Thomas, in his "Modern Practice of Physic" (1822), states the case thus :

"As in many cases of peripneumony the patient is destroyed in the course of a few days by the passage of the blood through the lungs being obstructed, the antiphlogistic plan, in its most rigorous extent, ought to be adopted on the very first attack of the disease. If the difficulty of breathing and pain are not relieved while it flows, the bleeding should be continued until the patient turns pale and seems likely to faint, as one copious evacuation will be far preferable to repeated small bleedings. If a powerful impression be produced by the abstraction of a large quantity at first, the disease is suddenly corrected and will often, in the course of a few hours, be converted from a most violent pneumonia to a simple catarrh."

This quotation from Thomas should be recalled when at the close of this paper I present the latest ideas upon the subject.

Little new is gleaned by a perusal of writers down to 1840, their efforts being confined to discussions as to which remedies of the classes before enumerated are to be preferred and as to the amount of blood to be let. Laennec cautions "that in every case the more feeble the pulse the less indication for venesection," and prefers tartar emetic to bleeding. Dewees—1830—says "perhaps there is no disease that attacks the human body in the treatment of which there is so much coincidence in the opinion of all practical writers." He names the principal remedies as: (1) Bloodletting, both general and local; (2) general evacuations; (3) blistering; (4) alteratives; (5) tonics; (6) large doses of tartar emetic.

Marshall Hall (1839) says, "if bleeding be done early, if the patient be placed perfectly upright and bled to incipient syncope, much blood flows and much benefit follows."

About 1845 mercury and opium were advocated in inflammations of the lungs, especially in the combination of calomel and Dover's powder. In the second stage of pneumonia, digitalis, squills and alkaline mixtures were used; in the third stage, carbonate of ammonia, lobelia, ether and camphor were advised.

In 1855 Dr. George B. Wood gives minute directions as to the use of previously known remedies, and refers to a paper by Varentrapp, of Frankfort, Germany, who employed chloroform by inhalation as the main or exclusive remedy, with remarkable success; having lost only 4½%, while of cases previously treated by him in the ordinary mode he lost 15%. About 60 drops were placed on compressed cotton and the vapor allowed to enter the lungs for 10 or 15 minutes, and the dose repeated every 2, 3 or 4 hours. It was not permitted to produce unconsciousness.

In the '60s and early '70s quinin, aconite and veratrum viride had the call. In the '80s the Germans introduced the cold-water compress and the wet pack. Herrick in "The Reference Handbook of the Medical Sciences" (1887) advocates, as the result of 20 years experience, blisters in croupous pneumonia. Juergensen, in Ziemensen's Cyclopaedia, cautions against collapse of the lobules from catarrhal accumulations in the catarrhal form of pneumonia, suggesting forced inflation of the lungs by pouring a small stream of cold water on the occipital region over the medulla oblongata, which induces violent respiratory efforts. In threatening pul-

monary edema, rapid emesis by a hypodermic of apomorphia is desirable.

Bartholow (1890) advocates local or systemic bloodletting as of the greatest value; he also values highly following this with calomel as an antipyretic, and mustard plasters as local counterirritants. He quotes Juergensen as to the value of the cold bath and quinin as antipyretics. In conclusion he emphasizes the evil effects of cardiac sedatives during the stage of exudation and of coagulation of the exudate, and says that the administration of veratrum viride, digitalis, aconite and tartar emetic can only add to the burden of the heart, already laboring in consequence of the stasis on the venous side, and lack of blood on the arterial side. Paralysis of the heart is one of the imminent dangers because of this state. It is true that a continued high temperature contributes to bring about this state of paralysis of the heart, but we possess the means of correcting this by the administration of quinin, and by the cold wet pack or cold baths.

Anders (1900) approves of venesection in sthenic cases of lobar pneumonia, urges cardiac stimulants, suggests saline injections to increase the blood pressure, and cold baths to overcome high temperature; he speaks approvingly of the antiseptic method, preferring carbolic acid, thymol or mercuric chlorid.

In the *Medical News* for December 16, 1899, Andrew H. Smith, of New York, published an article upon "The Treatment of Pneumonia as Based upon Views as to its Pathology." In this he restricts the word pneumonia to what is variously designated as lobar, fibrinous or croupous pneumonia. He argues that there is not a pneumonitis or local inflammation, but that all the phenomena of the disease center in the colonies of bacteria growing in the air cells; that, therefore, the problem is, first of all, to arrest this growth. These facts are established: first, that the life of the organism is short, not exceeding 10 or 12 days in artificial cultures; second, that it is very difficult to cultivate at all, *i. e.*, easy to kill, except under most favorable environments; third, the probability of successfully inhibiting the action of a germ through the influence of an agent diffused in the blood is greatly enhanced if the germ is located in the lung, as the whole mass of the blood passes through the comparatively small pulmonary circulation every time it passes the vastly greater systemic circuit, hence any substance in the blood comes into much more intimate contact with a germ in the lung than it would with a germ placed elsewhere, and the assault is proportionately concentrated and energetic. This, he claims, is why calomel is of value, not for its antiplastic, but for its antigermic effect. The article continues with a plea for the use of creasote with its compounds, or the salicylates, as germicides. These are to be given in large doses and pushed to the point of intolerance. Within 2 months after this paper appeared I had several cases in which I tested this treatment, with most happy results, using the salicylates for 24 hours, then pushing guaiacol and creasote in combination with liquid peptonoids.

In conclusion I will ask you to note that from the most remote ages to the present time we have the same verdict, that early and free bloodletting is of great clin-

ical value, its drawback being the weakening effect upon the patient. Recollect that modern medicine counteracts excessive bloodletting by injections of normal salt solution, and combine these in your cases of pneumonia and you have theoretically a valuable method of treatment. So far as I can ascertain this has been suggested first by Dr. William Porter, of St. Louis, in a communication published in the *Philadelphia Medical Journal* for December 15, 1900. Recalling the value of venesection and stating that within the last year or two injections of normal salt solution have been used in cases of lobar pneumonia with advantage, he continues, "It is a fair proposition that these two procedures can be combined, and while by venesection we attempt to relieve the tendency to right-sided heart failure and remove a certain amount of toxin-laden blood, we at the same time, by means of the salt solution, increase the pulmonary circulation, accomplish dilution of the toxins that remain and increase the oxygen-carrying capacity of the blood."

He reports an unusual case of marked lobar pneumonia of the right lung with threatened heart-failure, complicated by violent delirium tremens; the patient was bled to the extent of 18 ounces the day after admission, and normal salt solution of 24 ounces injected. No other treatment except strychnia was used and the patient made a good recovery. The salt solution used is as follows:

R	
Sodium chlorid	30 grains
Potassium chlorate	60 grains
Sodium sulfate	60 grains
Sodium phosphate	40 grains
Sodium carbonate	60 grains
Distilled water to make	6 fluidounces.
Mix. One part of this solution to 60 of distilled water.	

In concluding Dr. Porter expressed the hope that further investigation may justify this method as an *addition* to the treatment of pneumonia, not claiming it as a substitute, saying that the pathologic conditions outlined demand the greatest care in the ordinary methods of promoting elimination by the skin, bowels, and kidneys, and above all, of heart-support. He says the value of oxygen in cases of greatly impaired aeration is not sufficiently understood and that it seemed to be especially useful after the injections of the salt solution.

Dr. Porter's suggestions seem to me most valuable and I shall await the clinical reports of this method with the deepest interest.

ADDENDA.—Since writing the above article I find the credit of inaugurating the use of saline infusion belongs to Dr. Clarence A. Penrose, of Baltimore, who reported his case in *Johns Hopkins Hospital Medical Bulletin*, July, 1899. Dr. Penrose, in a recent letter confirms his report of 2 years before, endorsing this method of treatment most highly.

The Chilton Law.—The amendment to the bill for regulating the marriages of the insane and epileptic in Minnesota as it finally passed the Legislature, strikes out the penalties of fine and imprisonment and the clause requiring a physician's certificate. As it now reads it prevents any woman under 45 years of age or man of any age from marrying if afflicted with the disabilities the act mentions. The officers issuing the licenses are charged with the enforcing of the act, and any failure in this respect is made a misdemeanor.

PRACTICAL THERAPEUTICS

Under the charge of

A. A. STEVENS,

Assisted by

L. F. APPLEMAN.

The Treatment of Aortic Aneurysms.—Considering the very imperfect success which has attended the treatment of aortic aneurysms by the subcutaneous injection of gelatin, Hunner's recent review of the Moore-Corradi method of treatment (*Johns Hopkins Bulletin*, November, 1900,) is worthy of a most careful study. In 1864 Charles H. Moore, of the Middlesex Hospital, first suggested the introduction of wire into the sac, and subsequently Corradi suggested as an improvement the addition of electrolysis. With the combined method (Moore-Corradi) there have been treated 23 cases, 17 thoracic and 6 abdominal. Four of these, or 17%, 3 thoracic and 1 abdominal, were apparently cured; 9 cases, or 39%, attest the value of the operation by amelioration of the symptoms, and prolongation of life; and in 10 cases death was probably hastened by the treatment. The best results are obtained with fine wire (No. 27) of silver alloy (75 parts of copper to 1,000), or with gold wire (No. 28 or 30). In the successful cases no more than 10 feet was used, but it is probable that in some instances 20 feet might be employed with advantage. The strength of the current varies from 10 to 100 ma., and the duration of electrolysis from 30 to 60 minutes. The weaker currents, however, seem preferable, and the stronger currents above 70 ma., not altogether free from danger. In cases of thoracic aneurysm a general anesthetic is not required, cocain or ethyl chlorid being used locally. The needle is inserted where the sac wall seems nearest to the surface, and as nearly as possible in the direction of the entering current. The chief dangers are from (1) sepsis; (2) the development and rupture of a secondary sac on account of the rapid filling of the main sac by coagulum (apparently this occurred in 6 cases); (3) the entering of a loop of wire into the aorta (this accident occurred in 3 cases); (4) embolic breaking from the sac-wall (probably the cause of death in 1 case); and in abdominal aneurysms the closure of important vessels by the sudden filling of the sac with clot. Failure must be expected if an error in diagnosis be made or a *fusiform* sac is treated (as occurred in 5 cases). General arteriosclerosis should weigh against operation. In view of the gravity of the disease the results so far obtained from this method of treatment must be considered very encouraging, and with improvement in the technic it is highly probable that future reports will present even a more favorable showing.

Calcium Iodate as an External and Gastrointestinal Antiseptic.—Mackie (*Merck's Archives*, February, 1901), after extensive experimentation with calcium iodate as a surgical antiseptic, reaches the following conclusions as to its use: It is an excellent substitute for iodoform, its advantages over the latter being the absence of smell, the checking of fetor, the prevention of hypergranulation and the inhibition of pus formation. Besides, it can be used in cases where iodoform is inadmissible—for example, in gargles and mouth-washes, and for washing out the bladder, vagina or uterus, etc. Internally the author has used the drug but little, but he can testify from personal experience to its efficiency in checking fermentative processes in the stomach. The average internal dose for an adult is 3 or 4 grains.

Iodipin Hypodermically in Pulmonary Tuberculosis.—Croftan (*Jour. Amer. Med. Association*, November 17, 1900) has used hypodermic injections of iodipin in 27 cases of pulmonary tuberculosis with uniformly good results. Beginning with 1 drop of iodipin dissolved in 30 drops of sterilized oil, the injections were gradually increased 1 drop each day. The dosage was regulated by the symptoms; as soon as an improvement became apparent the dose exhibited at the time was continued for a period of 30 to 60 days; more than 60 minims a day have not been given. No discomfort of any kind was ever caused, no inflammatory reaction observed at the site of the injections,

though some patients received daily injections for a period of 3 or 4 months. In a few cases amelioration of the symptoms was marked from the beginning; appetite improved, the cough and night-sweats grew less severe, and the patients gained in weight and improved in spirits. The physical signs were modified and seemed to show that the process was at least being held in check and rendered latent.

Treatment of Acne Rosacea with Suprarenal Extract.—Munro (*Treatment*, March, 1901), administered suprarenal extract both internally and externally to cause constriction of the dilated bloodvessels in the affected area. Tablets to 5 grains are given at first twice daily, and afterwards increased to 6 daily. If giddiness or nausea occur, the dose is reduced or the drug temporarily discontinued. Locally the extract is applied as a paint by dissolving one tablet in a dram of sterilized water. This is painted on each night after hot bathing. The first application causes smarting and hyperemia, which soon passes off, leaving the parts anemic. In addition to this the face is bathed with hot water, and the following lotion applied and allowed to dry:

℞	
Precipit. sulfur	1½ drams
Zinc oxid	2 drams
Calamin	3 drams
Glycerin	2 drams
Rose water	6 ounces

The object of this is to prevent the formation of pustules. This treatment does not apply to hypertrophic forms of the disease.

The Bromids in the Treatment of Epilepsy.—According to the *Therapeutic Gazette* (November 15, 1900), the effectiveness of bromids in the treatment of epilepsy may be increased by withdrawing the chlorids from the diet, the bromids then taking the place of the chlorids in the system. In a diet of milk, eggs, meat, meal and potatoes, a small amount of chlorids is obtained. If it is necessary to cut the quantity of salt down to the lowest possible measure, an absolute milk diet should be insisted upon. If the bromids are then administered, Toulouse asserts as much as 60 grains of sodium bromid may be given each day, which may be later cut down to 30 grains daily, will diminish the number of convulsions 92% and the number of attacks of vertigo 80%. Further experiment showed that neither the diet nor the bromids alone produced equally good results, and it was proved that in the condition of the body brought about by this method of treatment, small doses of the bromids produce effects similar to large doses under ordinary conditions. Rumpf believes that epileptic attacks are excited by the accumulation of certain unknown products of metabolism, and thinks that the mixture of potassium bromid, sodium bromid and ammonium bromid produces better results than one of the bromids alone in a similar dose.

Intestinal Obstruction Relieved by Atropin.—Holz (*Munch. med. Woch.*, November 27, 1900) reports the case of a man, aged 42, who was suddenly seized with symptoms of acute intestinal obstruction. Opium injections and copious enemas were ineffective. On the fourth day he was given 1-60 of a grain of atropin hypodermically. In a short time flatus was expelled in large quantity, and the bowels moved normally. Demme (*ibid.*) reports 2 cases of intestinal obstruction relieved by injection 1-12 of a grain of atropin in the abdominal wall. Lutgen (*ibid.*) reports another case in woman with femoral hernia. Operation was performed, but the bowel was found normal. One-twelfth of a grain of atropin was then injected into the abdominal wall. Symptoms of poisoning followed, but the obstruction was relieved, and the patient soon made a good recovery. Ostermaier (*Munch. med. Woch.*, December 4, 1900) reports a case of acute fecal impaction in which hypodermic injections of 1-16 of a grain of atropin proved successful on the fifteenth day of treatment. [This treatment is not new; it has been very strenuously advocated by William Murray (Rough Notes on Remedies), who reports several cases to substantiate his claims for it.]

Lumbago.—Masse (*New York Medical Journal*, February 23, 1901) recommends energetic rubbing of the back with the following liniment:

℞	
Lime water	60 parts
Olive oil	60 parts
Chloral	30 parts

Hemorrhoids.—The following suppository is recommended by *La Presse Medicale* for hemorrhoids:

℞	
Aqueous extract of ergot	3-12 grains
Oil of theobroma	1 dram

Ichthyol in Deep-seated Inflammation.—W. T. Slevin (*New York Medical Journal*, March 9, 1901) has obtained excellent results from the following combination of ichthyol and lead iodid:

℞	
Ichthyol, lead iodid, of each	45 grains
Ammonium chlorid	10 grains
Petrolatum, to make	1 ounce

To be rubbed thoroughly into the affected part.

Thyroid Extract in Graves' Disease.—O. T. Osborne, of Yale University (*Journal of the American Medical Association*, March 23, 1901), believes that Graves' disease is due to hypersecretion of the thyroid gland, but that, ultimately, from retrograde changes in the gland, a condition results which is due to undersecretion. This latter state is characterized by increase in the body weight, muscular weakness and mental sluggishness, and is materially benefited by thyroid extract. He suggests the following rule regarding thyroid treatment in Graves' disease: "If there is cerebral excitement, palpitation and progressive loss of weight, thyroid treatment is contraindicated; if the patient is sleepy, apathetic, palpitation is not bad, has no headache and is putting on weight, thyroid treatment will probably benefit the case."

Membranous Enteritis.—M. A. Brown (*Journal of the American Medical Association*, March 23, 1901) reports the case of a woman, aged 28, well nourished, who for 9 months had been suffering with attacks of severe abdominal pain, colicky in character, followed by the appearance of mucous casts in the stools. The treatment, consisting of absolute rest in bed, milk diet and injection of silver nitrate, and later of boric acid, was without the slightest avail. The plan of astringent injections was finally abandoned and daily high injections of olive-oil substituted. These were given late in the morning or early in the afternoon, and were retained without discomfort for from 12 to 24 hours. Improvement was immediate, and in a week she was discharged practically well. Three months later there had been no return of the symptoms.

Heart Tonics.—J. N. Upshur (*Journal of the American Medical Association*, March 23, 1901) states that he has found caffeine, when given with spartein sulfate and lithium benzoate, especially useful in the dropsical conditions of parenchymatous nephritis, associated with secondary heart involvement. He believes that nitroglycerin is contraindicated in the weak heart of typhoid fever, septicemia and surgical shock. He has found opium in commanding doses a most reliable heart tonic in typhoid fever, when symptoms of heart failure and vasomotor paresis were prominent.

Treatment of Thoracic Aneurysm.—Kingston-Fowler (*Journal of the American Medical Association*, January 5, 1901) states that rest and iodid are very efficacious in the relief of pain. If no improvement takes place, he adds a modified Tufnell diet. Seven ounces of solids and 8 ounces of fluids daily are the quantities he has adopted. His experience has not been favorable to the gelatin treatment which he saw carried out in 3 cases. When spasm of the laryngeal muscles exist inhalation of oxygen and the injection of morphin are useful. He believes that the prognosis is better than is generally supposed. He has known several patients to live for years—one for 13 years, another for 6 and another for 9.

17. Two Cases of Scurvy Rickets. CHARLES FISHER.
18. Notes of Surgical Cases. I. G. MODLIN.
19. Intestinal Obstruction Caused by an Adherent Meckel's Diverticulum: Operation: Death. JAMES TAYLOR.
20. A Case of Acute Ascending Paralysis. F. LINDSAY DICKSON.
21. A Unilateral Coccygeal Cyst. STANLEY N. BABINGTON.

1.—Ballantyne makes a strong plea for the establishment of **promaternity hospitals** for the reception of women who are pregnant, but who are not yet in labor; particularly for those patients who in past pregnancies have suffered from one or more of the many complications of gestation, or in whose present condition some anomaly of the pregnant state has been diagnosed. Such an institution would make it possible to investigate scientifically many of the pathologic conditions of pregnancy, such as eclampsia, hyperemesis gravidarum, recurrent abortion, etc. He believes that the investigation of such cases in a promaternity hospital might lead to the adoption of a more scientific method of management than the artificial induction of abortion, which, of course, entails therapeutic feticide. He also emphasizes the more distinctly economic aspects of the case, especially the fact that working women who are able to rest for the last month or two of pregnancy give birth to larger and more healthy infants. [w.k.]

2.—Bland Sutton describes a case of **hysterectomy for fibroids**. The uterus, which scarcely exceeded the dimensions of the first, contained 120 fibroids. Careful examination was made, and even the smallest of these seedling tumors bore a remarkable similarity to the large, fully-developed fibroid; each was globular and one section quite white, so that the contrast in color with the red of the uterine muscle-fiber made them conspicuous objects on the cut surface. [w.k.]

3.—Ranken Lyle discusses the diagnosis, prognosis, and treatment of the various forms of **placenta prævia**. The treatment which has been adopted at the Rotunda Hospital for many years with marked success is as follows: In cases of central or complete placenta prævia, the placenta is perforated with the fingers; version, if necessary, is performed, and a foot brought down; a tight abdominal binder applied; and the subsequent delivery left to nature unless, of course, the continuance of hemorrhage should necessitate slight traction on the

foot. In cases of incomplete placenta prævia under this heading, the treatment, with the exception of the rupture of the membranes instead of perforation of the placenta, is identical. The advantages of version and bringing down a foot are: It does away with the tampon and consequent danger of infection. It allows early operation. It arrests the hemorrhage with great certainty. It gives time for the patient to rally. It gives time for labor pains to set in, and consequent natural dilation of the cervix, and there is less danger of post-partum hemorrhage. During the 10 years 1889-90, 74 cases of placenta prævia were treated in the Rotunda Hospital. There were 4 maternal deaths. The ages varied from 20 to 40, 68% being 30 years of age or over, and 33% being under 30 years of age; 3 cases only were primipara, the others occurring more or less uniformly from the second to the ninth pregnancy, and a few occurring in the tenth, eleventh, twelfth, and thirteenth pregnancies. [w.k.]

4.—Fraser reports a case of **puerperal infection**, the infection having been introduced from an external source during the first stage of labor. The symptoms not abating under medical treatment, the uterus was cureted and irrigated with salt solution; a broad incision was made into Douglas's pouch and enough 20% iodoform gauze applied to fill completely all the parts posterior to the uterus; the uterus also was packed. A pint of normal salt solution was injected into the cellular tissue of the back, and a quart into the colon every 8 hours. There was a marked decrease of temperature in 24 hours and on the seventh day after operation it was normal. Further convalescence was uninterrupted and no evil effects followed. [w.k.]

5.—Slight advances the hypothesis that in a "labor pain" the thin part of the uterine wall (that is, the placental site) is stretched and the separation of the placenta is unavoidable. Accordingly separation will in most cases occur first at the lower pole because of the proximity of the placental site to the thin lower uterine segment. The placenta having been thus freed is next expelled, and in this process of expulsion the membranes are stripped from the wall of the uterus. [w.k.]

6.—Patch reports a case of **ectopic gestation** in which, after opening the abdomen, he incised the tumor and finding it difficult to separate the membranes from the thickened walls, he connected the opening in the tumor to the abdominal opening by sutures, thus allowing the contents of the tumor to be expelled through the abdominal incision. A small body felt at the operation was expelled on the twenty-fourth day after the operation and proved to be a small ovum about the size of a broad bean. The membranes, coming away in pieces, were all finally expelled by the twenty-fifth day when the temperature became normal and the patient made a good recovery. [w.k.]

7.—Bruce, in the third Lettsomian lecture on **diseases and disorders of the heart and arteries in middle and advanced life**, discusses the prognosis and treatment of these affections. He refers to etiology as a factor in prognosis, to the interpretation of murmurs and other auscultatory signs, and to the interpretation of symptoms. Taking up different phases of the subject seriatim, he discusses the prognosis of the tobacco heart, the alcoholic heart, the gouty heart, the heart in syphilis, the heart the subject of muscular strain, and that the subject of nervous strain. With regard to treatment, he points out the necessity of the study of etiology, a knowledge of which furnishes many valuable therapeutic indications. In addition, one must have a clear idea of the pathologic anatomy of the conditions he would modify, and he must take into account the clinical characters and course of the case in hand. Preventive treatment is the most important; and this, whether the disorder be the result of tobacco, alcohol, gout, syphilis, or muscular or nervous strain. To repair the pathologic changes, if syphilitic, potassium iodid should be given freely. As atheroma depends upon toxemia and anemia, the obvious indication is to purify and enrich the blood. This, at least, in respect to gout, glycosuria, and corpulence must be effected by a thorough reform in every department of personal hygiene. Arsenic and moderate doses of iodids, combined with an excess of alkalis, are calculated to promote the same ends. With regard to the establishing and maintaining compensation, the nutrition and activity of the myocardium can be increased and sustained by

means of specific cardiac stimulants and tonics, such as strychnin, ammonia, and the digitalis group of drugs; with hematinics, stomachics, and laxatives to insure an abundant supply of wholesome food; by the control of nervous influences, one of the conditions of healthy nutrition; and by the employment of the nonmedicinal measures now so extensively used to increase the vigor and benefit the metabolism of the cardiac walls, particularly active and passive exercise and baths. When dilation occurs the measures to be employed are bodily rest, a light solid diet, and a definite allowance of alcohol, if required; active purgation with mercurials, salines, and jalap; and the exhibition of sufficiently large doses of digitalis or one of its congeners, in combination with saline and other diuretics. [A.O.J.K.]

8.—Robertson, writing of the new type of scarlet fever from a public health point of view, points out the difficulty in recognizing the mild form of the disease which may be manifested only by a trifling indisposition, and perhaps slight pain and stiffness about the neck due to enlargement of the glands. He records his experience with an epidemic that occurred in the town of Paisley. The infection is attributed to faulty sanitation—unpaved back-courts and badly constructed privy-ashpits; but especially to the promiscuous association of children that took place in the school-playgrounds during the vacation months. There was strong proof that the aggregation of the children at the see-saws and swings had everything to do with the spread of the disease. Boys especially are wont to wet their hands prior to seizing a rope or bar of wood. If then several infected patients damped their hands in this fashion, one can understand how the microorganisms would be conveyed to many children's mouths. To prevent the diffusion of the infection, Robertson advocates a better system of building houses for the artisan population at least and methodical examination of all scholars by medical men appointed by the School Boards. [A.O.J.K.]

9.—Grunbaum, in a preliminary note on the use of ox-serum in rectal feeding, speaks of the value of enemas consisting of ox-serum, glucose, and liquor pancreaticus (with the addition of 2 grains of chloreton to each ounce of the ox-serum for preservation). He prefers to inject 90 cc. of ox-serum with 60 cc. of milk every 4 hours, and to give a cleansing water enema every morning. The heat value of this injection is stated to be 578 calories. This may be increased by another 300 calories by the subcutaneous injection of sterilized olive oil—30 or 40 cc. daily. By this plan of exclusive rectal feeding it is believed that half of the necessary energy may be supplied and the loss in body weight reduced to 750 grams a week. [A.O.J.K.]

10.—D'Esterre in a note on the value of diphtheria antitoxin in the treatment of membranous nondiphtherial tonsillitis, reports 2 attacks of membranous streptococcal tonsillitis occurring at intervals of 6 months in a woman aged 35 years. The use of diphtheria antitoxin during both attacks was followed by quick subsidence of the manifestations, and its use is accordingly commended. [A.O.J.K.]

11.—Hall discusses the indications for tracheotomy in thoracic aneurysm. Stenosis of the main air-passage may arise in aneurysm from spasm of the abductors, or paralysis of the abductors of the vocal cords—often a combination of both—or by direct pressure on the trachea. In the first 2 conditions only will tracheotomy be of use. In the event of double stenosis due to bilateral abductor paralysis and direct tracheal pressure, if there is marked respiratory excursions of the larynx, indicating that the seat of the obstruction is in the glottis, tracheotomy is indicated. The absence of respiratory excursions point to tracheal stenosis. The importance of recording all cases in which tracheotomy has been performed, with the result in each case, is emphasized. [J.W.M.]

12.—O'Donnell reports a case of spontaneous version of the fetus. When called to the patient he found the arm protruding through the vagina, and the body occupying the abdominoposterior position. He replaced the arm but could not perform version on account of the very frequent and powerful contractions of the uterus. Going to his house for the necessary apparatus to administer an anesthetic, he was recalled by a messenger and found the legs of the fetus were

now protruding. On delivery the child was dead, owing no doubt to pressure on the umbilical cord. The mother explained how after a "terrible" pain she felt the baby turn right around. This case is interesting as showing to what a severe strain the healthy uterus may be subjected, and the great power it is capable of exerting upon the fetus even in such an unfavorable position. [W.K.]

13.—The passage of a salivary calculus without symptoms is the subject of an article by Maguire. Its presence was indicated by a small tumor in the floor of the mouth to the right of the frenum of the tongue. The calculus weighed 45 grains, was 2.5 cm. long, 1.4 cm. thick and 4 cm. in circumference. During the 4 years it was in Wharton's duct it did not give rise to any discomfort, and was extruded spontaneously. The patient suffered from chronic rheumatism. [J.W.M.]

14.—McElroy gives the history of a case of eclampsia, followed by temporary mental derangement. It differs materially from the majority: (1) The fits—followed by mental symptoms—occurred after the death of the fetus; (2) the patient recovered almost completely before the birth of the fetus; (3) albumen had completely disappeared from the urine before the birth of fetus; (4) the urine was copious throughout, and no coincident kidney disease was detected; (5) the temperature never rose above 100.4°. [W.K.]

15.—Mays asserts that the statement that bitharzia haematobia is "apparently unknown" in Cape Colony is not in accordance with facts, and quotes several authorities in corroboration. The idea regarding the manner in which the disease is acquired, is that the armed embryos find their way directly into the urethra of boys who bathe in the rivers near the coast. The life history of the parasite is but imperfectly known, and the treatment of the disease unsatisfactory. [J.W.M.]

16.—Hebb in a note on epilepsy and heart stoppage writes that while listening to the heart of a patient, aged 29 years, suffering with aortic insufficiency, he became aware that the heart had stopped beating; immediately a general convulsion ensued and lasted several minutes. After consciousness returned the patient talked coherently and lucidly and arose without the least difficulty. He had had several attacks previously. [A.O.J.K.]

17.—Fisher reports 2 cases of scurvy rickets occurring in female children, aged 9 and 12 months respectively. The characteristic feature of the cases was the extreme tenderness of the affected parts, the limbs being kept motionless as if paralyzed, and the children screaming even upon the approach of any one, as if fearing manipulation. There was also extreme anemia. In one case there was a history of improper feeding; in the other the history as regards the feeding was untrustworthy. The condition was immediately remedied upon the administration of $\frac{1}{2}$ ounce of orange juice and one dram of raw meat juice 3 times daily, and cow's milk. The first child was given also $\frac{1}{4}$ grain doses of mercury and chalk 3 times daily for 3 days, and the second child $\frac{1}{4}$ dram of equal parts of cod-liver oil and malt 3 times daily. [A.O.J.K.]

18.—Modlin reports a case of compound comminuted fracture of the patella, in which complete recovery followed prompt operation. The patella was diagonally fractured, the outer third only remaining intact. The remainder was broken into 8 fragments, 5 of which were inside the joint. The quadriceps expansion, both above and below the patella, and the periosteum were lacerated extensively. The fragments were removed, the periosteum and quadriceps tendon sutured, the joint irrigated, drainage established and the leg dressed on a posterior splint for 3 weeks, when passive motion was begun. Complete recovery followed, there being no impairment of the usefulness of the joint. He also reports 2 cases of spina bifida in infants 3 months old, successfully operated on. The tumor in each was situated in the lumbar region, and was about the size of an orange. In one a horseshoe-shaped incision was made at the base of the tumor and the skin dissected off. A similar incision, with the convexity opposite, was made through the membranes, the fluid evacuated, redundant skin and membrane removed and the wound closed, the membrane with catgut and the skin with silk-wormgut. The tumor did not recur, the cleft filled up, there being no impulse over the point of

operation, nor did hydrocephalus or convulsions follow. [J.W.M.]

19.—Markley reports a case of **intestinal obstruction due to an adherent Meckel's diverticulum** in which death followed operation. Indefinite abdominal symptoms accompanied by diarrhea had existed for a year. On admission he complained of severe pain in the umbilical, right lumbar, and hypochondriac regions; there was some distention with dullness in both flanks. Frequent vomiting had occurred, and there was complete intestinal obstruction for 2 days. On operation the peritoneal cavity was found to contain a large quantity of dark-colored fluid, the intestines were deeply congested and bound down by 2 bands of adhesions, which were severed. The bowel was opened, and the opening stitched to the lower part of the skin-wound. The patient died the following morning. On postmortem the band which tightly bound the intestines was found to be the diverticulum, the free end of which had become adherent to the intestine, binding down several coils, and causing obstruction. The position of Meckel's diverticulum has been found to vary from 11 to 20 inches from the ileocolic opening. [J.W.M.]

20.—Dickson reports a case of **acute ascending paralysis**—that of a man who was admitted to the hospital complaining of loss of power of the lower extremities and of inability to pass urine. Examination revealed complete motor paralysis of the lower extremities. Sensation was perfect, or there was slight hyperesthesia. The superficial and deep reflexes were absent. Within 24 hours the trunk and upper extremities became involved, and same phenomena being present. There was then difficulty in articulation and paresis of the left facial nerve. The course of the disease was then very rapid, with evidence of labioglossolaryngeal paralysis, and finally paralysis of the phrenics. There was no necropsy. [A.O.J.K.]

21.—Babington reports a case of **coccygeal cyst of the buttock** in a man aged 35. It had existed since birth, was gradually increasing in size, pearshaped, with its apex above, at the coccyx, and its base below on a level with the tuberosity of the ischium. Near the apex were 3 sinus openings one of which was discharging a foul smelling, straw colored fluid. Areas of fluctuation separated by thick bands could be detected on palpation. On rectal examination a fluctuating tumor was found posteriorly. An elliptic incision was made in the long axis of the tumor including the sinus openings. The cyst sac was entirely removed, and the skin around closed with drainage. Recovery followed. The origin of these cysts according to Bland-Sutton is from Luschka's gland, a rudiment of the post-anal gut of the embryo. [J.W.M.]

1.—See *British Medical Journal*, abstract No. 7.

2.—Kelly reports a case of **sclerotic hyperplasia of the pharynx** in a young man aged 34 years. For 3 years the patient

had the sensation of a foreign body in the pharynx, which excited fits of coughing by coming forward on the tongue or passing too far back. On examination the uvula was found to be greatly enlarged and thickened. On each side of the posterior pharyngeal wall was a broad, prominent band, extending into the nasopharynx above, and downward into the esophagus. They were of the consistence of muscle, greyish in color and smooth. The lumen of the nasopharynx was greatly lessened and the eustachian orifices were concealed. Removal of the greater portion of the uvula was followed by marked improvement. Microscopic examination of the tissue removed showed the condition to be a chronic hyperplasia of the interstitial tissue, nor was it considered to have any relation to syphilis, rhinoscleroma or other infective diseases. [J.W.M.]

3.—Nicol writing of the **existence of immunity after enteric fever** reports several cases that have come under his personal observation and that tend to show that immunity is more a fancy than a fact. The doubtful occurrence of a natural immunity after, an attack of the fever acquires also some importance in view of the suggested conferring of artificial immunity by the injection of antityphoid serums. As he had observed the occurrence of a second and even third attack of typhoid fever in the same patient; as under ordinary circumstances the cause of the disease is only occasionally present, and when it is present the predisposing circumstances favoring its development may be absent; and as a large number of persons though exposed to infection still escape the disease, Nicol believes that there is no proof of the presence of immunity after an attack of typhoid fever. [A.O.J.K.]

4.—Latham discussing the **pathology and treatment of rheumatoid arthritis**, refers to the distinctly neurotic character of the antecedents and accompaniments of the arthritic trouble, and concludes that it is not unreasonable to assume that the joint affections in rheumatoid illnesses are due to spinal congestion or chronic myelitis, affecting chiefly the ganglion cells of the anterior horns, but extending also, when the disease is associated with "glossy skin," to the ganglion cells in the posterior horns. He believes that in the earlier stages of the disease continuous counterirritation of the spine is of distinct service and that it may also be usefully employed in the acute polyarthritic variety. When, however, the disease is advanced, the ends of the bones enlarged, and the cartilages destroyed one cannot hope to restore these to the normal condition by counterirritation. Such a measure would only increase the patient's discomfort. Nevertheless in chronic cases, when there occur from time to time acute exacerbations of pain and swelling in the larger joints, the application of blisters to the spine is of use; these conditions being thereby quickly alleviated and further extension of the disease arrested. [A.O.J.K.]

5.—Jessett reports the **disappearance of a large pyloric tumor after gastroenterostomy**. The patient, a female, aged 56, had suffered from indigestion for several years. On admission to the hospital the symptoms were vomiting, acute pain, flatulence and constipation. A tumor which was increasing in size could be felt in the epigastric region, situated apparently at the pylorus and extending over the anterior wall of the stomach which was greatly dilated. On operation, the size and fixation of the growth, which was thought to be a scirrhus, did not permit of pylorotomy and a gastrojejunostomy was done. The patient enjoyed good health for 10 years afterwards and died of apoplexy. On postmortem examination it was found that the tumor had entirely disappeared leaving only a thickening of the pylorus. The stomach showed an hourglass constriction, the opening between the pouches admitting only one finger as did also the pyloric opening, while that between the distal pouch and the jejunum admitted 2 fingers and evidently formed the main opening for the passage of food from the stomach into the intestines. [J.W.M.]

6.—Flux in a paper on the **influence exerted by and upon the administration of anesthetics** states that the life of the patient as well as the degree of anesthesia depends on the air inhaled, as it is the medium by which the anesthetic is conveyed, and the careful adjustment of the 2 constant factors in every administration, viz., the air and the anesthetic is essen-

tial to reliable results. The amount of the anesthetic inhaled depends on the route the air has to take. If it passes over or under the evaporating surface, it will contain less vapor than if it passes through the evaporating substance, so that any change which occurs to the patient's air-supply will cause a corresponding change in the dose of the anesthetic. The effect should be regulated by the dose, and not the dose by the effect, as is so common. The essential point in the system is the regulation of the amount of fresh air which is permitted to take up fresh anesthetic vapor at each inspiration and the amount administered must vary in each case. [J.W.M.]

7.—Green gives the notes of 3 cases of acute ascending paralysis, hoping at some future time to discuss the condition in order to bring out some points he deems of interest. [A.O.J.K.]

9.—Baker reports a case thought possibly to have been laryngeal diphtheria, in which a speedy recovery followed injection of antidiphtheria serum. The use of the serum in doubtful cases is advocated. [A.O.J.K.]

10.—Snow reports a case of carcinoma of the prolapsed uterus occurring in a woman aged 73. The uterus had become precident at the climacteric period about 28 years before, and no pessary or other support than a napkin had been resorted to. Snow considers cancer of the prolapsed uterus as a very rare event, as neither he nor his medical friends had ever met one before. Presumably the rational explanation is that the existence of the disability induces a care of the exposed parts with concomitant cleanliness and health. Ordinarily, too, a pessary is worn. The disease in the case reported seems to have been the result of the neglect of all such precautions. [W.K.]

11.—Hanna details Berestneff's modification of the Romanowski-Ruge method of staining the plasmodium of malaria and other protozoa. For details reference must be had to the *British Medical Journal* or to the original report in the *Russian Archives of Pathology, Clinical Medicine and Bacteriology*, Vol. x, Part 4. [A.O.J.K.]

12.—A case is reported from St. George's Hospital of fracture dislocation of the cervical vertebra with fracture of the skull. The patient was a man, aged 25, who fell a distance of 30 feet. On admission immediately after he was conscious, there was fixation of the head with paralysis and loss of sensation of the body and arms. A diagnosis of dislocation of the sixth cervical vertebra was made and an effort was made to reduce it by traction. While this was being done a click was heard, followed by mobility of the head, and return of power and sensation in the arms. Later the abdomen became distended. This was relieved by enema and the rectal tube. About 18 hours after the injury he became comatose, his temperature rose, breathing became stertorous and he died. Post-mortem showed an extensive fracture of the vault and base of the skull, with a blood clot pressing on the left cerebral cortex. The body of the sixth vertebra was fractured and there was evidence of a recent dislocation. The cord and membranes were normal. [J.W.M.]

13.—Douglas-Crawford reports a case of coma from the application of carbolic acid to the unbroken skin occurring in a girl of 4. It having been proposed to perform MacEwen's osteotomy on both legs, lotions of carbolic acid (1 to 40) were applied. At the end of 4 hours, the child being as well as usual, the limbs were scrubbed with turpentine, and the compresses reapplied. At the end of 40 minutes the child was found in an unnatural deep sleep; at the end of 2 hours she was in marked collapse and coma. Upon removal of the compresses and active stimulation continued for a number of hours, the child recovered, and by the following day she was well, excepting for some pallor and rapidity of the pulse. [A.O.J.K.]

2.—In Newman's tracheloplasty the cervix is drawn down by a double tenaculum with reversed blades, the hooks directed from within outward into the tissue of the cervical canal. The posterior lip is now transfixed by a specially-devised knife with blade almost at a right angle with the handle, and a clean cut made from above downward. The anterior lip is transfixed from 1 to 1.5 em. in front of the other and cut in the same way. The tenaculum is changed to a lower position and the intervening plug of diseased tissue cut away. The flaps fall together and 3 sutures unite each to the shortened cervical canal, with 2 additional ones at each angle to prevent gaping. Silk-worm-gut is used and one end of each stitch is left long and the long ends are tied together in 4 groups to facilitate removal. An iodoform tampon is inserted in the canal after attachment to the gauze for packing the vagina, and remains until the second or third day and is not replaced, douches of 1 to 4,000 bichlorid being used subsequently. The sutures are removed in 2 weeks. [H.M.]

3.—The primary cause of colds is not exposure but imperfect elimination, due to depression from overwork or repletion from overeating. The impurities are discharged through the respiratory mucous membrane instead of the proper organs. Pure air and exercise are necessary for digestion and assimilation. In treatment alcohol and quinin are condemned. For radical cure is advised no food for 24 hours, flushing of inactive bowels with warm water, drinking freely of pure water, a brisk walk and then a Turkish bath, followed by an oil rub. All disease is due to some mistake in dietetic habits. [H.M.]

4.—Atrophy can be diagnosed only in complete absence of all normal constituents of gastric juice after repeated examinations. It is less rare than supposed. Under proper treatment apparently good health may be enjoyed. Treatment consists in general hygiene, a diet largely farinaceous, a diastatic ferment, a mild astringent for the diarrhea generally present, peptomangan of iron for the anemia, lavage and silver nitrate for an excess of mucus. Takadiastase is the best ferment, because it will act even in the presence of HCl.—[H.M.]

5.—In one case the fundamental tone is made by the "puckered up" aryepiglottic folds, the patient's mouth being open at the time. In the second case the man can produce 4 notes synchronously in the region of the larynx, but as the mouth is not opened the musculature cannot be studied by laryngoscopy. [H.M.]

6.—A review of normal embryonic development is given and a description of 6 cuts representing anomalies of the auricle.—[H.M.]

7.—Boiling cleans instruments best and does not dull them if distilled water is used. When honing a knife pull it from heel to point, the cutting edge leading at an angle of about 45°. When stropping the knife should be drawn from heel to point from the cutting edge. A saw for hard bone should have teeth no deeper but further apart than a fine one. Hard soap rubbed on a laryngeal mirror and cleaned off with a dry napkin will prevent condensation of moisture. [H.M.]

8.—Accurate diagnosis of abdominal tumors requires knowledge of the shape and boundary of the abdominal cavity, of the normal location, outlines and functions of its organs, of those tumors which frequently and infrequently affect these; familiarity with methods of examination, system and exactness

of procedure and coordination of mental and physical action on the part of the examiner. Attention should be given to the history of the case and general appearance of the patient. An anesthesia removes muscular resistance, but also the evidences from sensitiveness and pain of diseased organs. [H.M.]

9.—Widal's test gives a positive reaction in the majority of cases of typhoid, in mountain fever the majority of the tests are negative. The mortality is greater in typhoid, also the average duration of the disease. The rise and fall of temperature is more abrupt in "mountain fever," tympantitis and enteric hemorrhage are seldom present; the eruption covers almost the entire body, is raised, feels like shot and does not disappear on pressure. The pathology is not understood from lack of autopsies. The disease seems to affect the stomach and transverse colon and the nervous system, producing a condition that simulates paralysis agitans. Temperature charts illustrate the difference between it and typhoid. [H.M.]

10.—A large percentage of neurasthenics evidently anemic have a normal or supranormal blood count. Owing to poor vasomotor control, peripheral blood varies much in its character. Cold lowers the bulk of solids and increases the apparent quantity of red over white corpuscles, and allowance should be made in patients with clammy extremities. Warmth, massage and electricity raise the bulk of solids. When blood is centrifugated the heaviest corpuscles are thrown to the periphery. These show an increase of 20% in oxygen-carrying capacity over the layers near the center, and stain more deeply and quickly than any other layer. Blood drawn from animals previously bled has a higher oxygen capacity than that obtained before such bleeding, and stains more deeply. The conclusion is that the heavy cells are recently-formed cells. These are lenticular or biscuit-shaped. In old cells the cytoplasm is pushed to the periphery, giving a dumb-bell shape. In neurasthenics the erythrocyte has undergone this change. As a result the cells pack together closely and show a marked diminution in volume by the hematokrit. [H.M.]

11.—Previous to 1885 the mortality of diphtheritic croup was almost 100%. With tracheotomy it was reduced to 75% to 90%; with intubation to 60% to 75%, and with intubation supplemented with antitoxin to almost nothing. Any medical man who does not use antitoxin in diphtheric croup is guilty of malpractice. Intubation is still needed in cases in which treatment has not been begun early enough. [H.M.]

12.—Repeated attacks of colicky pain in the right hypochondrium with nausea and vomiting followed in a few hours by slight jaundice are characteristic. Calculi in the feces are pathognomonic of gallstones. The pain may be reflected to the right shoulder or even to the back or toward the genitalia or may be on the left of the medianline. Pain in the epigastrium frequently leads to a diagnosis of gastric neuralgia or acute indigestion. Icterus is frequently absent from stones dropping back into gallbladder or passing into the wider common duct before enough swelling has been produced to cause obstruction. Inflammation plays the important part in many cases. The bacteria producing it may be means of the inflammation primarily cause the formation of the stone or the movement of the stone may light up a dormant inflammation. Hepatic intermittent fever associated with stone may possibly be microbial, toxic or both. The paroxysms, accompanied by chill, sweating, pain, vomiting and increase of jaundice, are seemingly due to retention and absorption of some toxic material. In the adult and aged these symptoms may be due to carcinoma. Riedel's tongue-shaped process of the anterior border of the liver seen oftenest in the corset-liver and gallstone may be mistaken for a kidney or neoplasm of the intestine or omentum if it is crossed by adherent intestine. A history of typhoid a few months or years before adds probability to a diagnosis of cholelithiasis. The bacilli are formed in the bladder with great frequency and through their action furnish Naunyn's requirements for the production of calculi. They are found also in the nuclei of stones. Conditions sometimes emulating gallstones in addition to those mentioned in textbooks are tabes dorsalis, angina pectoris, senile pneumonia, local peritonitis, appendicitis, intestinal obstruction and hemorrhagic pancreatitis, etc. [H.M.]

13.—A table of growths which may involve the spine, with their region and frequency is given. With the probable existence of compression not amenable to medical treatment, surgical intervention should be the rule, even if, from the nature of the tumor, nothing can be hoped but relief from pressure symptoms. The history of 51 cases of operation is recorded. In fractures of the spine, neurology helps us to decide which cases are amenable to surgical treatment, but the rules cannot be absolutely applied. In the cervical region mortality is much greater and restoration of function much less than in the lower dorsal and lumbar regions. An indirect fracture with symptoms of complete separation or degeneration of the cord naturally contraindicates operation. Obliteration of the deep reflexes, especially kneejerks, while indicative as a rule of this condition, is not an absolute contraindication to operation, as several recorded cases, including one of Lloyd's, recovered after interference. When after recovery from shock, return of sensation, reaction, and deep reflexes show that the cord has not been destroyed operation may result in great benefit. Fracture dislocations may be followed by inflammatory softening and increasing paraplegia and anesthesia. Fracture of the arches without immediate injury to the cord may be followed later by paraplegia from pressure of callus or inflammatory exudation. We must decide whether complete degeneration or only compression exists. If the latter, in some cases Lloyd would operate at once, in others wait until shock was overcome or symptoms pointed to an extension of interference with the functions of the cord. In so-called concussion we must wait until it is evident there will be no spontaneous recovery. [H.M.]

1.—Many proposed schemes of reform affecting the position of the medical expert are impractical. Authorities are quoted as to the ability to obtain professional experts to testify to any theory however absurd. Lord Campbell's opinion that it is indispensable to the administration of justice that a witness should not be turned into an advocate is cited. To testify as an expert is becoming more and more repugnant to those physicians whose evidence would be of the most value. Contradictory testimony cannot be laid at the door of science, but is owing to defective methods of law. Under the Common Law of England, in vogue in most American States, in order to give an opinion as a medical expert a witness need not belong to any particular school of medicine; he may have acquired the knowledge by study alone or by practice alone; he need not have made the subject a specialty in his practice, and, except in Wisconsin, he need not be a graduate of a medical college, nor even be duly licensed; nor need he have met a similar case in the course of his reading or practice. The function of the medical experts is to judge facts and interpret them. For this reason in Germany they are called *judices facti*, as opposed to ordinary witnesses. In our law judges the two preeminent requisites are learning and disinterestedness. A mistake of law can be cured by appeal. A mistake in expert opinion is difficult to detect and generally impossible to revise. In Germany the expert is appointed by the court and his veracity cannot be impeached. The chief of staff of professional experts is the district physician, the statutory regulations requiring him to be skilled in medicine, surgery and obstetrics; while there is also an organized series of courts of professional experts to whose judgment the opinion of the medical men first employed may be referred. The legal apparatus is cumbrous but indubitably has its share in

the elevation of the practice of legal medicine in Prussia [H.M.]

3.—In the absence of definite instructions to medical examiners as to what shall constitute information of death by violence it is best to act on that which seems credible. We should act according to the dictates of common sense and for the best interests of the commonwealth, and in case of doubt err on the side of too much investigation. [H.M.]

4.—Russell gives the clinical notes of 6 cases of actual or simulated perforation in typhoid fever, with especial reference to the leukocytosis in each. He first states that 37 examinations of uncomplicated cases of typhoid fever showed a variation in the leukocytes of from 2,000 to 12,000, the average being about 6,500. He concludes (1) In perforation it is the general rule to have leukocytosis, but the degree may vary within wide limits; (2) leukocytosis, as a rule, appears early, but may not be marked until general peritonitis and collapse intervene; (3) there may be an utter absence of leukocytosis with marked perforation and peritonitis; (4) with typical signs of perforation and a definite leukocytosis, there may be no such complication present, and an operation may be performed unnecessarily; (5) with pain and tenderness in the abdomen, coming on suddenly during an attack of typhoid fever (and in the absence of evidences of other definite complication, as cholecystitis), and a distinct leukocytosis, even without other signs of perforation, an exploratory operation is justified, even advisable, thereby obviating the dangers of a fatal issue from too great a delay. [A.G.E.]

5.—Scudder reports the case of a man who was crushed. Rupture of the colon was not attended by the ordinary symptoms which would lead to the supposition that a serious injury had been received. A suppurating hematoma above the left iliac crest was opened the sixth day after the injury and revealed a fecal abscess. Scudder states that an important sign was misinterpreted. That was vomiting which occurred several times. He concludes that vomiting once of stomach contents, after an abdominal contusion, is of no special importance. Continuous, unexpected vomiting, without any apparent reason, is significant of an intestinal lesion. This is true in spite of the absence of other signs of involvement of the peritoneum. [A.G.E.]

9. Suppurative Parotitis Complicating Croupous Pneumonia. ARTHUR STERN.
10. A New Local Treatment for Erysipelas. G. LENOX CURTIS.

1.—Marx discusses the subject of toxemia of pregnancy and reports 2 cases with his method of treatment. His conclusions are: (1) Toxemia of pregnancy is a complex condition depending on more than one factor; (2) many women go to term with albuminuria, without symptoms referable to toxemia; when such symptoms arise they are not caused by the albumin present but by faulty urea secretions; (3) in the most desperate and malignant cases there is found neither albumin nor casts; (4) urea is always found markedly diminished in the so-called true toxemias of pregnancy or urinemias; (5) finally he makes a strong plea for a regular and methodical course of urea esti-

mation in all cases of toxemia, or for the relegation to secondary importance of the time-honored examination for albumin; (6) progressive diminution of urea excretion, with or without albuminuria is the sole indication for the induction of premature labor, which is especially indicated when conscientious medical treatment fails. [W.K.]

3.—Measles as a cause of malignant endocarditis is rare. Cases have been noticed by Boulland, Stokes and Roger, but these are the only ones Roussel finds on record. The second case was remarkable as occurring in a boy of only 9 years of age, and which, except for the number and differential count of the white corpuscles, presented an almost typical picture of splenic-lymphatic leukemia. Facts in favor of a correct diagnosis in the case of recovery are a previous successful examination for life insurance, absence of compensatory hypertrophy, the positive nature of the symptoms and the continued existence of a valvular lesion. Four other cases of recovery have been reported. Authorities are quoted to show that the more modern view is that the difference between simple and malignant endocarditis depends upon the virulence of the microorganisms or their toxins. When bacteria have not been found they have either escaped detection or died. In the malignant form there is a difference of opinion as to the necessity for a previous lesion. [H.M.]

4.—Moschowitz reports 2 unusual cases of strangulated hernia in infants, with heretofore unrecognized origin and seat of strangulation. The first case, in an infant aged 4 months, about 2 hours before it came under observation, developed a small, painful, pear-shaped mass about the size of a small hen's egg extending from the region of the right inguinal canal into the scrotum. The child had vomited repeatedly and its bowels, regular until that day, had not moved. Gentle taxis was unsuccessful; and the child was then admitted to the hospital for operation. The same day, 7 hours after the strangulation was first noticed, Dr. Moschowitz operated on the child, finding a congenital hernia. As rapidly as possible the entire sac was liberated from the surrounding structures, when, without opening of the sac and without cutting or dilation at the neck, there was no trouble in reducing the hernial contents. The second case was that of a child, aged 3 months, of premature birth and weighing, a few days before admission to the hospital, a trifle less than 6 pounds. The child had cried continually for 3 days, and had vomited fecal matter. On the day of admission there was noticed for the first time in the left side of the scrotum a tense painful swelling about the size of an egg, and the skin covering it was red and edematous. Immediate operation was performed, and there was at first no trouble in reducing the greatest portion of the hernial contents, but one loop of small intestine resisted all attempts at reduction. The incision therefore was extended downward upon the scrotum, and, beyond a constricting ring within the hernial sac, a loop of strangulated small intestine about 4 inches in length, of a deep purplish color, with its peritoneum still glistening, was found. Under hot applications it rapidly regained its color. Later the child developed mastoiditis, and was transferred for operation with the herniotomy wound practically healed. While strangulated hernia in infants of 3 and 4 months is comparatively rare, there is sufficient justification for publishing these cases, in the previously unrecognized location of the constriction low down in the scrotum, and which curiously occurred in both these patients. Although there may be uncertainty as to the seat of the constriction, it is certain that in by far the greatest majority of observed cases the strangulation occurred at the external ring, the internal ring, or at some point between the two. It is therefore noteworthy that the strangulation in both cases reported occurred in the scrotum proper and some distance from the external inguinal ring. Moschowitz explains these occurrences of strangulation low down in the scrotum by quoting Lockwood, who says regarding the closure of the vaginal process: "There seems to be, as others have remarked, a strong tendency for it to close in 2 places, which are some distance apart; namely, just above the testicle and near the internal ring." [G.C.C.H.]

6.—The illness followed a maternal attack of malaria on the eighth day of the puerperium. Cyanosis and spasms occurred

daily at 3 or 4 o'clock. The infant was first seen on the twelfth day of the disease. Quinin, 4 grains daily, reduced to 2 later, worked a complete cure in 5 days. [H.M.]

7.—Biggs recommends elaterin, grains, $\frac{1}{15}$; strychnin sulfate, grains, $\frac{1}{30}$; glonoin, grains, $\frac{1}{30}$; extract of digitalis, grains, $\frac{1}{4}$; citrated caffeine, grains 1; powdered cloves, grains, 1; every 3 to 6 hours for the removal of ascitic fluid. Four to 6 copious evacuations a day should be maintained until permanent relief is secured. A weak heart, when supported by cardiac stimulants, is no contraindication to the use of elaterin. [H.M.]

8.—At the time of operation for the extrauterine pregnancy it was noted that the uterus was larger than usual. The next day a 3 months' fetus was expelled, and one day later the placenta, membranes, and decidua. The extrauterine fetus had but 2 or 3 weeks' development, and was much macerated. This was probably a twin pregnancy, and not superfetation. The uterine fetus probably passed through the tube first, causing a change in the lining, which arrested the advance of the second. The latter died early, probably from pressure. The tube was much thinned, but not ruptured, bleeding having occurred through the fimbriated extremity. [H.M.]

9.—This is very rare, having occurred in Vienna hospitals only 6 times in 5,738 cases. Symptoms of parotitis appeared the day after the crisis. The whole gland sloughed away. The diplococcus found in the pus was supposed to be *D. pneumoniae*. Its presence may be explained by migration through Steno's duct. Pneumococci were found by Kohn in the blood only in cases ending fatally, or complicated by severe pyemia or empyema. Metastasis was therefore improbable in this case. [H.M.]

10.—The parts affected with erysipelas are thoroughly cleansed, particularly of all greasy substances. A piece of gauze is laid on the skin, and this is covered with a thick poultice of sodium sulfate and cold distilled water. This is secured in place by another layer of gauze. The salt acts by depriving the germs of oxygen. Ice water is applied to the poultice to reduce inflammation and prevent incubation. From 6 to 8 hours is generally sufficient for the application. [H.M.]

New York Medical Journal.

April 13, 1901. [Vol. LXXIII, No. 15.]

1. German Textbooks Half a Century Ago: History and Reminiscences. A. JACOBI.
2. A Shielded Piston Syringe for Urethral and Vesical Irrigation. RILUS EASTMAN.
3. The Correction of the Deviations of the Nasal Septum, with Special Reference to the Use of the Author's Fenestrated Comminuting Forceps. JOHN O. ROE.
4. The Pathology of Intrauterine Death. NEIL MACPHATTER.
5. The Preponderance of Male Stammerers over Females. DAVID GREENE.
6. The Management of Gonorrhoea. BOLESŁAW LAPOWSKI.

1.—In a paper read at a reception given by Dr. Jacobi to his friends in the New York Academy of Medicine in commemoration of the fiftieth anniversary of his graduation, he gives a delightful sketch of his student life abroad and of the difficulties he had to contend with in the shape of the obscure and abstruse textbooks of that day. [H.H.C.]

2.—Eastman describes a new piston syringe for urethral and vesical irrigation. It is a metallic, 5-ounce syringe with detachable blunt nozzles and a movable shield which prevents soiling of the operator's apparel when using the syringe. It is claimed that by its use urethral and vesical irrigation can be accomplished much more satisfactorily than by the use of a fountain syringe. [J.W.M.]

3.—Roe describes in detail his method of correcting deviations of the nasal septum, and refers to the use of his fenestrated comminuting forceps which consists of a fenestrated or ring blade, and a single blade, both of which are attached to a handle by a curved stem long enough to pass around the fidemum of the nostril when the force of the blades is applied to the septum. It is made with blades of different sizes to suit different sized nasal passages, or septums, or deflec-

tions. By its use a deviated septum is straightened by introducing the single blade into the nostril on the convex side of the deflection and the ring into the other. By closing the blades the deflected portion of the septum is fractured. By its use also the bone just adjacent to the cartilage is fractured, and this is important in the retaining of the cartilage in its corrected position. [J.W.M.]

5.—As a result of examining 256 adult stammerers, 229 male and 27 female, Greene found that in 60% of the male and 11% of the female cases stammering was due to defective inspiration, while in 35% of the male and 88% of the female cases the trouble was caused by mismanagement of the voice. His explanation is that owing to the almost purely diaphragmatic breathing of the male the necessary amount of air for vocalization is not obtained until the ribs are expanded, and that, as it were, "the two mechanisms are out of gear"; while in the female, although the costal type of breathing supplies air enough, there is a futile attempt to vocalize by means of the muscles of the larynx in place of using the full respiratory current to produce vibratory motion of the vocal cords. [H.H.C.]

6. Grippe, Pneumonia, and Insanity. EMILE ARONSON.
7. Notes on the Treatment of Diphtheria, Based on the Methods of the New York City Hospitals. WILLIAM L. SOMERSET.

1.—According to Currier the symptoms which determine the diagnosis of tubal gestation may be divided into the ordinary, or those which belong to gestation under normal conditions, and the extraordinary, or those which are peculiar to this form of gestation. By all odds the most important of the extraordinary signs is hemorrhage. This is seldom external or manifest and is most likely to occur, and occur early, when the seat of gestation is the fimbriated end of the tube. In that situation the fetal sac seldom progresses to the end of the first month without rupture. As a diagnostic symptom, pain is next in importance to bleeding. It is usually paroxysmal, it is sharp and darting, and inclines the patient to relax the muscles of the thighs and flex the thighs on the abdomen. The third diagnostic point consists in the presence of a pelvic tumor. It is usually best determined by examination per rectum, the patient's thighs being flexed upon the abdomen. In most cases an anesthetic is essential to success in such an examination. By the bimanual palpation through the relaxed abdominal walls the dimensions and location of the tubal mass, and its relation to the uterus and other pelvic structures, can readily be outlined. Hemorrhage, pain, and tumor are the most important of the extraordinary symptoms and the most constant. The passing of decidual membrane by the vagina, hemorrhage from the uterus, pulsation of the vaginal arteries, and various other signs are all of minor importance. [W.K.]

2.—The principles underlying the rational application of the hot-water vaginal injection are very simple. The initial effect on the tissues of water at a temperature of from 105° to 120° F., is to dilate the contained bloodvessels and thus cause congestion, or to increase that which may already be present; the secondary effect is that of contraction and consequent lessening of the congestion, the excess of blood being driven out. When the therapeutic douche is indicated, Burtenshaw gives the following rules for its use: (1) Use a large-sized fountain syringe or douche can attached to a support 3 or 4 feet above the body; (2) always lie flat on the back when taking a douche, with the hips slightly elevated and the shoulders depressed; (3) always use at least 3 gallons of plain water, hot as can be borne (at a temperature of from 107° to 120° F.) for each douche; (4) take the injection twice daily, morning and evening, except on the 2 days preceding and the 2 days following the menstrual period, when it should be omitted; (5) rest for half an hour in

a recumbent position after taking each douche. Large hot-water vaginal irrigations should never be employed by a healthy pregnant woman, for the reason that they reduce the bactericidal power of the vaginal secretions. Reclus, of Paris, asserts that the use of hot enemias in pelvic inflammation is much preferable to the vaginal douche, since the hot water in this way comes into much closer contact with the organs which it is proposed to influence, and is correspondingly more beneficial in its action. Burtenshaw has used this method in a few cases, but not with very satisfactory results. The introduction of water at such a high temperature into the rectum produces great discomfort, and the patient can rarely accustom herself to its use. [W.K.]

3.—Reid reports a case of **cystinuria** occurring in a man of 32 who had for ever 6 years been suffering with painful micturition, and had been treated for gravel and muscular rheumatism by his family physician. Examination of the urethra revealed ulceration, and of the urine the presence of cystin. Acting on the theory that cystinuria is due to arrested metabolism, Reid started treatment with quinin, nitric acid, tolu, salicylic acid and rhubarb in a mixture, and later iron and strychnin, at the same time using mild lead astringent injections as a local application. Recovery was apparently complete, even after a year had passed, a circumstance all the more remarkable as no case of cure had ever been previously reported. [H.H.C.]

4.—Dana reports in detail one case of **acute bulbar ataxia** and 4 of **acute spinal ataxia** coming under his observation. In all of the latter cases "the ataxia was especially marked. The patients did not know the position of their limbs and could not stand or walk except in the characteristic ataxic manner. On the other hand, cutaneous sensations were not markedly involved in any case. There was always some tactile anesthesia, but no marked loss of pain or thermic sense. The kneejerks were abolished in 2 cases, but not in the third, in which case they were slightly exaggerated. There was some loss of motor strength, but the patient could always move the limbs freely in every direction and could stand with help. There was loss of cutaneous reflexes. The Babinski phenomenon was not tested for. There was no special wasting of the limbs or change in electrical reaction. There was weakness of the bladder, with some constipation, but these functions were not entirely in abeyance. The patient suffered no pain, either at the time of onset or later. There were no lightning pains, no crampings or jerking, no girdle pains, though there were some girdle sensations. The vascular and glandular functions of the limbs were not especially disturbed. There was in no cases any lesion of the cranial nerves, nor were the arms affected, except in one case, in which there was some paresthesia of the fingers for a time." Etiologically Dana concludes that these cases are due to senile arterial changes or to syphilitic lesion of the posterior blood-vessels of the spinal cord, causing either a blocking up, or hemorrhage, or both, with the usual reactive process. In all cases the patients rapidly improved. [H.H.C.]

5.—MacPhatter describes the **pathology of intrauterine death**. He believes that syphilis is one of the most potent influences in causing the destruction of the fetus. The effect of this disease upon the placenta varies according to its severity and has certain definite characteristics by which it can be recognized. When the syphilis is derived from the father the effects are chiefly centered in the fetal part of the placenta. When derived from the mother the maternal portion is primarily affected. These changes are carefully described. Various other causes of intrauterine death, such as fatty degeneration, edema, calcareous degeneration, myxoma fibrosa and cystic disease of the placenta are described and the treatment for complications of pregnancy detailed. When Caesarian section is indicated he prefers Porre's method, as the procedure leaves the woman's life free from further dangers from this source. [W.K.]

6.—Aronson reports an interesting case of **grip-pneumonia with cerebral involvement** taking the form of maniacal delirium followed by periods of stupor and coma, with general apathy and suicidal tendencies during the gradual convalescence. [H.H.C.]

7.—Semerslet concludes an interesting historic sketch of

diphtheria treatment with a valuable summary of the modern methods as used today in the New York City hospitals. He advises the injection of from 2,500 to 4,000 units of antitoxin and condemns the practice recommended from Boston, viz., of using 20,000 units daily for 3 or 4 successive days. Irrigations are recommended (preferably with salt water, a teaspoonful to the quart), and hot if intended for the relief of pain, even to 138° F. Medicated steam, if properly applied, is beneficial in some cases—especially to prevent the necessity of reintubation. A rapid and feeble, or worst of all, an intermittent pulse should be met with absolute rest (morphin), stimulation and every possible attention to the nourishment of the patient. Gavage is frequently indicated. Paralysis of the abductors of the vocal cords may necessitate intubation. Ventilation, air space (150 square feet of floor space with walls at least 10 feet high) proper room temperature (72°-76°), and frequent change of air without draughts, and freedom from the presence of pneumonic or septic patients, are the desiderata in all cases. In cases in which the pseudomembrane has extended below the larynx and in cases in which the nasopharynx is extensively involved, primary tracheotomy is indicated. In feeding, whenever possible the child should drink from its cup in the ordinary way. Internal medication should be reduced to a minimum. After intubation the stay of the tube should be as short as possible. When the tube is removed the first consideration is to avoid the necessity for its return. Morphin sulfate ($\frac{1}{16}$ to $\frac{1}{12}$ gr.) given 15 minutes before extubation is an excellent precaution. Should dyspnea recur, poultices, hot baths, narcotics and steaming are all important aids. [H.H.C.]

1. An Historical Sketch of the Department of Medicine and Surgery of the University of Michigan.
2. Some Errors in the Examination of Urine. LOUIS HEITZMANN.
3. Acute Traumatic Malignancy. WILLIAM B. COLEY.
4. Epistaxis. CHARLES N. COX.

2.—Many make a diagnosis of nephritis from albumin in the urine without any microscopic examination. Others, after the latter, if they find no casts, call the case one of "functional albuminuria." Cold tests do not show small quantities of albumin, and other substances besides albumin give the same reaction. Nitric acid should not be used for differentiation in the heat test as no precipitation takes place if the amount of albumin is small. Use 2 or 3 drops of a 50% aqueous solution of glacial acetic acid, and compare the appearance with an unboiled sample. True casts are always from the kidney. Mucus cylinders are often mistaken for hyaline casts, and when partly covered with bacteria, for granular casts. Careful focusing prevents this error. It is a mistake to suppose waxy casts may have no special significance. They always indicate amyloid degeneration. [H.M.]

3.—Coley, in discussing the relation of traumatism to acute malignancy, states that after a careful clinical study of malignant tumors he is convinced that injury constitutes a more important factor in their causation than is generally recognized. Of a series of 270 cases under his own care, 31.8% gave a distinct history of trauma. The time which intervened between the occurrence of the injury and the development of the tumor varied from almost immediately after the injury to 4 years. The injury may be very slight and in those cases in which the tumor does not appear for months or years, may be forgotten. Butlin and other German surgeons believe that this etiological relationship is due to a constitutional predisposition on the part of the patient; Virchow claims that a special disposition for tumor development is produced by the injury; Löwenthal believes that injury may be considered as a direct etiologic factor. The writer regards the infectious theory as the most rational and states that evidence in its support is increasing. Reference is made to the similarity between sarcoma and tuberculous disease, osteomyelitis and periostitis in this respect and 29 cases in which sarcoma and 2 in which carcinoma followed injury are reported. [J.W.M.]

4.—Cox in discussing epistaxis states that the cause may

be systemic or local. Of the former, plethora, anemia, hemorrhagic diathesis, and organic heart, liver or kidney disease are mentioned. Of the latter, trauma, operative or accidental abrasions, varicose veins, angioma and intranasal growths as sarcoma and fibroma. The treatment consists in first locating if possible the bleeding point and applying pressure by means of a small tampon, or if the hemorrhage be profuse by plugging the nostril from before backward with sterile or iodoform gauze. It is seldom necessary to introduce posterior plugs. Rubber finger cots which are introduced into the nostril and then packed with cotton or gauze have been used, also sponges of compressed cotton which on absorbing moisture expand and thus exert pressure. Of local styptics silver nitrate solution 50%, chromic acid crystals, electrocautery, powdered suprarenal extract, alum, hydrogen-peroxid, antipyrin and ferropyrin 20% solution in water are mentioned. In some conditions fluid extract of ergot or gallic acid may be given internally. In recurrent nasal hemorrhage due to a local condition the cause should be removed. [J.W.M.]

5. Susceptibility to Disease and Physical Development in College Women. ARTHUR MACDONALD.
6. Operative Treatment for Prostatic Hypertrophy. RAMON GUIERAS.

1.—Mills reports 5 cases of brain tumor and 1 case of softening and degeneration. Symptoms are given in detail and conclusions regarding localization are drawn therefrom. CASE 1: Tumor of the superior parietal gyrus; localizing symptoms, impairment of cutaneous sensibility, loss of muscular sense, astereognosis, ataxia, paresis, and ultimately paralysis; operation, recovery. CASE 2: Tumor of the superior parietal and middle portions of the central gyre; localizing symptoms, impaired cutaneous sensibility, loss of muscular sense, astereognosis, ataxia and late paralysis; operation, death. CASE 3: Tumor of the superior parietal gyrus; localizing symptoms, impairment of muscular sense, astereognosis, ataxia, paresis; operation, recovery. CASE 4: Necrotic and degenerated area with focus at junction of inferior parietal and first gyre; localizing symptoms, astereognosis, diminution in pain and temperature senses, word deafness, etc. Recovery from operation, but symptoms remaining about the same. The 2 remaining cases will be published in full later by Drs. Mitchell and Sinkler. Mills states that the first 3 cases afford confirmation of the views long defended by him, namely, that the sensory and motor areas of the cerebrum are, for practical purposes, distinct. He concludes that the diagnosis of brain tumor can sometimes be made even in the absence of most of the general symptoms, such as optic neuritis, headache, vertigo and vomiting, chiefly by the close study of localizing and invasion symptoms. Tumors of the posteroparietal region, especially of the superior parietal lobule, give as their most important localizing symptoms, disorders of cutaneous and muscular sensibility, and especially astereognosis. Just as the centers of hearing, vision and speech are more highly differentiated in the left hemisphere, so it is probable that the stereognostic sense is more highly evolved in this hemisphere. A tumor strictly confined to the motor regions does not give objective, sensory phenomena of a persisting character. In tumors of the motor subcortex, tonic spasticity is usually a marked system. [A.G.E.]

2.—Goelet discusses the nonsurgical treatment of fibroid tumors of the uterus, and considers that electricity stands foremost among the nonsurgical measures, and that galvanic, faradic, and even static current, may be employed with benefit; and if proper aseptic precautions are used perituterine inflammations and adhesions will not result. The method of application, strength of current, apparatus required are described. He

has also secured remarkable results by the use of certain proprietary remedies. [W.K.]

3.—Shallcross reports in detail 2 typical cases of akromegaly which came under his observation in the Pennsylvania Training School for Feeble Minded Children. [H.H.C.]

4.—Mastin reports several cases occurring in his own practice tending to show that infantile scurvy is not such a rare disease as may be supposed. His cases "demonstrate that errors in the diagnosis of infantile scurvy are not confined alone to rheumatic affections, but may extend to the domain of surgical disorders—tuberculous bone lesions, sprains and contusions; to the nervous system—disease of the cord; and even include hereditary syphilis. They show also that scurvy may arise during the exhibition of several of the most popular artificial or prepared foods, and, in addition, what is of much consequence, that its occurrence under the use of sterilized milk must be undoubtedly conceded. Again, one of the cases suggests the possible intimacy, or, at least, association, of scurvy with a form of pernicious anemia. [H.H.C.]

6.—Guiéras, after mentioning the various methods of dealing with prostatic hypertrophy, considers what he designates the 2 great operative procedures—prostatotomy and prostatectomy. Of the former the Bottini operation is stated to be the sole surviving method which is used at the present day. The relative merits of the Bottini operation as compared with prostatectomy in general are then discussed. Guiéras says that the advocates of each are right when they say that the other operation is a blind one because both are blind operations and the operator has to be governed by the sense of touch. The Bottini, while not so dangerous, does not produce such good results, and enucleation, while more dangerous, produces better results if the patient survives, but the patient's life must never be endangered by the use of an operation considered more scientific. [A.G.E.]

Zeitschrift für Heilkunde.

1901 [Vol. XXII., Part I.]

1. Mixed Tumors of the Parotid Gland. KARL LANDSTEINER.
2. A Case of Influenza-Endocarditis of the Aortic Valves and Patulous Arterial Duct. FRIEDRICH SCHLAGENHAUFER.
3. The Morphology and Pathology of the Influenza Bacillus. H. ALBRECHT and A. GHON.
4. Elongation of the Tubes Associated with Ovarian and Parovarian Cysts. HARRY LEPMANN.

1.—Landsteiner reports several mixed tumors of the parotid gland and discusses their histology and histogenesis with special reference to the much disputed question of their derivation from epithelial or connective tissue elements. In contradistinction to the more recently accepted view of the sarcomatous or endotheliomatous nature of most of the growths, he believes them to be of epithelial origin and subject to the various metamorphoses common to epithelial tumors. [A.O.J.K.]

2.—Schlagenhafer reports a case of endocarditis of the aortic valves and patulous arterial duct, in a boy aged 13 years. Cover-slip preparations from the vegetations revealed a thin, small bacillus, but cultures were not conclusive. The organism, however, is thought to have been the influenza bacillus, and this opinion is strengthened by the detection of a similar bacillus in sections of the vegetations and in sections of the lung (in the purulent exudate in the bronchioles). The case is thought to be the fourth in which there is anatomic evidence that the endocarditis process was in all probability due to the influenza bacillus. The repeated occurrence of pulmonary infarction in the case, induces him to suggest that in cases of evident valvular disease of the left side of the heart, especially aortic disease, the development of so-called crossed embolism might lead the clinician to suspect the possibility of patulous arterial duct (or patulous foramen ovale or ventricular defect). [A.O.J.K.]

3.—Albrecht and Ghon make an interesting contribution to our knowledge of the morphology and pathology of the influenza bacillus and allied organisms. Of clinical interest is the occurrence in a child, aged 2½ years, of an extensive and

fatal phlegmonous inflammation of the right arm, with fatty degeneration of the heart-muscle, liver and kidneys, and septicaemia. From the phlegmonous inflammation of the arm the influenza bacillus only was recovered, and from this it is concluded that it is in the highest degree probable that the influenza bacillus alone is capable of engendering such inflammation. [A.O.J.K.]

The American Gynecological and Obstetrical Journal.

January, 1901. [Vol. XVIII, No. 1.]

1. Deep Imprints. WILLIAM H. HINGSTON.
2. Intra-Pelvic Operations for Relief of Posterior Uterine Displacements. WALTER B. CHASE.
3. A Case of Congenital Hypertrophy of the Cervix, complicated by Prolapsus and Bilateral Pyosalpinx, in a Girl 17 years old; Vaginal Hysterectomy. ABRAM BROTHERS.
4. Uterine Curetment. DOUGLAS C. MORIARTA.
5. A Solid Ovarian Tumor. JOHN G. EARNEST.
6. An Unique Case of Intrapelvic Hemorrhage due to a hitherto Undescribed New Growth. W. P. MANTON.

2.—Chase recapitulates his article as follows: (a) **Posterior deviations with fixation** from adhesions is usually a serious menace to health and often a barrier to childbearing; (b) this condition of affairs can best be treated by laparotomy; (c) after the adhesions have been severed the cure should be completed by maintaining the uterus in an anterior position: first by intraperitoneal shortening of the round ligaments; second, if this is insufficient, resort should be had to anterior abdominal suspension or fixation; (d) that experience, while not settling all points associated with this subject, nevertheless has demonstrated that efforts to maintain the uterus in an anterior position either by ventrosuspension or ventrofixation, are from the uncertainty of the degree and extent of the adhesion, not devoid of danger in the case of conception; (e) that ligation or resection of the Fallopian tube is a more rational procedure than ovariectomy, for the prevention of conception, where justifiable, as it does not unsex the woman, and saves her from the premature menopause and its unpleasant consequences—a physiologic reason of much weight—and (f) that the value of these methods of treatment of posterior deviations is amply demonstrated and their employment should be more generally adopted. [F.C.H.]

3.—After detailing the history of the patient, Brothers describes the specimen which was removed. It consists of the **uterus both tubes filled with pus, and the ovaries**. A portion of the vagina was dissected downward and removed with the uterus in order to guard against prolapsus of the vagina in the future. It is of interest to note that it was possible to remove all of these organs in one mass in an undersized girl of 17, and by the vagina. In order to render this easier of accomplishment the uterine wall anteriorly was submitted to a hemisection, ligatures were applied to the lower portion of the broad ligaments, and clamps to the uppermost portion; the latter were removed at the end of 48 hours. By actual measurement of the specimen, the distance from the fundus uteri to the internal os is 1 inch, and that between internal os and external os 2½ inches. There is no reason to suspect a gonorrhoeal origin as the uterus protruded from the vulva, the girl was a chronic invalid, and her home surroundings excluded such a suspicion. [F.C.H.]

4.—Moriarta considers only the **curetment of septic and sapremic conditions** which occur as puerperal complications. Early abortions affect the endometrium more markedly, the uterine walls and general system less. Marked symptoms may occur in these puerperal cases with no apparent gross local lesion when the peritoneum, pleura, or heart membranes are involved. Care should be exercised to empty the uterus, for during a second curetment fresh abrasions will be new foci for infection. [F.C.H.]

5.—Earnest reports a **solid ovarian tumor** which reached above the umbilicus. It was situated in the median line, perfectly symmetrical, smooth and hard; so firmly fixed that it could not be moved. The diagnosis of uterine fibroid was made. The tumor measured 20 centimeters in length, and

about 14 in breadth at its widest point. No microscopic examination was made. [F.C.H.]

6.—Manton reports this unique case, also of clinical and pathological interest and importance. Upon examining the patient, the parietes were thin, the abdomen slightly distended. The lower portion of the vagina was partially blocked by a swelling on the left side, which extended downward to within about an inch and a half of the introitus, the uterus was slightly enlarged, acutely anteflexed, and pushed to the right. The pelvic fossa was occupied by a soft mass, which could not be clearly outlined on account of the sensitiveness. The tube could be felt to the left of the uterus greatly enlarged, elongated, sausage-shaped, somewhat irregular and hard. Continuous with the tube was a yielding mass which completely filled this half of the lower pelvis. On opening the abdominal cavity both sides of the pelvis were seen to be symmetrically involved, the tubes were enlarged to the size of small bananas, and were attached to the pelvic wall and intestines. While enucleating the left tube it ruptured, and a quantity of dark fluid blood escaped. This tube was removed. The same experience was met in the right tube, while attempting its removal. More than a pint of liquid blood and clots were removed by hand and sponging from each broad ligament. The pathological examination was made by Heneage Gibbes. The growth resembled forms of recurrent fibroids which he has examined. There is no doubt that the aneurysmal dilations on both sides had the same cause. Bilateral occurrence would negative the idea of a malignant neoplasm. One characteristic of the growth, and the one that has brought about the condition in this case demanding operative interference, is its action on the bloodvessels. All through the sections the same condition is found, varying from a small hemorrhage to a large extravasation, the rupture of some vessel and the filling of the spaces in the surrounding tissues with blood corpuscles. **The aneurysmal dilations in both broad ligaments** have, in all probability, been formed by the occlusion of large vessels by the degeneration of their wall owing to the growth of a fibroid material, as is well shown in the walls of the large and small arteries, and more especially in the valves and walls of the large veins. By the complete removal of the parts in which the pathologic process was in active progress the disease was checked, and the patient now after a period of three years remains in very good health. (F.C.H.)

THE PUBLIC SERVICE

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine Hospital-Service, during the week ended April 20, 1901:

Appointments, Promotions, Retirements, Transfers, etc., of Medical Commissioned Officers, U. S. Army, Recorded in the Adjutant General's Office, between March 15 and April 15, 1901:

Volunteers.—HONORABLY DISCHARGED.

- BEESON, Captain EDWARD G., assistant surgeon, 39th Inf., March 31, 1901.
- FOXWORTHY, Captain FRANK W., assistant surgeon, 34th Inf., February 28, 1901.
- ANDREWS, First Lieutenant ROBERT W., assistant surgeon, 46th inf., March 17, 1901.
- WINTER, Major FRANCIS A., surgeon, 37th Inf., February 20, 1901.
- ANDERSON, Captain THOMAS B., assistant surgeon, 37th Inf., February 20, 1901.
- RAFFERTY, Major OGDEN, surgeon, 27th Inf., April 1, 1901.

COMMISSIONS VACATED BY NEW APPOINTMENT.

- EDIE, Major GUY L., surgeon, by promotion to major and surgeon, U. S. Army, February 2, 1901.
- IVES, Major FRANCIS J., surgeon, by promotion to major and surgeon, U. S. Army, February 2, 1901.
- KENDALL, Major WILLIAM P., surgeon, by promotion to major and surgeon, U. S. Army, February 2, 1901.
- HARRIS, Major HENRY S. T., surgeon, by promotion to major and surgeon, U. S. Army, February 4, 1901.
- KEAN, Major JEFFERSON R., surgeon, by promotion to major and surgeon, U. S. Army, February 4, 1901.
- EWING, Major CHARLES B., surgeon, by promotion to major and surgeon, U. S. Army, February 2, 1901.
- KNEEDLER, Major WILLIAM L., surgeon, by promotion to major and surgeon, U. S. Army, February 2, 1901.
- GRANDY, Major LUTHER B., surgeon, 35th infantry, by appointment as major and surgeon, U. S. volunteers, March 26, 1901.
- CHALMERS, Major THOMAS C., surgeon, 28th Infantry, by appointment as major and surgeon, U. S. volunteers, March 26, 1901.
- MCDILL, Major JOHN R., surgeon, 30th Infantry, by appointment as major and surgeon, U. S. volunteers, March 22, 1901.
- HEREFORD, Major JOHN R., surgeon, 32d Infantry, by appointment as major and surgeon, U. S. volunteers, March 21, 1901.
- NORMAN, Major SEATON, surgeon, 39th Infantry, by appointment as major and surgeon, U. S. volunteers, March 22, 1901.
- HENRY, Major JOSEPH N., surgeon, 31st Infantry, by appointment as major and surgeon, U. S. volunteers, April 6, 1901.
- ERWIN, Captain JAMES J., assistant surgeon, 30th infantry, by appointment as captain and assistant surgeon, U. S. volunteers, March 1, 1901.
- BREWER, Captain ISAAC W., assistant surgeon, 36th Infantry, by

- appointment as captain and assistant surgeon, U. S. volunteers, March 11, 1901.
- METZGER, Captain JOHN A., assistant surgeon, 35th infantry, by appointment as major and surgeon, U. S. volunteers, March 26, 1901.
- BOWEN, Captain WILLIAM, assistant surgeon, 27th Infantry by appointment as major and surgeon, U. S. volunteers, March 23, 1901.
- HADRA, Captain FREDERICK, assistant surgeon, 33d Infantry, by appointment as major and surgeon, U. S. volunteers, March 30, 1901.
- MINOR, Captain JAMES C., assistant surgeon, 29th Infantry, by appointment as major and surgeon, U. S. volunteers, March 21, 1901.
- ROBINS, Captain ROBERT P., assistant surgeon, 47th Infantry by appointment as major and surgeon, U. S. volunteers, March 23, 1901.
- COOK, Captain WILLIAM H., assistant surgeon, 32d Infantry, by appointment as major and surgeon, U. S. volunteers, March 21, 1901.
- PEED, First Lieutenant GEORGE P., assistant surgeon, 33th Infantry, by appointment as captain and assistant surgeon, U. S. volunteers, March 24, 1901.
- CARLING, First Lieutenant JOHN, assistant surgeon, 35th Infantry, by appointment as captain and assistant surgeon, U. S. volunteers, March 23, 1901.
- DUDLEY, First Lieutenant FRANK W., assistant surgeon, 32d Infantry, by appointment as captain and assistant surgeon, U. S. volunteers, March 21, 1901.
- WALLACE, First Lieutenant GEORGE S., assistant surgeon, 42d Infantry, by appointment as captain and assistant surgeon, U. S. volunteers, March 22, 1901.

Changes in the Medical Corps of the U. S. Navy, for the week ended April 20, 1901:

- URIE, J. F., surgeon, detached from the Dolphin, April 20, and ordered to the marine recruiting rendezvous, Boston, Mass., April 22, as relief of Surgeon J. E. Gardner.
 - STONE, E. P., surgeon, detached from the naval dispensary, Washington, D. C., April 19, and ordered to the Dolphin, April 20, as relief of Surgeon J. F. Urie.
 - ANDERSON, F., surgeon, ordered to the naval dispensary, Washington, D. C., April 19, as relief of Surgeon E. Stone.
 - GARDNER, J. E., surgeon, detached from the marine recruiting rendezvous, Boston, Mass., April 22, and ordered to the naval hospital, Cavite, P. I., for duty, via steamer sailing from San Francisco, Cal., May 11.
 - SMITH, C. G., assistant surgeon, appointed assistant surgeon from April 12, 1901.
 - ARNOLD, W. F., surgeon, detached from the New Orleans and ordered to duty at Olongapo, P. I.
 - ALFRED, A., passed assistant surgeon, ordered to duty with the marine brigade, Cavite, P. I.
 - GROW, E. H. J., assistant surgeon, detached from the Glacier and from duty at the Cavite Naval Station and ordered to the Isla de Luzon.
 - STEEP, J., assistant surgeon, detached from duty with the 1st regiment of marines, Cavite, P. I., and ordered to the Castine.
 - CURL, H. C., assistant surgeon, detached from the Castine and ordered to the Cavite Naval Station.
 - ROSE, W. V. H., passed assistant surgeon, detached from the Monterey and ordered to the Newark.
 - BLACKWOOD, N. J., passed assistant surgeon, detached from duty at the naval hospital, Philadelphia, Pa., April 17, and ordered to duty in connection with fitting out the Alliance, April 20, and to that vessel, when placed in commission.
 - MORRIS, L., passed assistant surgeon, detached from the Naval Academy and ordered to the naval hospital, Philadelphia, Pa., April 17, as relief of Passed Assistant Surgeon N. J. Blackwood.
 - SMITH, W. S., assistant surgeon, retired, detached from the Cavite Naval Station and ordered to the Oregon.
 - PECK, R. E., assistant surgeon, ordered to the Pensacola, April 25.
- Changes in the U. S. Marine Hospital Service for the 14 days ended April 18, 1901:**
- BANKS, G. E., surgeon, granted leave of absence for 6 days from April 15-April 11.
 - KINYOUN, J. J., surgeon, relieved from duty at San Francisco quarantine, and directed to proceed to Detroit, Mich., and assume command of the service—April 6. Granted leave of absence for 15 days—April 11.
 - PERRY, T. B., surgeon, department letter of March 2, granting Surgeon Perry leave of absence for 30 days, amended so that said leave shall be for 20 days—April 15.
 - GREENE, J. B., passed assistant surgeon, relieved from duty at Berlin, Germany, and directed to proceed to Washington, D. C.—April 5.
 - COFER, L. E., passed assistant surgeon, designated as chief quarantine officer of the Territory of Hawaii, relieving Surgeon D. A. Carinichael—April 6.
 - HASTINGS, HILL, assistant surgeon, to proceed to Santa Barbara, Cal., for special temporary duty—April 6.
 - GRUBBS, S. B., assistant surgeon, granted leave of absence for 7 days—April 10. Upon expiration of leave, proceed to Washington, D. C., and report at bureau for duty—April 10.
 - LAVINDER, G. H., assistant surgeon, bureau, telegram, granting Assis-

ant Surgeon Lavinder leave of absence for 10 days, amended so that said leave shall begin April 1 instead of March 27—April 5.

LUMSDEN, L. L., assistant surgeon, upon departure of Surgeon J. J. Klynon, to assume temporary command of San Francisco quarantine station—April 6.

FRANCIS, EDWARD, assistant surgeon, to proceed to New York and report to medical officer in command, immigration depot, for duty—April 8.

ALFRED, G. H., acting assistant surgeon, granted leave of absence for 4 days from April 10—April 6.

GAHN, HENRY, hospital steward and chemist, to assume temporary charge of purveying depot during absence of medical purveyor—April 8.

BROWN, F. L., hospital steward, relieved of duty at Boston, Mass., and directed to proceed to Cape Charles quarantine station and report to medical officer in command for duty and assignment to quarters—April 10.

PECK, F. H., hospital steward, to proceed to San Francisco, Cal., for special temporary duty—April 5.

MATHEWSON, H. S., assistant surgeon, promoted and appointed passed assistant surgeon to rank as such from April 7—April 6.

MONCURE, J. A., reinstated and appointed acting assistant surgeon, U. S. Marine Hospital Service, for duty at the Gulf quarantine station—March 29.

VAUGHAN, G. T., surgeon, reassigned to duty in Marine Hospital bureau—April 13.

GEDDINGS, H. D., passed assistant surgeon, directed to proceed to Buffalo, N. Y., for special temporary duty in connection with the installation of the Marine-Hospital Service exhibit at the Pan-American Exposition—April 18.

BLUE, RUPERT, passed assistant surgeon, directed to proceed to San Francisco, Cal., and report to Surgeon J. H. White for special temporary duty—April 16.

PARKER, H. B., assistant surgeon, directed to proceed to San Francisco, Cal., and report to Surgeon J. H. White for special temporary duty—April 15.

FOSTER, M. H., assistant surgeon, 2 days of the leave of absence granted Assistant Surgeon Foster by bureau letter of March 11, revoked—April 18.

CORPUT, G. M., assistant surgeon, directed to proceed to San Francisco, Cal., and report to Surgeon J. H. White for special temporary duty—April 15.

MOORE, DUNLOP, assistant surgeon, relieved from duty at Port Townsend quarantine, and directed to proceed to San Francisco, Cal., and report to Surgeon J. H. White for special temporary duty—April 18.

BERRY, T. D., assistant surgeon, granted leave of absence for 30 days from May 2—April 13.

BALLARD, J. C., acting assistant surgeon, leave of absence granted Acting Assistant Surgeon Ballard by bureau letter of February 4, amended to read, 6 days from April 23—April 16.

GOLDSBOROUGH, B. W., acting assistant surgeon, granted leave of absence for 7 days—April 13.

MCGINNIS, R. H., acting assistant surgeon, directed to proceed to St. Augustine, Fla., for special temporary duty—April 12.

RICHARDSON, S. W., hospital steward, directed to proceed to Buffalo, N. Y., and report to Passed Assistant Surgeon H. D. Geddings, for special temporary duty—April 17.

HALL, L. P., hospital steward, directed to proceed to Boston, Mass., and report to medical officer in command for duty and assignment to quarters—April 13.

HALL, LOUIS P., of New York, appointed junior hospital steward in the U. S. Marine-Hospital Service—April 12.

Changes in the Medical Corps of the U. S. Army for the week ended April 20, 1901:

BLOCK, WILLIAM H., acting assistant surgeon, is granted leave for 1 month, with permission to go beyond the limits of the department of Cuba.

BUFORD, OLIVER H., acting assistant surgeon, granted leave for 7 days, is extended 12 days.

SUMMERALL, Captain WILLIAM B., assistant surgeon, recently appointed, is relieved from duty in the department of Cuba, to take effect when his services can be spared by the commanding general of that department, and will then proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

BOWEN, Major WILLIAM, surgeon, is granted leave of absence until April 28.

HADRA, Major FREDERICK, surgeon, is granted leave for 1 month.

ANDERSON, Captain CHARLES, assistant surgeon, is assigned to temporary duty with troops on the army transport Ohio, to sail for the Philippine Islands. Upon the arrival of the transport at Manila, Captain Anderson will report for assignment to duty.

LEPERE, Captain MATTHEW, assistant surgeon, is assigned to temporary duty with troops on the army transport Ohio, to sail for the Philippine Islands. Upon arrival of the transport at Manila, Captain Lepere will report for assignment to duty.

BEASLEY, Major CHADWORTH O., surgeon, is assigned to temporary duty with troops on the army transport Logan, to sail for the Philippine Islands. Upon arrival of the transport at Manila, Major Beasley will report for assignment to duty.

MEARNS, Major EDGAR A., surgeon, granted leave on surgeon's certificate, is extended 6 months.

KILBOURNE, Major HENRY S., surgeon, is detailed as a member of the board of officers appointed to meet at the U. S. General Hospital, Presidio, for the examination of candidates for admission to the medical corps of the Army, vice Lieut. Col. Benjamin F. Pope, D. S. G., relieved.

EBER, Captain ALBERT H., assistant surgeon, upon the expiration of the leave granted him April 11, will proceed from St. Clair, Mich.,

to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

MADARA, Captain JAMES W., assistant surgeon, recently appointed, will proceed from Lexington, Ky., to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

ADOLPH K. BERNERS, ERNEST A. BOECKH, ROBERT CONARD EDWARD M. CHERVENKA, HARRY G. CIAMRERS, CHARLES S. ELLIOT, OTTO F. FRESE, CARL GRANER, JAMES W. GORIN, WILLIAM C. JONES, ANGUS MCLEOD, CLIFFORD H. PERRY, ALBERT A. ROBY, HARRY A. SAGER, EMIL STRAND, GEORGE C. VAN SICKLE and WILLIAM VOGT, hospital stewards, (appointed April 15, from acting hospital stewards, hospital corps), now at Manila, P. I., are assigned to duty in the division of the Philippines.

MAX ARENDT, LAFAYETTE JOSEPH and GEORGE E. VASS, hospital stewards, (appointed April 15, from privates of the hospital corps), now at Manila, P. I., are assigned to duty in the division of the Philippines.

The retirement from active service, April 13, 1901 of Col. Alfred A. Woodhull, A. S. G., by operation of law, under the provisions of the act of Congress approved June 30, 1882, is announced. Col. Woodhull will proceed to his home.

APPEL, Major AARON H., surgeon, leave for three months is granted, to take effect upon his being relieved from duty in the department of the East.

POINDEXTER, Captain JEFFERSON D., assistant surgeon, having been examined for promotion by a board of officers and found physically disqualified for the duties of a major and surgeon, by reason of disability incident to the service, his retirement from active service as a major, under the provisions of the act of Congress approved October 1, 1890, is announced, to date from April 13, 1901, the date he would have been promoted to that grade by reason of seniority if found qualified. He will proceed to his home.

COMBE, JOSEPH K., acting assistant surgeon, leave for 30 days is granted. The following named contract dental surgeons, will proceed from the places designated to San Francisco, Cal., and report for transportation to Manila, P. I., where they will report for assignment to duty: S. DAVIS BOAK, from Martinsburg, W. Va.; CLARENCE E. LAUDERDALE, from Naples, N. Y.

AMES, ROGER POST, acting assistant surgeon, leave for two months, with permission to go beyond sea, is granted.

AMERICAN MEDICINE

1321 Walnut Street

Philadelphia

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may begin at any time. Volumes begin with the first issue of April and of October.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles, will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is one dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to American-Medicine Publishing Company. Address all correspondence to 1321 Walnut Street, Philadelphia.

Hospital Service as a Prerequisite of Admission to Practice, has been recommended. It is already the law in Germany that one year of residence in a hospital is necessary before receiving the degree of M.D. It is said that this is still more necessary in the United States because only the best students obtain hospital positions, and the worst, those needing such practical instruction more, go directly into practice. In reply it may be urged, (1) that there are not hospitals enough in the country to furnish a year's residence to all the graduates that are required by a rapidly growing nation; and (2) that the true remedy consists in a demand upon the schools that they make thorough and needed clinical and practical instruction a part of undergraduate work. Lengthen the course of study if necessary; but the college should not give the degree unless the graduate possesses what his piece of parchment certifies—the ability to practise medicine.

Crime Against Criminals is criminal, although the work of civilized peoples. Indeed many of our prisons seem designed to prevent all possibility of reform, and to increase the viciousness and criminality of the inmates. Conditions in the Virginia penitentiary, for instance, as described by Dr. Charles V. Carrington, the surgeon at the institution, are fully as bad as those which required legislative correction in Georgia, Florida and other states. Both body and soul are ruined in the Virginia prison. The faulty, antiquated construction of the buildings and their crowded condition make impossible the provision of ordinary means for the preservation of health. In the prison for men an average number of 1,200 convicts are confined in 192 cells, and pure air is, of course, unknown. There is no sewerage system except in the hospital. The food is of poor quality, and the manner of its distribution makes it worse. Only the fact that criminals are generally young, vigorous and accustomed to privations prevents the annual death rate from rising above 40 per thousand. By the congregate plan in vogue, hardened criminals are thrown together with young offenders. Lessons in crime are the result, and vice for which the cities of Sodom and Gomorrah were destroyed.

Women's Clubs and Sanitary Effort.—The enlistment of every active intellectual element of the community in measures for the betterment of sanitary conditions should not be neglected. Many sanitary measures fail

of full acceptance by the people, and consequently of the best results, simply because of lack of comprehension of the true principles involved. It has been the experience of many sanitarians that the active cooperation of intelligent women is a most potent element of successful administration of sanitary regulations. In these days it is happily an easy matter to secure a hearing upon such subjects before representative bodies of women in the women's clubs that abound throughout the whole country. Not only by personal appearances and explanatory talks can the active health officer promote hygienic reforms, but he can enlist the aid of bright, public spirited women of culture, who in discussion and debate will uphold and advance scientific reforms. Women physicians are of the greatest help in such movements and will usually be found most ready to cooperate with the health authorities in presenting every subject of legitimate interest to the women's organizations in which they have membership. By nature and necessity woman has been the hygienist of the household; let us enlarge this function to civic and even national uses.

Premature Presbyopia or Accommodation Paresis, we believe, is more frequent and more often the cause of severe eye-strain, reflex neuroses, etc., than is generally suspected. In private practice several cases have illustrated this fact, and explained the inability to do near-work with any glasses given, until the suspicion as to the parietic or paralytic condition of the accommodative apparatus dawned upon the physician's mind. That such cases had passed through the offices of other most reputable oculists, or had long been unsuspected in old patients, demonstrates the lack of attention to the explanation. Into the question of etiology it is unnecessary to go at this time. When the accommodation is normally active and powerful the mistake of over-correction or of not waiting for real presbyopia is a bad one, though not so great as that of not recognizing premature presbyopia or chronic weakness of the ciliary muscle.

The old Professor in our medical colleges—what shall be done with him when for any reason he has outlived his usefulness? Of all the questions a Board of Trustees has to solve, this is the most difficult and perplexing. At several classical colleges—Harvard, Yale, Columbia—a pension system has been adopted, but so long as our rich men think that ignorance of Latin and

Greek are more important than disease and death, so long will our unendowed medical schools be incapable of establishing the pension system. Flattering the retired or resigning Professor with an "Emeritus" in return for the continued use of his name is another plan, but it is one open to grave objections. There are many reasons why, with growing age or under changed conditions, a teacher should discontinue his work. Medical education and science are both rapidly changing methods and even objects, the college itself may also suddenly become revolutionized, and the teacher who carries on the ways of ten years ago cannot meet the rivalry of other institutions and the demands of the modern practitioner. In all things the good of the many must be preferred to that of the one, and when for any reason the occupant of a chair fails to meet the requirements of our progressive profession, sympathy with the individual must yield to the requirement of the common good. Whether his own fault or not, when another can do the work much better, his resignation should be accepted. But it should be certain that an overpushing ambition and medical politics have not artificially created a desired condition.

The Man Who Never Makes Mistakes in diagnosis, or commits an error of judgment in treatment, is sometimes a member of our medical societies. He never has any unpleasant complications in his surgical manipulations and his cases are particularly free from unfavorable sequels; uniformly good results and phenomenal success invariably crown his efforts. He is a self-satisfied, complacent gentleman, extremely optimistic when reviewing his own handiwork, but coldly impartial and, perhaps, slightly hypercritical when surveying that of his conferees. He becomes particularly impressive when some younger man details the history of an unfortunate and unavoidable accident, or when some conscientious colleague makes a frank and truthful recital of his experiences. Then he manifests his surprise and, by his comments in the discussion, indicates his calm superiority, and advertises his personal ability. He knows full well that society reports are often perused by credulous readers with more receptive minds than the actual auditors, and hence he looks carefully after the stenographer. However, few are deceived except himself and an occasional neophyte. Fortunately such men are but a small minority of contributors, and the papers and clinical reports are usually provocative of veracious and beneficial discussions.

The Prevention and Cure of Insanity has too long been neglected by the profession, and we are glad to see that the Eighth Annual Report of the State Charities Aid Association, of New York, has determined to take up the work in a systematic manner. The report should be read by every one interested in the subject. It sets forth the reasons why insanity should not be considered an incurable disease, that it is not necessarily a disease of the brain alone, etc., and thus states the purpose it has formed:

The plan we would advocate is the erection, in several of our largest cities, of comparatively small Reception Hospitals, or Psychopathic Hospitals, as branches of existing State Hospitals

and governed by the same boards of managers. These hospitals, designed for the reception and temporary treatment of insane patients, should be organized on the same general plan as are the New York, Presbyterian, St. Luke's, St. Vincent's, Roosevelt, and Mount Sinai hospitals of this city, and other well managed hospitals elsewhere; with a superintendent and nursing staff, resident physicians, and attending and consulting physicians who should be alienists and neurologists.

An out-door department is recommended; the establishment also of pay and gratuitous treatment, and a department for clinical teaching. The Pathological Institute (already established) should also become a part of the general system. This most praiseworthy plan is not new, except in America, and for several years has been urged by Dr. Frederick Peterson of New York City.

Pelvic Inflammatory Diseases in Women.—Except cancer of the uterus there is no subject of such vital importance to the gynecologist as pelvic inflammatory disease. In this group of cases those of puerperal origin command the greatest attention; for, excepting cancer, probably no one class of gynecologic disease results in such a high percentage of deaths.

If the gynecologist is alive to these facts and always on the alert, deaths from this cause may be largely averted. He should remember that a large proportion of puerperal infections are due to the streptococcus; and that, of those severe infections at labor which go on to persistent inflammatory disease and drive the woman to the gynecologist for relief, a very large majority are of streptococcal origin. Bearing this in mind the gynecologist will generally make a correct diagnosis from the patient's history alone.

Knowing that these puerperal infections are usually of the subperitoneal connective tissues and localized on one side of, or anterior or posterior to, the uterus, the physician is enabled by his local examination to strengthen or weaken his probable diagnosis made from the history. A diagnosis of streptococcus infection being made, the problem is to reach and drain the mass without entering the peritoneal cavity. This can generally be accomplished by the vaginal incision or by the extraperitoneal inguinal incision of Bardenheuer. If it be found necessary to enter the peritoneal cavity, the intestines, during the operation, should be packed away with the utmost care; a dry technique should be followed, and if pus escapes, the contaminated region should finally be well covered by gauze carried out vaginally, abdominally, or by both routes. The purpose of this gauze is not that of drainage; it is used to keep the intestines from the infected region until protective granulations are formed.

Those who must Sleep in the Day are seldom thought of by the noise-makers. Indeed, how few have ever considered the fact that in every city there are thousands whose occupation compels them to sleep during the day. The sick, and all those of sensitive natures know the great influence of noise, at least during the night, in retarding convalescence, in lessening the resisting power of the organism, and in keeping up a high death-rate. How much worse the fate of those who are compelled to work all night and are prevented

by noise from securing normal sleep during the day. The hygienic value of quiet is one we are too slow in recognizing.

A Bureau for the Engagement of Clinical Assistants.—Cooperation of all sorts is now the rule in most systematized lines of activity. The medical profession is still much hampered by its unfortunately antiquated methods. The nursing profession has adopted, in most communities, registration of its members, preserving records of the character of education, the training, experience and preferences for lines of work, along with references to physicians who have practical knowledge of the person thus registered. Why not adopt the same plan in the securing of clinical assistants? When a clinical assistant is needed it usually happens that one can be found, but the process is largely accidental, like the old methods of securing a nurse, and as a rule it is only possible to accept the first willing person who offers himself. It often occurs that a physician would much prefer to exercise a larger choice in the matter, selecting one whose credentials are more varied or satisfactory. This is seldom possible, at least for the rank and file of hospital workers, because changes in the department occur seldom, and the attention of qualified or willing young medical men is not directed that way. Again, how is a young man seeking clinical opportunities to know of possibilities or openings which he may greatly desire, except again, by accident? Then too often he may suddenly learn of, and accept work, which though desirable, at least is not what he would prefer, but only what he can get. Hence the choice is forced upon him, not made with judgment and care.

If now, a systematic record, card-index, could be kept at some central point, on which shall appear his name, address, collegiate degree or evidences of education, medical degrees, experience, clinical and practical, and above all his preferences, there can be found by the one seeking an opening, opportunity for choice. It will afford important opportunities, too, for inquiries from the sources of information referred to. It would seem that such a center for obtaining this much needed knowledge would not only facilitate the securing of clinical helpers, but greatly encourage medical students and young practitioners to seek for such.

Recent Studies of the Etiology of Diabetes.—For some time it has been well known that certain forms of diabetes frequently follow injury of the pancreas or occur during the course of diseases affecting that organ. In a limited number of cases in which partial operative removal of the pancreas has been undertaken in man diabetes has followed. Experiments by several observers have shown that total removal or nearly total removal of the pancreas in animals is always followed by diabetes. But that the entire pancreas is not concerned in producing such forms of pancreatic diabetes has seemed probable from the fact that diabetes occasionally, but not always, is present in diseases affecting that organ. Exactly where the lesion has been located which has produced the trouble in those cases of pancreatic disease in which diabetes has been present has been a matter for

much speculation and considerable study. Certain peculiar groups of cells in the pancreas which were first described by Langerhans (*Beitrage zur mikroskopischen Anatomie der Bauchspeicheldruse, Inaugural Dissertation, Berlin, 1869*) and are usually known as the islands of Langerhans, have been mentioned as possibly the part affected, but in the past there has been no very definite evidence in support of this theory.

The islands of Langerhans have been thoroughly studied by Dr. Eugene L. Opie, recently, with a view to determining their origin and their importance as a causative factor in diabetes. His first paper on the histology of the islands of Langerhans appeared in the *Johns Hopkins Bulletin*, September, 1900. Later papers in the *Journal of Experimental Medicine*, January 15, and March 25, 1901, report the results of a study of the relations of chronic interstitial pancreatitis and of hyaline degeneration of the islands of Langerhans to diabetes. He distinguishes two types of inflammation affecting the developed pancreas: Interlobular pancreatitis, affecting chiefly the periphery of the lobules, and interacinar pancreatitis, invading the islands of Langerhans as is not the case with the first named variety unless the sclerotic process has reached a very advanced grade. In one of eleven cases of interlobular pancreatitis, diabetes of a mild variety occurred. Advanced sclerosis, following obstruction of the ducts by calculi, affected the islands of Langerhans in this case. In two of three cases of interacinar pancreatitis diabetes was present. In a fourth case of diabetes, hyaline deposit between the capillaries and the parenchymatous cells had so completely altered the islands of Langerhans that they were no longer recognizable. But a case reported in Dr. Opie's last paper is the most interesting and remarkable of the series. In this case the hyaline metamorphosis was limited strictly to the islands of Langerhaus, the glandular acini remaining intact.

Limited space forbids even mention of the features of these extremely interesting cases, or of the methods employed in their study. The importance of the results obtained in the case last mentioned will be readily appreciated, however, by those interested in the question of the etiology of this form of diabetes, and they seem to demonstrate very positively that the islands of Langerhans are parts responsible for the disturbance of carbohydrate metabolism present in this disease.

The Association of Convict Insane With Other Patients in Hospitals is justly criticized by Dr. B. D. Evans, and by the Board of Managers of the New Jersey State Hospital at Morris Plains, in their reports for the year 1900. In many States (*e. g.*, New York, Illinois, Michigan) the segregation of convicts who have become insane during imprisonment has been provided for in special institutions. But in others the old method of association in the State hospitals is still in vogue. And it is a great wrong, first to the innocent insane or convalescent to whom the association must be repugnant, or who learn crime of the old convicts; secondly to the hospital officers, who are tormented to prevent this, to keep the prisoners from escaping, etc.; and lastly to the State, which by the association really increases the num-

ber of criminals and the public cost of crime. Numerous illustrations are cited in the Report, nor does the evil always end with the discharge of the convicts, as it is said of some that "after their discharge from the hospital and from the State prison they succeeded in luring away certain previously moral patients who had been forced into their society by the transfer of the convicts to the State hospital.

Nostrum Mania.—The nostrum vendors and the newspapers and the United States copyright laws are responsible for a new type of disease. In his professional experience almost every physician must have learned of people afflicted with a genuine mania for taking so-called patent medicines. Many a man is made poor and kept so by this strange insanity. The most typical case of the disease is one cited by the *Practical Druggist* in which a Philadelphian was arrested by his wife for failure to support his family. For several years he had followed the newspaper advertisements and imagined himself the victim of all the diseases described by the enterprising advertisers. Apparently both poverty and pathology increased. A partial list of the takings is appended, "washed down with 2 gallons of lithia water each week:

48 bottles	Swamp Root.
24 bottles	Celery Compound.
60 bottles	Expectorant.
80 bottles	Vermifuge.
75 bottles	Kidney Cure.
60 bottles	Peruna.
36 bottles	Swayne's Specific.
57 bottles	Omega Oil.
75 bottles	Catarrh Remedy.
30 bottles	Munyon's Remedies.
50 bottles	Nervura.
24 boxes	Skin Ointment.
60 boxes	Magnetic Ointment.
36 boxes	Cough and Catarrh Root.
15 bottles	Glycerine Tonic.
37 boxes	Tar Tablets.
25 boxes	Cold Cure Pills.

And yet,—he died!

The Patient's Mental Condition is often quite as important a matter in the proper treatment of disease, as is his physical status. Failure to realize this fact has doubtless been in the past a professional sin, for which we are duly and justly punished by Unchristian Unscience, Faith-cure, and the rest. Our textbooks on therapeutics and materia medica tell us about hundreds of drugs; some of them will allude with too vague indifference to hygienic methods of treatment, but how many of them recognize and advise as to the highly important conditions of the patient's will, disposition, etc.? Every physician of discernment knows that the mental attitude of the patient governs, often entirely, always to some extent, the morbid processes and the nutritional reactions. The cheerfulness and friendliness of the old time general practitioner was perhaps needed to neutralize his bad medicines, and they were certainly powerful therapeutic agents. Choate found the dying Lowell reading "Rob Roy," whereby, the poet said, he forgot his bodily pains. Two items universally omitted from the books on Therapeutics and Treatment should be henceforth important constituent parts—music and

books. Above all things nurses should be good readers, and, if possible, good musicians. Physicians should advise about what books to be read, as much as about what drugs to be given and what food to be eaten. The best nurses' training schools should have teachers of music and of literature, as well as professors of surgery, obstetrics, etc., etc.

The Complications of Diphtheria.—One of the most important sections of the monograph on diphtheria by Councilman, Mallory and Pearce, to which reference has already been made, is that which records the results of the bacteriologic investigations and the study of certain complications. Probably the most interesting and instructive result of the bacteriologic study was the demonstration of the fact that general infection with the diphtheria bacillus is much more frequent than is generally supposed. It is not so frequent, however, as is general infection with the streptococcus. Infection with either or both of these organisms is most common in the so-called "septic" or malignant cases. In the production of bronchopneumonia which was present in 131 of the cases, the pus cocci and the pneumococcus appear to be important etiologic agents; the diphtheria bacillus alone, however, may give rise to the bronchopneumonia as well as to abscess and necrosis of the lung. These latter facts have an extremely important practical bearing, especially with regard to treatment and the mortality statistics of cases treated with antitoxin. Naturally it can hardly be expected that the diphtheria-antitoxin can influence an infection due to pus cocci, and a fatal termination in such cases should hardly be ascribed to failure of the antitoxin. It would seem logical also in view of the possible dependence of bronchopneumonia upon infection of the lung with diphtheria bacilli to increase largely the dose of the antitoxin in the event of the development of such complication. If it were possible to settle upon the streptococcus as the cause of the bronchopneumonia in a given case, it would also seem the part of wisdom to consider seriously the desirability of administering some antistreptococcal serum. Of great interest and practical importance are the results of the examinations of the accessory sinuses of the nose. In 39 of 63 cases investigated they were found the seat of inflammation, and from most of these cases diphtheria bacilli, generally in association with pus cocci, were recovered. Another interesting result of the investigation was the detection of complicating tuberculosis in 16% of the cases. This the authors are disposed to consider the expression of an old infection to which diphtheria may have predisposed. All of these questions have extremely important practical bearings, and not the least important, certainly one of the most interesting, is that with reference to the accessory sinuses of the nose. The authors believe that these inflammatory conditions do not subside quickly, and they consider that the persistence of diphtheria bacilli in cultures from the throat and nose after all symptoms of diphtheria have subsided, may be attributed to gradual drainage of these sinuses. If this view is confirmed, it would seem that more energetic treatment should be directed to the local conditions in the nose and throat during what might

be termed the convalescence than is generally the case. Certainly the question merits further consideration.

A Proposed National Bureau of Materia Medica.

—In the *Journal of the American Medical Association* for April 20, 1901, Dr. F. E. Stewart proposes a National Bureau of Materia Medica to furnish the medical and pharmaceutical professions with accurate information concerning the commercial materia medica; to protect the public from those who exploit the sick by misleading advertisements, adulterations, sophistications and fraudulent substitutions; to promote fair competition in trade; to aid pharmacists and manufacturers by providing a place where they can standardize their products and preparations and keep them under chemical and pharmacodynamic observation; to aid the professions of medicine and pharmacy in the cooperative introduction of new products and preparations to science; to aid pharmacists and manufacturers in the introduction of new brands to commerce; and to appeal to physicians to support manufacturing houses which conform to proper scientific and professional requirements by specifying their products when prescribing, and to discriminate in favor of pharmacists who carry standard and standardized preparations for dispensing in physicians' prescriptions. The method by which the author hopes to accomplish these objects is given in a prospectus which forms part of his paper. On account of the great importance of the subject and the impossibility of doing justice either to the subject or the paper in the limits of an abstract we must refer our readers to the original text for detailed information. Reprints may be had by addressing the author, at 67 Prospect Street, East Orange, N. J.

Learning Nursing by Correspondence, reminds one of the daughter who should learn to swim without going near the water; and yet there lie before us circulars, Applications for Enrollment, Why-I-should-take-this-Scientific-Course-of-Training, Rates-of-Tuition, etc., explicitly setting forth the scheme. The English and Latin by which the girl in the store or "factory" is induced to remit, are outdone only by the ethicality and religiosity of the arguments. An abstract cannot quite equal quotation:—

WHY SHOULD I TAKE THIS SCIENTIFIC COURSE OF TRAINING?

First.—Because the Trained Nurse is now compelled to register, and very soon it will be a law that all nurses must be graduates of some first class Training School, or undergo an examination, before they can nurse in serious cases, and get the fees of the Trained Nurse. If I matriculate, or register as a student in the American Correspondence School of Nursing, I will not be affected by any law which may be made hereafter, compelling women to be examined before entering into practice.

Second.—Because in taking the training of the Nurse in the American Correspondence School of Nursing, I do not consume much time, nor need I leave my home, nor am I prevented from nursing, or from being in the store or factory—in short, I can study my lessons at night, and in 13 months I can have a diploma which will entitle me to high wages if I want to nurse, and if I do not, then I have acquired knowledge of how to take care of myself, and the family I belong to, and I will in this way escape from many a disease and much suffering all my life.

Third.—Because in this course I learn all about myself, and when I get sick I can tell whether the proper thing is done for me. In fact, it will possibly save myself and my family many a doctor's bill.

I am also, in the Primary and Normal courses, taught to be a Masseuse, and if I do not wish to nurse, I can give Massage Treatments, and get the regular \$2 fee, which is everywhere paid for these treatments.

1. Every pupil is accepted, no matter how little she knows.
2. If I cannot read nor write I will be taught.
3. The work is simple and easy to learn.
4. I need not go away from home, nor give but one hour a day.
5. The expenses are very reasonable.
6. I like this school best, because the graduates are now taking the highest rank as Nurses.
7. If I do not get my lessons readily the Professors help me.
8. Everyone knows this is the only Correspondence School for Nurses, and the course of study is unsurpassed.

TO THE UNEDUCATED A SURE HOPE.

PREPARATORY EDUCATION FURNISHED.

The management of this modern training school have appreciated the fact, in taking up training school work among the non-graduate nurses, that many will be found who have shared absolutely no educational advantages and are deficient in the common English branches of reading, writing and arithmetic, and yet, notwithstanding this obvious disadvantage, they have served as nurses and are now regarded as essentially "good" nurses.

We desire a literary fitness and general scholarship, as well as a distinct technical education.

Let every pupil nurse who enrolls with us cultivate lofty aspirations and a broad scholarship, and realize that the calling of the nurse is a little less than divine, as will be shown some day when all other aims, save the aims and objects of the human healer, will have proven by comparison to be impractical, visionary and unsuccessful.

What a way to make money! And the poor girls!

Where Are Your Clothes Made?—asks the *College Settlement* of Philadelphia citizens, and answers by saying that it is not only the ready-made clothing that is made in the unhealthy sweatshops and crowded back alleys. The following advice is urged as to the finest tailor-made clothing:

If you are a good customer and deal at a first-class house, demand of your tailor that he give you an assurance that your clothing will be made on the premises or in sanitary workrooms suitable for the purpose. Your tailor has, even under the present system of home work, a room in connection with his store used for bnsheing and altering. He can meet your demand, if it is the first, without increasing his rent, by calling in one of his journeymen to do your work in his repair shop. If ten or more of his customers make such a demand he will be forced to consider seriously the subject of workrooms on his own premises and under his own supervision.

That fine champion of sound science and christianity, Dr. J. M. Buckley, challenged the Unchristian Unscientist Mr. Carol Norton to a debate. At the last moment, "after deep and prayerful consideration," Mr. Norton concluded not to appear, and wrote instead:

A further examination of his (Dr. Buckley's) recent utterances on Christian Science and a fuller analysis of his attitude, based on a line of opposition over a period of years, leads me to feel that the best interests of Christian Science will not be served by my speaking. . . . The statements necessary of correction which Dr. Buckley could make in forty minutes could not be decently made by me in ten times that amount of time. . . . A forty-minute address on Christian Science can hardly touch even the hem of the garment.

A noteworthy advance in Penology is the isolation of its consumptive convicts by the State of Texas. The patients receive treatment as in the best sanatoriums. The experiment has proved successful, and financially the farm has yielded the State a net profit of about \$2,500. A similar segregation has been ordered by Alabama. If the sick convict can be cured and also made profitable, why are the penitentiaries for the healthy so burdensome to the taxpayers? Because of "politics."

The physician is not compelled to practise, nor compelled to answer calls, is the decision of the Indiana Supreme Court. He is not, the Court holds, in the position of a railway company which has certain public duties by virtue of its office and charter. When no contract exists, the physician should not legally be compelled to respond to every call that may be made upon him any more than a lawyer should be compelled to take the case of every client that may come for advice.

Sir William MacDonald, of Montreal, Canada, proposes the endowment of a crematory whereby the poor may have incinerations made for a very small fee or gratis. The object is to lessen the lavish funeral expenses of the foolish poor. In Cleveland, Ohio, the ostentatious hearse and long string of carriages are considered necessary by them, while persons of means use the funeral car on the street railroads at a cost of only \$10.00.

Weltmerism has at last been taught a lesson, and the Nevada, Mo., postoffice, raised by its influence from a fourth-class to a first-class office, may have to return to its former humble status. The President and the Secretary of the "Institute of Magnetic Healing" have pleaded guilty to indictments charging them with using the mails to defraud. "All diseases known to man or woman" were cured by "absent treatment."

The Board of Education of Philadelphia has decided to try the experiment of abolishing the examination of pupils in the public schools, the teachers and principals, from the record of the term work, determining whether the pupils are to be promoted or not. The strain and danger to the health, of the examinations, will thus be avoided. This is a most commendable movement.

"It sickens one not a little to hear a beneficent millionaire spoken of as the 'largest-hearted person in the universe,' when perhaps in the next street there lies dying a doctor who has sucked the poison from a patient with diphtheria; but that is the fault of the praiser, not of the praised."—[*The Spectator*.]

The gunmakers and powder manufacturers sent their agents to Albany, and their lobby was so powerful and successful that the proposed law against dove-shooting or pigeon-shooting under the name of sport, failed of passage. Where were the antivivisectionists?

Ten blind physicians, it is said, are active practitioners in the United States.

AMERICAN NEWS AND NOTES

GENERAL.

Right to Quarantine.—The United States Supreme Court has affirmed in a late decision the right of one State to quarantine against another in case of contagious disease.

Contract Surgeons.—At the request of the Surgeon General of the Army, the Secretary of War has directed that on all official orders and records of the War Department and of the army, doctors serving under contract with the army shall be designated as "contract surgeons," in lieu of "acting assistant surgeons," as heretofore.

The National Association for the study of epilepsy and the care and treatment of epileptics will meet in Washington, D. C., on the afternoons of May 14 and 15, 1901. It has for its aim the welfare of epileptics, the stimulation of causes and cure of the disease and the advocacy of treating this class in institutions. Wm. Pryor Letchworth, Portage, N. Y., is president, and Dr. Wm. P. Spratling, superintendent; Craig Colony, Sonyea, N. Y., secretary.

The National Sanitarium at Fort Stanton for the treatment of tuberculosis, though exclusively for the use of patients sent from the Marine Hospital, is expected to help materially in the international fight against this dread disease. Surgeon-General Wyman will detail one of his most experienced men to attend the Medical Congress, which will be held in London on July 22 to discuss the extermination of tuberculosis. Fort Stanton is situated in a peculiarly adapted climate 6,126 feet above the sea. The purpose of the sanitarium is threefold: To save the consumptive sailor; to prevent contagion at the Marine Hospital; to prevent contagion on shipboard. The treatment followed is largely one of diet and exposure to the open air. The Medical Bureau of the Army has established a similar hospital at Fort Bayard, New Mexico.

Obituary.—FREDERICK J. BROCKWAY of New York, at Brattleborough, Vt., April 21, aged 41. JAMES H. WOODBURN of Indianapolis, Ind., April 23. FREDERICK A. LARKIN of Chicago, in Philadelphia, April 23, aged 40. EDWARD F. MORRIS of Birmingham, Ala., April 23, aged 36. HENRY BYRON McKELLOPS of St. Louis, April 23, aged 78. PERCY M. GRAHAM of Philadelphia, April 23, aged 40. HORACIO GUZMAN of Washington, April 23, aged 55. RICHARD C. BAKER at Otego, N. Y., April 24, aged 47. ROY INGLIS of Jersey City, at Denver Col., April 23. J. A. McINTOSH of Nashville, Tenn., April 23, aged 60. W. H. DRAPER of New York, April 27, aged 71. WILLIAM BOVIE of Augusta, Mich., April 25, aged 73. T. H. LITTLE of Toronto, April 25, aged 40. THOMAS RITCHIE ALMON of Halifax, N. S., April 25, aged 65. F. B. R. YOUNG at Dallas, Texas, April 24. WILLIAM H. BURR of Madison, Ga., April 24, aged 85. GEORGE DALE of Iola, Wis., April 24. M. B. BALDWIN of Wardencliffe, L. I., April 27. ALBERT HARE of McKeesport, Pa., April 26. E. CONKEY of Indianapolis, April 24. OLIVER H. SULLIVAN of Alexandria, Ind., April 12. WYLLIS F. WOOD of Rensselaer, N. Y., April 11, aged 50. ANNER E. GORE of Paris, Mo., aged 78. JOHN B. O. LANDRUM of Campobello, April 13, aged 70.

Smallpox.—In Philadelphia a few cases were reported last week in the northwestern part of the city and in New York City 9 new cases were reported April 24; the total number since November 1, 1900, in that city is 599; the deaths from smallpox have been about 20% of cases whereas in other epidemic years it has ranged from 23% to 28%. New cases are reported from Albany, N. Y. In Pittsburgh, Pa., there has been a wholesale vaccination of the Italian population, who were opposed to it, and 20 health officers and the police were required for this compulsory measure. At Cohoes, Pa., 12 cases of smallpox have been discovered and it is reported as prevailing at Cumberland, Md., and as critical in Barbour and Randolph counties, W. Va., 30 new cases having been discovered at Weaver, 10 at Moore, and 6 at Bellington, though only 3 deaths have occurred. On April 1, there were 491 cases in Tennessee, 49 counties being infected. At present the disease is to be found in only 28 counties. It has been of a mild type. At Guthrie, Ky., the smallpox is nearly stamped out. In Jacksonville, Fla., there are 24 cases—mainly among the negroes. The colored people of the South make light of the smallpox and avoid vaccination as far as possible. At Brockton, Ill., a member of the State Board of Health diagnosed April 24 as smallpox an epidemic which had prevailed there for 3 weeks and the local physicians had not recognized the disease. There are 65 cases in Brockton and as many more at Garland, a village 6 miles east of that place. In Cleveland, Ohio, 22 cases have been found by the Health Board through tips received from informants and Gilbert School has been closed because of the disease in that locality. At Hudson, Ohio, the local health officers have been powerless to enforce the quarantine against the students of the Western Reserve Academy in which smallpox had developed, and a number of them took the train for their homes. From Brantford, Ont., an outbreak of smallpox is reported among the Indians on the Six Nations reserve and the situation is regarded

as serious. In Great Falls, Mont., 200 cases are reported and it is said to have a foothold among the Kootenay towns and the Crow's Nest Pass. The smallpox epidemic is reported as likely to become general among the Indians of Southeastern Alaska, 80 cases in the Sitka Indian village and the Indians stampeding and carrying the infection. The transport Kilpatrick arrived at Honolulu from San Francisco with 2 cases of smallpox on board and several cases of mumps and measles.

EASTERN STATES.

Antivivisection a Failure.—On April 22, the Massachusetts Senate accepted the adverse report on the bill in further restriction of vivisection.

The Instructive District Nursing Association in Boston and vicinity recently issued its fifteenth annual report. The records show that the Association's nurses had 6,235 patients and made 61,665 visits. The object of this institution is to provide trained nurses to care for the sick poor in their homes, and to instruct the patients and their families in simple nursing and wholesome living.

Physiology in Public Schools.—On April 1 it was decided to take all textbooks on physiology out of the public schools of Somerville, Mass. As a reason for this movement School Committeeman Sanborn says it is claimed that the books now in use are undesirable and the matter they contain unfit for the perusal of young children. Hereafter the necessary instruction will be given orally by the teacher, said instruction to be limited to the care of the teeth, proper clothing and care of the body.

An Appendicitis Club.—Station Agent Fernald, at Old Orchard, Me., underwent a very successful operation for appendicitis in 1898 and since then has been an enthusiastic student of this affection and keeps a map of the human frame, showing in cross section the development of the disease, and has collected literature on the subject and the names of those who have been operated upon for it. He is now interested in the formation of an appendicitis club, in which only those who have been operated upon are eligible to membership.

River Pollution.—An outgrowth of the numerous complaints about the pollution of the Passaic River which is thought responsible for the recent typhoid cases, will be the establishment by the Government of a gauging station at some suitable point on the river far enough above any particular dam so that the full flow of the water will not be checked, and above any of the pumping stations, as the flow below them would be less than the regular river capacity. The exact current past the station will be measured and daily readings of the height of the river will be made. Two Bridges, 3 miles above Little Falls, has been decided upon as the best location.

Shooting of Human Beings by Hunters.—The Legislature of Maine has passed a law recently fixing a penalty of imprisonment not exceeding 10 years or a fine not exceeding \$1,000 for the wounding and killing of human beings in mistake for wild game. The duty of investigating violations of this law and prosecuting the offenders is incumbent upon the county attorney and sheriff and in case of failure to do so they lay themselves liable to a fine of \$1,000. Mistakes of this kind have been of such frequent occurrence in the State of Maine during the past few years that many people have feared to go into the woods and this law has been passed in response to popular demand.

NEW YORK.

Protection of Eyesight.—The public health committee of the assembly have reported favorably upon the bill giving the New York State Board of Health power to regulate the type and leading of books, newspapers and serial literature.

Insanity Increasing in New York.—The Commission on Lunacy, of New York, reports 23,000 insane patients in the various institutions throughout the State. Dr. T. J. Currie, assistant physician of the Willard State Hospital, states that the number of people who become insane is increasing each year. He attributes this increase to hereditary causes, to intemperance, alcoholic drugs and other excesses. The "strenuous life" is also responsible for many cases. He reports the Willard asylum as having 2,300 patients, 1,800 of whom are incurable. These chronically demented ones farm the estate of 1,200 acres which belongs to the institution.

A New Disease of Cattle is reported from Wood Stock, New York, in the herd of Henry Miller. It has caused the death of 6 cows in a week by rupturing the bloodvessels, the animal bleeding to death internally a few hours after it is attacked. Prof. Law, of Cornell University, to whom the case was submitted, found in the blood-clot a red-shaped organism which is being cultivated for identification. Prof. Law injected into the necks of 2 other cows which showed symptoms of disease, and all the other cows of the herd, serum made from the sterilized blood of some of the dead animals previously sent him—and this seemed to arrest the disease at once.

PHILADELPHIA, PENNSYLVANIA, ETC.

Dr. C. A. Veasey has been appointed Ophthalmic Surgeon to the Methodist Episcopal Hospital of Philadelphia.

The Ptolemy Society for the dissemination of medical science and social intercourse has had its charter approved.

The Alleghany General Hospital will have erected in its stead a new institution costing \$350,000. The State is expected to give \$100,000 of this.

Homes for Tuberculous Patients.—The Legislature of Pennsylvania has been asked for an appropriation of \$60,000 for the founding of free homes for tuberculous patients in the mountains near White Haven. The present plan provides for the erection of 10 cottages.

Philadelphia Almshouse.—A resolution was adopted at a recent meeting of the medical staff of the Philadelphia Hospital petitioning the Board of Charities and Correction, the Mayor and the City Councils to remove the Almshouse from the grounds of the Philadelphia Hospital.

Dr. Aloysius O. J. Kelly, instructor in clinical medicine in the University of Pennsylvania, recently was elected professor of the theory and practice of medicine in the University of Vermont. He leaves Philadelphia shortly for Burlington to begin his duties, but will return to Philadelphia in the early fall.

Medical Director Walter K. Scofield has been placed on the retired list. His rank is that of Rear Admiral and he retains the title of medical director. Medical Director W. G. Farrel succeeds Dr. Scofield in the work of the recruiting district. Dr. Clement Biddle takes Dr. Farrel's place at League Island Navy Yard.

The Polyclinic Hospital with a record of 213,181 patients treated in 18 years, asks of its friends a donation of \$100,000 as a special Twentieth Century Fund to put it on a sound financial basis, as the number of its patients steadily increases. In addition, special donations are asked for an electric light plant, a power laundry, a nurses' home, an isolating ward, a new dispensary building and laboratory endowment. Endowments for free beds are also greatly needed.

Fangotherapy, the treatment of disease by clay from small lakes near Battaglia, Italy, has been tested as to its efficacy in the last 2 years by Dr. W. C. Hollopeter, of Philadelphia, who recently reported his experiments with some which a patient of his brought from Italy. It is a greyish-brown, smooth mud, rich in iron, argillaceous herbs, lime and alkalies united to phosphates, sulphuric acid and carbonic acid gas. He has found fango useful in articular rheumatism, gout, localized neuralgias, sciatica, etc. It is applied warm in layers on the affected surfaces and retains its artificial heat for a long time.

SOUTHERN STATES.

Selling Cocain.—Three negroes have been fined \$100 and cost each for peddling cocain in the streets of Atlanta, Ga.

Insanity a Cause for Divorce.—A bill has been passed by the Florida Legislature declaring that incurable insanity shall be legal cause for divorce. It provides that the husband shall support the wife after getting a divorce for that cause, and shall put her in an asylum and pay all expenses. It is asserted that this bill was not enacted because of public demand, but in the interest of one person, who wished to dispose of the property of an insane wife.

A Change in Quarantine Regulations is about to be made which will benefit Norfolk and Portsmouth, Va. Dr. Gregory, of the United States Marine-Hospital Service, will establish a quarantine station at Tampico, Mexico, of which he will have charge. Vessels bound from this port to the United States will be inspected prior to sailing, and if necessary, will be fumigated. Upon arrival at their destination, they will, provided no disease has developed on board, be allowed to land without detention. The action of the Surgeon-General in thus preventing vessels being held at quarantine will be of great advantage to Norfolk and Portsmouth, between which and Tampico a great and growing trade exists.

The Antispitting Law.—Great interest is expressed in New Orleans over the recent passage of an antispitting ordinance by the City Councils. Dr. Scheppegrell, chairman of the Orleans Parish Medical Society, which proposed and recommended the law, says that expectoration can be banished effectually from all public places by law, and that the health of the community will be benefited greatly thereby. On the other hand a great number of persons oppose the law on the ground that though the law is a good one if properly enforced its execution is practically impossible on account of the inadequate police force. Therefore it is claimed that the City Councils made a mistake in enacting a law which in a short time would be disregarded and thereby a distinct tendency added to the volume of lawlessness that now exists through neglected ordinances.

WESTERN STATES.

Dr. Reuben Peterson, of Chicago has been appointed to the Bates professorship of the diseases of women in Michigan University, to succeed Dr. J. N. Martin.

Excision of Stomach.—At the hospital of the Illinois Medical College, Dr. B. B. Eads successfully removed the stomach of a patient suffering from carcinoma.

No Quarantine Law exists in Multnomah county, Washington, and the authorities are powerless to act in contagious diseases. There is also no law to protect cattle from contagion.

St. Peter's Hospital in Helena, Mont., destroyed recently by fire has had a donation of \$15,000 from an unknown New York woman. This, with the \$60,000 bequest of Felix R. Brunot, of Pittsburg, will restore the building.

A Blind Student.—George S. Dobbins has graduated with honor from the Chicago Homeopathic Medical College. Owing to his refined sense of hearing he will devote his professional efforts to diseases of the respiratory organs.

Typhoid Fever.—The chemist of the health department of Merton, Wisconsin, has shown that the typhoid fever epidemic has its rise from milk infected by poisoned well water or from river and country ice. It is asked that the authorities of the city compel owners of dairies to conform to sanitary regulations and submit to periodical inspection. The harvesting of the city's ice on Lake Michigan is suggested as a means of obtaining a pure supply, as the waters of the river and country lakes will grow worse as the population increases.

Baby Farm Ordinance.—An ordinance designed to provide for the licensing, inspection and regulation of all foundling homes in Chicago, was introduced in the Council of that city on April 22. It is proposed to place all private parties who have the control of more than 3 children not their own in charge of the proper authorities. All State, county and incorporated charities which are at present inspected by the County Visiting Committee, and such institutions that do not retain the children for more than 24 hours consecutively, will be excepted.

CANADA.

An Amalgamation of Trinity Medical College, Toronto, and the Toronto Medical College is under way.

Smallpox.—The city of Toronto has spent more than \$1,400 during 1901 in the care of its smallpox patients.

Dr. J. H. King has been appointed provincial health officer for the district between Kootenay Lake and Mielhel.

Examination of Immigrants.—An office has been opened in Montreal by the Immigration Department of the United States Government for the examination of all foreigners destined for the United States.

Medical Legislation.—A bill is before the Canadian House of Commons which provides for the establishment of medical qualifications which shall be valid for the whole of Canada. At present each province confers medical qualifications which are only recognizable in the Province in which they were granted.

Barber-Shop Sanitation is carried out in the Province of Quebec, where the existing law compels barbers to take out a license or abandon business and customers affected with any skin disease are obliged to furnish their own razors, soap, brushes, etc., which are kept in a specially constructed cabinet approved by the Provincial Board of Health.

Cremation Forbidden.—The Archbishop of Montreal, in a pastoral letter dated April 3, strongly opposes cremation, and regrets that the Quebec Legislature has made it legal. He says that cremation is formally prohibited for all the children of the Roman Catholic Church. None of them may encourage it, or take any part whatever in it.

Increase of Insanity.—The annual report of the Protestant Hospital for the Insane, Verdun, Quebec, shows an increased number of patients in that institution. During the year 1900 there were 497 patients treated; 265 males and 232 females. During the year 93 patients were discharged, 52 of whom were recovered, 28 improved; 13 unimproved; a discharge rate of 66.90% and a recovery rate of 37.41%.

Guarding Against Plague.—The Canadian Director of Public Health, Dr. Montzambert, is taking active measures to prevent the introduction of plague and smallpox into Canada. All Orientals entering by way of the Pacific are compelled to undergo a bath at the quarantine station, and their clothing and effects are disinfected. To guard against smallpox 40 officers have been detailed to watch the main avenues of access from the United States, and all suspected cases are ordered into quarantine.

FOREIGN NEWS AND NOTES

GENERAL.

Obituary.—WILLIAM FORBES of Gippsland, Victoria, April 5, aged 69. GIULIO BIZZOZERO of Turin, April 8, aged 55. IVOR A. LEWIS of Cymmer, Porth, April 8, aged 53. DR. MENKE, leader of a German scientific expedition in the South Sea Islands, murdered by natives of Mac Quari Island.

The Record of Vital Statistics for Great Britain has just been issued. They show a total of 262,334 marriages and 353 divorces for the entire year. The births number 928,646, and the deaths 581,799. These figures show that the population of the United Kingdom is steadily increasing; the immigration from the continent almost offsets the emigration to the United States and other countries. Not a single death from hydrophobia was reported which would indicate that the English are more particular with their dogs than we are.

GREAT BRITAIN.

An Outbreak of Typhoid in Lamberth, England, amounting to 41 cases in 24 hours in a limited area is reported.

Misadventure and the advice that the doctor be cautioned was the verdict returned by the jury in the case of Marion Davies, a school girl who died from the poison given to her in mistake for medicine by Dr. Smith, of Aston, Birmingham.

The Jacksonian Prize has been awarded to Mr. McAdam Eccles, M. S., for his dissertation on The Pathology, Diagnosis and Treatment of the Diseases caused by and connected with Imperfect Descent of the Testicle, by the Royal College of Surgeons of England.

Marine Biological Station, founded by the late Dr. David Robertson at Millport, Scotland, will hold a course of lectures on zoology and botany with practical demonstrations on Saturdays from April 27 to June 15, to encourage the practical study of natural history among the teachers and among science students in the University of Glasgow.

The British Congress on Tuberculosis will convene in Queen's Hall, London, from July 22 to July 26, 1901, under the patronage of Edward VII and connected with it are the names of the best known physicians and surgeons of the empire. All of England's colonies are invited to send delegates and foreign nations are requested to send representative men of science who will be classed as Honorary Members of the Congress. The provisional program provides for the consideration of all subjects bearing directly or indirectly upon the disease and modes of treatment—infection and prophylaxis. The languages of the Congress will be English, German and French.

CONTINENTAL EUROPE.

Mosquitos in Paris have increased to such a degree that the Academy of Medicine has debated on measures to reduce the pests. Dr. Debove attributes this increase to stagnant water in public and private gardens.

Foot and Mouth Disease Serum.—Prof. Loeffler and Dr. Ulenruth, Austrian scientists, announce their discovery of a serum to protect animals against the foot and mouth disease, which will be placed at the disposal of the public as soon as the government authorizes them to do so.

Malaria in Italy.—A consular report illustrates what has already been accomplished in Italy in allaying the ravages of malaria there. The Mediterranean Railway Company has equipped all stations and employees' houses in malarial districts with mosquito-proof screens, and those who are obliged to be out after night are provided with mosquito-proof clothing. By this means the railway company has secured complete immunity for its servants and their families even in the worst localities as Battipaglia and San Nicola. Formerly an appointment to these districts meant little less than a death sentence and no man could hope to have his family with him. The families have been perfectly healthy in these protected houses.

Training of the Blind.—Director Keller, of the Institute for the Blind, at Vienna, exhibited before the Physicians' Society, a 7-year-old boy, born blind, but with perfectly formed eyes, whom he taught in 14 months to discern colors, forms and objects; also to read. His method is first to put the child in a dark room, and by means of a movable disk of light teach him to distinguish light from darkness. Then objects are placed on the light disk and the child given their names; colored glass placed before a lamp teaches him colors; then geometric figures are shown on the disk, slowly leading to the formation of letters, and finally reading is taught. Next the disk is removed and objects shown in the dark room with the light rays full on them, and from this point the sight is gradually accustomed to the daylight.

SOCIETY REPORTS

XXX CONGRESS OF THE GERMAN SURGICAL ASSOCIATION.*

HELD AT BERLIN, APRIL 10, 11 AND 12, 1901.

The Congress was formally opened for the presentation of scientific papers by PROF. CZERNY of Heidelberg with an address in which the president expressed the hope that the value of the Association's work in the century upon which they were entering would be even greater than that of the past. Among the important questions which concern the surgeon equally as much as the physician are: The origin of many of the infectious diseases, a more thorough knowledge of tuberculosis, a better understanding of the means by which nature combats disease, and the cause of carcinoma. In order that advances be made in the study of carcinoma new methods of investigation are needed. Russia has set the world a good example in the establishment of a hospital for incurable cases of carcinoma, which is in charge of Prof. Lewschin and in connection with the medical clinic of the University of Moscow. Teachers in the universities should give their students encouragement in original work and give them opportunities for such investigation, for in this way they are best prepared to meet the difficulties of practice.

Czerny, like most members of the German profession, is opposed to admitting graduates of the Real gymnasiums (the higher German schools in which the classics are not taught) to medical study in the universities, as has been suggested the past year. The members of the Association who had died, and their works, were mentioned, a special tribute of honor being given to Professor Ollier of Lyons, France. The president reported the affairs of the association to be in unusually favorable condition both financially and as regards the membership. The number of members is now about 1,050, of whom 665 were registered in attendance at this session. The following papers were then presented:

Renal Surgery in the 19th Century: KÜSTER (Marburg). The speaker first gave a historical sketch of the development of the surgery of the kidney. This branch of modern surgery has been put on a recognized basis almost entirely as the result of the efforts of one generation of surgeons. Simon was credited with being its founder and from Germany came the stimulus for its beginnings. Anglo-Saxon surgeons, particularly Morris, and somewhat later the French surgeons, LeDentu and Guyon, added noteworthy contributions. During the past 3 decades renal surgery has passed through 3 stages of development: first a cautious experimental stage, then a period of somewhat indiscriminate operating and now the subject seems established on a thoroughly scientific basis. As is well known Simon's work was not the first; in 1868 an American (E. B. Woleott of Milwaukee) performed a nephrectomy without having made a definite diagnosis as to the conditions present; following him Spencer Wells also performed the operation and then followed Simon's operation, the first operation to be undertaken with a full knowledge of the conditions present. [Küster is evidently not fully informed as to the literature of this subject as Peaslee and others also operated before Simon.] After Simon's operation in 1875 very few nephrectomies were performed for several years and not until after his death did renal surgery begin to develop rapidly.

The first statistics of the operation showed a mortality of 44.6%, later statistics only 25% and in the last 10 years the percentage of mortality has fallen to 16%. The favorable results of the past 10 years may be assigned as much to more exact methods of diagnosis and a more thorough pathologic knowledge as to improved operative technic and after-treatment. Even when pain, the urine and a tumor indicated a diseased kidney, we were formerly sometimes in doubt as to whether one or both kidneys were involved until the cystoscope and catheterization of the ureters cleared up these doubtful cases. The x-rays often give valuable information in cases of renal calculus. The phloridzin test and the determination of the freezing point have given us other important means of definitely determining the functional capacity of the kidney. Küster then took up the chief pathologic conditions of the kidney and their surgical treatment. Movable kidney is much more common in women than men but Küster does not attribute as much importance to the difference in the clothing of men and women in the causation of floating kidney as is usual. Nephrectomy, which was performed by Simon for the relief of this condition, is no longer necessary since Hahn has introduced nephropexy. Küster finds the results of this operation very good, recurrences being seldom seen. In the treatment of injuries of the kidney when accompanied by profuse hemorrhage surgical intervention is indicated. Nephrectomy was also performed in the treatment of these cases by Simon but unless the organ is much lacerated, suture and the use of the tampon are all that is necessary.

*Reported specially for AMERICAN MEDICINE by Martin B. Tinker, M.D., University of Berlin, member of the German Surgical Association, with grateful acknowledgment of the aid of Dr. Wohlgemuth, authorized reporter for the German Medical Press, and the members of the Association who kindly furnished abstracts.

The term **empyema of the kidney** is suggested for cases of pyelonephrosis having their origin primarily in the pelvis of the kidney and cystonephrosis would be an appropriate term with which to designate the abscesses in the renal parenchyma which may later convert the kidney into a pus sac (Sacnière or pyonephrosis). Küster recalled the time when Albert of Vienna stated that nephrectomy for tuberculosis of the kidney was a waste of time. That renal tuberculosis is ever primary is extremely doubtful, but in spite of this the results of nephrectomy for this condition are at present good. Perfect recovery may even follow in cases in which the ureter and bladder are affected. The x-rays give valuable information in the diagnosis of renal calculus, particularly with phosphatic stones, which may then be removed by nephrotomy or pyelotomy. Stone in the ureter often necessitates extensive operations, particularly if the stone be located low down near the bladder. In these cases resection of the sacrum or colotomy must be performed. Hydronephrosis is either congenital or acquired and is frequently caused by movable kidney. In such cases nephropexy gives very satisfactory results.

In the **treatment of newgrowths of the kidney** resection may often be substituted for nephrectomy with very satisfactory results. Abdominal incision is preferable to lumbar incision in the treatment of tumors in many cases; but in other conditions lumbar incision is usually preferable.

Progress in Renal Surgery.—CASPER (Berlin), reporting investigations with P. FR. RICHTER. Bad results frequently follow operations on the kidneys which are the natural result of imperfect diagnosis. It matters not so much whether the remaining kidney is absolutely healthy, for a man can live with a diseased kidney, but whether the kidney has sufficient functional capacity. The determination of the percentage of sugar and nitrogenous products and the freezing point give valuable information in this connection. The freezing point of the blood and urine approximates that of distilled water the more closely, the better the kidney's functional capacity. The sugar content of the urine is determined by phloridzin injection. The speaker explained by means of tables for demonstration the different relations of these factors with diseased and with healthy kidneys and reported 14 cases in which he had determined the functional capacity of the kidney by such methods. Caspar believes that in this way we can discover the functional capacity of the kidney when by the usual chemical and microscopic tests nothing could be determined.

Practical Experience in the Diagnosis and Treatment of Renal Disease: KÜMMELL (Hamburg). Since his report on this at last year's congress, Kümmell has continued his experiments in the determination of the freezing-point of the blood and the urine as a means of diagnosis in renal disease, and he gave the results of his experience in over 100 cases. He considers this one of our most important means of diagnosis. The normal freezing point of the blood is 0.56; 0.55 or 0.57 is fairly good, but if the freezing point is 0.58 or more, operation is inadvisable. The determination of the freezing-point, the estimation of urea and the phloridzin test are among the most necessary diagnostic tests.

Kümmell first determines the freezing-point of a mixed specimen of urine; if this is normal it is certain that at least one kidney is functionally sound; then both ureters are catheterized and the freezing point is tested to determine the functional capacity of each kidney. By this method operation under dangerous conditions is avoided, for example in cases of stone in the kidney or tumor in which it seems likely from the clinical symptoms that there is full functional capacity. However, there are operative cases in which the freezing point is relatively low. Kümmell mentioned a case of tumor with this condition in which the freezing point became normal after removal of the newgrowth. The technic of determining the freezing point was demonstrated with apparatus. Kümmell also demonstrated a transverse section of a kidney which showed that the incision behind the usual median section incision as proposed by Zondeek does not always divide less bloodvessels, but may divide more as was true in this case. Examination of the kidney at operation in 27 cases has demonstrated to Kümmell the value of the phloridzin, freezing-point and urea tests when used together, and in the other cases in which he has refused to operate because of the information thus obtained he has frequently found by pathologic examination that the tests are reliable.

A Contribution to Renal Surgery: BRAATZ (Königsberg) described the changes which result in the kidney after incisions. In a case in which he had previously made a median incision he was obliged to perform nephrectomy some time after healing had occurred. He found decided contraction and an excessive connective tissue formation, and he believes that such changes usually follow extensive incisions into the kidney substance.

A Demonstration of Skiagraphs of Renal Calculi: ALBERT SCHÖNBERG (Hamburg). Renal and biliary calculi are not readily demonstrable in skiagrams because of their low atomic weight. From their atomic weight it would seem that the phosphatic stones should be specially readily photographed, but their specific gravity is too low. Hence the relative ease with which calculi are skiagraphed is in the following order: first, the oxalate, then phosphatic and uric acid stones. The cystin and xanthin stones cannot be skiagraphed. The chief

reason why it is so difficult to get skiagrams of calculi is because the rays are diffused in the human body. To prevent such diffusion Schönberg suggests the use of a thin lead envelope for the tube. By this means he believes that the leads are forced to take a direct course and they maintain their intensity. Photographs of large areas necessitate the taking of many plates by this method. A plate taken by this method, on which very minute calculi were shown.

An Unusual Renal Anomaly: STEINER (Berlin) presented a patient upon whom he had operated, who had been taken ill with severe abdominal pain, distention, bloody urine in which there were casts, red blood-cells and a large percentage of albumin. In the region of the right kidney was a very tender mass. Urine was obtained on catheterization of the ureter only when the pelvis of the kidney was reached. At the operation congenital absence of the left kidney was found, while the right kidney was divided into an upper and lower kidney. There was a large tumor of the upper kidney, which was removed, and the patient made a good recovery. The patient had a twin brother who was very like him in appearance, and it is probable that the twins developed from the same ovum.

A Contribution to the Treatment of Prostatic Hypertrophy: GOLDMANN (Freiburg) has been struck by the fact that in suprapubic cystostomy tension on the anterior wall of the bladder makes catheterization easier and favors the outflow of urine. He first tried a series of experiments on the cadaver, in which he drew the bladder forward and stitched it to the abdominal wall. After this experimental work he performed this operation on a patient who had been suffering from retention from prostatic hypertrophy and whose bladder had been emptied by a suprapubic aspiration. The patient lived 2 years after the operation, and after death he obtained a necropsy, at which he found the bladder wall adherent to the abdominal wall over an extensive surface, and this produced a considerable tension on that region of the bladder about the internal opening of the urethra. During life the patient had never again suffered from any difficulty in urination after the operation. Goldmann recommends this method of cystopexy in certain cases of prostatic hypertrophy.

In Discussion, RYDQIER (Lemberg) stated that a former assistant of his had recommended this method of cystopexy years ago.

The Treatment of Tumors of the Bladder: LOWENHARDT (Breslau) reports a number of cases in which he has performed intravesical operation for tumors of the bladder. Before operating he practised this method with the cystoscope on a mannikin. His results by this method were excellent. The discomfort of the patient is slight, since the apparatus is so arranged that no change is necessary in using the snare canter or irrigator. This new method is so simple that colpocystostomy, which was formerly practised for tumors of the trigone, has been abandoned. Kelly's method of dilation of the urethra also has its disadvantages, and should be superseded by this method. The possibility of operating without a general anesthetic, and the small amount of blood lost often makes it possible to operate without confining the patient to bed afterwards. The large size of the instrument renders local anesthesia with cocaine necessary when operating upon the male, and urethral fever and cystitis have sometimes followed. The operation is usually sufficiently thorough. In one case no recurrence has followed a removal of a malignant papilloma.

The Disinfection of Infected Wounds with Pure Carbolic Acid: v. BRUNS (Tübingen). While our means and methods of treating aseptic wounds are now approximately perfect, there is much to be wished for in the treatment of infected wounds. Flooding wounds with antiseptic solutions as was formerly the custom is not without danger of poisoning the patient, and for some time most surgeons have felt that it is impossible by disinfectants to make a septic wound aseptic; hence our chief reliance has been placed in the use of free incisions, flushing out the secretions and providing for free drainage by the use of moist dressings frequently changed. Burns has felt the necessity for some chemical disinfectant to use in connection with these means of treatment, which should kill germs and not work harm to the tissues. With this end in view he has recently been testing various measures, among others the disinfection with pure carbolic acid. Many have feared to use this disinfectant, remembering the numerous cases of eczema, intoxication, and gangrene which followed its use in the early days of Listerism.

Recently the use of the pure drug by Lewis in the treatment of hydrocele, and by Phelps in the treatment of tuberculous joint-diseases, has shown that there need be no danger of poisoning, slight reaction, and absolutely no pain. Before using this method, v. Bruns had a series of experiments carried out by his assistant, Dr. Honsall, which showed that concentrated solutions of carbolic acid have a less harmful effect than weak solutions, and that the bactericidal action, when we are dealing with tissues containing albumin, is greater than that of mercuric chloride. Since these experiments, pure carbolic acid has been used in the treatment of more than 80 infected wounds at the Tübingen clinic. After adequate incisions have been made, curetting or excision if necessary, and protection of the skin, covering it with gauze pads saturated in absolute alcohol,

the wound is thoroughly swabbed with pure carbolic acid and immediately afterward washed with absolute alcohol. The caustic action is not specially painful, and many times anesthesia is unnecessary. The wound secretion is usually slight, and frequently it is unnecessary to change the dressings for from 2 to 4 days instead of every 12 to 24 hours, as was formerly necessary.

Wounds treated in this way have progressed well; there has never been any local damage, never a trace of poisoning. The favorable results are due to the fact that this antiseptic is one of the few which have a bactericidal action which is uninfluenced by the body's secretions. The bacteria of the superficial parts of the wound are certainly destroyed, and when cauterized surface cleans off, a beneficial reaction is produced. V. Bruns highly recommends that this method be used in connection with our other means of treating infected wounds.

The Treatment of Wounds after Operation for Local Tuberculosis: FRÄNKEL (Vienna) believes that even the smallest tuberculous foci are not usually removed at operation and he recommends therefore the after-treatment with iodiform, which tends to prevent recurrence by producing inflammation and overgrowth of connective tissue.

Discussion. KÜSTER (Marburg) recommends the treatment of infected wounds with the thermocautery, as was formerly much practised. He distrusts the efficacy of carbolic acid.

KÖNIG (Berlin) does not believe that our results in the treatment of septic wounds need necessarily be bad. He advises free incisions, and in cases in which Küster would use the thermocautery he applies zinc chloride. In the treatment of tuberculosis we will obtain better results if we extirpate the entire disease and have a clean wound to deal with.

SECOND SESSION.

A Report of the Second Thousand of Extirpations of Goiter: The Operation for Intrathoracic Struma: The Nonoperative Treatment of Goiter. KOCHER (Bern) emphasized the fact that he has nearly always practised excision, and only in exceptional cases enucleation. In operating, the muscles are never divided transversely. For compression of the isthmus he has devised a forceps which makes firm pressure but is not an angistrife. It is designed only to make the ligature smaller. Altogether he has had 4% mortality. Infection is no longer a matter of importance. He uses no antiseptic in the wound except as it is introduced through the silk, which is antiseptically prepared. In the prophylactic treatment he has often used thyroid treatment in cases of diffuse struma which has existed for some time. General narcosis is never, or at least very seldom, used. By cocaine anesthesia, hemorrhage and after-nausea and vomiting are avoided.

As a result of struma profunda, Kocher has seen emphysema and bronchitis, as well as tachycardia, etc., and he believes that the lungs may be affected, as well as the heart, in cases of struma.

Mediastinal struma often gives rise to extensive stasis, accompanied by exophthalmos, and the condition may be confused with Graves' disease. In intrathoracic struma it is a question of great importance whether the tumor is movable or not; the more movable the struma the better the chances of operative success. In the diagnosis the Röntgen rays may be used in connection with percussion to good advantage. Skiagrams were demonstrated. At the operation all vessels should be tied and the isthmus divided before an attempt is made to free the tumor from below, for at this part of the operation rapid work is frequently necessary. A forceps and spoon were shown, which were devised to facilitate these operations. Packing to arrest hemorrhage in these cases is out of the question because of the danger of suffocation; moreover, it is an uncertain way of arresting hemorrhage. Of 22 cases of intrathoracic struma, Kocher has not lost a single case. Iodin has always been considered the most important medicament in the non-operative treatment of these cases, but of late Kocher's son Albert has been testing the value of sodium phosphate. The fact that the inhabitants of regions where struma is common use foods poor in phosphates chiefly led to these experiments. On the contrary, in England, where meats are the most important part of the diet of the inhabitants, struma is very rarely seen. It may be found that the question of food has an important influence in the origin of struma.

The Treatment of Thyroid Struma with a Report of the Operations at the Clinic at Freiburg: KRASKE (Freiburg i. B.) reported 425 operations for struma, 12 malignant, of which 3 were in men. In 220 cases the operation was on one side; some of the earlier operations were total extirpations, the remainder enucleations or resections. Nodular tumors were most frequently met, simple hypertrophies seldom; there were 10 cases of malignant struma; in one case a metastatic nodule was successfully removed from the sternum; in 2 cases there were accessory strumas, one of the tongue, one in the supraclavicular fossa. Like Kocher he avoids general anesthesia. There were but 2 deaths in the entire series, one from heart disease, unfavorably influenced perhaps by pushing previous thyroid treatment too far; one from tetanus following extirpation from both sides. Hemorrhage followed in some cases after enucleation, but since giving up this enucleation and general anesthesia no important hemorrhage has occurred. The even-

ing after operation there is usually a rise of temperature which is attributed to absorption of glandular material. Thyroid therapy in these cases is considered of little value.

Discussion. GOLDMANN (Freiburg i. B.) mentioned an operation for the removal of an intrathoracic struma which was found to be tuberculous on pathologic examination. RIEDEL (Jena) has operated upon 500 cases of struma, many of them large tumors, several intrathoracic. He finds that the intrathoracic form is more common on the left side while extensive development in the upper part of the neck is more frequent on the right side. Any special instruments for facilitating removal he considers unnecessary. He finds that Kocher's incision does not give sufficient room, and he advocates a curved incision with its convexity just over the suprasternal notch and its ends extending upward to the ears on each side. He operates without general anesthesia, and finds the veins a more important source of hemorrhage than the arteries.

REHN (Frankfurt a. M.) mentioned a case that was considered too extensive for operation in which the entire tumor disappeared under iodine therapy.

KÖNIG (Berlin) believes that struma may be frequently seen in low lying level countries. He has operated in 70 or 80 cases in Berlin, more than half of whom were born in that city, and developed the tumor while living there. He usually leaves $\frac{1}{2}$ of 1 side of the tumor. KOCHER (Bern) has frequently seen a struma extending high into the neck on the right and intrathoracic on the left side, as mentioned by Riedel. In case both sides of the thyroid are diseased he believes that it is sufficient to prevent syptoms if $\frac{1}{2}$ of 1 side is left.

Twenty-seven Intraeranian Operations for Trigeminal Neuralgia, of which 25 were Extractions of the Gasserian Ganglion: FEDOR KRAUSE (Berlin). The reaction of the branches of the trigeminus intracranially is not followed by certain cure, hence Kranse advises removal of the gasserian ganglion in cases of severe trigeminal neuralgia. He has always employed the method by temporal route, which he described in 1892. He has had 3 deaths following the operation. A woman of 58, apparently healthy and strong, died of collapse. A man of 72 recovered from the operation without elevation of temperature and his wound healed by first intention, but death occurred 6 days after the operation from heart failure, associated with sclerosis of the coronary arteries; a woman of 60 died 21 days after operation with a perfectly healed wound. Six of his patients are living from 5 to 8 $\frac{1}{2}$ years after operation: 8 $\frac{1}{2}$ years, a man, age 63; 8 years, woman of 76; 6 $\frac{1}{2}$ years, woman age 77 and 51; 5 $\frac{1}{2}$ years, a woman of 43; 5 years, a woman of 51. All patients who have recovered have been completely relieved of their pain, and the suffering is often so intense before operation that an operation which promises such certain relief seems perfectly justifiable.

Extirpation of Brain Tumors: HEIDENHAIN (Worms) reported 4 cases of brain tumors, of which 3 were operable. In the first case a man was taken ill with paralysis in one leg, Jacksonian epilepsy, optic neuritis and paranoia, with delusions of persecution. At the operation the diagnosis of brain tumor in the region of the leg center was proved correct, and a solitary tubercle the size of a walnut was removed. The after disturbances were attacks of cramps with loss of consciousness, cramps in the arms without loss of consciousness, and incomplete paralysis of the leg.

In the second case there was headache, paresthesia and anesthesia of the right side, choked disc, but no vomiting. A diagnosis of tumor in the right arm center was made. At the operation a sarcoma the size of a hen's egg was removed, which made necessary the removal of a portion of the cortex the size of a dollar. The severe headache and choked disc disappeared, and there remained only disturbance of sensation and slight disturbance of motion in the right hand.

In a third case a laborer was taken ill with severe symptoms of intracranial pressure and double optic neuritis. At the operation a melanotic sarcoma was found, which necessitated the extirpation of the entire lower portion of the right temporal lobe. It is interesting to note that no disturbance of hearing followed.

The patient died some time later of apoplexy, and at the necropsy many small tumors were found in the brain.

In the fourth case, occurring in a boy of 12, the entire occipital bone was removed, but no tumor was discovered. At the necropsy a large median sarcoma was discovered.

The Operative Treatment of Purulent Meningitis: BARTH (Danzig). A young man received a stab wound in the back at the ninth dorsal vertebra. Seven days later a rise of temperature occurred followed by meningitis. Lumbar puncture showed the presence of numerous staphylococci. Laminectomy was performed and a pus cavity evacuated and the wound tamponed with gauze. Headache was relieved but the temperature rose still higher. Another lumbar puncture showed the presence of pus. A second laminectomy was performed at the region of the second and third lumbar vertebrae, and after the incision of the dura a large quantity of pus escaped. The dura was drained, the gauze being removed 7 days later. There was temporary paralysis of both legs, rectum and bladder, but complete recovery followed. In spite of the fact that a corset was worn a decided gibbosity developed in the regions of the operations. There is still some weakness in the legs, pares-

thesia and some areas of anesthesia and some weakness of the bladder.

THIRD SESSION.

ZONDECK (Berlin) in a verbal communication defended his method of incision of the kidney at a plane behind the usual autopsy incision, answering the criticisms which Kümmell had made. He demonstrated preparations which showed the importance and value of this incision in avoiding the great vessels.

KÜMMELL (Hamburg) defended the position he had formerly taken that in certain cases more vessels would be injured and presented photographs of his cases.

The Scientific Basis of the Carbolic Acid Treatment of Infected Wounds: HONSELL (Tübingen). By experiment he has proved that pure carbolic is harmless if properly used in the treatment of wounds. Fatal poisoning in man results from doses of 8 grams or more of the pure drug, while diluted solution of 2 or 3 grams are fatal. He has injected from 1 to 6 grams of carbolic acid into hydroceles without bad effects, and he takes 6 grams as the maximum amount which should be employed on the surface of wounds. Of this amount probably 4 grams is removed by the gauze. Poisoning has followed in no case. The deep tissues are affected only when the acid is in contact for a long time. The time of application is one minute. The wound is then washed out with absolute alcohol as has been suggested by American writers as an antidote for carbolic acid. It does not prevent the formation of a slough, but it removes more of the carbolic acid from the tissues than water. The permanent results of the treatment are much greater than those of mercuric chlorid.

Suppurations Around Ligatures: HAEGLER (Basel). Drawings of microscopic sections of tissues from which ligatures have worked out by suppuration were shown. There were also drawings of sections through silk which had been sterilized by steam but which gave rise to growth of germs 48 hours later.

With catgut there was growth of germs only on the surface. Haegler is of the opinion that where suppuration occurs about catgut the wound is infected. It is always preferable to silk but for buried sutures silk wormgut is the best material, its only objection is that it is so brittle. The impregnated materials such as celluloid thread are not better than others. The best of such preparations are paraffin and wax.

Experimental Investigations with Mercuric Ethyldiamin in Solid Form as a Means of Disinfection for the Hands and Skin: BLUMBERG (Berlin). The well known disadvantages of disinfection by mercuric chlorid are the irritation of the skin and the slight depth affected. Blumberg has undertaken investigations with several mercury preparations in an effort to find a preparation not possessing these disadvantages. In mercuric citrate with ethyldiamin in a 2-3% solution he has found an effectual disinfectant. This can be used only in solution, while on the contrary mercuric sulfate with ethyldiamin may be obtained in solid form. Experiments with the micrococcus tetragenus have given entirely satisfactory results.

A Contribution to Brain Surgery: KRÖNLEIN (Zürich) has demonstrated a beautiful preparation of brain tumor the size of a hen's egg which he was able to diagnose correctly but did not find on operation.

Encephalitis of the Temporal Lobe and Other Complications After Otitis: MERKENS (Berlin). Encephalitis of the temporal lobe is more uncommon than abscess and may be mistaken for it as happened in a case occurring in the Moabite Hospital, the clinical history of which was read. In another case following otitis adhesions between the dura and the brain were found at resection of the temporal region.

Gunshot Injuries with Modern Firearms: SCHJERNING (Berlin). By means of numerous skiagraphs, tables, and diagrams the effects of modern weapons were graphically presented and an idea was given of the effect of modern firearms as compared with those used in previous wars. The speaker also gave the results of his personal experience as a surgeon in the South African war. [His observations confirm those made by American surgeons in the Spanish war and those of the English surgeons in the South African campaign almost completely.] The best results in gunshot wounds of the abdomen are obtained by nonoperative treatment. Injuries of the joints frequently demand resection. Injuries of the chest and brain are among the most fatal but as a whole the mortality is greatly reduced as compared with that of previous wars: the result of improved hospital service and modern antiseptics and the more humane modern weapons.

Paired Projectiles: KRÖNLEIN (Zürich) showed some bullets from an English target-practice field.

Krönlein's Gunshot Wound of the Skull: REGER (Danzig) believes that there is a decided difference in the effect on the skull of an individual when the brain is functioning and filled with blood than on the skull of a cadaver which is frequently taken for experimental purposes.

Personal Experience with Gunshot Wounds in the South African Campaign: RINGEL (Hamburg). From his experience with gunshot wounds in South Africa, Ringel believes that all such wounds should be treated as aseptic

wounds; that compound fractures should be treated as simple fractures, unless the injury be extensive; that we should not abstain from operation in all cases of gunshot wounds of the abdomen, but should treat cases according to the indications present. He reported performing celiotomy for a gunshot wound of the abdomen in which the intestine had been perforated but was sealed by adhesions but the hemorrhage was great enough to indicate intervention.

The After-Treatment of Invalid Soldiers at Baths and Health Resorts: ZIEMSEN (Wiesbaden) believes that the general treatment which patients receive at health resorts would be as beneficial to invalid soldiers as the treatment of their wounds. Such treatment is specially valuable in certain neuroses.

TILLMANN (Greifswald) gave the results of his study of 5,000 fractures in the Army Museum at Washington, D. C., very briefly.

Castration for Tuberculosis of the Testicle: v. BRUNS (Tübingen). Many surgeons question whether castration for tuberculosis of the testicle is a justifiable operation, for the reason that they believe that other organs are usually simultaneously affected with tuberculosis. The advisability of double castration has been considered specially questionable. From his experience v. Bruns has been led to believe that the disease is not infrequently primary in the testicle, and to obtain some idea as to this question he has studied the records of the Tübingen clinic during the past 50 years. Altogether 105 castrations for tuberculosis have been made, and of this number 33 were double. The epididymis is almost invariably first affected, but within 6 months the disease has extended beyond it; early diagnosis is difficult, often impossible, hence resection of the epididymis should not be considered. Clinical evidence and the experiments of his assistant, Dr. Baumgarten, have shown the tendency for the disease to travel up the vas, hence the importance of early castration to avoid spread of the disease to other organs.

v. Bruns believes that in more than $\frac{1}{2}$ of all cases a cure may be obtained by early castration, though about 15% die later of pulmonary tuberculosis. In his series of cases 46% were permanently cured by castration on one side. Of the cases of double castration about 44% are permanently cured. The patients considered cured have lived from 3 to 34 years after the operations. The deaths in cases not cured are from tuberculosis of other organs, many of them from urogenital tuberculosis. The statistics of early castration are much more favorable than is generally believed and the operation does not deserve the condemnation it has generally received.

Experimental Studies with Tuberculosis of the Testicle: v. BAUMGARTEN (Tübingen). The speaker demonstrated by means of diagrams the results of a series of experiments on rabbits to determine the way in which tuberculosis of the urogenital tract spreads. In his first experiments he tried the effect of inoculating the anterior urethra and the prostate, but he found that the disease never spread from thence to the bladder and ureters or to the vasa and testicles. If the disease were introduced into the testicle, however, it spread up the vas, involving the seminal vesicles and prostate of the same side but never spreading to the opposite side. The disease did not spread up the ureter to the kidney or into the urethra. v. Baumgarten believes that the infection is spread by the blood and lymph streams, for experimentally it never extends in a direction opposite to these currents. The spread of the disease was gradual in the experiments, so that early castration would have avoided the spread of the disease to the vas, and in some cases the testicle remained the only organ affected. The results of this experiment agree entirely with those of clinical and pathologic study, and indicate that early castration should be a curative operation.

The Treatment of Tuberculosis of the Male Generative Organs: v. BUNGER (Hanan). By experiments on the cadaver, v. Bunger found that by steadily pulling on the vas through an inguinal incision $\frac{1}{2}$ of it could be drawn out before it gave way. From clinical and operative experience we know that tuberculosis first affects the epididymis, then travels up the vas, finally involving the seminal vesicles. Hence the necessity for removing as much of the vas as is possible, even early in the disease. It has been suggested that in pulling out the vas in the way he suggests in order to remove as much of it high up as possible that there is danger of hemorrhage and of infecting the peritoneum at the site of rupture, but he has never had any accidents of this kind.

In extensive disease the removal of the seminal vesicles, with prostate, vas and testicles seems the only method of cure, but the patients are often in too low a condition to permit such an extensive operation. If removal is possible Bunger advocates the operation by the sacral route, and reports 2 recoveries following such operations, in which the indications are that the cure will be permanent. One of the patients is apparently in perfect health and about at his usual work. In cases in which the disease has extended far and the patient is too reduced in strength to permit an extensive operation the injection of iodoform oil is advised. In experiments on the cadaver Bunger found it possible to inject a solution of Berlin blue into the vas at the inguinal ring and have it reach the seminal vesicles regularly, and he believes that the iodoform oil could be forced up

equally readily. He has used the injection in 1 case with apparent benefit.

Tuberculosis of the Testicle: SIMON (Heidelberg) gave a brief report of the results of castration for tuberculosis of the testicle at the Heidelberg clinic. His results agree with those of v. Bruns entirely as to the possibility of cure. From 107 castrations he was able to obtain a late report as to the condition of the patient in 92 cases, and the percentage of recoveries was 66. Out of 29 cases of double castration 8 died and 21 remained well, some of them over 20 years. There was psychic disturbance in 1 case. Castration can be recommended in such cases.

The Operation for Tuberculosis of the Testicle and Epididymis: KÖNIG (Altona): Two preparations were demonstrated in which the testicle and the vasa as far as the epigastric vessels had been removed. In these cases König operated by inguinal incision, working down beside the bladder and pushing the peritoneum up and the ureters to the side. In a third case he removed the seminal vesicles and prostate as well. In this operation he divided the sacrum and turned it downward with a flap as was suggested by Schlange in operations for carcinoma of the rectum.

Discussion. KÖNIG (Berlin) believes that tuberculosis may, but not of necessity must, be primary in the testicle. How does it happen the tubercle bacilli travel only in the direction of the lymph current while other bacteria may travel by direct extension; for example, there can be no question but what gonorrhoeal infection extends from the urethra to the testicle. Baumgarten did not state whether he found his tubercle bacilli in the bloodvessels or intracanalicular. Again, are the conditions the same in an animal in which the structures are very minute as in man? From his experience in the past 10 years he had gained the impression that tuberculosis frequently extended down the vas from the prostate and seminal vesicles. He has tried iodoform injections but without success though he only injected into the epididymis.

GUSSENBAUER (Vienna) doubts whether tuberculosis of the testicle is so frequently primary. At the necropsy we usually find it associated with disease of other organs. He has seen recovery in cases which had even gone to the formation of fistula without operation, the tuberculous area becoming calcified.

CRÄMER (Cannstadt) thinks that the results of Baumgarten's experiments agree with what we learn by operative experience. Tuberculosis of the seminal vesicles and prostate may improve after castration which would not probably be the case if the disease were not primary in the testicle.

HENLE (Breslau) said that the results of injection of iodoform at the Breslau clinic had not been very satisfactory.

BIER (Kiel) recommends sea bathing in the treatment of tuberculosis. He doubts whether the results of double castration justify its use.

SCHLANGE (Hanover) gives the history of a case in which spontaneous recovery had occurred.

Wednesday evening was devoted to the demonstration of skiagraphs by several members of the Association.

FIFTH SESSION.

Resection of the Lung: HEIDENHAIN (Worms). A patient was presented upon whom resection of the lung had been performed for the removal of carcinoma. Bronchiectasis resulted, and to evacuate the pus longitudinal incisions were made in the bronchial tubes. The large cavity which resulted is now completely lined with mucous membrane.

Conservative Operations on the Testicle and Epididymis: PAYR (Graz), reported a severe case of orchitis, which followed an attack of acute gonorrhoea and which was accompanied by severe pain, high fever and a bad general condition. An incision was made through the tunica albuginea and an abscess was evacuated. In spite of this gangrene followed and castration was necessary. The testicle had been converted into a perfect pus sac. Recovery was very slow, and was hardly complete when 2 years later orchitis of the other side developed, with a chill and rise of temperature to 41° C. The cavity of the tunica vaginalis testis was opened, and before incising the albuginea catgut sutures were inserted, for at the previous operation the glandular substance had bulged after incision, so as to endanger its integrity. After evacuation of the pus, which was in the testicle, the tunica albuginea was sutured, as was also the external wound; drainage was inserted. The wound healed well, and the patient, who was a physician, found spermatozoa in his semen several months later, indicating that perfect recovery had taken place.

Plastic Operations for Complete Loss of the Skin of the Penis and Scrotum: BESSEL-HAGEN (Charlottenburg). In the case of a man who had lost the skin of the penis and scrotum as the result of a severe phlegmonous process, the speaker had made a foreskin from the skin of the abdominal wall (method much similar to that suggested by Semm).

The Methods of Anesthesia and Their Indications: v. MIKULICZ (Breslau). From his studies of this subject, Mikulicz has come to the conclusion that the most important question is not which is the safer anesthetic, chloroform or ether, but which is the safer anesthetic in the particular case under observation. At the present time it is something of a

question whether general anesthesia should be used at all in most cases, so much has been accomplished with local anesthesia. A historic sketch of the various methods was given, in which the early work of Halsted and Corning was mentioned; first came local anesthesia by freezing; then by cocaine injection; then Schleich's infiltration anesthesia (and to Schleich belongs the greatest credit for the introduction of local anesthesia); the Oberst method of injecting into nerve trunks and finally by injections into the spinal canal. Mikulicz has used the spinal anesthesia in 40 cases with satisfactory results, and he predicts that this will be one of the most important methods of anesthesia in the future. As yet the spinal injection is imperfectly understood; he has had no deaths following its use, but there were some very disagreeable after-effects. From a study of the statistics of general and local anesthesia it is readily seen that the value of local anesthesia is far too little appreciated, and general anesthesia is much too commonly used. Very many cases are not suitable for local anesthesia, such as: many celiotomies, breast operations, operations on bones, etc. In other cases it is doubtful whether local anesthesia should be used; operations on the stomach and intestines, hernia, and the excision of strumas.

Deaths after local anesthesia are by no means uncommon. By a series of diagrams Mikulicz showed very graphically the comparative mortality of various operations with local and general anesthesia. Patients suffering from heart or lung affections would better be operated upon by local than by general anesthesia, but, as was shown by his statistics, the number of postoperative pneumonias following anesthetics with Schleich's solution is very great. The relations are considerably changed by infiltration often making the identification of anatomic structures quite difficult. There are the greatest differences in susceptibility to pain: some patients are quite unable to undergo even a trifling operation; in other cases the suffering, even in extensive operations, is apparently slight.

As an example of the latter class of patients, Mikulicz mentioned the case of a butcher who was specially anxious to see his own stomach, and who, by means of a mirror, witnessed a gastrostomy which was performed upon him, apparently without the slightest discomfort. Pain alone may be an important cause of shock, and in many operations the shock from this cause would be greater than from general anesthesia. Formerly Mikulicz used chloroform exclusively, but at present, since having learned better methods of administering ether, he uses more ether. The skill of the anesthetist is a matter of great importance and the administration of a general anesthetic is a fine art.

Spinal Anesthesia: BIER (Griefswald) has been able to collect records of 1,200 operations which have been performed under spinal anesthesia since its introduction. There are the greatest individual differences as to the amount of solution required to produce anesthesia but as a rule after the injection of from 1 to 3 cgm. of cocaine the sensations disappear. The sense of pain is first benumbed, then that of heat and cold finally the sphincters are affected and the anesthesia extends upward so that in some cases operations such as excision of the breast and resection of ribs have been performed. In many cases symptoms of cocaine poisoning develop such as headache, dizziness, nausea, vomiting, chills, rise of temperature, disturbances of circulation, paresis, and in rare cases even collapse and death have followed.

To determine the best way of avoiding such symptoms Bier has carried out numerous investigations. He first tried substituting other drugs and other derivatives of cocaine for cocaine: Tropacocain, eucain, weak solutions of carbolic acid and numerous other drugs were tried but the results were not as satisfactory as those obtained by using Schleich's solution. It is interesting to note that normal salt solution when injected into the spinal canal of cats readily produces anesthesia but this result is not obtained when the solution is used in man. Most of the cocaine derivatives produced anesthesia which was not permanent enough or complete enough for practical purposes. Tropacocain for example produces partial anesthesia which extends far up, but is never complete. The sensations of touch and of heat and cold are always retained. Bier considers it very important not to change the pressure of cerebrospinal fluid and to avoid this the same quantity of fluid as is to be injected should always be withdrawn before making the injection. He also suggests the use of a very tight bandage about the neck to cyanosis as a means of preventing absorption of the cocaine. (It is difficult to see in what way such a result will be produced.) Bier considers this method of anesthesia still in process of development and still unsuited for general use.

Mixed Anesthesia: BRAUN (Leipzig) demonstrated an apparatus for using chloroform and ether combined. A rubber bulb connected by a Y-tube both with a flask containing ether and a flask containing chloroform, forces air through the anesthetics: these flasks are connected directly with the mask. The amount of vapor from each flask may be accurately regulated by a valve.

A New Chloroform and Oxygen Apparatus: WOLFGEMUTH (Berlin) demonstrated an apparatus consisting of a cylinder containing compressed oxygen, an automatic apparatus for dropping chloroform and a mask provided with a valve, permitting of the escape of gases only during expiration. The oxygen is conducted through a chamber in which it is thor-

oughly mixed with the chloroform vapor, and from the chamber to the mask with rubber tubing. Wohlgenuth claims that with this apparatus anesthesia can be produced very rapidly, with almost no disturbance of pulse or respiration, without any disagreeable after-effects and with a minimum amount of chloroform. The apparatus has been introduced in the clinics of v. Bergmann and Israel and has been used with great satisfaction in over 180 cases.

A Study of Intracranial Pressure: TILLMANN'S (Greifswald) reported 2 cases of injury of the skull accompanied by intradural hemorrhage, in which the patients both retained consciousness while in the upright position but sank into coma on lying down. This suggested to him a series of experiments on dogs to determine the cause of these peculiar conditions. He concludes that in injuries of the skull accompanied by intradural hemorrhage that the cause of loss of consciousness is not only the increased intracranial pressure caused by the lessening of space inside the skull by blood-clot, but also by the downward pressure as a weight when the patient is in the upright posture.

Resection of the Cervical Sympathetic for Epilepsy: BRAUN (Göttingen) reports his experience with 9 cases in which he removed the cervical ganglion of the sympathetic for the cure of epilepsy as was suggested by Jonnesco of Bucharest. He finds it impossible to remove all 3 ganglion because of anatomic difficulties. He considers the incision posterior to the sternal mastoid best adapted for removal of the ganglion, but he demonstrated by photographs that the upper ganglion is difficult and the lower ganglion impossible to locate. Because of the difficulties and danger, the lower ganglion was not removed. After removal of the superior ganglion there was always ptosis, contraction of the pupil and dilation of the vessels, but no change in the heart's action, pulse or respiration. The contraction of the pupil disappeared gradually; the dilation of the vessels disappeared after 24 hours. There were 2 deaths following the 9 operations: 1 patient died during a convulsion after extirpation of the ganglion on both sides; 5 of the patients were improved, perhaps as a result of the operation. Braun does not consider the operation a dangerous one but it is of very doubtful value.

The Operative Treatment of Carcinoma of the Uterus: JORDAN (Heidelberg) mentioned the tendency among many surgeons, specially the French to readopt the abdominal route for hysterectomy. The possibility of thorough extirpation of the lymph glands is only present with the abdominal method, but examination of the statistics of the Heidelberg clinic shows very satisfactory results as to mortality and recurrences from the vaginal method. Moreover the lymphatic glands are by no means constantly affected, and according to Jordan's experience, usually late. In any case it is impossible to entirely remove all the glands of that region. He considers the abdominal method more dangerous and believes that it should be chosen only in exceptional cases. Carcinomatous invasion of intestine or bladder was not considered a contraindication to the vaginal operation. He uses Schuchardt's paravaginal incision.

The Paravaginal Method of Hysterectomy and its Results: SCHUCHARDT (Stettin) states that with his incision the entire parametrium can be removed, hence by its use many cases usually considered inoperable can be treated. The incision always heals per primam. His mortality is 12% for all operations. Out of 60 operations counting cases living 5 years after operation he claims 40% of permanent recoveries, 4 times as great a rate as the best statistics shown by all other operators.

Vaginal Laparotomy Compared with Ventral Laparotomy: Results of 874 Operations; DÜRRSEN (Berlin). Since his introduction of the incision through the anterior vaginal wall Dürrsen has found abdominal operations almost unnecessary. The technic of operation was demonstrated by means of numerous instantaneous photographs. The advantages of the vaginal operation are: The lessened mortality (2% in 874 cases, many of them quite difficult), more rapid recovery, the avoidance of an abdominal scar with all its disadvantages. Dürrsen has operated 700 times for retroflexion of the uterus, and in most of the cases there was also present disease of the adnexa or chronic peritonitis. In such cases the adhesions come directly into view with the vaginal incision, they can be readily separated and recurrence avoided by careful suture of the peritoneum over raw surfaces. There is no difficulty in childbirth after vaginal fixation, as may be seen from 37 normal labors which have followed. Inflammations or newgrowths of the ovaries or oviducts were present in 300 cases. An ovary or portion of an ovary was always left in these cases in order that the menopause with its disturbances might be avoided.

Even the largest ovarian tumors may be removed by this route and their pedicles securely tied. Conservative operations on the adnexa were undertaken in 200 cases; resections of the tubes, salpingostomy, for severe inflammatory affections of the tubes; ligipuncture or resection of cystic ovaries were frequently followed by pregnancy. Conservative operations on the uterus itself were undertaken in 74 cases. Most of these were enucleations of myomas. In 6 cases of intractable hemorrhage, excision of the entire mucous membrane of the uterus was performed instead of total extirpation. The mortality of these operations was greater than that of operations on the adnexa in spite of the fact that the technic was easier. In the removal of pus tubes a lateral incision was joined with the anterior vaginal incision.

A New Method of Total Vaginal Extirpation: DÖDERLEIN (Tübingen) believes that the vaginal method should neither be too highly lauded nor entirely condemned. He prefers the incision through the posterior vaginal wall and demonstrated preparations showing what extensive operations are possible by this method. Döderlein's procedure is as follows: The vaginal cervix is seized and drawn well upward, and an incision is made into the cervix through the posterior vaginal wall. The uterus is then drawn out and the splitting process is continued through the body of the uterus to the wall of the cervix. The cervix is split forward from within out and the halves of the uterus are each extirpated. In the process of splitting the incision is into the retrovesical space and the bladder is not injured.

Carcinoma of the Uterus: OLSHAUSEN (Berlin) agreed with Jordan in most of his statements. He has always been of the opinion that there is no chance of success if the growth has extended beyond the uterus. He never considered extirpation of the lymphatic glands justifiable, though he has extended the indications for operation somewhat of late. Recurrences appear even after 4 to 5 years; he has seen 38.9% after 5 years. He also considers abdominal operation only justifiable when vaginal operation is impossible for some reason. Schuchardt's incision he admits is necessary in certain cases, but at the most in not over 3 to 4% of all cases. Hemorrhage and infection are by no means out of the question with this incision. We have learned to avoid infections for the most part but there is special danger in carcinoma operations. For this reason he considers Döderlein's method only adapted to beginning carcinoma.

Discussion. MARTIN (Greifswald) has not usually found glands which were removed carcinomatous and an attempt to remove renders the operation unnecessarily difficult. He had severe hemorrhage in one case while operating with Schuchardt's incision, but believes it has its advantages. There are great differences as to the extent of the attachment between the bladder and anterior vaginal which might make Döderlein's method difficult in some cases. Whether the anterior or posterior vault of the vagina be incised will depend on the individual operator.

WERTHEIM (Vienna) operates chiefly by the abdominal route, and removes the glands and surrounding tissue in all cases. Investigation has shown that the glands were diseased in 18 out of 50 of his last cases, even when the disease was apparently not far advanced. The removal of the surrounding tissues was considered more important than the removal of the glands even, and this is impossible by any route, except the abdominal one. His results were at first bad—11 deaths in 33 cases—but at that time he undertook the operation in too extensive cases. In the last 20 cases he has had but 3 deaths, in one of which there was metastasis in the liver. He believes that in the future the abdominal operation will be generally adopted.

DÜRRESSEN emphasized the fact that the paravaginal incision had been advocated in obstetrics in difficult labors as early as 1887.

KÜMMELL (Hamburg) mentioned 2 advanced cases in which he felt obliged to operate in spite of their hopelessness because of the involvement of both ureters. He transplanted the ureters into the bladder in these cases.

FREUND (Strassburg) considers vaginal hysterectomy palliative, and suitable for use only in cases in which there is no prospect of permanent success. The abdominal method is indicated in all early cases.

The Structure, Growth, and Histogenesis of Carcinoma: PETERSEN (Heidelberg) has tried the method of study by reconstructing in wax sheets from serial sections, introduced by Born and Strasser in embryology, in the study of carcinoma. He demonstrated 4 models of skin carcinoma, with corresponding drawings and photographs. These models, he believes, will be very useful in teaching, and will help to settle doubtful questions.

The Origin of Carcinoma of the Ovary: KOSSMANN (Berlin) demonstrated sections of microphotographs of an ovary in which both cylindrical-celled and flat-epithelial carcinoma was present and he questioned whether, if carcinoma were of parasite origin, both forms would be present.

Killing Remnants of Tumors in Wounds with Hot Water: EHRARDT (Königsberg) recommends the pouring of boiling water into wounds made by the removal of malignant growths instead of the use of the Paquelin cautery.

HOLLÄNDER (Berlin) showed a patient upon whom he had operated for carcinoma of the nose, and repaired the defect by a rhinoplastic operation. At present the patient has multiple carcinomatous nodules over her entire body.

Should Anesthesia be Used in Resection of the Upper Jaw: KRÖNLEIN (Zürich) presented a tabulation of resections of the lower jaw which seemed to show that the results of the surgeons in the past were better than those at the present. The introduction of asepsis and antiseptics should have given better statistics and the only factor to which Krönlein can attribute the less favorable results is anesthesia, which is used at present but not in the past. The great danger is the inspiration of blood causing bronchopneumonia. In the experience of Küster and König, half their patients died from this cause. The danger is not avoided by half anesthesia and to avoid it Krönlein usually operates without any anesthesia. Of his 35 patients only 1 died and the cause of death was meningitis.

The Disappearance of the Poisonous Properties of Cocain in the Animal Body: KOHLHARDT (Halle) after determining that 0.2 gm. cocain is an absolutely fatal dose for a rabbit, bound a piece of rubber tubing about one extremity and injected this amount of cocain. The band was loosened 30 minutes later and though symptoms of poisoning developed the animal readily recovered. Repeating the experiment and leaving the band for an hour there were no symptoms or only very slight symptoms. This seems reasonably convincing proof that cocain loses its poisonous properties if allowed to remain in the animal (gradual absorption?).

Discussion. BLAU (Breslau) in discussing anesthesia showed 2 blood pressure curves, showing that with ether blood-pressure rises, while with chloroform it falls.

RYDYGIER (Lemberg) and RIEDEL (Jena) in discussing resection of the sympathetic, both reported bad results from preliminary tracheotomy and the use of the tampon camula. Riedel still uses anesthesia, but operates with head of the patient hanging over the end of the table.

KADER (Breslau) has had favorable results with spinal anesthesia. He removes 1½ times as much cerebrospinal fluid as he injects cocain, and immediately elevates the pelvis of the patient. One or 2 days before the anesthesia he begins to administer digitalis, and if there is any change in the pulse rate during operation he administers camphor.

GUSSENBAUR (Vienna) usually operates in resection of the upper jaw with the head bent far forward, and he uses complete anesthesia. Twice he has found tracheotomy necessary, because of the inspiration of blood. The blood was immediately sponged out of the patient's mouth and recovery followed.

Antitoxin in Diphtheria Cases.—Drs. Matas and Landfried, of New Orleans, take exception to the statement of Dr. Girdner, of New York, in his paper to the *Junior Munnsey* that: "The antitoxin treatment of diphtheria has not proved entirely satisfactory, either as a curative or preventive remedy; it is still under judgment." Both physicians stated that their experience has shown that for prophylactic and curative purposes antitoxin, when used in cases of diphtheria, has proved highly successful; the serum is so efficacious that the probability of death is reduced to a minimum, and if a patient is treated within 3 days after the germs of the disease have begun to work, there is absolutely no danger. The mortality from diphtheria in New Orleans is only ¼ of what it was 10 years ago; this is attributed to the extensive use of the serum.

Pasteur Treatment of Rabies.—The Department for the Preventive Treatment of Rabies of the Baltimore College of Physicians and Surgeons report 209 cases successfully treated, of which 85% were from the rural districts. Of those treated 159 were males, 50 females, 70 children, none of whom were over 10 years of age. The wounds were inflicted by dogs in 188 cases, in 13 cases by cats, in 1 by a calf, and in 1 by a pig. Those who came to receive treatment during the first week after being bitten numbered 147, those in the second week 27, those in the third week 11, those in the fourth week 7, those in the fifth week 11, and 4 and 2 came in the sixth and eighth week respectively. There were 5 abscesses in 6,270 injections. There was but 1 death from any cause. This death was caused by rabies. A lad, 8 years old, bitten February 2, 1900, was admitted February 4. He received only 1 treatment, consisting of 2 hypodermic injections. He was removed from the institution and treatment discontinued on February 5 against the advice of the physicians. After the inoculated rabbits and a cow bitten by the same dog developed rabies, the child was brought back on February 25. He developed rabies March 14, and died March 17. A case of this character cannot be attributed to failure of the treatment, but to delay in resorting to treatment.

The State Charities Aid Association has issued its eighth annual report to the State Commission of Lunacy, and urges that reception hospitals for the insane shall be established in New York and other cities of the State, as there is no existing place in the borough except the insane pavilion at Bellevue Hospital to which a patient seized with sudden mania can be removed for early and preventive treatment. The report states that there are now 22,000 dependent insane patients in the State, and statistics show an increase out of proportion to the increase in population; for several years past the annual increase has been over 700. This means additional accommodations to be provided for during the next 3 years for over 2,100 patients. Insanity might in many cases be speedily cured if the patients could have the benefit of the best medical skill such as is given in hospitals for patients suffering from other diseases. The report advises that these small reception hospitals, or psychopathic hospitals, as branches of the existing State institutions and under the same management, should be organized on the same plan as any well-managed hospital and should receive not only the destitute but those able to pay, that all may receive the best neurologic and alienist skill that New York City can provide. Such hospitals have long been established in German, Austrian and other European cities. The report further states that several eminent alienists have expressed their willingness to serve as consulting or attending physicians to reception hospitals in accessible localities.

AN ANALYSIS OF MY VAGINAL ABLATIONS IN 181 CASES OF PELVIC INFLAMMATION AND UTERINE FIBROID DEGENERATION.*

BY

W. R. PRYOR, M.D.,
of New York City.

Professor of Gynecology, New York Polyclinic; Consulting Surgeon, City (Charity) Hospital; Visiting Surgeon, St. Elizabeth Hospital; Founding Member Internat. Gynec. and Obstet. Society; Fellow American Gynecological Soc.; Fellow New York Academy of Medicine; Fellow New York Obstetrical Society, etc., etc.

[Concluded from page 153.]

In my practice I have been unable to divorce the fibroid from the inflammatory cases. I have so often found pus cases associated with fibroid growths, and fibroid tumors complicated by inflammatory lesions, that I could not exclude these from my paper without being unjust to both classes. I have therefore included all the vaginal ablations for inflammatory and fibroid lesions.

In reviewing such an amount of material it is incumbent upon me to give my reasons for performing the radical operation upon these women and to demonstrate the advantages of the method of operating which I have selected.

Indications for the Radical Operation.—My position in this regard is very much at variance with that of most gynecologists, and it is just as well that I state my views, leaving it to you to express yours in the general discussion. In the first place I do not consider the presence of pus an invariable indication for the removal of the pus-sac. Young women who develop large pus-foci in first attacks of gonorrhoea can very safely be subjected to the operation of broad incision into these, for they still have remaining much repair-power in the pelvic organs. At least, in view of the disagreeable effects of a too early and too precipitate menopause, the surgeon is warranted in attempting palliative work, particularly if he explains to the patient the certainty of a relapse if reinfection takes place. I, therefore, rarely perform the radical operation in young women with first attacks of inflammation but content myself with the palliative procedure of evacuation. But in those who have suffered from repeated attacks, such as old prostitutes, the radical operation is preferable. It is a significant fact that where I have adhered to this rule of palliative procedures in first attacks not one case has returned for the radical operation, though a few may have fallen into other hands later. When I find ectopic gestation of one side associated with inflamed adnexa of the other, I invariably perform ablation; for to remove the ectopic sac and leave a damaged tube is to invite the formation of another ectopic sac, or a pus focus. If a patient has had a very general septic peritonitis, not due to salpingitis, which leaves many adhesions and occluded tubes, I do not consider her a fit subject for ablation; but if I find such lesions associated with a history of and evidences of salpingitis apart from the peritonitic involvement, I prefer to perform ablation.

When hydrosalpinx of both sides is found associated with many adhesions, I practise conservatism or radicalism as the extraneous circumstances and local lesions demand. For instance, I will again take the case of a very young woman who is loth to be sterilized surgically. Inasmuch as she has no pus focus present, it is eminently proper to open the euldesac, incise the tubes and sever adhesions. The surgeon's judgment must often give way to the sentiments, and very proper ones they are, too, of the patient.

The indications for operation in the cases of genital sclerosis are always for the radical operation. Either let these women alone or cure them.

In brief, I may state that for 10 years I have felt that when the adnexa of both sides were so damaged as to require removal, the uterus was thereby rendered not only a useless organ but remained a mischievous one.

The recent advocacy of conservative and complicated operations upon pus foci, necessitating as they do the use of much ligature and suture material, finds no response in me. I have never been able to lose sight of that fundamental principle: Suppuration in a preformed sac is surely cured by removal of the sac only. And whereas we can evacuate these, we yet leave them, and do so wittingly, as damaged organs which we never expect to be restored to a normal condition.

Furthermore, I go so far as to protest against the removal of one pyosalpinx and leaving the other tube, although apparently normal. Too many of such cases furnish a pus-tube on the other side. It may be answered that one tube was normal. You can point to about enough of such cases which have conceived subsequent to a unilateral salpingo-oophorectomy to prove exceptions to the rule and that my position is correct. I have never met one. Lawson Tait never saw one. Henrotin tells me he has had just one. Surgical rules are not based upon exceptional occurrences. I may remind these gentlemen that conception has been known to follow a mere evacuating operation without section of the body or removal of any structure. I maintain that when an infectious process has passed through the uterus and has been severe enough to cause one tube to become a purulent cyst of retention, it has also damaged the other tube. And when such a unilateral pus-tube is found the indication is not for its removal alone, but for either a merely palliative evacuation or for a total extirpation. Both of these procedures are best applied through the vagina.

The indications for ablation in the cases of genital sclerosis are found in the subjective symptoms which these women suffer rather than in the physical signs. Many of these women have more severe and continuous pain than do the pus cases. The radical operation in them is infinitely more difficult than in pus cases owing to the inelasticity of the tissues. In my fibroid cases I operate only for symptoms, either pressure, pain, hemorrhage or inflammation in the pelvis.

I am outspoken in my opposition to myomectomy except in rare instances. A clean curettage supplemented by the administration of mummy extract is devoid of risk and causes greater reduction in the size of the uterus than myomectomy. If I operate for fibroids I prefer the

* Read before the Medical Society of Tennessee, April 10, 1901.

radical operation. But I never operate unless disagreeable symptoms are present. Still, here again the inclinations of the patient must be consulted. The mere presence of a fibroid is not an indication for operation. I have stated the indications for my operations and it but remains for me to tell why I prefer the vaginal route.

Why I Prefer the Vaginal Route.—I might point to the results of my work as sufficient answer, but such an act would be unfair. There are certain cases of pus and fibroid which I never approach through the vagina. If I find symptoms of appendicitis present I invariably operate through the abdomen.

Again, cases of puerperal sepsis in which the uterus is broken down demand laparotomy. There are also very large fibroids which cannot be removed through the vagina, but must be approached through the abdomen. These excepted cases are the very ones which furnish mortality to the confirmed laparotomist and really render a strict comparison between the two methods unfair to both.

How frequently these excepted cases occur in proportion to those which can be treated through the vagina, I know not. I can only state my own experience. I find that in all my fibroid and pus cases I have been able to relieve my patients by the vaginal route in 83% of cases.

In reference to the pus cases, I find that when the complications are distinctively abdominal, such as appendicular and cecal, the operation must proceed through the abdomen, while if they be pelvic, they can be operated upon through the vagina.

No such distinction can be made in cases of fibroid and fibrocystic growths. A very large, firm, fibroid uterus can be removed through the vagina, while a much smaller markedly cystic growth must be approached through the abdomen.

The firmness of structure and character of the vaginal canal have much to do with the facility of operating through the vagina in fibroid cases.

The vaginal method is particularly applicable in intraligamentous and retroperitoneal fibroids, and in fibroids associated with pus. Thus we find that those fibroids which are with difficulty and some risk to the patient approached through the abdomen are readily removed by the vagina.

COMPLICATIONS AND ACCIDENTS.

Appendicitis, with some operators, constitutes a great objection to the vaginal method. But one case in all my vaginal ablations required a secondary section for appendicitis while in my care. Many operators consider all adherent appendixes diseased. I do not, any more than adherent knuckles of other parts of the gut. Perfectly normal appendixes are often adherent to the diseased right adnexa. I have no difficulty in freeing them through the vagina. Intestinal adhesions are likewise loosened without damage to the walls of the gut.

I have never wounded a ureter nor had one injured in convalescence. Such accidents are not infrequent in laparotomy.

Three times I have wounded the bladder. In 1 case

only was it necessary to secondarily suture the wound, the other 2 closing spontaneously. I have found 4 fecal fistulas at the time of operating and 1 found after a patient went home, caused by her carelessness. Three closed without operation, 1 by operation, and 1 has failed to close after operation the patient being syphilitic. This is not a large proportion of fistulas, for in the first report of suprapubic operations made by me of 85 cases I found 5 fistulas. *Interintestinal* adhesions do not result from vaginal ablation although frequently found to cause chronic constipation after laparotomy. *Hernia* through the vaginal scar is not seen, though hernia through the abdominal incision is found in at least 5% of abdominal sections. *Secondary hemorrhage* has occurred 4 times. When it does occur it can always be controlled by the vagina, though before I found this out I twice did a secondary laparotomy, in a fibroid case once, in a pus case once. In fact, these 2 unnecessary secondary operations taught me much regarding the distribution of the pelvic contents after vaginal ablation.

Kelly found that 44% of his laparotomies had secondary hemorrhage requiring supplemental abdominal sections. I find that in my 180 cases of vaginal ablation I have had 2 secondary hemorrhages requiring supplemental abdominal section, or 1%.

I have lost no case from *postoperative pneumonia* or from *nephritis*. Slight *iodoform intoxication* has occurred 3 times, but soon passed off without deleterious effects. I have had no case of *sudden death* due to cerebral lesions. With one exception the convalescence of the cases has been smooth and I have seen no evidence of that "late infection" which gives the European surgeons a considerable mortality.

Ségond has reported several cases of *acute decubitus*, but so far I have not encountered it. *Mild phlebitis* has occurred 3 times only, a small percentage when we consider the gravity of many of the cases and the frequency of this complication after abdominal hysterectomy. In 1 case in which I operated late after a puerperal infection in which a left broad-ligament abscess has formed, I was compelled to open a secondary abscess above Poupert's ligament. Not the least attractive feature of this operation is its simplicity and the rapidity with which it can be performed under an incomplete narcosis. It is not necessary to secure that absolute muscular relaxation which is an essential of laparotomy. But 1 patient operated upon failed to leave my service cured, and she died during convalescence from typhoid fever. She reacted to the Widal test and the autopsy showed typhoid perforations, so the death cannot be charged against the operation.

In not a few cases of laparotomy which have been drained an abdominal fistula will form which resists all attempts at closure. I have found that these tracts lead down to a pocket in the pelvis. Sometimes there will be found a small opening into the rectum, or the bottom of the sinus will be occupied by an infected ligature or only by a mass of infected granulation-tissue. I have in a number of such cases effected a prompt cure by removing below the uterus and thoroughly cleansing the bottom of the sinus and its track. In this way I secure

drainage from the lowest point and readily close the fistula above. So the vaginal method not only produces few complications but relieves many of those caused by abdominal section.

The longest operation (a large fibroid in a virgin) occupied 1½ hours, and the shortest 4 minutes. The average time in bed is about 3 weeks, and most patients return home within 4 weeks. I never seek to make a record in this respect, but try to so conduct the convalescence as to put the least tax upon the patient.

Altogether I am exceedingly pleased with this method of operation, and while not germane to this paper, I may say that I treat all my ectopic cases and small ovarian cysts through the vagina. In other words, as dexterity in operating comes to me I am disposed to extend the application of the method. Not only do I advocate the application of this method because of the absence of risk, but because I am convinced that the convalescence after it is more smooth and free from complications than after laparotomy.

There is one phase of the question which must be touched on only because a certain element in the profession considers it important: I have found no shortening of the vagina after vaginal ablation. We have measured the distance from the urethra to the vaginal scar in a number of cases and find it more often over than under 3 inches. I have heard no complaint of dyspareunia.

INGUINAL HERNIA.*

BY

B. MERRILL RICKETTS, PH.B., M.D.,
of Cincinnati, Ohio.

Many methods for treating the same pathologic lesion indicate vacillation and doubt on the part of operators. They indicate also that a satisfactory method has not been devised.

It is worthy of note that ¾ of all cases of hernia are inguinal. In the Civil War (1861-65) 82% of all hernia of soldiers was inguinal; and generally the hernia was found on the right side.

Malgaigne's statistics show that 1 out of 13 males had hernia, and in females 1 in 52; the average for France, both male and female, being 1 in 20, the laboring class suffering most frequently.

Krassnow found on examining recruits in Russia that there were 5 times as many cases of hernia among Jews as among Christians. This fact would no doubt be substantiated in America and England.

Many of the methods thus far adopted have been of great benefit to those afflicted, and have also done much toward the discovery of a procedure that, meeting all the requirements, will therefore be ideal.

The injection of astringents and massage have proven efficacious in a small percentage of a certain class of cases. But injection should not be employed, because of the danger and uncertainty. Although injection and massage have failed to prevent recurrences (so have operations), the latter has proven to be a great remedial agent in certain

forms of hernia, especially in children. There will be a demand by the laity, in certain cases, for the continued use of injection and massage until their futility is seen.

Many terms are used in a wrong sense or improperly applied. This is true regarding many words peculiar to the science of medicine. There is no advantage in having technical terms if they are not properly applied. It is supposed that technical words, to justify their existence, will promote economy in the use of words. Now we have the term inguinal canal. Canal is improperly used in this connection.

Canal:—(1) A canal is a tube or duct for carrying the fluids of the body; (2) a hollow instrument used as a splint.

Channel:—(French, chanel—canal).

Annulus:—A ring, circular or rounded opening; a circular or rounded margin; in biology, an encircling band, *e. g.*, annulus abdominalis, external and internal abdominal rings; annulus abdominis, the inguinal ring.

A ring is a circular opening or aperture; the structure surrounding a circular opening. (Gould's Dictionary of Medicine, etc., fifth edition, Philadelphia, 1900.)

"The author has expressly stated that the inguinal and femoral canals are not properly canals. . . . In a normal state they are simply flattened passages." "Hernia," by Joseph Warren, M.D., second edition, p. 6.)

The inguinal ring (annulus abdominis) is a rounded or oval passage formed by the aponeurosis of the external oblique, the internal oblique, transversalis fascia, subperitoneal fat and the peritoneum. In a normal state its average length is from 1 to 2 inches. Through it passes the spermatic cord, vas deferens and ilioinguinal nerve.

The internal abdominal ring (annulus abdominalis) is situated in the transversalis fascia, midway between the anterior superior spine of the ilium and the symphysis pubis, and about ½ inch above Poupart's ligament. It is oval in form, and the extremities of the oval are directed upward and downward. The size varies. It is larger in the male.

The peritoneal surface opposite the internal ring (annulus abdominalis) forms a pouch for the cord and testes. This is called the infundibulum processus peritonei. Dr. Marcy says that this appellation is wrong; that normally there is no funnel-shaped depression. It is only formed by traction on the cord. He says the ideas usually held concerning this structure are due to the erroneous conclusions of Cloquet's work, published in 1835. Cloquet had dissected over 500 subjects who had suffered from hernia. He mistook a pathologic for a normal condition, and his error continues to be taught to this day. Gross terms this the *infundibuliform fascia*, and states that when the sac of an oblique inguinal hernia passes through the internal ring, the *infundibuliform process of the transversalis fascia* forms one of its coverings. The epigastric artery lies along the lower and inner margin of the internal ring.

"In very young children the inguinal ring is much shorter and less oblique; the internal ring being immediately behind the external ring." (Gross.)

With the growth of the pelvis in its transverse

*Read before Medical Society of the State of New York, Albany, January 29, 30, and 31, 1901.

direction the anterior spines of the ilia become farther apart, and thus draw the internal ring more and more away from (*i. e.*, to the outer side of) the external ring. Hence, the inguinal ring (*annulus abdominalis*) becomes more elongated and flattened.

The Superficial Fascia.—This is the first structure met after the skin has been incised. On being divided and reflected downward the superficial epigastric, superficial circumflex, iliac arteries and superficial external pudic vessels are exposed. The terminal filaments of the hypogastric branch of the iliohypogastric nerve, and the upper inguinal lymphatic glands will also be exposed.

Aponeurosis of the external oblique muscle, Poupart's ligament or the crural arch is that part of the aponeurosis which extends from the anterior superior spine of the ilium to the spine of the pubes. This ligament is supplied by the superficial epigastric artery.

Gimbernat's ligament is that part which is reflected downward and outward and inserted into the pectineal line.

The external abdominal ring (*annulus abdominalis*) is a triangular opening in the aponeurosis of the external oblique formed by the separation of the fibers of the aponeurosis. It is bounded below by the crest of the os pubis and on either side by margins of the aponeurosis. The artery of the vas deferens supplies this muscle.

The Internal Oblique Muscle.—This muscle is thinner and smaller than the external oblique muscle, beneath which it lies. Its aponeurosis is inserted into the crest of the os pubis, and, with the aponeurosis of the transversalis, forms the "conjoined tendon." The latter is behind Gimbernat's ligament and the external abdominal ring. Gross says that the insertion of the lower fibers of the internal oblique and transversalis extend $\frac{1}{2}$ inch laterally. Dr. Coley, quoting Dr. Blake, says that, "in a majority of cases the extent is less than $\frac{1}{2}$ inch, and sometimes inappreciable, in this case, the insertion is almost wholly formed from the internal oblique." Its external surface is connected with the external oblique, latissimus dorsi, spermatic cord, and external ring; by its internal surface with the transversalis muscle, fascia transversalis, internal ring, and spermatic cord. The circumflex iliac artery supplies this muscle.

The Cremaster Muscle is formed of numerous fasciculi arising from the middle of Poupart's ligament at the inner side of the internal oblique. The origin and insertion of the cremaster is the same as that of the internal oblique. It is supplied by the cremasteric artery.

The Transversalis Muscle arises from the outer third of Poupart's ligament and from the cartilages of the 6 lower ribs and interdigitates with the diaphragm. Its lowest fibers unite with the internal oblique, thus helping to form the "conjoined tendon."

The Fascia Transversalis is an aponeurotic membrane between the transversalis muscle and peritoneum. It is thick in the inguinal region. The epigastric and circumflex arteries furnish the blood-supply.

The Internal Abdominal Ring (*annulus abdominalis*) is situated in the transversalis fascia about $\frac{1}{2}$ inch above Poupart's ligament. It is oval in form, larger in the male than in the female. A quantity of areola tissue is

between the fascia transversalis and the peritoneum opposite the internal ring. The epigastric artery lies along the lower and inner margin of the internal ring.

Peritoneum forms a well-marked depression of varying depth opposite the inner ring; the epigastric artery furnishes the blood-supply.

The insertion of the lower fibers of the internal oblique and transversalis extends $\frac{1}{2}$ inch on the average, but in some cases it is much less. This small extent of connection of the muscles is one of the causes of failure of operations for the radical cure of inguinal hernia. The restoration of the parallelism of the fibers of the internal oblique with those of Poupart's ligament is claimed by some operators to be the main dependence for nonrecurrence, but this is extremely doubtful.

From a consideration of the anatomy of the structures involved in inguinal hernia it will be seen that they lack vascularity and nerve supply.

In an operation the nerves and bloodvessels must necessarily be severed. This prevents their perfect repair, and they are less able to withstand the intraabdominal pressure.

The imperfect state of the muscles and the lax condition of tissues due to sedentary habits render hernia more liable to happen suddenly upon violent strain.

Persons suffering with hernia complain that they have more difficulty to retain the parts in place when weakened or debilitated by disease. This may explain why elderly people, as age advances, become more subject to this misfortune.

It is well known that the changes which take place in tissue that has been subjected to reformation are uncertain, but the many causes which produce this uncertainty are not known, or if known, not well understood.

Dr. P. Assmy assigns the division of the motor nerves as the cause of ventral hernia following laparotomy. In such cases the intercostal nerves are divided. There can be no anastomosis with the nerves of the other side, and probably none with the neighboring nerves. Consequently the muscle loses its innervation and undergoes paralysis and atrophy. Hence, the atrophic and weakened abdominal walls are easily protruded in response to intraabdominal pressure. This is also true in cases when operation for inguinal hernia has been performed.

Many operators advocate the entire removal of the sac. This is necessary, as often when the sac is allowed to remain it becomes gangrenous. Other operators claim that to effect a permanent cure it is necessary to restore the obliquity of the inguinal ring. But this is impossible, especially in a large or longstanding hernia, for in such cases the ring has become obliterated. There is no passage, and the external and internal rings become one.

All herniotomies should be regarded as modified laparotomies. The only death that occurred in my practice was due to the fact that I failed to make an incision sufficiently long to make a thorough examination of the gut.

In at least 10% of cases operated upon the adhesions in repair resulting from closure of the inguinal

ring are inefficient. This is true with all kinds of suture material, that is, if suture alone be used. The ideal material for this purpose is one of sufficient life to permit a deposit of new tissue upon the peritoneum externally, in connection with that upon the transversalis fasciae directly, and the remaining tissues indirectly. Through-and-through sutures equalize the pressure on all the tissues involved. This is important with muscular tissue, which is on the stretch, and fibrous tissue. Shepherd, of Montreal, says all kinds of sutures will not last more than 3 or 4 weeks when placed in tissues on the stretch. It can readily be seen that either the sutures must give way or the tissues themselves tear. Most operators strongly favor some one kind of suture material. Nonabsorbable sutures have powerful advocates, while absorbable sutures have just as able advocates. Many statistics are given showing the advantage of one kind of suture over the other, but statistics are not always reliable. Still, the preponderance of opinion is in favor of nonabsorbable sutures, silver wire and silk-wormgut. One report states that in 116 cases in which silk was used, suppuration occurred in 24%, while in 330 cases in which silver wire was employed, only 4.2% suppurated.

If animal sutures are as short-lived as some claim them to be, patients should not be allowed to sit erect or get out of bed on the eighth or tenth day, as Bassini directs.

Those operators who favor buried suture claim that infection occurs less often when wire is used. Many oppose leaving wire sutures in place. What real objection can be raised to this procedure? The presence of wire will not interfere with the natural movements of the tissues any more than does a linear cicatrix produced by absorbable sutures. In addition, it prevents the rupture of the cicatrix by intraabdominal pressure, and, therefore, contributes to the prevention of relapse.

The use of a wire mattress meets all objections that can be urged against other methods of uniting the several tissues. If sufficient quantity of wire is used, and if the mattress is properly and permanently placed, sutures may not be necessary. If the mattress be properly placed over the opening, I doubt the necessity of suturing the tissues beyond. Of course, at times, fixation sutures may be needed. Such a procedure interferes the least with the vascularity and innervation of the tissues involved.

Absorbable sutures defeat the very object desired. The conditions are such that only a nonabsorbable and elastic material should be used.

The fear of infection need deter no one from the use of the wire mattress. If infection should occur, the method employed by the originator of the use of the mattress, Dr. A. M. Phelps, is satisfactory. He cures at all the infected portion, fills the wound with carbolic acid, and washes the latter with alcohol. Dr. Phelps claims that in all cases, in which he employed the wire mattress, not a single relapse occurred, and that the strongest part of the abdominal walls is that part involved in the field operation.

Many surgeons claim that if they could prevent relapse they would be certain of a perfect cure. Others

claim that a very large percentage of their cases are septic, but only a small percent relapse; while the former class state that their relapses will amount to 10 or 15%.

What deductions are to be made from these conflicting statements? Does infection cause recurrence? If so, what degree of infection is necessary to produce relapse? Is it not time to draw a halt, in this seeking excuses for what, in reality, is caused not by infection, but by imperfect methods and imperfect work? It is probably the patient's skin and hands which are responsible for infection. It is impossible to sterilize the skin or hands of the patient. All kinds of suture material can be sterilized.

Varicocele* is said to be a causative factor in producing inguinal hernia. Now statistics show that inguinal hernia is more frequent on the right side, while varicocele is more frequent on the left. It is reasonable to infer that if varicosis has anything to do with inguinal hernia the latter should be found more frequently on the left side than on the right, or that varicocele should be more frequent on the right side. Might not varicocele act as a preventative to inguinal hernia? If varicosis does act so, the veins of the scrotum should not be excised, and since there is no positive proof that varicosis is a causative factor in inguinal hernia, the veins should not be excised because of any fancied effect on the hernia. There are many other conditions which imperatively demand their excision, but their excision for the relief of hernia is uncalled for.

In attempting the reduction of a hernial tumor it should be borne in mind that the formation of the peritoneal sac may be double or multiple, though this is a rare condition. Therefore, it is best never to assume, but determine from positive knowledge, the actual condition. Always give the patient the benefit of the doubt.

Dr. R. H. Russell claims that inguinal hernia in children occurs because of the presence of the hernial sac, which has remained after the testicle descends into the scrotum. A permanent cure may be effected by simply excising the sac. Funke and others claim that atrophy of the testicle often follows herniotomies in children. This is caused by the cord being compressed by the cicatricial tissue.

The statistics of infection and recurrence in inguinal hernia are interesting and instructive. Dr. Marcy claims that only 2% of his cases suppurated. In 500 operations there were about 10% of recurrences. One well-known surgeon claims that suppuration is always followed by a recurrence. Dr. J. Collins Warren claims that the percentage of recurrences will average less than 8%. He favors silk for suture. According to this writer only 2% of adults are cured by wearing a truss. He differs from Drs. Bull and Coley in placing the age limit for operative treatment at 50. He has had good results in cases much older. I secured as good a result in the case of a man 78 years old as I did in any younger man. Dr. Warren claims that if a relapse does not occur within a year after the operation the patient may be considered in

*Varicocele=(varus, varix, crooked; and *εήλη*, tumor). Why not form the entire word from the Greek *Clreocle* (*κίρρός*, varix and *εήλη*, tumor)?

safe condition. In the last 14 years I have operated on 47 cases of nonstrangulated inguinal hernia. There was 1 death. This occurred, suddenly, 16 days after operation, while the patient was on the commode. Death, probably, was due to perforation of the gut, caused by internal strangulation. There was one relapse, 2 recurrences (4.22%). One case was the third operation upon a man who had undergone 2 previous operations before I attended him. Another was the second operation for a recurrence. In the first operation I used silver wire. The ages of my patients ranged from 18 months to 78 years. Including stitch-hole infection, suppuration occurred in 23 cases (49%). In one case a very deep and severe abscess developed; the source of infection was determined. Metal sutures were employed in 4 cases and kangaroo tendon in 43. Suppuration occurred in 2 cases sutured with silver wire (50%). It was not necessary to remove the wire. Twenty-one case suppurred which had been sutured with kangaroo tendon (49%). As one year is generally taken as the limit for recurrence, if the 10 operations performed during the last year be omitted, the percentage of recurrence in my practice will be 5.4%. All except 6 of these cases occurred in private practice; the 6 were performed in public hospitals. The large percentage of infection was due, probably, to the imperfect means, in private homes, to secure asepsis.

Dr. Coley, in his latest published paper on inguinal hernia in the female, states that in every case in which suppuration occurred it was due to stitch-hole infection. The Johns Hopkins Hospital Report (Vol. VII) gives 20% as the percent of infection in 366.

Dr. Coley is a firm advocate of the use of catgut and kangaroo tendon. On page 5 of his reprint, "The Radical Cure of Inguinal Hernia in the Female," he states that absorbable sutures can be made absolutely sterile. He also claims that he and Dr. Bull have used catgut and kangaroo tendon 10 years, implying that they obtained good results. Then he states that the clinical results regarding primary union are unfavorable to the use of absorbable sutures. He immediately states that the use of nonabsorbable sutures has its disadvantages, and argues against their use. He quotes Dr. Bloodgood's report to support his argument. These very tables, or his own quotations from them, are contradictory. Where silk was used suppuration rose to 24%, while where wire was used, only 4.2% suppurred. So, too, with regard to the formation of sinuses. Coley says that not alone in cases which suppurred that sinuses developed, but they may develop months and years after the operation, and that they occur when there is perfect primary union. Quoting Dr. Bloodgood again, he says, of 22 cases closed with silk only 3 healed without discharging some of the deep sutures, while 9 out of 13 closed with silver wire had no sinus formations. On page 8, he says in effect that having proven the superiority of chromicized catgut and kangaroo tendon over silver wire, silkwormgut, etc., it remains for the users of the latter materials to prove why they should not abandon their use. To an unprejudiced person it seems that if he has proved anything he has proved the superiority of silver wire and silkwormgut. Then, on the

last page, he says that 6.5% of his last series of operations suppurred, and that this took place when he used absorbable suturing material; 4.2% suppurred when wire was used, and only (?) 6.5% with the boasted absorbable sutures. The very fact that many surgeons are using chromicized kangaroo tendon is a self-evident fact that they are seeking something longer lived than the suture material ordinarily used.

One hundred and sixty-one circular letters were sent out to as many different surgeons in this country, requesting the approximate percentage of recurrence in cases upon which they had operated for inguinal hernia. Only 66 replied. Of these, 3 say they had but a few recurrences, but give no definite percentage; 8 claim to have had no recurrences; 7 give no percentage; 15 say they know nothing definite regarding the latter history of their patients; 33 give a definite approximate percentage. This varies from 1.0% to 15%. The average percentage given is 5.6%. This percentage agrees with that stated in the latest textbooks. By taking the percentage as given by these 33 operators and adding the percentage of recurrences in my own practice, the average percentage for 34 operators will be 5.58%. This percentage is based on the aggregate number of operations reported by these 34 surgeons, 6,027. Some of the figures given seem very low, while others seem excessively high. Still, the highest percentage given only equals the average percent for Europe. Prof. Girard, of Berne, says that the average percentage for Europe is 15%. His statement is corroborated by Kuemmel, of Hamburg. Dr. A. H. Ferguson gives the following statistics: Number of patients, 227; double hernia, 32; total number of operations, 259; number of patients heard from, 165; number of relapses known and reported, 0; reward offered for every case of relapse after "typic operation," \$10.00; number of cases in which the reward has been claimed, 0. He is the authority for the statement that Drs. William and Charles Mayo have performed over 500 herniotomies, using Ferguson's "typic operation," without a single relapse.

Dr. Christian Fenger says: "I should judge that the recurrences do not exceed 5%. I have myself certainly not operated a second time on 3%."

All those writers who have given a definite, approximate percentage base it on their total number of operations. This is not exactly fair if it is true that at least one year must elapse before an operation can be considered successful.

Now, if the approximate percentage of recurrence equals 5.58% on the cases that are known, how much greater would the percentage be if the fate of all the patients was known?

It is but common justice to say that those who reported no percentage or know nothing of the after history of their patients, or who do not report an approximate percentage, are just as prominent as those who did and have performed at least as many operations.

One prominent surgeon says: "The observations in these cases show that nearly $\frac{1}{2}$ have recurrence. The more modern methods of operation seem to have lowered this percentage."

Another claim that relapse is caused when there is "either sigmoid or cecal hernia where the bowel has come through the canal without peritoneal covering upon its posterior surface," and when the patient has been a heavy beer drinker and has fatty degeneration of the muscular tissue. Dr. Abbe says that since he has used the Bassini method he has had no relapse. He uses silkwormgut in all cases to suture Poupart's ligament to the internal abdominal wall. He further says: "I have never had one thrown out—nor suppurate so as to require removal."

The preferred operations today for the radical cure of inguinal hernia are 7, namely: the Marcy-Bassini, Macewen's, Andrews', Halsted's, Ferguson's, Phelps' and Bloodgood's. The expression, "Marcy-Bassini," is used advisedly, because Dr. Marcy discovered and employed this method long before Bassini announced to the world the method which bears his name. Dr. J. Collins Warren claims also hit upon this method of operation, which he to be the nearest to nature's method, independently of Bassini's. The Marcy-Bassini method seems to be most popular. From statistics it is permissible to venture the assertion that 95% of herniotomies performed are according to the Marcy-Bassini methods or modifications thereof; 3% will cover all other methods in which absorbable or buried sutures are employed; 2% will cover all operations in which wire is used. There are on record about 1,000 operations in which wire was employed. Witzel, of Germany, closes hernial orifices with deep sutures, he then weaves the silver wire in and out the strands; in other words, he "darns" the opening. The Marcy-Bassini operation was a great advance in surgical technic. A professor of surgery said that the recurrence amounted to over 50% when he employed the McBurney and Macewen operations. There was but one relapse in his last series of operations. The Bassini method was employed in 23 cases and the Halsted in 2. The relapse was a Bassini.

In conclusion, permit me to call your attention to 3 additional causes of failure in radical operations for inguinal hernia: (1) Deficient origin (attachment) of the internal oblique; (2) pressure on the walls of the abdomen by the truss (where one has been worn); (3) the length of time the hernia has existed, especially in the aged.

In making a radical operation do not divide fibers of tissue, do not cut bloodvessels, do not cut nerves. If there is no cutting of nerves or bloodvessels repair will be more certain and rapid, for the reason that the vitality and innervation of the tissues will be preserved. But the operator should cut out the fat.

The question of evolution, perhaps, plays an important part in arriving at a true philosophy of the etiology of inguinal hernia, at least in the male.

Is inguinal hernia more prevalent today than in past ages? Is inguinal hernia, or rather the structural peculiarity which makes it possible a reversion to the type? Or is there a failure during fetal life of certain metamorphosis in the morphology of the pelvic structures and organs? All of these are interesting questions, and our answers to them will determine finally the disputed theories concerning the philosophy or etiology of hernia.

It might also be well to examine into the question whether anything in the habits produced by our rapidly advancing civilization has anything to do with it. Is man advancing toward perfection morphologically, or degenerating? In the time of the Emperor Constantine operations for hernia, which involved the loss of the cord and testicle, were so numerous that they were checked by a royal decree for fear that the country would suffer from the lack of population.

Perhaps an apology is due concerning the use of names. The writer has not felt at liberty to use the names of those who imparted information through personal communications, except in a few instances. But he has felt at liberty to use the names of the authors of published articles to which he has referred in this paper.

VAGINAL FALSE MEMBRANE DUE TO BACTERIUM COLI.

BY

J. N. HALL, M.D.,
of Denver, Colo.

In the *Philadelphia Medical Journal* of December 30, 1899, I published a report of certain cases seen by Dr. L. Freeman and myself under the title, "General and Local Infection by Bacterium Coli, with Report of Cases." An extensive search of the literature at that time failed to show any record of a vaginal false membrane such as appears in the case to be quoted:

On September 4, a healthy girl of 14 years began to complain of headache and general malaise, and I found her with a temperature of 101.8°. The case had the appearance of one of incipient typhoid fever, and received appropriate treatment. On the fifth the temperature was slightly increased, and on the sixth a false membrane was discovered by the mother, and shown to me the next morning. On the seventh the temperature was 104°, and the smarting and burning which had attracted the mother's attention to the membrane continued. A dark patch of 2 cm. across covered the inner surface of the right labium majus, a smaller one covering the opposing surface. An examination of a piece of the membrane by Dr. W. C. Mitchell showed a pure culture of *Bacillus coli*. Gonococci were sought for in vain in the secretion and the membrane.

The urine was acid, S. G. 1025, and contained neither albumin nor sugar. The sediment, after centrifugation, contained nothing abnormal. The absence of colon bacilli should be noted.

Under the application of a 1 to 5,000 bichlorid solution the membrane was detached on the sixth day, the temperature became normal and the girl has remained well ever since. Phenacetin was given for the headache and pain, and salol to avoid, if possible, any ascent of the infection along the urinary tract. This was especially important in this case, for another member of the family, a year before, had had a long and severe infection of the entire tract by this bacillus.

The infection of 2 members of the family a year apart by the bacillus seemed to Dr. Freeman and myself rather indicative of a family susceptibility to the germ than as evidence of any possible contagion.

From the article referred to I quote the following: "Bacillus coli may and often does cause many diseases, as cystitis, nephritis, pyelonephritis, perinephritis, peritonitis, endocarditis, icterus, disease of the gallbladder, meningitis, lymphangitis, urethritis (1 case), abscess, sepsis, pyemia and septicemia. The culture is sometimes a pure one, but often mixed with pus-organisms, and of greatly varying virulence."

It is noteworthy that the diseases caused by this bacillus are rather within the body than on the external surfaces, although it is well known that *Bacillus coli* is found as a harmless inhabitant of the vulva, foreskin and anterior urethra in many cases. No history of any possible injury to the parts could be obtained. The girl had recently menstruated normally. Under the circumstances, and especially with the family history and a temperature of 104°, it was a relief to find the urine normal, and not, to quote again, "acid, foul smelling, cloudy, and loaded with the bacteria mentioned." In spite of the purely local involvement, the temperature was as high as in the grave systemic forms previously reported. The prompt subsidence of temperature at the time of separation of the membrane would confirm the idea that there was no undiscovered constitutional infection, the general symptoms being well explained by the absorption from the local lesion, as in diphtheria. It is possible that other membranes ordinarily considered diphtheric may be found to be due to *Bacterium coli*.

A NEW SERIES OF ANAEROBIC BACTERIA.

BY

LOUIS LEROY, B. Sc., M.D.,
of Nashville, Tenn.

Director Microscopical Laboratories, Medical Department, Vanderbilt University.

At the International Medical Convention, held at Paris last summer, some very interesting reports were read by Dr. Veillon concerning the hitherto overlooked and unknown anaerobic bacteria. Doubtless it will be demonstrated thoroughly that many of the conditions mentioned in the following translation are caused frequently by some of the series of organisms which he and his followers describe. These may account, for instance, for the grave results observed in cases of hepatic or pelvic abscess in which only the *Bacillus coli* has been found and which have led us possibly at times to ascribe too great pathogenicity to that usually benign bacillus. The following is a fairly close translation of an extract from his report, as distributed at the congress:

ANAEROBIC BACTERIA IN PATHOLOGY, WITH ESPECIAL REFERENCE TO INFANTILE PATHOLOGY.—There exists besides the known, aerobic, pathogenic bacteria, a large number of equally pathogenic microorganism which are unable to develop in the presence of oxygen; these are the strict anaerobic bacteria. Their importance has been overlooked in the past and with the exception of malignant edema (vibrion septique), symptomatic

anthrax, and tetanus, we have but vague notions of their role in human pathology.

Following an extensive systematic series of researches we have been able to isolate 14 species of strictly anaerobic organisms. These anaerobes are the principal agents of a whole series of affections of a gangrenous or putrid nature. They have been isolated in otitis, mastoiditis, cerebral abscess, pulmonary gangrene, putrid pleurisies, dental caries and suppurations of dental origin, sinuses, phlegmons of the orbit, gangrenous pericystitis, appendicitis, peritonitis, hepatic abscess, periuterine suppurations, certain puerperal infections, bartholinitis, urinary abscesses, extravasation of urine, vesico-renal and peri-renal infections, and gangrenous phlegmons. The details of the technic employed in the special study of each of the diseases in which these bacteria have been encountered will be found in a series of works undertaken in the laboratory of Prof. Grancher. We will here content ourselves with giving a resume of the biologic properties of these microorganisms. Exclusively anaerobic, they have the property of necrosing living tissues and at the same time to cause them to undergo a process of disintegration analogous to putrefaction; these are the agents of the gangrenous and putrid processes. Not only do they act locally but by the toxins which they secrete as well, they provoke a veritable general poisoning which is evidenced by the symptoms of constitutional infection and in typical cases by an alteration in general condition which may be termed the putrid facies or cachexia. In the study of their toxins and by immunization we soon hope to have a serotherapeutic treatment which will be truly rational and efficacious.

The following is a list of the publications upon the subject, which have been written by Dr. Veillon and his followers, chiefly working in the laboratories of Dr. Grancher in the Hôpital des Enfants Malades:

- Veillon, Sur un microcoque anaerobic trouvé dans les suppurations fétides (Soc. de Biol. 1898).
Veillon et Zuber, sur quelques microbes strictement anaérobies et leur rôle dans la pathologie humaine (Soc. de Biol. 1897).
Veillon et Zuber, Recherches sur quelques microbes strictement anaérobies et leur rôle en pathologie (Arch. Méd. exp. 1898).
J. Hallé, Recherches sur la bacteriologie du canal génital de la femme. Thèse, Paris, 1898.
Rist, Etudes bactériologiques sur les infections d'origine optique. Thèse, Paris, 1898.
Cottet, Recherches bactériologiques sur les suppurations peri-urethrales. Thèse, Paris, 1899.
Guillemot, Recherches sur la Gangrène Pulmonaire. Thèse, Paris, 1899.
H. Tissier, Etudes sur la flore intestinale du nourrisson à l'état normal et pathologique. Thèse, Paris, 1900.

We have in progress some work in the same line, and hope in a short time to be able to verify some of the reports noted above.

Plague in San Francisco.—Surgeon-General Wyman, of the United States Marine-Hospital Service, reports from January 1, 1901, to April 19, 1901, 12 fatal cases of plague.

CONCLUSIONS FROM PERSONAL OBSERVATIONS OF COMPOUND FRACTURES.*

BY

DOUGLAS C. MORIARTA, M.D.,
of Saratoga Springs, N. Y.

Senior Surgeon Saratoga Hospital; Visiting Surgeon St. Christina Hospital.

How shall we treat compound fractures? though an easy problem to propound, is one at times difficult of solution for us all. I do not propose to present a review of the subject but to urge the adoption of conclusions that my personal observations of the past have taught me. I neither have nor make any claim to originality for the thoughts or procedures suggested in this paper, but urge acceptance of these conclusions, as they are essential at times to assure proper results and eliminate avoidable unfortunate conditions.

In these cases it is well to have the physician's personal interests protected by doing that which can be shown to be the very best thing for the patient. In the patient we have to consider general condition, age and any organic trouble that may exist, the peculiarity of the fracture, the condition under which it occurred, the conditions incident to the primary dressing and the time that has elapsed since its occurrence. When, because of a very small or incomplete opening, we are unable to determine the relative condition of the tissues involved, the character of the fracture, the proper approximation of the ends of the bone, it is our duty to determine these facts promptly and positively. Unless this is done a naturally protracted illness is markedly prolonged, with all the concomitant dangers, suffering, annoyance and expense.

In speaking of compound fractures, we almost always associate them with the long bones, and it is these I have in mind; for it is the exception when compound fractures of other bones occur. I do not propose to consider those cases in which great contusion, extensive comminution and laceration of the parts exist, such as result from great force or weight, gunshot-wounds or railroad accidents, when the vitality of the tissues is destroyed or the member partly severed. In these cases, the cause of the traumatism is a factor of no small moment. As you are aware, injuries from rapidly-moving bodies produce a change in the tissues, which we might designate molecular, and trophic disturbance are sure to occur in the tissues beyond the immediate point of traumatism. In such cases, the question is not whether we shall open up the wound or not, but usually one of amputation to save a life.

Another class of compound fractures is more common, which general practitioners have to meet, and which require greater skill, care and judgment to have terminate successfully, than those just mentioned. They come along irregularly in practice, and unless we have given this class of compound fractures some thought and have their peculiarities clearly in mind, we will have an occasional result that is very ugly and unsatisfactory, both to our patient and to ourselves. To show that we may obviate these occasional unsatisfactory results, is the purpose of this paper.

In these cases the skin and tissues are torn and penetrated by the ends of the fractured bone. The laceration varies from a small hole or puncture to a wound of several inches in extent, the size of the puncture bearing no relation to the possible complications or termination of the fracture. I believe it to be the common practice with most physicians to try to replace the ends of the fractured bone in the best possible apposition by extreme extension; if apparently successful, to accept it as such, then seal the wound up, put on a retaining splint and trust in God for the rest. Or sometimes, when this cannot be accomplished, the end of the bone is sawed off, replaced without thoroughly opening down to the bone, and then dressed in the manner described. To such methods and procedures, I wish to take exceptions; not because I have not had some good results when treating cases in this way, but because I have most positive convictions that there is a percentage of avoidable poor results. I recall quite a number of primary cases in which I am sure if this method had been pursued, union could not have occurred. I have also observed late cases, when this method has been followed, which presented vicious union or nonunion, a most unfortunate termination both for patient and attendant. These would have resulted differently, in my judgment, had the wound been fully opened up and the conditions determined and corrected. Such observations, occurring frequently, furnish ample reason for attempting, and, if found feasible, adopting, a method which will eliminate these uncertain results and so give us a higher percentage of satisfactory recoveries.

Unless we can conclude that infection has not occurred from the patient's skin, clothing or primary dressing; that the tissues are not buttonholed by the end of the fracture under the skin unrecognized; that there has been no foreign substance carried into the wound, such as bits of clothing, dirt, etc.; that the ends of the fracture can be approximated and remain there; that the ends of the fracture can be placed in apposition without sawing the ends of the bone; that there is no danger from the bruised tissues or loose spicules of bone I believe that we should promptly cut down on and fully open up the tissues in this class of fracture at the laceration and definitely determine these points. The wound can then be cleansed, the torn tissues cared for, all foreign substance removed, and the bone thoroughly and promptly exposed. The ends of the fractured bone can be approximated, wired or nailed as determined, the periosteum replaced as far as possible, and if thought necessary a drain for 24 or 48 hours is admissible. If the fracture is an oblique one it is very much the wiser method to wire it through and through with heavy silver wire*; while if it is a transverse fracture, once it is

* I say, "If it is the wiser method." Each case I see impresses me more forcibly that it is the imperative method. Since this paper was written, I have seen 2 cases of oblique fracture of the tibia, one compound, the other simple, which reassured me of the correctness of this statement. One was in a brother practitioner, and while I advised as I have written, an eminent consultant did not agree with me because of the patient's condition, so he approximated the fractured ends and applied a fixed dressing. At the end of 6 weeks we had a most unsatisfactory condition—only fibrous union and that in a most vicious position which required secondary operation—the simpler one was later compound by the end of the bone forcing itself through the tissues, because the end was not held securely in place, which, as you will know, is always difficult and the accomplishment of which is uncertain in markedly oblique fracture.

* Read before the Saratoga Medical Society, February 14, 1901.

replaced it will probably remain so with the usual retaining splint and dressing.

I grant that this procedure is not admissible unless we are first absolutely sure of our surgical technic, and, second, that the patient's condition does not contraindicate it. If we are not sure of our technic, then I believe we should promptly adjust a sterile dressing, without attempting to clean up the member, and turn it over to some one who is so situated that a perfect technic can be observed. If we attempt to clean up the wound for the primary dressing and cannot observe perfect asepsis, the patient is much more liable to infection than if a simple primary dressing of sterile gauze had been adjusted. If this is not at hand, a clean piece of linen or muslin can be employed with safety. If one has these cases referred to him for treatment, he is fortunate if nothing more than this has been attempted.

You must all agree with me that it is not only difficult but impossible to determine the points I have mentioned through a small punctured wound. If the wound is not enlarged and sepsis occurs, it may burrow along the muscular planes, causing danger by destruction of tissues or impairing the usefulness of the member; or it may extend to the medullary portion of the bone causing diffuse osteomyelitis, ending in extensive necrosis or pyemia. In any case the repair will be by granulation and correspondingly slow, which under the most favorable circumstances means increased suffering and expense. Thus a compound fracture that is infected or improperly cared for is an alarming condition, and may easily lead to loss of limb, life, or both. In fact, before the days of aseptic surgery this was such a well-recognized fact that amputation was the not uncommon treatment for compound fractures.

I expect that some will take exception to my broad statement as to the proper treatment for these cases, and support it by the results obtained in some or all of their cases, particularly if they are not many; 5 years ago I would have done so myself. During that time, however, my observations have forced me to change my conclusions in this class of work. I am sure if the practitioner will observe and analyze his own cases he will find some in which faulty and delayed union, or non-union has existed, which would not have been the case if the method suggested had been followed.

I review, in the briefest way, a few cases. I have a goodly number more which could be cited, but mere numbers would not change my conclusions, as I believe one avoidable poor outcome is sufficient to condemn any set line of procedure.

CASE I.—Male, age 23. Both bones of leg broken, tibia protruding through skin, laceration considerable but not sufficient to determine the condition of the tissues. On opening down to the bone we found the proximal end had buttonholed a portion of the muscular tissue, which was not determinable until this was done; and while approximation could apparently be made, union could not have occurred. In addition we found considerable comminution of the bone, and some fibers of cloth in the wound. This fracture was markedly oblique and required wiring.

CASE II.—Male, age 25. This was also an oblique compound fracture of the tibia. It was thought to have been thoroughly and successfully reduced and placed in a proper fixation splint. After 8 weeks osseous union had not occurred, although there

was faulty fibrous union. Six months later an opening showed there was tissue between the ends of the fractured bone; when this was removed and the bone wired union promptly occurred.

CASE III.—Male, age 20. Incision showed transverse fracture, both bones broken, considerable laceration of skin; proximal end overriding distal end, requiring unusual force and leverage to replace it. When this was accomplished, it remained in apposition with usual dressing.

CASE IV.—Mrs. X., age 50. Compound fracture at ankle which could not be replaced to our satisfaction. When the opening was enlarged, we found a quantity of earth in the wound.

CASE V.—Male, age 45. Fracture of both bones of the leg and compound of the tibia. We prepared to cut down at the fracture. The patient's condition was such that the anesthetizer could not go on, so we were forced to dress it in the usual way. Six weeks later, union not having occurred, we opened up the wound and found the bone comminuted, and tissues between the ends of the fracture which prevented union. This was removed, the bone wired, and union occurred.

Thus, if I had only met these 5 cases, I should conclude, and expect others to sustain me in my conclusions, that the correct way to meet these conditions is with an exploratory incision, accordingly, that we are not justified if we merely try to approximate the ends of the bone, put on an aseptic dressing and retaining splint, when there is any doubt concerning the pathologic conditions. While I have not had the opportunity of examining a sufficient number of cases to attract the attention of statisticians or authorities, yet my clinical observations from the cases I have seen teaches me that I am right in my deductions. For, any method which is generally accepted and which is liable to have primary unobserved conditions resulting in complications such as I have enumerated, is radically wrong, and our teachers would do well to emphasize this point in their lectures on the subject.

It is well to have in mind our own position from a medicolegal standpoint. In a recent paper on "Fractures at the Hipjoint," I said:

"In all cases of fracture, it is particularly essential that the physician in charge should protect himself in his prognosis, as nowadays there are so many instances of suits being brought for malpractice. It has been my practice for several years to make my prognosis in the presence of some reliable individual in all cases of fracture. And I have another rule from which I have not deviated in the past 10 years, *i.e.*, not to put up a fracture permanently alone under any circumstances. Those of you who have done otherwise and have not given this matter a thought should do so, for there is surely trouble ahead for the general practitioner who treats fractures without this precaution."

In conclusion, I earnestly urge that in compound fractures, when the pathologic condition is not positively determined, that the puncture or laceration be enlarged, the bone fully exposed, approximated and held there, if you are sure of your technic and the patient's condition does not contraindicate it. I am sure that the dangers of such procedure are nil, while its advantages may save a life or limb; that the results are more perfect and quicker; and that many unsatisfactory secondary operations may be avoided.

Indiana Reform School for Boys.—An investigation by the trustees reveals the following facts: Of the 571 boys there nearly 400 have been committed for the minor offenses, mainly incorrigibility. It is peculiarly striking that by actual numbers 300 of these incorrigibles are the children of step-parents.

THE FOOD VALUE OF ALCOHOL, AND PROFESSOR ATWATER'S EXPERIMENTS AND TEACHING.

BY

JOHN MADDEN, M.D.,

of Milwaukee, Wis.

Of those whom we regard as competent to speak on the subject, Professor Atwater is, perhaps, the strongest advocate that alcohol has had in a scientific man since the days of Liebig and Moleschott. In a recent article he says: "The testimony of the experiments now available, is, on the whole, to the effect that alcohol resembles fats and carbohydrates in the protection of fat from consumption, but is inferior to them as a protector of protein."¹ Moreover, he quotes with approval the opinions of physicians who say that "there are many cases in which the bodily functions are maintained and life even saved by alcohol when ordinary food could not be endured." Speaking of certain cases in which "the bodily functions are weakened and the power of digestion impaired," he thinks that "what is wanted is a material which will not have to be digested, can be easily absorbed, is readily oxidized and will supply the requisite energy. I know of no material which would seem to meet these requirements so naturally and so fully as alcohol."

A fairly representative opinion of the latter (those who do not agree with Professor Atwater) is that given by Dr. Winfield S. Hall, Professor of Physiology in The Northwestern University, in a paper read before The American Medical Association at its meeting held in Atlantic City last June. "Not since the days of Liebig," says Professor Hall, "have the bars which set the boundary of foods been so ruthlessly torn down. Even iron filings and phosphorous satisfy the terms of this definition (Professor Atwater's definition of a food, "that which taken into the body yields energy or builds tissue"), and a long list of ptomaines, leukomains and toxins, come clearly in the definition."²

Before making an examination of the evidence which has led Professor Atwater to regard alcohol as a food, indispensable in certain conditions, we shall the better understand his position if we first obtain the views of his predecessors upon this mooted point.

Liebig classified foods into "plastic" and "respiratory," or those which build up the tissues and those which are burned to supply the body with heat and energy. The proteid foods, meat, eggs, and the like, made up the former class; and fats, starches, sugar³, the latter class. The latter class was called respiratory because their oxidized products are eliminated chiefly through the lungs. It is, perhaps, not necessary to point out here that the proteids are also "respiratory," inasmuch as their oxidation produces energy; and that, therefore, Liebig's classification is wrong. He regarded alcohol as a respiratory food, and he classified it with the fats and carbohydrates. He recognized that alcohol was an excitant of the nervous tissue, "which through its effects upon the nerves enables the laborer to renew his failing strength, which he could not do for lack of a sufficient amount of food. He does this, however, at the expense of those tissues, and the inevitable result is

bankruptcy."⁴ Nevertheless, in spite of its evident irritating properties, Liebig put alcohol in the list of useful "respiratory" foods.

Moleschott⁵ did not agree with Liebig in his opinion that by taking alcohol the laborer bankrupts himself, but held to the opinion that when alcohol is taken it is oxidized and the laborer "saves fat and albumin" which would be oxidized in the absence of alcohol. To prove this he referred to the experiments of Scharling and Vierordt, showing that the ingestion of alcohol was followed by a diminished output of carbonic dioxide. Alcohol was, therefore, in his estimation, an economizer of tissue. He raised the point, however, whether it would not be better to let the tissues be oxidized in the normal way and provide for their renewal by appropriate food rather than to do anything to interfere with the normal process of oxidation. Furthermore, Moleschott made a distinction between alcohol and real food by pointing out that, unlike the carbohydrates and fats, alcohol could not build up wasted tissues, but could only retard their destruction by itself oxidizing and supplying the bodily energy needed.

This theory, that alcohol, being more easily oxidized than the tissues, was invariably oxidized and the tissues spared whenever alcohol was ingested, found almost universal acceptance among members of the medical profession until comparatively very recent times. This was taught to me as an established fact by one of the best known chemical physiologists of the country 16 years ago.

J. R. Mayer⁶ was even more radical than Moleschott. He declared that we must regard as a food any substance which places its chemical agency at the disposal of the tissues; that the value of a food lay in its combustibility; that substances were nourishing in proportion to their combustibility; that fats, starches, and sugars were highly combustible, therefore highly nourishing; and that alcoholic liquors derived from the sugars are not the less nutritious. Mayer went further still than this, inasmuch as he looked upon the "stimulating" effects of alcoholic liquors as being a real aid for the accomplishment of both mental and physical work.

The opinion of Voit⁷ was the same as that of Mayer and he valued a substance as a food just in proportion to the amount of calories it was able to furnish when oxidized. His definition of food was exactly the same as that Professor Atwater has given this year. He called any substance a food which would cause a deposit of material necessary for the construction of the body, or which would prevent the destruction of such material when deposited. Alcohol was a material oxidized in the body. Being oxidized, the tissues must have been spared, therefore alcohol, in his opinion, was a food. He recognizes the fact that the disturbances it produces when taken in considerable quantities very greatly limits its use as a food. That, indeed, so small is the amount which can be taken without producing derangement of function that its value as a food is not worthy of attention. Its oxidation, no doubt, gives rise to heat, and may give rise to muscular energy. The latter, however, has not been proven.

Here again we meet an opinion identical with that

formulated by Professor Atwater, "It seems probable that it also yields energy for muscular work; but to prove this absolutely is not easy. The difficulty is to make experiments which show conclusively that energy used by the muscles comes from the alcohol and not from the other materials of either the food or the body itself."

Up to very recent times, therefore (as has already been stated) medical men the world over believed that the nitrogenous tissues were protected by the ingestion of alcohol, and that alcohol was, therefore, as valuable as any of the carbohydrate foods to the extent that it exercised this sparing function. Less nitrogen was thought to be eliminated, therefore, there must have been a smaller amount of nitrogenous tissue destroyed during the period when alcohol was ingested. Binz remarked at the Congress for Internal Medicine, held in Weisbaden, in 1888, that there was one thing in this question of the disposal of alcohol in the human body about which there was no difference of opinion, and that thing was the power of alcohol to diminish the output of nitrogen. Romeyn,⁹ however, a year before that time, in connection with Forster, performed experiments the results of which were already published, showing that this was by no means true.

In these experiments alcohol was given to fasting persons; but instead of a decrease there was, in every instance, a decided increase in the nitrogen output, showing an increase in destruction of the albuminous tissues. It is only just to experimenters who have obtained contrary results to say that the subjects of these experiments were said to have received "large doses" of alcohol; how much we are not told.

Others found that while the nitrogen output was less on the day or two during which the alcohol was ingested, there was a noticeable increase in nitrogen excretion on the days immediately following the alcohol day or days.

Kellar¹⁰ experimented with himself; on the 3 days preceding the day upon which alcohol was ingested the output was 20.9, 22.0, 22.2 grams, respectively. On the alcohol day the nitrogen loss was 20.8 grams; but on 3 days immediately following the alcohol day the nitrogen loss was increased to 23.1, 23.1, and 23.1 grams, respectively. In the experiments of Van Noorden, in only 2 cases during alcohol ingestion did he find a decrease, and that was very small. In all his other experiments the nitrogen loss was augmented during the alcohol exhibition, and invariably there was an increased loss during the days immediately following. The difference in some instances was marked; in one 6.80 grams on a non-alcohol day, against 8.85 grams on an alcohol day.

Chittenden's¹¹ 3 experiments are also highly instructive. In the first, during the alcohol period, there was a great increase in the nitrogen output; in the second, a very small increase; and in the third, a somewhat larger decrease than in the second. Like Van Noorden's cases, in every instance the after period was attended by an increase in nitrogen output over the normal, and in 1 case this increase was very large.

Weiske and Flehsig¹² experimented with a sheep, giving it a food containing a liberal supply of nitrogenous material, but an insufficient quantity of carbohydrate

food, the caloric deficiency being supplied in alcohol. Here, too, there was an increase in nitrogenous output greatly above the normal, instead of a saving, as the experimenters expected.

The work of the Japanese physiologist, Miura¹³, produced the same results as the experiments of those investigators already mentioned. Setting out with a diet free from alcohol, he put himself into a condition in which he was obtaining just enough nitrogenous material to compensate for the normal daily loss (nitrogen equilibrium). He then left out a part of his carbohydrate food and took its caloric equivalent in alcohol. In the 3 experiments thus carried out the nitrogen loss was always and notably increased. Immediately after the withdrawal of alcohol he returned to his former diet, which had been found to be sufficient to preserve the nitrogenous tissues intact, but it did not then, nor for several days thereafter, suffice to yield complete protection. He then dropped the same amount of carbohydrate material from his diet that he did during the alcohol period, *but took nothing in its place*. During this time the nitrogen output was, as ought to be expected, increased, *but it still fell below the amount which was excreted when an attempt to prevent waste with alcohol was made*. In other words, Miura's experiments justified him in thinking that it was better for the tissues to suffer a mild form of starvation than to attempt to make alcohol supply the deficiency in carbohydrates causing the starvation. Alcohol here acted as a poison to the protoplasm.

The experiments of Schmidt¹⁴ under Rosemann at Griefswald differed from those mentioned above: A subject in whom nitrogenous equilibrium had been established had added to his dietary a considerable quantity of alcohol. So much alcohol, indeed, was added that had it been utilized as carbohydrate food is utilized a considerable gain in body weight would have attended its ingestion. Instead of there being an increase, however, there was a noticeable loss in the albuminous tissues of the body.

In the experiments of Schönseifen¹⁵ an insufficient quantity of carbohydrate food was given, its place being taken by a quantity of alcohol having a considerably greater caloric value than the carbohydrate food left out, but in spite of the fact that the alcohol in the experiments contained a much greater number of calories than a true food necessary to keep the nitrogenous tissues intact, it did not stop nitrogen loss, and the subject's tissues steadily lost.

In Professor Atwater's own experiments the results do not differ materially from those cited above, though he seems to be somewhat reluctant to find the verdict against alcohol. He says¹⁶: "In 2 series of experiments, in 10 of which alcohol formed a part of the diet, we were unable to detect any general result which warranted us in ascribing to either the ordinary rations or to those with alcohol any advantage in respect to protein protection. There were individual cases in which the body lost more protein with the alcohol than with the ordinary diet, but in some of them the differences were within the limits of error. In one or two instances there appeared to be a direct but temporary influence of

the alcohol in increasing the metabolism of nitrogen, *i. e.*, the increase of tissue destruction. But the results likewise varied in the ordinary diet so that, taking the experiments as a whole, we do not feel authorized in ascribing to the alcohol any specific influence different from starch, sugar and fat. The most of these experiments were made with a man who had been accustomed to the occasional use of alcoholic beverages in moderate amounts."

Further on Professor Atwater tells of another series of experiments just made, and "not yet ready for publication," with a man who is a total abstainer. "In his case there was an evident increase in the metabolism of nitrogen (*i. e.*, loss of nitrogen) during periods of 3 days each, when the alcohol was given. How long this would have continued the experiments, of course, do not show."

This latter statement is significant enough. In the non-user of alcohol we have, according to Professor Atwater's testimony as well as that of all others, the sufficiently proven fact that alcohol causes a more rapid breaking down of the tissues. We might answer the question as to how long this state of affairs would continue by saying that it would last until tissue resistance had been established against the poisonous effects of alcohol. It is not entirely unthinkable that this immunity might be complete against small quantities of alcohol in the regular user of alcoholic liquors. Why should we not assume that the subject of Professor Atwater's first series of experiments had gained that immunity in his "occasional use of alcoholic beverages in moderate amounts"? Elsewhere we shall show that, unless the subject of these experiments is an absolute non-user of alcohol the results have no value as scientific data.

Speaking of the investigation of others into this phase of the alcohol question, Professor Atwater says: (*loc. cit.*): "With several associates I have lately been going over the literature of this subject. So far as we can judge from the original data of the experiments, there appear to be cases in which the manifest tendency of alcohol has been to increase the metabolism of nitrogen" (*i. e.* tissue destruction). "In some this is very marked, but the effect in a number of instances has been only temporary."

"There are other well attested cases in which the quantity of nitrogen metabolized has been less with alcohol than without. In the majority of the most reliable experiments, so far as we can judge, the alcohol has exerted no certain influence in one direction or the other."

It is regrettable that Prof. Atwater has not given us a short resume of the results obtained by different investigators so that we might compare the facts for and against alcohol as a conservator of the albuminous tissues and determine upon which side the weight of evidence lies. In his own investigations, as we have just shown, the case is clearly against alcohol, and all the evidence cited above by many of the ablest physiologists and clinicians known to science, fully corroborates him. For my own part, I have been unable to find a single case in which experiments were carried

on with a non-user of alcoholic beverages, and the nitrogen metabolism estimated by an examination of the nitrogen excreted, in which the exhibition of alcohol has not been attended by an increase in the loss of nitrogen metabolism. As a matter of fact, much of the evidence giving to alcohol its reputation for tissue-sparing, arose from examining the respiratory output. Thus Zuntz and Geppart, finding that there was no increase in the oxygen consumption and the carbonic dioxid output, concluded that the alcohol ingested was oxidized while the other tissues were spared. Indeed, it was upon this basis alone that the idea of the tissue-sparing properties of alcohol were founded, and only in recent years has it been shown that this conclusion is almost certainly erroneous.

Another probable source of error is the taking as a subject for determining this question one accustomed to the daily use of alcoholic beverages. With alcohol, as with opium, chloral and all other narcotic substances, an immunity against its toxic effects is gained through its continued use. After a longer or shorter period of time, not only is the giving of small quantities of a narcotic not attended by any noticeable derangement, but a sudden withdrawal of the accustomed narcotic is often attended by great disturbance of all the vital functions. Suppose one is accustomed to taking the equivalent of 3 or 4 ounces of alcohol daily. He is put in a calorimeter, and, after withdrawing all alcohol and putting him in a state of nitrogenous equilibrium, his nitrogen metabolism is determined. He is now given 2 or 2½ ounces of alcohol daily. Is it not quite likely that a return to his old friend, the alcoholic beverage, will be attended by a decrease in nitrogen metabolism? Suppose the subject of our experiment has long taken a small quantity of alcohol daily, as wine or beer with his meals; how much value, with this subject, would an experiment which had for its object a determination of the effects of alcohol on nitrogen metabolism have? No value whatever. Professor Atwater has hinted at this immunity when, in several places, he speaks of a "temporary increase in nitrogen metabolism," but it is with this temporary increase we are alone concerned. The question will lose interest for us when an immunity from long use of alcohol has been established.

Thus far no attempt has been made to put what constitutes a food within the bounds of a definition. Liebig of more than 50 years ago, and Atwater of the present time, regard as a food "any substance which, taken into the body, builds tissue or yields energy." As we have already seen that this definition would include numerous oxidizable poisons, it must be rejected. "Speaking broadly," says Professor W. H. Howells, of Johns Hopkins University, "what we eat and drink for the purpose of nourishing the body constitutes a food." If we mean by "nourishing" protecting the tissues from waste as well as repairing them after waste has already taken place, then we have here a good definition. "To supply with matter which increases bulk or supplies waste," is the definition of "nourish" in one of our standard dictionaries. We are well aware of the fact that "what we eat and drink for the purpose of nourishing the body" does not cover all the possible food

materials. Indeed, it covers only the lesser percentage of them. The muscle and fat of the domestic horse, the dog, and cat, and a multitude of both land and sea animals in their native state, as well as a multitude of the uncultivated graminaceous plants, are possible sources of an abundance of food as nutritious as that which we take for the purpose of nourishing the body, and are, of course, real foods.

Now, alcohol, containing no nitrogen, cannot repair waste and cannot be converted into and stored as fat; therefore, according to the definition, it cannot "nourish." Indeed, the great weight of evidence arrived at by the most competent and careful investigators, by direct methods of examination, shows that it cannot protect the nitrogenous tissues, but, on the other hand, increases their metabolism, their breaking down into urea and other excretory products.

Recognizing the fact that alcohol has been shown not to contain the nitrogenous tissue-sparing functions which were formerly attributed to it, certain investigators have still held to the fact that it spared the consumption of fat; that while it was in process of oxidation in the body, the stored fat remained intact. In other words, as long as the body was burning alcohol to furnish the requisite number of calories, the stored fat was not called upon for any energy, and therefore it was reserved for a future time. A great deal of disputation and confusion has arisen over this point. Professor Max Kassowitz¹⁸, in an admirable critical paper, has said of this controversy: "Yet it is claimed that alcohol must of necessity spare fat. Upon what does this claim rest? Only and solely upon the fact that during the burning of alcohol in the living body the consumption of oxygen and the production of carbonic acid are not increased in the amount, but simply correspond with the amounts which would (otherwise) be used and excreted in the oxidation of alcohol alone." It is from exactly this same evidence that Professor Atwater concludes: "The testimony of the experiments now available is, on the whole, to the effect that alcohol resembles fats and carbohydrates in the protection of fat from consumption."

A statement, no matter how false, gains a certain amount of credence by iteration. Indeed, scientific literature has many propositions which would not bear investigation because they rest upon statements not at all or only partly proved, which have been passed on from writer to writer until they seem to be entitled to their places in science. Such a statement is that which declares that alcohol is, in its behavior in the body, like the carbohydrates and fats. Inquiry into this subject will show that there are many more points of dissimilarity than similarity existing between them.

1. The fats and carbohydrates are not poisonous in any quantity; alcohol, on the other hand, is a violent protoplasm poison.

2. The fats and carbohydrates are capable of being changed into a reserve supply of fat which is deposited chiefly beneath the skin and constitutes a store of latent energy upon which the organism calls whenever stress of circumstances makes increased expenditure of energy necessary. Alcohol cannot be thus converted and stored.

3. The carbohydrates and fats protect the nitrogenous tissues from undue waste. Alcohol hastens their waste.

4. The oxidation of the carbohydrates and fats proceeds in such a manner that all the oxygen necessary for their conversion is supplied by the normal process of respiration. Alcohol, on the other hand, makes a demand for oxygen so great that it cannot be supplied by the normal process of respiration. Oxygen to supply this demand is, therefore, abstracted from the tissues, causing a derangement in their functions and metabolism.

5. All tissue activity is immediately accelerated by the ingestion of a real food. The ingestion of alcohol is followed by a partial or incomplete inhibition of both glandular and muscular activity, as well as a marked diminution in the quality of the mental processes.

Of course we are speaking now of the effects of food contrasted with the effects of alcohol in normal persons not accustomed to alcohol nor any similar drug in any quantity.

NOTE.—In making any scientific investigation, it is always incumbent upon the investigator to go to original sources to verify his quotations. This, however, is not always possible. For instance, a friend wishing to trace an expression finds that it occurred originally in "The German Emin Pasha Expedition," but he could not find a copy of it in any library in New York. I have not gone to original for all of the above material, but much of it has been the common property of the profession for years, and it is, undoubtedly, all perfectly reliable.

[TO BE CONCLUDED.]

SOME REMARKS ON THE CUMULATIVE ACTION OF DIGITALIS, WITH AN ILLUSTRATIVE CASE.

BY

EDWIN ZUGSMITH, M.D.,
of Pittsburg, Pa.

The cumulative action of digitalis is a quality spoken of by all writers on the drug that are known to me, and has been noted by a large proportion of practitioners that have had occasion to use the drug. Personally, I have noted it many times in adults, in one of whom the pulse fell to between 30 and 40 per minute, but in none of these did the symptoms go beyond this simple slowing of the pulse or appear alarming. In addition, withdrawal of the drug was followed by alleviation in comparatively short order.

This peculiar result from digitalis is said to be dependent in some way upon its slowness of absorption and elimination, and is particularly liable to be manifest in dropsical conditions with rapid absorption of the effusion, after fevers, and where there is scantiness of urine.

The symptoms of the cumulative effect of digitalis usually abate on the withdrawal of the drug, and are, according to the books, not usually of any gravity, the

cessation of the administration of the drug being about all the treatment required.

Systemically, digitalis poisoning is shown by the slow pulse becoming irregular, with quick beat, which ends very sharply (a sort of staccato), the diastole being comparatively long, and the artery large, tense and hard; dilation of the pupils, diarrhea, vomiting, suppression of urine, prostration, delirium or coma, perhaps convulsions and death.

The treatment given as applicable to this state and as gathered from several textbooks, consists in the administration of tannic acid as a chemical antidote, followed by a purge, aconite as the physiologic antidote, morphia if the pulse is irregular and requires steadying, and, as the signs of growing weakness come on, stimulants, such as caffeine, strychnia and nitroglycerin.

That the impression one is tempted to gather from textbooks to the effect that the symptoms of cumulative digitalis poisoning have no real gravity about them is erroneous, is demonstrated by the following case:

A female child of 23 months had bronchopneumonia secondary to whoopingcough. After several days' illness her pulse became weak and irregular. On February 23 a digitalis mixture was begun, a fraction less than 2 drops of the tincture being given by mouth every 3 hours or less. This was continued for 5 days, until February 28, when a total of 50-55 minims had been administered. On this date, in the 20 hours from midnight to 8 p. m., the temperature fell rapidly from 102.8° to 97.6°, and the digitalis was stopped, the other symptoms of the disease changing *pari passu* with the temperature. At 9 p. m. the pulse had fallen to 60, and was somewhat irregular and hard. The child's condition seemed good. Three doses of nitroglycerin, each 1-300 gr., were administered, with a slight improvement after the last one at 4 a. m., March 1. At 10.30 a. m., March 1, 10 grains of compound jalap powder was given, and several watery movements followed without other appreciable effect. Toward evening the pulse became gradually slower and more irregular, at one count being 48 to the minute, and of such a character that at times only a single beat occurred in 2 seconds or more. In addition, the respirations were rapid, the pupils were as large as the corneas themselves, prostration was marked and stupor was coming on. The case looked decidedly serious. A few doses of morphia of 1-200 each were given, and the pulse became a little more steady. About midnight, tincture aconite was begun in 1-10 drop doses, at intervals of 40 to 60 minutes, with apparently a little improvement in the tension of the pulse. As much water as the child could be induced to take was given, with the double idea of weakening the solution of digitalis in the blood and of favoring diuresis, which had become very scant.

But all these measures were of little value compared with another of which I am about to speak, and which to me appeared to be the prime factor in abating the lessening pulse-rate as well as relieving the other symptoms, all of which together made me very anxious. I have seen no reference to the measure to which I refer having been used for the purpose, and this forms my sole excuse for adding another paper to overburdened literature. It seemed reasonable that, since fever is an admitted hindrance to the action of digitalis, if the child's temperature could be raised by harmless means the digitalis might be rendered inactive for a long enough time to permit of its excretion. Accordingly, the child's bed was drawn before the register and a tent constructed, such as is used when vapors are to be inhaled, only the head was left free. The register was opened and the heat allowed to stream into the tent.

Within one or two minutes the effect was apparent. The pulse, while still hard, was yet softer than before; it became fuller, and quite regular and fast; the mental faculties became brighter and the child began to drink considerable water. There was no sensible perspiration. The pulse-rate within a very few minutes was at 130, and after a half-hour the heat was turned off with a brighter aspect to the case. It was not long, however, until the pulse began to slow again, but when it reached 60 the heat was reapplied. This alternation of heat and no heat was kept up *pro re nata*, the intervals of no heat gradually becoming longer until at the end of 60 hours it could be discontinued altogether, although the evidence of the digitalis had not entirely disappeared. A thermometer placed in the tent registered 120° F. Twelve hours after the hot air baths were found to be efficient, caffeine citrate, in doses of one-half grain every 2 hours, was given by mouth. It seemed to have little effect beyond steadying the pulse to a degree and producing wakefulness.

Weighing therapeutic facts, there seems to be no drugs to meet the indications present in digitalis poisoning of the cumulative variety, with the exception of aconite and some other less-known drugs, such as muscarine. Heart stimulants are hardly to be given to a heart already overstimulated, and which is found tetanic after death. Even nitroglycerin seems an illogic remedy. Aconite, to be effective, must be used in large and dangerous dosage.

Two other remedies suggest themselves as being theoretically valuable, although to be used with caution. They are chloroform inhalations—the long-continued administration of which, which would no doubt be requisite, constituting a serious objection—and bleeding, either with or without saline transfusion. It may be that the warm, moist bath would prove more effective than the dry one.

While the result was according to my hopes, it would appear that the theory which led to the use of the hot air was wrong, for the child's temperature, just after a hot-air application, was just about 99° in the rectum. However, there can be no doubt of the efficacy of the treatment, for the heat was applied and withdrawn at least a score of times, and always with the result of increasing the pulse-rate and relieving the symptoms while it was turned on, and of permitting the symptoms to return when it was turned off.

The Prophylaxis of Glanders and Tuberculosis.—Upon the recommendation of the Secretary of State, the Military Governor of Cuba has published general rules for the prophylaxis of the glanders and tuberculosis in the city and province of Havana. They provide for the inspection of all the stables and ranches in the city and province, the employment of a veterinary surgeon in all stables of cattle and industrious establishments using horses and mules, who shall be accountable for the sanitary condition of the animals. All horses and cows suspected of having glanders or tuberculosis shall be at the disposal of the commission until properly diagnosed and if the existence of such disease is confirmed the animal shall be killed and cremated immediately and the owner paid one-half of the valuation which the commission may have put upon the animal. The owners of stables shall not bring into their places any new animal without first announcing it to the commission for the purpose of the proper inspection of such animal under penalty of from \$10 to \$100, and under the same penalty the owners are obliged to report the deaths and removal of the animals. The maximum price to be paid for animals killed, \$200 (U. S. money) for each horse and \$75 for each cow.

PROLONGED INTUBATION.

BY

EDWIN ROSENTHAL, M.D.,
of Philadelphia, Pa.

With the advent of diphtheria antitoxin, the operation of intubation obtained an exact position.

Before that time, the practice of intubating the larynx for an infectious stenosis was an expectant procedure, and was in a great measure experimental. While it was practised to as great an extent as it is now, a recovery was looked upon as an exception, and in the statistical records, the percentages were written in recoveries, not as at present, in deaths. This change in the method of recording results, is perhaps one of the most striking results of the efficacy of the serum treatment of diphtheria.

To the antitoxin is also due the very many accurate results obtained in the study of the progress as well as sequel of diphtheria, especially of the laryngeal type, and those most serious cases requiring intubation.

We have thus been enabled to study more fully the value of this procedure, and we have found that we are not only able to relieve the impending suffocation—the most urgent symptom—but that we cure, and where before we were expectant we are now more certain.

In studying this operation various authors have taken up the different difficulties frequently met with. Some have studied the injuries resulting in intubating or extubating. Others have devised methods of extubating, whilst some have taken up the object of the operation, and have investigated the time required for the tube to do its work.

A statistical study of results obtained by the use of the serum has proved that there has been a very material reduction in the time required and the joint result of these labors has given well-marked rules for the guidance of all. As a very brief summary, we may say: It should be a rule of practice to remove the tube within 5 days, unless it be removed by expectoration before, and then be no longer required.

The first attempt at extubation should then be made on the fifth day. If the tube is required longer than this time, it will be an impossibility to state when the patient will no longer require the tube. If, therefore, the child requires a reintubation at once, or even in a week, the case may be assumed to be abnormal, and should come under the category of prolonged intubations, and treatment should be special to meet such indication.

Cases of this kind have been recorded by many. Welch, of the Philadelphia Municipal Hospital, records a case in which the patient required a tube 11 months, and died at last from suffocation. Engelmann and others report the same results.

While such instances have been placed on record, no remedy has ever been given, and to assist in coming to a certain method of treatment, I wish to record the following case, No. 344 in my case book, and my method of procedure, inasmuch as this patient recovered:

Herbert D., aged 2 years and 7 months. Treated with an insufficient quantity of the serum (1,000 units) 3 days after

the disappearance of the primary evidence (faucial diphtheria), or on the seventh day of his illness, began a reinfection of the laryngeal type, progressively so severe that he required intubation on the tenth, or 3 days after this symptom. The child, almost in extremis, was intubated, 3,000 units of antitoxin administered and 1-40th of strychnin nitrate given hypodermically, within the shortest space of time. In this case a No. 2 tube was first used, but failing to give relief, a No. 3 (that is, one for a child one year older) was employed, with a gratifying result. The case progressed as the average case, and extubation was performed on the fifth day. Relief was so marked that the tube was left out. But in 24 to 36 hours, stenosis became so marked that reintubation was required, and the tube was worn with prompt reintubations after as prompt extubations for a period of 36 days.

The diagnosis was of paralysis of the vocal cords as the result of the diphtheric infection, the only reason why the prolonged intubation was required; hence the following method of treatment was pursued: Strychnin in progressively larger doses until the maximum, 1-40 grain, was given 4 times a day. Regarding the tube: The large tube was required for 30 days, when the next size smaller was inserted. The child could breathe quite well, though there were frequent attacks of coughing, when the tube was twice expelled. After the fourth day the smallest size was used. This was expelled on the next day and reinserted. On the last day of the intubation, the tube was removed by coughing, and before I reached the child he was sleeping with all the marks of stenosis entirely gone. As he no longer required the tube it was left out.

As a summary, I might add: All cases requiring a tube longer than 5 days must be classified as cases of prolonged intubation. The treatment consists in large doses of strychnia and the constant reintubation and extubation, daily or every second day, of progressively smaller tubes, until the case no longer requires it.

Physical Culture.—At the twelfth convention of the American Association for the Advancement of Physical Education, held recently in New York, the substantial progress which has been made in the matter of physical education in colleges and schools in the last 25 years was demonstrated. In 270 colleges and universities special attention is given to it. In 98 of these it is in the shape of organized work, in 72 of them it is required and 24 give credit for it which is counted in the conferring of a diploma. In 300 cities physical culture has been taken up in the schools, and in 100 cities there are special teachers in the public schools.

"The popular conception of a country doctor is ludicrously wide of the mark," said a man who sells surgical instruments and spends a good deal of time with the rural trade. "It is based on novels mainly, where the rustic practitioner is generally pictured as a half-starved martyr to duty, who either drives about in a ramshackle gig or rides a 'gaunt gray mare,' with his medicines in a pair of saddlebags. The doctor's old gray mare, as I remember her, is quite a standard character in fiction. The average country doctor is far more prosperous than the average doctor in a city. I know at least half a dozen who earn fully \$10,000 a year, and a \$5,000 practice is comparatively common. This is not mere guessing, but I speak from a personal knowledge of the facts, gleaned in the course of long business relations. To be sure, it takes hard work to earn such sums. One physician of my acquaintance, who lives 40 miles from a railroad, uses 8 horses in making the rounds of his patients. He keeps several at points remote from his home, as relays. Often he is on the go for 2 or 3 days at a stretch, but he is healthy and happy in spite of the strain, and last year he collected \$9,200 cash. He expects to keep up this pace for 6 or 8 years, and then take a young partner and gradually retire from active life. This is the plan of most of our successful country doctors, and it has made fine openings for many bright graduates from the medical colleges. I have noticed, incidentally, that the country doctor usually retires at an earlier age than the city man and is able to enjoy life before he becomes decrepit. One great advantage of a rural practice is that there are comparatively few bad bills—exactly the reverse of the conditions in a city. When a farmer sends for a physician he pays him. A customer of mine in one of the river parishes lost only 4 accounts last year out of a total of over \$6,000. If you are looking for medical starvelings you'll have to go to town to find them. The country is not their habitat except in stories."—*N. O. Times-Democrat.*

PRACTICAL THERAPEUTICS

Under the charge of
A. A. STEVENS,
Assisted by
L. F. APPLEMAN.

Resorcin as a Preservative of Suprarenal Extract.—S. Oppenheimer (*New York Medical Journal*, March 9, 1901) has found resorcin an excellent preservative of solutions containing suprarenal extract. He adds 60 grains of the desiccated extract to 1 ounce of a 1% solution of resorcin, and filters a sufficient quantity for daily use.

Acute Cystitis and Urethritis.—Aronstam (*Physician and Surgeon*) has obtained good results from pichi, combined with an alkali, as in the following formula:

- ℞ Fluid extract of pichi 4 drams
- Potassium citrate 3 drams
- Tincture of hyoseyanus 2 drams
- Spirit of nitrous ether 3 drams
- Elixir of orange, to make 2 ounces

One teaspoonful in water one hour and a half after meals.

The Treatment of Migraine.—H. T. Patrick (*Medicine*, January 1, 1901) states that scrupulous attention to the general health, the best of hygiene, especially hygiene of the nervous system, and careful removal of all local abnormalities which may act as general depletants or as fretters of the nervous system, must be the first care. The author has found treatment based on the uric acid theory of the disease a relative failure, and the record of operative interference discouraging. He has yet to hear of the radical cure of a bad case of typical migraine, although considerable amelioration, amounting to a practical cure, is attained in a few cases. The affection may cease spontaneously in women after the menopause, and in men after the age of 60. In medicinal treatment his preference is for cannabis indica, but he states that success with this remedy will largely depend upon the recognition of 3 variant factors, namely: quality of preparations of the drug, difference in individual susceptibility and substitution by druggists. Many preparations on the market are worthless. The initial dose of a good fluid extract is 3 or 4 drops after each meal, and the amount is to be rather rapidly increased until the limit is reached for the case in hand. In some patients 3 drops may produce symptoms; in others 60 drops may have no effect. When cannabis indica fails, a course of bromid as for epilepsy, or of nitroglycerin, or of the two combined, may be of distinct assistance. Mendels' mixture of sodium salicylate, sodium bromid and aconit the author has found useful in a few cases when given regularly for a long time.

Tropacocain for Subarachnoid Injection.—Schwarz (*Centralbl. fur Chirurgie*, March 2, 1901) reports 16 operations in which he used tropacocain instead of cocain for subarachnoid injection. The analgesia was complete in every instance and none of the ill-effects of cocain (pallor, vertigo, pyrexia, headache and vomiting) were observed. The amount of tropacocain injected varied from .5 to .8 of a grain.

Membranous Colitis.—J. A. Robinson (*Medicine*, January 1, 1901) believes that when enteroptosis is a cause of membranous colitis it affords a reasonable ground for surgical interference. Occasionally it is necessary in severe cases to restrict the diet closely, but generally the diet should be ample, varied and digestible. Of the first importance is the protection of the intestines by wearing the entire year a flannel abdominal bandage. Every means which increases bodily vigor should be employed. Exercise, sunshine, change of scene and freedom from care are important adjuncts in the treatment. When there is renal insufficiency (a frequent accompaniment) saline diuretics, alkaline waters, chalybeate waters and an occasional hot-air bath are indicated. Rectal irrigation with hot water (100 F.) gives great relief. To avoid irritating the bowel, a soft-rubber rectal tube should be used. Except in severe cases, high hot

colonic flushings, with 1% solution of boric acid and sodium chlorid are very beneficial. They should be given by an experienced person, since undue tension of the bowel must be guarded against. Letcheff recommends hot solutions of 1 to 1,000-2,000 of silver nitrate. The author has used with great benefit a solution of methylene blue (1 grain to a quart of water) by rectal injection, the patient reclining and the injection given high. Care is necessary to avoid staining the clothes. Defective digestion calls for digestive ferments or hydrochloric acid, and in neurotic subjects nervines are indicated. The intestinal antiseptics which have given the author the best results have been bismuth salicylate, salol, betanaphthol, thymol, benzoic acid, guaiacol carbonate and creasote.

Bromin with Oil of Sesamum.—In epilepsy L. P. Clark (*Buffalo Medical Journal*, February, 1901) recommends bromin in cases of epilepsy that do not stand large doses of the bromids. One grain of bromin is equal to 2 grains of bromid salts. The following formulas are recommended:

- ℞ Oil of sesamum 9 ounces
- Pure bromin 1 ounce

A tablespoonful night and morning, increased as directed.

Or the following nutritive and sedative emulsion:

- ℞ Oil of sesamum 8 ounces
- Powdered acacia 2 ounces
- Syrup 2 ounces
- Oil of gaultheria 40 minims
- Water 6 ounces

Make an emulsion and add 1,460 grains of pure bromin. A tablespoonful night and morning, increased as directed.

Or, in order that the pure bromin shall not be lost by fuming, it may be given in emulsion with potassium bromid:

- ℞ Pulverized acacia 2 ounces
- Oil of sesamum or cod-liver oil 8 ounces
- Water 6 ounces
- Oil of gaultheria 40 minims

Make an emulsion; add 1,460 grains of pure bromin and 480 grains of potassium bromid. A tablespoonful night and morning, increased as directed.

The author claims that bromin given in this way is less irritating to the digestive tract, is not constipating, is markedly less toxic and seems to be much more lasting in its effects.

The Saline Treatment of Dysentery.—Buchanan (*British Medical Journal*, April 13, 1901) reports 300 cases of acute dysentery treated with salines with only 3 deaths. These cases added to 555 previously reported with 6 deaths, make a total of 855, with a mortality of a little over 1%. The average stay in the hospital was 11 days. One dram of sodium sulfate dissolved in an ounce of fennel-water was given 4, 6, or 8 times a day. The dose was repeated on the following day until the stool had been inspected. The saline was continued until every trace of mucus and blood had disappeared. The author does not consider this method safe for chronic or relapsing cases with ulceration of the colon.

Homatropin as a Cycloplegic.—E. Jackson (*Annals of Ophthalmology*, January, 1901), has found homatropin to be a satisfactory and reliable cycloplegic, both for children and those who have reached the age of 40 years. He recommends a 2% or 3% solution. Of this a small drop is to be instilled at the upper corneal margin every 5 minutes until 4 or 5 drops have been introduced. Homatropin, according to the author, far more rarely induces intoxication than other cycloplegics. The only common extraocular symptom is the bitter taste.

Gonorrhoea and its Sequels.—The treatment of gonorrhoea and its sequels was discussed at the meeting of the New York Academy of Medicine, held March 21, 1901 (*Journal of the American Medical Association*, April 6, 1901). G. K. Swinburne believed in the early use of urethral irrigations of a 1 to 4,000 solution of potassium permanganate at a temperature of 105° to 120° F. These should be given twice daily for the first few days, then once daily, and the interval gradually lengthened.

Ordinarily a .5 to 2% solution of protargol would be appropriate after the first few days. Van Der Poel recommended for anterior urethritis a .5 to 1.5% solution of protargol, and for posterior urethritis a strength of .5% to 1%. After all organisms have disappeared, weak solutions of the acetate or sulfate of zinc or of the acetate of lead are beneficial. At times it is necessary to treat certain areas topically through the endoscope with silver-nitrate solution (.5% to 5%). It is a good general rule not to use dilating sounds until all organisms have disappeared. R. W. Taylor did not favor active treatment in the early stages. After the acute symptoms have subsided he employs injections of warm lead water and administers antibleorrhagics. He prefers silver nitrate to protargol, and begins with irrigations of a strength of 1 to 32,000, gradually increasing the strength so that after 5 or 6 weeks a strength of 1 to 500 is attained. Hill praised picric acid for the treatment of chronic gonorrhoea when the mucoid stage is present. It should be used in a 1 to 100, or 1 to 2,000 solution, about 60 minims being employed for each instillation. F. C. Valentine expressed the belief that there are different forms of gonococci, and that each wanted remedy is most efficient in combating the inroads of these special forms.

Treatment of Influenza.—According to *Public Health Reports*, Nos. 6, 7, 8, 9, 10, 11 and 12, influenza occurred in Omaha, Nebraska, during December, 1900, but in very mild form. The best treatment consisted in the administration of calomel, quinin being especially applicable to cases occurring in the country, which required tonic and stimulative treatment. To the better-housed and protected class, quinin is injurious. Combinations of calomel, $\frac{1}{4}$ grain; codein, $\frac{1}{4}$ grain; sodium bromid, 5 grains, with quinin salicylat, are prescribed. Solitude is advocated. Cases occurring in El Paso, Texas, received a purgative dose of calomel as the main treatment. Quinin was found of no benefit, and in cases in which the digestive symptoms predominated it was injurious. Extreme prostration sometimes followed the use of quinin. Aconit was used with benefit in cases of fever. Ammonium bromid, chloral hydrat and codein were used to control persistent cough. The coal-tar products were used in severe rheumatic cases.

Toxic Action of Sodium Cacodylat.—Murrell (*British Medical Journal*, No. 2086) reports a case of poisoning from the administration of sodium cacodylat. The patient was a young woman suffering from moderately advanced tuberculosis. He ordered pills containing 1 grain of the drug to be taken 3 times a day. After taking 11 pills the patient suddenly developed symptoms of arsenical poisoning, with inability to move the left leg or extend the left wrist. Upon discontinuing the treatment the acute symptoms subsided in 24 hours, but the loss of power in the leg and wrist lasted for 3 days. The author states that his patient may have been particularly susceptible, but he considers it advisable to administer the drug in much smaller doses than those recommended by the French physicians.

Veratrin in Pruritus.—Lutaud (*Jour. de Médecin de Paris*, No. 11, 1900) recommends the external application, morning and night, of an ointment of 2½ grains of veratrin to 1 ounce of lard in localized, obstinate pruritus of women at the menopause. If the pruritus is general, he uses the drug internally in the dose of 1-180 of a grain in pill form once a day, gradually increased to 6 times a day, given half an hour before meals or 3 hours after meals.

Formic Aldehyd in Tuberculosis.—Maguire (*Harveian Lectures*, 1900) recommends a solution of 1 part of formic aldehyd to 2,000 parts of normal salt solution as a remedy for pulmonary tuberculosis, to be given by intravenous injection, using 50 cc. at one time. The results of 50 observations are reported, in all of which there was diminution of expectoration, decrease of fever, and in several instances disappearance of tubercle bacilli from the sputum.

The Value of Inoculation Against Enteric Fever.—Cayley (*British Medical Journal*, January 12, 1901) publishes some facts with regard to the protective value of inoculation in typhoid fever, as practised upon members of the staff of the Scottish National Red Cross Hospital in South Africa. Sixty-

one persons, constituting the first section of this hospital, left Southampton on April 21, 1900. All but four of this number were inoculated twice during this voyage, at an interval of 10 days, with recent material obtained from Professor Wright, of Netley. In from 2 to 10 hours after each injection, both local and constitutional symptoms were manifested, lasting from 2 to 5 days. Two nurses who had suffered from enteric fever were not inoculated, and 2 orderlies were only inoculated once. Many cases of enteric fever were treated in the hospital subsequent to its arrival at Kroonstadt in South Africa, but no case occurred amongst the personnel of this first section. The second section of 82 members left Southampton in May, 1900. All were inoculated, but many of them only once, with material which was not so fresh as in the first instance. One nurse of this section had enteric fever at Kroonstadt, she being the only one out of 36 nurses who was not inoculated, excepting the 2 of the first section who were protected by a previous attack. Five orderlies of this section had the disease, of whom 2 died. Of these 5, 2 had been inoculated once and 3 noninoculated. Of the 2 who died, 1 had been inoculated and the other had not. In August, 1900, Widal's test of the blood was made of those who had been inoculated. Twenty-three of the first section were tested, of whom 21 gave good reactions with dilutions ranging from 1 in 40 to 1 in 500; 2 gave only slight reaction—these being the 2 orderlies who were only inoculated once. Of the second section, 22 were tested. Of these, 11 gave no reaction, 9 gave very slight reaction, and only 2 gave a good reaction. The members of the first section appear, therefore, to have been much more fully protected against enteric fever than those of the second section. These results are strong evidence in favor of the protective power of the antityphoid inoculation when these inoculations are carefully performed, and when 2 inoculations have been given at a suitable interval of time.

Brush Massage.—Fry (*Journal of Nervous and Mental Diseases*, January, 1901) recommends massage by means of dry bristle brushes as an excellent mode of relieving lithemic and neurasthenic pains of all descriptions.

Fissured Nipples.—The treatment of this painful affection by the local application of orthoform has recently been commented upon very favorably. Oni recommends a saturated alcoholic solution on a compress, which he directs to remain for at least 15 minutes. Bardet has found orthoform in oil efficacious. He suggests the following formula:

℞ Orthoform 75 grains
Ether, sufficient to dissolve oil, of sweet
almond 5 drams.

Migraine.—W. Whitehead (consulting surgeon Manchester Royal Infirmary, *British Medical Journal*, February 9, 1901). states that during the last 25 years he has never failed to treat successfully the most inveterate case of migraine by the introduction of an ordinary tape seton through the skin at the back of the neck. Some of the cases were of the greatest severity, and all of them had been previously under medical treatment without avail. Several interesting cases are reported. The operation is performed as follows: The skin at the back of the neck is grasped between the finger and thumb of the left hand, and behind the fingers a long-bladed scalpel is forced so as to transfix the skin. Before the knife is removed, a long probe provided with a suitable eye is passed through the wound, using the knife as a guide. The scalpel is then withdrawn. A piece of ordinary household tape $\frac{1}{4}$ inch wide is then attached by a ligature to the eye of the probe and the probe pulled through the wound, bringing the tape with it. Four inches of tape is left free at each side, and these are gently tied together to prevent the tape being accidentally withdrawn. Instructions are given to the patient to move the tape from side to side each day. The operation need only occupy half a minute, and nitrous oxid is all-sufficient as an anesthetic. The seton ought to be worn uninterruptedly for 3 months at least in the first instance, and should the symptoms recur, a second seton ought to be introduced.

1.—Morton, in a lecture on the surgery of the large intestine, discusses ventrofixation of the sigmoid flexure for prolapse of the rectum. This has been done in 29 cases, with encouraging results. The operation consists in making an incision parallel to and about an inch above Poupart's ligament, separating the muscular fibers, drawing up the sigmoid flexure until the prolapse disappears and fixing it by suturing the mesosigmoid, mesocolon, peritoneum or appendices epiploicæ into the upper portion of the peritoneal incision with silk sutures. He next refers to a case of excision of the cecum and some mesenteric glands for malignant disease. Excision of a malignant growth with some involved glands and end to end anastomosis by means of Murphy's button was done. Two years later there is no recurrence. He also refers to a case of obstruction due to malignant disease of the colon. In such cases he holds it best to relieve the obstruction first, and remove the growth later, as the strength of the patient is thus conserved. [J.W.M.]

2.—Stevens reports a case of malignant disease involving the gallbladder, pylorus, and liver in which cholecystectomy, pylorotomy, and partial hepatectomy were successfully performed. The patient, a female, aged 54, presented the following symptoms: Pain in the right hypochondrium with vomiting, slight jaundice, swelling of the legs and abdomen, and emaciation. A distinct tumor could be felt beneath the right costal margin. The diagnosis of gallstones with malignant disease of the gallbladder and surrounding parts was made. On operation an abscess was found in the sheath of the rectus muscle. A fistula existed between the gallbladder and stomach. The gallbladder, adjacent portion of the liver, and the pylorus were found affected with malignant disease. A V-shaped portion of the liver, with nearly all of the gallbladder was removed. The hemorrhage from the liver was controlled by pressure, and the gap closed by means of chromicized catgut. A tube was placed in the common duct. After removal of the pylorus the duodenum and stomach were united around a bone hobbin by means of chromicized catgut in the mucosa, and silk in the peritoneum, and covered with an omental graft. Carcinoma of the gallbladder is usually secondary to gallstones. The frequent association of gallstones and malignant disease is attributed to the irritation caused by the stones. Zeuker found gallstones in 85% of cases of carcinoma of the gallbladder. The jaundice in such cases may arise from obstruction or from extension of the catarrh along the mucosa of the bile ducts. [J.W.M.]

3.—Clark and Lansdown report a case of sarcoma of the brain in which a first operation was followed by recur-

rence and a second by recovery. The patient a young man, presented symptoms of an intracranial tumor. On operation a small tumor was removed by enucleation from the left parieto-occipital region. The relief hoped for did not follow, and a few weeks later there was evidence of a return of the growth at the same site. A second operation was performed and a rounded sarcoma which on account of its size had to be removed in 3 pieces was found. Following the operation there was some dulness of perception, impairment of power and sensation in the right arm, hemianopsia, and loss of vision in the lower halves of each retina. Seven days after operation his temperature began to rise and continued high for 2 weeks, during which time there was a free discharge of cerebrospinal fluid from the wound. Seven months after the last operation there is no recurrence, and, excepting the impairment of vision, and slight mental inactivity the patient is well. [J.W.M.]

6.—Wright, conducting experiments to determine the resistance of the larval mosquito to cold, observed that the larvae are able to withstand low temperatures, and that in some cases the larval stage may be extremely prolonged—extending over a period of months. Larvae were found active in pools during winter when snow was heavy and ice thick. It is thought that it is by means of the larvae that the mosquito provides for perpetuation of the species, rather than by hibernating, and that it is during winter that one may hope to do most toward exterminating mosquitos, by searching for and destroying larvae rather than mosquitos that are said to hibernate in out-of-the-way corners. Kerosene oil is a most efficient larvicide. [A.O.J.K.]

7.—Jones reports a case of recurrent alcoholic peripheral neuritis in a woman exposed to exhausting domestic duties, but who partook of but little alcohol. [A.O.J.K.]

8.—Benson reports a case of neuritis of the optic and cervical nerves with carcinoma of the breast in a woman who was not an alcoholic nor could arsenic be found in any of the beer or foods she took. Four years after the removal of a small lump from the right breast she had the left breast removed for carcinoma. Following this she suffered from pain and a "shivering" sensation in the arms, neck and head, with cramp in the calves of the legs, and later with total blindness and slight external squint of the left eye. Later, speech became thick, the tongue was puckered and wasted on the right side, and on protrusion was deflected to the right. The hands and arms tingled and felt lifeless; and there was atrophy of the thenar, hypothenar, and interosscus muscles. Herpes appeared over the musculospiral area of both arms. The disease ceased spreading and during convalescence a carcinomatous mass was removed from the right pectoral muscle and the axilla cleaned out. [J.W.M.]

9.—Baldwin reports a case of foreign body in the bronchus in which recovery followed tracheotomy. The patient, a boy aged 5 years, having put a cracked nut in his mouth, at once began to cough and his voice became husky. Laryngoscopic examination showed nearly complete bilateral paralysis of the abductors, but no foreign body. Two days later owing to increased and difficult respiration tracheotomy was performed. A tube was kept in place for 7 days when 2 small pieces of nut were expelled. Recovery followed. [J.W.M.]

10.—Nicholson, in a note on acute dilatation of the heart, refers to the accentuation of the aortic second sound, recently mentioned by Lees, and suggests that it may indicate that the left ventricle is straining every sinew and that the heart is arriving at a stage in which no further response to stimulation is possible. It is, therefore, a danger signal of grave significance and its persistence should lead one to exercise extreme watchfulness. [A.O.J.K.]

11.—Little describes a splint for the correction of genu valgum which he has used with satisfaction. It consists of a ham splint which is attached to the posterior edge of a long external splint, the lower end of which is inserted into a pocket on the outer surface of the boot. The ham splint is fastened in front to the anterior edge of the outer splint by means of webbing straps and bandages. These splints maintain the leg in extension in which position mechanical treatment is effective. [J.W.M.]

12.—Yonge reports a case of **polypoid growth of the tonsil** in a young girl whose tonsils were hypertrophied and who had recurrent attacks of sore throat. From the left tonsil an elongated pedunculated growth was removed. It was found to consist of lymphoid tissue with numerous dilated lymph vessels and covered with epithelium. [J.W.M.]

The Lancet.

April 30, 1901. [No. 4050.]

11. Two Cases of Suppurative Appendicitis with Septicæmia: Recovery of One Patient after the Use of Antistreptococcal Serum. W. GIFFORD NASH.

2.—Rose emphasizes the importance of the consideration of every possible means of early diagnosis of **surgical diseases of the abdomen**, in view of the fact that the life of the patient depends upon prompt operation in cases of perforated gastric ulcer, which involves most frequently the anterior wall, rupture of the intestine affecting the upper part of the jejunum or lower part of the ileum and perforation of the appendix, all of which are indicated by shock, pain, vomiting and tenderness. In carcinoma of the cardia of the stomach the main symptom is regurgitation of food at a variable time after its ingestion. Symptoms and phenomena indicative of carcinoma of the body of the stomach, carcinoma of the intestine and of the pylorus are detailed and the fitting operation in each event. In doubtful diagnosis he advises an exploratory incision. [J.W.M.]

3.—Bishop thinks that **postpartum hemorrhage** is divisible into 2 classes according to the cause: (1) Those due to the conduct of the obstetrician, as torn cervix or vagina, inversion of the uterus, tearing of cord, partially separated placenta, or too rapid and unskillful use of forceps; (2) those, embracing $\frac{100}{100}$ of the cases, in which the uterine muscle is tired out at the close of the second stage of labor, the causes of this fatigue being presence of fibroids in the wall, overdistention from hydramnios, development of twin or more children, and relaxation of muscular fiber from previous habits or life in hot climates, or from prolonged labor. In the second class of cases it becomes necessary to check the hemorrhage by some artificial means until the uterine muscle can rest and then contract. The blood essential to the uterus during this period of rest may be obtained through the ovarian vessels, and Bishop advises that the flow through the uterine arteries be cut off by pressure on the aorta. The closed fist is applied with its ulnar surface resting upon the aorta as it lies over the left side of the vertebral column, and just sufficient pressure is exerted obliquely backward and toward the right so as to enable it to compress that vessel against the unyielding surface beneath. At any point accessible over the course of the abdominal aorta this compression can be exerted and there is always a sufficient extent to enable us to vary the site of impact. As to the duration of the compression on the aorta, it should continue until the uterine fibers begin to contract, and it will generally occur in practice that when the firm, strong impact of the blood current against the compressing hand has revived, the muscular force of the uterus will be rejuvenated; and the other hand of the surgeon can judge of this by gently touching it, and when it begins to

contract of its own free will the compressing hand is very slowly and gradually lifted, and the contraction now established will generally be found a trustworthy one. Whilst this compression is kept up, it is an easy matter to clear the uterus of clots, portions of placenta, membranes, etc., so that when the uterus begins again to contract its newly regained strength may find no needless work to do in ejecting them. [W.K.]

4.—Cooper in discussing enlargement of the inguinal glands in connection with the **diagnosis of primary syphilis** emphasizes the importance of this condition as a factor in the diagnosis of affections of the genitourinary organs, and states that its significance is not always apparent. In typical cases of syphilis the glands become palpable about the tenth day. The enlargement is progressive, the inflammation extending to a group of glands on both sides usually. They are indolent, painless, distinctly movable and more or less hard. In a suspected case where uncertainty arises due to a condition susceptible to glandular enlargement from slight causes, the condition must be noted from time to time, as the progressive character of the change in size of the glands is the most important point. The glands may enlarge as a part of a general adenopathy of the secondary stage of syphilis independent of the location of the lesion. Inflammation and suppuration of glands seldom arise from primary syphilis itself, but are due to mixed infection. The diagnosis of primary syphilis are based on 3 things: "(1) the history, (2) the primary lesion, and (3) the state of the nearest gland." [J.W.M.]

5.—Edridge-Green cites the opinions of a number of writers respecting the inefficacy of the **Holmgren test** and urges a fresh inquiry into the methods of detecting color blindness. [A.O.J.K.]

6.—Mott and Halliburton direct attention to the fact that in general paralysis of the insane **products of nerve degeneration** pass into the cerebrospinal fluid and may be readily detected, especially nucleoprotein and cholin. Cholin may also be found in the blood; but not alone in general paralysis of the insane, but also in combined sclerosis, disseminated sclerosis, alcoholic sclerosis, and beri-beri. Two tests—a chemie and a physiologic—are serviceable. A similar condition was produced in cats by division of both sciatic nerves, the reaction being most marked when the degenerative process is at its height, as indicated by the Marchi reaction. The chemie explanation of the Marchi reaction appears to be the replacement of phosphorized fat by non-phosphorized fat. [A.O.J.K.]

7.—Millard reports a case of **erythema scarlatiniforme desquamativum** in a man, aged 36 years, who had suffered many attacks since he was a child. The disorder is to be distinguished from scarlet fever by the absence of throat symptoms, by the disproportion between the intensity of the eruption and the amount of pyrexia, by the absence of the "circum-oral ring," and by the early onset of desquamation. [A.O.J.K.]

8.—Hunter published a short note on **neutral red** as a means of detecting the presence of **Bacillus coli communis** in water supplies. Details are promised in a paper shortly by Makgill. [A.O.J.K.]

9.—Rawlings reports a case of **measles and diphtheria** occurring concurrently in a child aged 13 months, and terminating fatally. The recognition of the diphtheria was due to the quantity of albumin in the urine and to the fact that the signs of laryngeal obstruction, although not great, were more than are generally found in the catarrh of uncomplicated measles. [A.O.J.K.]

10.—A case of **subphrenic and splenic abscess** successfully operated on is reported from St. Mary's Hospital. The patient, a young woman, presented the following symptoms: Pain in the left side, chest and back, fever, dyspnea, with rapid pulse and respiration. Examination showed consolidation of the base of the left lung, pleural effusion, some gastric dilation with no evidence of peritonitis or gastric ulcer, although the patient suffered 2 years before from pain with occasional vomiting after taking food. Clear fluid to the amount of 20 ounces was drawn from the pleural cavity by aspiration. Temporary improvement was followed by an exacerbation and a temperature which suggested pus. Examination showed it came from beneath the diaphragm especially from a splenic cavity. The

diaphragm was sutured to the thoracic wall, but this gave way and communication was established between the splenic and pleural cavities. Both were drained and irrigated daily with iodine solution. The condition of the patient was critical for some time. Convalescence was slow, but recovery was complete. [J.W.M.]

11.—Nash reports 2 cases in which **septicemia** followed **suppurative appendicitis**, and recovery in 1 case following the use of antistreptococci serum. In the first case, drainage of an appendicular abscess was followed by some improvement, but later death ensued. Necropsy showed the mesenteric glands enlarged and infiltrated with pus, and numerous hepatic abscesses, which arose from the septic mesenteric phlebitis. The second case was complicated by local abscesses. Recovery followed the use of antistreptococci serum. This serum is of use only in streptococci infections, and as each variety requires a different serum it should be used only after a careful bacteriologic examination of the blood. [J.W.M.]

10. A Rule for Combining Crossed Cylinders. HARRY S. PEARSE.

1.—**Adrenalin** in various solutions has proved an effectual astringent in acute and subacute inflammations of the nose and larynx, and in epistaxis. Before operation, 1 to 5,000 acts as powerfully as a solution of desiccated glands, gr. 30 to the ounce. When combined with boric acid in cinnamon, camphor and distilled water it will keep for several weeks. [H.M.]

2.—Mayo describes **operations for hypospadias** by simple canalization, by penile, scrotal and abdominal flaps and combinations of these and operation by mobilization and dislocation of the urethra. In cases that cannot be relieved by the latter alone, the tube may be built from the prepuce. This is extended and 2 incisions 1 inch apart made from the free border to the cervix, and, if necessary, along the dorsum. A transverse incision on the dorsum unites the two. A tube is constructed with the skin surface within and attached to the cervix. The penis is tunneled from the glands to a point beneath and a little to one side of the hypospadiac opening; the tube is drawn through and sutured at each end. In 10 days the pedicle is cut through close to the new meatus. Later a self-retaining catheter is inserted through a perineal opening and the 2 urethras are accurately coapted by sutures. A silk worm drain is used for the urethra. [H.M.]

3.—After discussing the composition and **pollution of river water** and chemical analysis of the Potomac, and the increase of fecal bacteria with turbidity, some of the statistics of typhoid and other water-borne diseases are given, and the prevention of pollution and **purification** is considered. England has had a river pollution commission since 1855, which has reduced water-borne diseases over 50%. Bartholet's bill, introduced 5 years ago, has not yet become a law. The Marine-Hospital Service could perform this service without great expense. Tables are given of plants established for the disposal of sewage in the United States, and others showing the great advantage of sand over mechanical filtration. [H.M.]

4.—**Floating kidney in children** is infrequent. It is congenital or may be brought on by trauma, especially when there is a congenital predisposition. The symptoms are noted and 5 cases are reported. [H.M.]

5.—The differentiation of the gynecologist was a comparative deathknell to the **advance of obstetrics**. Little progress has been made, except in asepsis, anesthesia and the introduction of symphysiotomy. The greatest epoch ended with the death of Hodge and Meigs, but revulsion is sure to come and obstetrics will again resume the importance of 50 years ago. Of more value than the various antiseptic agents are cleanliness and the avoidance of meddling midwifery, as the healthy vaginal secretions are germicidal themselves. Obstetricians do not take kindly to anesthetics, although the parturient state is the only condition in which, judiciously administered, they are without danger. Their application is universal. They are especially indicated in eclampsia, and neither lung nor heart-disease nor uterine inertia are contraindications. In the latter case their use should be combined with an oxytocic. They should be used in the first as well as the second stage for the relief of pain. The A. C. E. mixture is preferred. [H.M.]

6.—A large proportion of **chronic ailments** are due directly or indirectly to **wrong eating and drinking**. The normal food requirements are about $\frac{1}{2}$ part each of proteids and fats and $\frac{2}{3}$ carbohydrates. In the average table d'hôte dinner, as well as breakfast and luncheon, the albuminoids are rarely brought as low as $\frac{1}{2}$, and the carbohydrates come at the end of the meal when there is too much HCl to permit further salivary digestion, and in hyperchloridies often enough to impair the action of the pancreatic juice. The sharp condiments used overstimulate the glands, causing premature exhaustion, and the alcohol, even when taken moderately, retards digestion and impairs the motor function of the stomach. Under the guidance, then, of our ignorant French cooks, it is not safe to advise even the well to "eat everything," and still less others. [H.M.]

7.—The ordinary beer-drinker is the most prominent example of **autointoxication**. Alcohol impairs growth, repair and functional activity of the tissues. Nutrition for the cell is diverted and becomes waste product, the capillaries are diluted, the oxygen-carrying property of the blood is diminished. As the waste increases the power of elimination decreases and the processes of digestion are disturbed and altered. The starvation and irritation merge into inflammation and exhaustion, and the products of these metamorphoses become real poisons, causing many obscure symptoms. Unexplainable nervous and nutrient disturbances will often completely disappear on abstinence and an antiseptic and eliminative treatment. [H.M.]

8.—Stewart's paper is arranged in the form of a prospectus of such a **bureau** the objects of which are to establish standards of preparation, to act as a medium between scientific workers and manufacturers, to collect knowledge of **materia medica** products, and to aid manufacturers whose goods conform to the standards in introducing their brands to the medical profession. Compliance in this country with the Pharmacopeia not being obligatory, products differ widely, and the first essential to uniformity in therapeutic effects is uniformity in products. Pharmacists are bound by the same ethical obligations as physicians to give publicity to the results of original investigation. Exception can be made, without danger to science, of patents for new processes and apparatus for manufacturing so long as these patents do not cover the products themselves. The significance of trade-marks is discussed, and among the rules suggested for the bureau are those dealing with improper methods of advertisement. An appendix contains various legal decisions as to trade-marks. [H.M.]

9.—In the year ending September, 1900, there were 51,743 railroad casualties in the United States. The total casualties in the South African War to that date were about 48,000, and yet on many of our railroads there is scarcely any efficient system for first aid and comfortable transportation. For fulfilling these functions **hospital cars** are not suitable for trunk lines on account of the immense expense of fitting out and maintaining a sufficient number, and the difficulty of moving them quickly and promptly, as well as the practical impossibility of equipping them with experienced surgeons. At centers with many radiating lines, or on short suburban lines, or on those with emergency hospitals at intervals these cars would prove very useful. Such cars should also be used for isolating tuber-

cular passengers, and others with infectious diseases, in this case being attached to regular trains. It is astonishing that laws in regard to transporting the corpses of such persons are so stringent when they may travel without hindrance while still alive. [H.M.]

Boston Medical and Surgical Journal.

April 25, 1901. [Vol. CXLIV, No. 17.]

1. Remarks on Anesthesia—General, Local and Spinal. MAURICE H. RICHARDSON.
2. Experience in Search of a Cure for Asthma In the Far Southwest; With Observation of the Comparative Value of Different Sections in Respiratory Diseases. ROBERT BELL.
3. Chorea During Pregnancy. F. S. NEWELL.
4. Notes on X-Light. WILLIAM ROLLINS.

1.—Richardson, in discussing general, local and spinal anesthesia, believes that the dangers of etherization in healthy subjects are less than those attending the subcutaneous use of cocaine in extensive operations. Local or spinal anesthesia has an important field of usefulness in cases of general peritonitis, or other conditions in which regurgitation is likely to occur during general anesthesia; in diseases of the lungs, and in cervical operations, in which the respiratory passages are apt to be interfered with. He believes that spinal or local anesthesia will not, after a thorough test, compare in safety with ether or chloroform. [J.W.M.]

2.—A high altitude, dry atmosphere and abundant sunshine are best to relieve asthma. Colorado fulfils these conditions. Southern California cannot be recommended, as the climate is not dry owing to the dense fogs. Arizona stands first as a climate for all respiratory diseases. Nasal and postnasal catarrh are prevalent and aggravated in Colorado and Southern California. For tubercular patients Colorado is favorable, except for its dust and high winds. Southern California is not condemned, but other places are better. Patients should be sent west in the first stage of their disease; those in the second and third rarely recover. For nervous patients, or those liable to hemorrhage, select a moderate altitude. Advise everyone to remain for many months after the cough has ceased. [H.M.]

3.—Symptomatically the chorea which occurs in pregnancy is identical with infantile chorea. Its etiology also is similar; the tendency may be inherited, or it may be the result of previous chorea during childhood. The general opinion in England is that the chorea of pregnancy is entirely of nervous origin, and in almost all well-marked cases some more or less violent nervous shock is the apparent starting point of the trouble. The disease occurs most commonly in young women from 18 to 24 years old, and is very rare after 30 years of age. The prognosis of chorea in pregnancy is much more grave than in early life. The fetus may, in mild cases, live and be born at term; but in severe cases it usually dies and causes abortion or premature labor. In the treatment of chorea the principal drugs are the sedatives, bromid, chloral, and morphia, and the alteratives, arsenic and iron. In grave cases ether and chloroform may be given as in eclampsia. Rest in bed and freedom from worry are also valuable adjuncts. Every effort to improve the general nutrition of the patient should be made. [W.K.]

4.—Rollins in some notes on x-light states that all tubes deteriorate in use. The light is produced by the amalgamation of gas particles with metal terminals in a vacuum tube. The lower the resistance met by these particles as they are driven by the electric current from the cathode against the target the more penetrating the light produced. To overcome this resistance a reservoir and dam are used to restrain the current and send it in powerful surges, thus increasing the velocity of the cathode particles. The duration of these surges should be as short as possible, and the volume sufficient to produce the required light. By the continued formation of a cathode stream there is a reduction in the number of cathode particles until finally the tube gives no light. Rollins thinks the ideal remedy for this condition would be the restoration to the tube of the same kind of gas as was used in making the cathode stream. An important discovery to be made is a means of keeping the light constant. [J.W.M.]

Medical Record.

April 27, 1901. [Vol. 59, No. 17.]

1. Experiences with Tracheotomy. JOHN ROGERS.
2. Recurrent Vomiting of Nervous Origin. LOUIS FISCHER.
3. Tobacco as a Factor in Glycosuria. HEINRICH STERN.
4. Pityriasis Versicolor of the Face. WILLIAM S. GOTTHEIL.
5. An Extreme Case of Simple Anemia. ROLFE FLOYD, and WILLIAM J. GIES.
6. Albuminuric Retinitis In Pregnancy: Premature Labor: Death In Utero of Twin Child: Puerperal Convulsions: Hemiplegia: Acute Mania: Death. JOSEPH N. STUDY.

1.—Rogers, in reviewing experiences with tracheotomy, states that the dangers attending the operation are less than those of prolonged dyspnea. When a general anesthetic is necessary during the operation, chloroform should be employed. Laryngotomy, except in tumors, is useless. In emergency cases and chronic stenosis, except in short necked individuals and children, high tracheotomy is usually done. In chronic stenosis in which a careful dissection is possible, and in which a cure may be hoped for from the wearing of a canula for a few weeks, the low tracheotomy is preferable, although it is more difficult to pass a tube by it, and to prevent its slipping out and catching in the wound which may be a serious accident. The development of granulation tissue in cases of long-retained canula is considered neither dangerous nor of frequent occurrence. When there is uncertainty as to the location of the obstruction and the dyspnea is not relieved by a short canula, a longer one, for which a stomach tube is a good substitute, should be employed. [J.W.M.]

2.—The usual symptoms of recurrent vomiting are noted and a case in a child of 14 is reported. This followed a prolonged attack of pertussis at 8 years of age. The vomiting occurred from 1 to 12 times daily. Repeated examination of stomach contents excluded gastric disease. The trouble was believed to be of neurotic origin. There were symptoms of hysteria minor. [H.M.]

3.—Tobacco not only aggravates a glycosuria, but also—though less frequently—is a causative factor. Literature contains almost nothing as to its relation to this and to diabetes mellitus. In the cases reported by Stern, nicotine poisoning was excluded on account of the mild neurotic phenomena, and the empyreumatic poisons of the smoke affect principally mucous membranes. The condition is attributed to the CO liberated in the imperfect combustion of cigars. This is known to cause glycosuria. The blood of several patients showed carbon-monoxid hemoglobin. In some cases the sugar disappeared with restriction of smoking, and in chronic and aggravated cases it was much diminished. [H.M.]

4.—The dingy white spots were diagnosed as leukoderma at first, but the microscope showed the microsporion. [H.M.]

5.—A case of simple and another of pernicious anemia are reported in minute detail, showing striking similarity in the condition of the blood. The first case is classed as simple from the rapidity and degree of recovery and continued absence of symptoms after cessation of treatment. The conclusion is that clinical features must weigh equally with the results of the blood examination in establishing a diagnosis. [H.M.]

New York Medical Journal.

3. Hospital Appointments. Are They Open to Women? MISS HELEN MACMURCHY.
4. A Contribution to the Explanation of the Nature of the So-called Predisposition to Infection with Staphylococci. F. W. GAERTNER.
5. Pneumonia, Its Proper Management in Children: Hygienic, Drug and Dietetic Details. LOUIS FISCHER.
6. Peripheral "Anesthesia-Paralysis"—Report of an Unusual Case of Bilateral Brachial Paralysis Occurring During Narcosis (for Appendicitis). WALTER M. BRICKNER.

7. The Relation of Arterial Changes to the Heart. BEVERLY ROBINSON.

1.—Beck reports the case of a Russian tailor from whom he removed the great toe 13 years ago, the joint containing some calcareous concretions. In 1900 the patient returned with a large globular tumor on the dorsum of the right hand. Operation showed the third metacarpophalangeal joint filled with cheesy material and the extensor tendons of the digits cemented together in a mortar-like mass of calcareous material. The toe is believed to have been affected in the same way and Beck has suggested as a name for the condition *tenonitis* and *tenonothecitis prolifera calcarea*. [A.G.E.]

2.—Booth details an operation upon the nose in which the intranasal portion was done under cocain anesthesia with adrenal capsule as a hemostat. He believes that this combination is preferable to general anesthesia in a large proportion of cases. [A.G.E.]

3.—Helen MacMurchy compiles a list showing a total of 559 medical appointments—government, municipal and hospital—held by women physicians, with 11 appointments recently opened to competition. Of these, 215 are resident; 302 (including 114 resident) are in the United States, and 188 (including 99 resident) are in the British Empire. [H.H.C.]

4.—Gaertner, from a series of experiments carried out on rabbit material with injections of pure cultures of *Staphylococcus pyogenes aureus*, reaches the conclusion "that the conditions which favor a disposition to infectious diseases have to be looked for in the hydremia of anemia." [H.H.C.]

5.—Fischer, in a paper on the treatment of pneumonia, gives a short resume of the modern management of the disease in children. [H.H.C.]

6.—Brickner reports a case of bilateral brachial paralysis occurring during narcosis. He concludes that the care of the arms is as important a part of the anesthetist's duty as is the administration of the narcotic. As in some of the cases collected by Brickner the arms were lying alongside the body during operation, he believes that the arms should not be allowed to remain for more than a few minutes in any one position, however innocent that position may appear to be. [A.G.E.]

7.—Robinson, in discussing the relation of arterial changes to the heart, points out that in the nodular form of arteriosclerosis aneurysmal dilation is no uncommon sequence. In those cases in which the pulmonary artery is sclerosed a certain degree of cardiac hypertrophy must be expected. In many cases this condition extends generally to the veins. In mitral stenosis it is especially to be remarked that we have a sclerotic state of the pulmonary veins. In the treatment of these cases, while it is often manifestly indicated for a while to give heart tonics and stimulants, such as strychnin, digitalis, and strophanthus, it is also wise to administer in moderate doses potassium iodid, and for long periods with occasional interruptions. [H.H.C.]

Medical News.

April 27, 1901. [Vol. LXXVIII, No. 17.]

1. The Study of Internal Medicine. WILLIAM OSLER.
2. The Relation of the Student of Medicine and the Recent Graduate to the Field of Surgery. GEORGE RYERSON FOWLER.
3. The Medical Man in the Navy. W. K. VAN REYPEN.
4. The Municipal Health Department System, and More Especially in Reference to its Advantages and Disadvantages as an Opening for the Young Medical Graduate. ARTHUR R. GUERARD.
5. The Advantages of Examining for Life Insurance. BRANDRETH SYMONDS.
6. The Outlook for the Young Physician in State Hospital and Sanitarium Work. CARLOS F. MACDONALD.
7. The Medical Man in the United States Marine-Hospital Service.

1.—Osler advises for the student of internal medicine ambitious to become in time a consultant, an occasional few months abroad or 2 or 3 weeks each year spent in the hospitals at various medical centers at home, in order to enlarge the capacity for appreciation. During the first few years he must

be satisfied though barely eking out a living while gaining experience. He should stick close to the dispensaries, collecting material for papers, but should be careful how he writes, doing thorough work under guidance, and attempting nothing startlingly original. Three lines of work may be followed, chemistry, physiology and morbid anatomy. We sorely want men thoroughly trained in organic chemistry. To Traube and men of his stamp, physiologic clinicians, this generation owes much more than to the chemic or postmortem group, but if work must be limited, our prospective consultant must yield to the claims of the dead house. [H.M.]

2.—To the student intending to fit himself for the practice of surgery 2 courses are open on graduation. One, to enter in his practice the field of general medicine, doing what surgical work comes to him and supplementing this by operating on animals. As he builds up a clientele he should begin to turn away medical work, giving more attention to his surgical cases thus increasing the confidence of his fellow practitioners in his honesty of purpose. The better course, however, is to seek an internship in some large hospital where he may serve in both medical and surgical wards, thus gaining not only experience but self-confidence and the confidence of his chiefs. If the hospital does not afford opportunities for acquiring practical bacteriology and pathology, subsequent work should be done in some pathologic institute at home or abroad. He should endeavor to obtain a position as assistant to some surgeon on a hospital staff, should keep abreast of current literature, and make occasional visits to the surgical clinics of other medical centers. [H.M.]

3.—The medical corps of the navy is recruited directly from civil life. The test for admission is one simply of merit. Two examining boards are kept constantly organized, one at Brooklyn and the other at Mare Island. The order of examination is: (1) Physical, (2) Written, (3) Oral, (4) Clinical, (5) Practical. The paper considers these in detail. After successful examination appointment as assistant surgeon, with rank of lieutenant, is made without delay. The order of promotion with accompanying pay is given, and the conditions of naval life, with its opportunities and responsibilities, is described. [H.M.]

4.—Health Department work is comparatively new, and therefore not quite so overstocked as some other departments of medicine. Unfortunately, there are as yet no schools in this country for education in matters pertaining to public health. Such knowledge can be obtained only in this branch of the public service, and the duties of sanitary authorities are far-reaching and complex. An account is given of the organization of New York City Department of Health and the work it has accomplished, and of the number of physicians employed with their remuneration and privileges and the advantages and disadvantages connected with the work. [H.M.]

5.—The writer speaks only for what are called "old line companies." The pay for each examination is good, the fee being larger than that ordinarily received for first visits in general practice. The physician has the endorsement of competent authorities and the public, and the profession appreciate this. From a scientific point of view the necessity of relying on physical diagnosis has its advantages, and socially the cultivation of tact and backbone is encouraged. [H.M.]

6.—The inducements to enter this field are the immense amount of clinical material for the study of mental disease, the liberal pecuniary compensation, the opportunity for promotion and for making a reputation as an alienist and of preparing for the management of private institutions. A detailed account of the grading and pay in the New York State hospitals is given. [H.M.]

7.—The department offers an assured income, excellent social position, and practically an appointment for life to those best qualified. The examinations are severe and knowledge must be thorough and practical. The physical examination throws out all but the robust. The location and equipment of marine hospitals are given. The service conducts one of the best laboratories in the world. Special encouragement is given to those with particular aptitudes. The general requirements of the service are described. [H.M.]

Philadelphia Medical Journal.

April 27, 1901. [Vol. 7, No. 17.]

1. Scurvy in Infants. LOUIS STARR.
2. Notes on Leukemia, with a Report of 3 Cases. CHARLES S. JEWETT.
3. Clinical Experience With Adrenalin. EMIL MAYER.
4. Observations and Tabulated Report of the Results of 150 Operations for Appendicitis. LEON BRINKMAN.
5. Points Connected With the General Etiology and Pathogenesis of Diabetes Mellitus. HEINRICH STERN.

1.—Besides discussing the etiology, pathology, symptomatology and treatment of infantile scurvy, Starr gives a tabulated report of a number of cases occurring in his own practice. In discussing the food question he says: "The faulty foods may be classed in the order of their potency: (1) The different proprietary infants' foods administered without the addition of cow's milk; (2) proprietary foods employed with the addition of insufficient quantities of cow's milk; (3) oatmeal or wheat gruel, barley and other farinaceous foods administered with water alone or with water and insufficient cow's milk; (4) condensed milk and water; (5) sterilized milk; properly modified milk subjected to a temperature of 212° F. for 30 minutes to an hour or more; (6) too dilute milk and cream mixtures; laboratory mixtures with too low albuminoid percentage." [H.H.C.]

2.—Jewett reports 3 cases of leukemia, 2 of which differ from v. Jakseh's description of this disease in the following points: (a) Neither the number of red cells nor the amount of hemoglobin is reduced below the findings in well authenticated cases of leukemia. (b) Extraordinarily large neutrophiles are not found. (c) No white cells have been found which contain red cells or portions of red cells within their protoplasm. (d) The great majority of leukocytes are lymphocytes and not polymorphonuclear neutrophiles. [H.H.C.]

3.—See Therapeutic Department.

4.—Brinkman discusses the differential diagnosis between appendicitis and typhoid fever, acute intestinal obstruction, and cholecystitis. Tabulated details of 150 operations for the former condition are given. The mortality was 23%. [A.G.E.]

5.—Stern, in his study of diabetes mellitus, as recorded in the mortality statistics of New York City for a period of 11 years (1889-99, inclusive), states that of 1,867 deaths from diabetes mellitus, 931, that is, almost 50%, occurred in females. This proportion differs widely from the supposition that the disease is much more fatal in males than in females. The total mortality from diabetes in infancy being 79, forms about 4.25% of the total deaths from this disease. Of the 13 deaths occurring under 5 years of age, 3 took place in females. Among the 66 other instances of deaths from diabetes in early life, 33 ensued in females and 33 in males, exactly 50% in each sex. The death rate from diabetes in the colored race is exceedingly low. Hebrews, no doubt, are more commonly affected with chronic glycosuria than is the nation among whom they dwell. Those born in Ireland or of Irish descent contribute over 25% of the total mortality from diabetes mellitus. The disease is not a special visitation upon the well-to-do, as is commonly supposed, but occurs frequently among the working people who, as a rule, are not addicted to gluttony or leisure hours. He describes a third clinical form of diabetes which he terms "diabetic deterioration." [H.H.C.]

1. Primitive Organs of Vision. THEODOR BEER.
2. Ligature of the Jugular Vein in Otitic Sinus Thrombosis. FERDINAND ALT.
3. Suture of the Heart. HEINRICH ZULCHNER.

2.—Alt reports 2 successful cases of operation for otitic sinus-thrombosis, in one of which the ligation of the jugular vein was necessary before opening the sigmoid sinus. [H.H.C.]

3.—Zulchner reports an interesting case of a 35-year-old man who, among other injuries, received in a stabbing affray, a thrust in the left thoracic region at about the insertion of the sixth costal cartilage. The wound penetrated through the

pericardium into the right ventricle about 1 cm. from the apex. Under narcosis parts of the fifth, sixth and seventh costal cartilages were resected and the left pleural cavity opened. Ligation of the 2 cm. long incision was unsuccessful with fine silk, so coarse thread was used with the result that it also tore through making the original simple incision into an ugly cruciform opening from which the blood escaped in a stream which soon ended the life of the patient. [H.H.C.]

Berliner klinische Wochenschrift.

March 18, 1901. [38 Jahrg., No. 11.]

10. Otitic Cerebral Abscess. STENGER.
11. The Technique and Indication for Metreuryasis. KRUMMACHER.
12. Early Syphilitic Basilar Meningitis. HOFFMANN.
13. Max v. Pettenkofer. KUBNER.

1.—In this article Shaper gives an outline of the advanced instruction given to German military surgeons in the various universities and hospitals, more particularly in Berlin. [H.H.C.]

2.—After mentioning several drugs (including creasote and creasotal), which have a disturbing effect on Ehrlich's diazo-reaction, Burghart states that the phenols, whether given internally or produced by a diseased condition in the body, have a decidedly disturbing action. [H.H.C.]

3.—In the entire literature only 11 cases of hernia of the diaphragm have been reported in which a correct diagnosis has been established during life. A new case is reported by Wiedenmann of a man, aged 48, who had had 4 attacks of pleuritis and was finally admitted to the Charité in Berlin suffering with lancinating pain in the left thorax and hemoptysis. After a careful examination, both physical and by means of the Röntgen apparatus, a diagnosis of left-sided diaphragmatic hernia was made, with the probability that the stomach was partially displaced and prolapsed into the hernial sac. [H.H.C.]

4.—Dorendorf reports 2 cases of one-sided paralysis of the superior laryngeal nerve resulting, in the first case, in paresis of the musculus vocalis. Both cases were greatly benefited by electric treatment. [H.H.C.]

5.—Menzel reports a case of cerebrospinal meningitis in which the pus obtained from a lumbar puncture showed, besides extracellular streptococci and intracellular diplococci (meningococci?), distinctly intra-cellular streptococci. [H.H.C.]

6.—Glatzel reports a case of influenzal laryngitis differing from those reported by Fraenkel, P. Heymann and P. Koch in that the dirty-white patches found on the laryngeal mucosa were situated symmetrically along the lips of the ventricles. The patient was a servant maid aged 24 who complained of a burning and itching sensation in the throat together with hoarseness. A bacteriologic examination revealed the presence of influenza bacilli in the fibrinous patches. [H.H.C.]

7.—Braun discusses various treatments for hypertrophy of the prostate, and recommends the boutonniere operative treatment in advanced cases with retention of urine. He reports 2 cases cured by this method of procedure. [H.H.C.]

8.—Wegner describes the case of a woman, 65 years old, who had suffered for 15 years with a chronic ulcer and fistula on the inner side of the lower third of the left tibia. On examination with the probe rough pieces of bone were felt, resembling sequestrae. Operation revealed the presence of a tough fibrous connective tissue mass 15 x 5 x 0.5 cm. in size, containing a number of small pieces of true bone. Wegner attributes their presence to the long continued irritation and not to myositis ossi-

ficans, since they were not imbedded in the muscle tissue, but lay between the fascias. [H.H.C.]

9.—An interesting case of **right-sided tenonitis serosa** is reported by Nicolai in a woman 52 years old. The affection was, as is usually the case, very evidently closely connected with the rheumatic condition of some of the larger joints. Indeed, Nicolai is of the opinion that the disease is probably a metastatic result of the primary articular rheumatism, more especially since in its course it so closely resembles that of articular rheumatism. [H.H.C.]

10.—A case of **intracranial abscess**, following a left-sided otitis of 3 years' standing, is reported by Stenger, in a child 13 years old. The radical operation was followed 6 days later by trepanation of the left temporal bone and the liberation of over 250 cc. of pus and broken down brain-tissue. A bacteriologic examination revealed the presence of staphylococci in the pus. Recovery was slow, and marked by the large amount of pus escaping with every change of bandages. [H.H.C.]

11.—Krummacker discusses the technic as well as the indications for the use of Champetier de Riter's **metreurynter**, an apparatus for vaginal or cervical dilation. [O.R.]

12.—Hoffmann reports the case of a young man 26 years old who, 4½ months after infection and 2½ months after the appearance of the roseola, showed symptoms of **syphilitic meningitis**. He bases the diagnosis on the complete paralysis of the right facialis, the decided paresis of the right abducens, the weakness of the right lypoglossus and the sensory disturbance on the right side of the tongue together with severe headache and bilateral choked disc. Almost complete recovery followed energetic treatment by means of innuctions and injections of bichlorid. The case is of interest because (1) the disease manifested itself 2½ months after the outbreak of the roseola in spite of energetic antisiphilitic treatment, (2) because the motor and sensory disturbances were strictly unilateral, and (3) because the lesion was a circumscribed inflammation of the dura, corresponding in general to the periostites so often found in the early period of syphilis. [H.H.C.]

March 25, 1901. [38 Jahrg., No. 12.]

1. Prognosis of Brain Diseases in Childhood. H. OPPENHEIM.
2. A Case of Pneumopyopericardium. R. SIEVERS.
3. Operative Treatment of Varices and of Varicose Phlebitis. KAREWSKI.
4. The Progress of Malarial Investigation in Italy. M. KOCH and H. COENEN.
5. Max v. Pettenkofer (Conclusion). M. KUBNER.

1.—In the first installment of an article on the **prognosis of brain diseases in children** Oppenheim reports 5 cases which came under his observation. [H.H.C.]

2.—A rare case of **pneumopyopericardium** is reported by Sievers in a woman of 32, who, after suffering from a severe syphilitic infection, developed a left-sided croupous pneumonia. The lung became gangrenous, and a communication was established with the pericardial cavity, resulting in the presence there of pus and air. Percussion revealed no heart-dulness, but deep, sonorous sounds over the entire left thorax, such as present in emphysema. Auscultation brought out metallic sounds over the pericardium of a gurgling and splashing character, together with pericarditic friction-sounds of an amphoric nature. The autopsy confirmed the diagnosis. [H.H.C.]

3.—After discussing the advantages and disadvantages of Freudenberg's and Madelun's **operations for varicose veins** of the lower extremities, Karewski suggests the advisability of combining both. For several years he has adopted the following method in serious cases, avoiding thereby thrombosis and recurrence of varicosities: A small incision is made over the fossa ovalis, and after double ligation, the saphena is cut. The vein is then isolated from the subcutaneous fat for some distance by means of a dull instrument, and a new incision made about 20 cm. lower down. Here also the double ligation is followed by separation and excision, the bleeding from the side branches being stopped by compression. A third

incision in the neighborhood of the kneejoint allows of the extirpation of the vein to this joint, after which the second part of the operation—the removal of the varicosities—may be completed. [H.H.C.]

4.—In the conclusion of their paper on **malarial investigations** in Italy, Max Koch and Coenen give some very interesting facts concerning the mosquito-etiologies of the 3 forms of malaria, together with reports of experiments carried out by Celli, Grassi, and others in the malaria-infected districts of Italy. [H.H.C.]

1. The Distribution of Tetanus Toxin and Tetanus Antitoxin in Living Animal Bodies. F. RANSOM.
2. A Case of Splenic Anemia with Many Mononuclear Neutrophile Leukocytes. G. FREUND.
3. A Case of Idiopathic Hemorrhage Between the Retina and the Vitreous Humor. H. ZIEGNER.
4. The Prognosis of Brain Diseases in Childhood. H. OPPENHEIM.

1.—In the first part of a paper reporting a series of experiments on the **absorption of tetanus toxin and antitoxin** in animals, Ransom finds that the poison is absorbed chiefly by means of the lymphatics, only a relatively small quantity entering the vascular system. In the case of the antitoxin, the absorption also takes place principally through the lymphatic system. In intravenous injections of antitoxin the latter soon begins to leave the vascular system and enters the lymph system. [H.H.C.]

2.—Freund reports an interesting case of **splenic anemia** characterized by an unusual number of mononuclear neutrophiles in a day laborer, 58 years old. [H.H.C.]

3.—Ziegner reports a case of **idiopathic hemorrhage between the retina and vitreous humor** in a 52-year-old man. A complete absorption of the clot in the unusually short period of 3 months followed the repeated subconjunctival injection of physiologic saline solution. [H.H.C.]

4.—In the conclusion of his paper on the **prognosis of the cerebral diseases of childhood**, Oppenheim states that localized tubercular meningoencephalitis of the motor zone is, especially when occurring in childhood, an affection capable of cure. [H.H.C.]

April 8, 1901. [38 Jahrg. No. 13.]

1. A Special Form of Urticaria Factitia with Scleroderma. BETTMANN.
2. Membranous Enteritis. H. WESTPHALEN.
3. The Resection of the Lower Turbinal Bone. A. KUTTNER.
4. The Distribution of Tetanus Toxin and Tetanus Antitoxin in Living Animal Bodies. F. RANSOM.

1.—Bettmann reports 2 peculiar cases of **urticaria factitia** preceding a general scleroderma. In one case gentle tracing with the finger nail over the apparently intact skin of the chest and back produced lines of urticaria factitia which persisted for the unusual period of *six* days. [H.H.C.]

2.—Westphalen reports 3 cases of **membranous enteritis**, giving in detail the clinical symptoms and the gross and microscopic characteristics of the mucous and membranous stools. [H.H.C.]

3.—As a result of his operative experience in 50 to 60 cases, Kuttner concludes that **resection of the inferior turbinates** is indicated in *all* cases in which there exists a decided hyperplasia of the solid tissue-elements with diffuse increase in volume leading to disturbances of speech, respiration or circulation. He gives a short review of his methods of operation. [H.H.C.]

4.—In the conclusion of his paper on the **absorption of tetanus poison and its antitoxin**, Ransom states that injection of tetanus antitoxin into the subarachnoid space gives rise to no increase in the normal immunizing power of the nerve substance, and that the antitoxin passes rapidly and almost completely over into the vascular system. Injection of the antitoxin into the central nervous system causes the nerve substance to lose, at least for a time, its power to neutralize the poison, thus becoming itself toxic. [H.H.C.]

Deutsche medicinische Wochenschrift.

March 14, 1901. [27 Jahr. No. 11.]

1. A Biologic Evidence that the Albumin in Nephritic Urine is Derived from the Blood. V. E. MERTENS.
2. The Destruction of Tubercle Bacilli in Foodfats. A. GOTTSSTEIN and H. MICHAELIS.
3. The Lipochrome of Ganglion-cells. M. ROTHMANN.
4. Multiform Exudative Erythema Following Chemical Irritation of the Urethra. J. HELLER.
5. The Genesis of Adolescent Mastitis. E. FRANCK.
6. The Pathologic Fixation of the Uterus.

1.—From a series of experiments consisting in the intravenous injection of solutions of egg albumen and of albumen laden blood-serums into rabbits, Mertens reaches the same conclusion as do Tschistowitsch, Bordet, Uhlenhuth, Wasserman and Schütze, viz., that the **albumen of nephritic urine** is derived from the blood. [H.H.C.]

2.—By means of **intrapertitoneal injections** into guineapigs of a mixture of various oils containing tubercle bacilli (the whole heated to 87° C.), Gottstein and Michaelis find that this temperature is amply sufficient to kill the bacilli in oily mixtures, thus disproving the theory of Rabinowitsch that a temperature of 100° or even more is necessary for the purpose.

3.—Rothmann confirms the investigations of Nissl as to the presence in the **ganglion cells** of various animals, including man, of a light yellow pigment which takes on a deep black color on being treated with osmic acid.

4.—Heller reports a case of **multiform exudative erythema** in a man following the external use of a 20% solution of creolin before coition. The case was complicated by affection of the wrist joint, but was otherwise similar to the 4 cases reported by Lewin. Heller concludes that the condition is not due to a reflex action, but to an intoxication, or better, an antointoxication, and that such a thing as an idiopathic type of the disease does not exist. With regard to the exanthemas which sometimes follow the rectal injection of saponaceous fluids in children, Heller, after mentioning the 3 possible casual theories put forward by Still, suggests as a fourth and more plausible one the possibility that the mechanical irritation induces a serious exudation of the rectal mucosa, which, on being absorbed, gives rise to antointoxication and hence to erythema after from 24 to 48 hours.

5.—Franck reports 2 cases of **adolescent mastitis** in youths of 15 and 16 years respectively which were evidently the result of excessive masturbation. [H.H.C.]

March 21, 1901. [27 Jahr. No. 12.]

5. The Pretended Immunity of the Hedgehog to Cantharides and its Active Constituent. L. LEWIN.
6. Disease of the Trigeminal an Initial Symptom of Tabes. V. FRAGSTEIN.
7. A Short Observation on the Demonstration of the Progov Stumps of Solger. KERN.

1.—Fränkel gives the statistics of the severe **typhoid epidemic** in Göttingen (summer 1900) in which 56 cases were reported. [H.H.C.]

2.—Körte gives his observations on a series of 38 operations for **gastic ulcer** which came under his notice. [H.H.C.]

5.—After a series of experiments Lewin finds that the **hedgehog**, contrary to the theory of Ellinger, does not possess an **immunity from poisoning with cantharides**.

6.—Fragstein reports the case of a middle aged man who 13 years previously had contracted **syphilis**, and who suddenly began to complain of shooting neuralgic pains throughout the entire area supplied by the right trigeminal nerve. After 18 months there was a gradual loss of sensation, although the sense

of taste remained. At the same time the typical shooting pains of tabes began to occur in the lower extremities followed by other pronounced tabetic symptoms. [H.H.C.]

March 28, 1901. [28 Jahr., No. 13.]

1. A Case of Nephrotomy on Account of Hematuria Resulting from a One-sided Hemorrhagic Nephritis. H. LAURENT.
2. Saponin and Its Antidote. F. RANSOM.
3. The Göttingen Typhus Epidemic during the Summer of 1900. (Conclusion.) P. Fränkel.
4. Experimental Lumbar Puncture for Detection of Tubercle Bacilli. H. HELLENDALL.
5. A Noteworthy Case of Dissecting Aneurysm of the Abdominal Aorta. FAST.

1.—A fatal case of **nephrotomy** for hemorrhage as a result of right-sided hemorrhagic nephritis is reported by Laurent. The operative treatment was successful, as far as relieving the hemorrhagic condition was concerned, the patient eventually dying from erysipelatos infection of the wound. [H.H.C.]

2.—A result of experimental research on the hemolytic action of **saponin** and on its **antidote, cholesterin**, Ransom finds that there exists a sort of affinity between saponin and cholesterin by means of which the former acts as a poison to tissues containing the latter, but that at the same time the latter, under certain conditions, serves as a protecting agent against the former. Saponin is a poison to the erythrocytes, since it attacks the cholesterin contained within them. This does not occur at once, there being an "incubation period," after which a second stage sets in lasting until the completion of the process and the total liberation of the hemoglobin. Emulsions of saponin and cholesterin in certain proportions have no hemolytic action whatsoever on the blood. [H.H.C.]

3.—In the conclusion of his article on the **typhoid epidemic at Göttingen** in the summer of 1900, Fränkel continues his statistic observations, taking up the temperature-phenomena, and the intestinal, cardiac, and nervous complications of the epidemic. [H.H.C.]

4.—Following out the experiments of Martin, who was able to produce **tubercular meningitis** in guineapigs by means of intrameningeal injections of cerebrospinal fluid from patients suffering with tubercular meningitis, Helledall attained widely different results. In no case was he successful by the use of the typical lumbar puncture in producing tubercular meningitis in guineapigs with injections of undoubtedly tubercular human cerebrospinal fluid. On the contrary, a diffuse miliary tuberculosis was the result. In spite of this, however, he believes that the method is preferable to microscope methods on account of its extreme delicacy and sensitiveness, and that it is even to be preferred to intraperitoneal injections. [H.H.C.]

5.—Fast reports a case of **aneurysm of the abdominal aorta**, in which the antemortem diagnosis was confirmed by the autopsy. [H.H.C.]

9. Septic Processes as a Complication of Necrosis of the Pancreas. STRUPPLER.

1.—**Intermittent hepatic fever**—so called Charcot's intermittent fever—is quite well known to clinicians in this country, particularly since the publication of Osler's papers; but strange

to say, it has received scarcely any attention in Germany. Pick reports 2 cases in which careful estimation of the urea elimination was made, in order to throw light upon the ureogenic function of the liver. The first case occurred in a man of 49, who had been sick for a year with mild jaundice, with chills and fever, rising to 40° C. (140° F.), accompanied at times by colicky pains. The attacks occurred at regular intervals and were accompanied by more or less stupor. The liver was enlarged. During the period of observation (6 months), 46 febrile paroxysms occurred. The patient died with symptoms of complete obstruction of the common duct, ascites developing toward the end. At the autopsy it was found that a stone was compacted in the common duct, and had perforated the duodenum. The gall passages were dilated and filled with glairy mucus. The liver was small, granular, and the seat of biliary cirrhosis. The gallbladder was contracted. It was interesting to note that previous to each attack of fever the epigastric region became prominent and borborygmus developed. The second patient was a woman of 53, who had had typhoid fever in 1892. In 1895 she had gallstone colic, with the passage of stones. In 1896 intermittent attacks, with chill, fever and pain, developed, associated with marked stupor. The patient recovered. Charcot, on the strength of an observation of Regnard, had asserted that during the febrile attack the elimination of urea was greatly lessened. This effect was ascribed to an inability on the part of the liver to convert the ammonia salts, which are the supposed antecedents of urea, into the latter. If this were true there should be an increased elimination of ammonia salts coincident with the decrease in the urea; but Pick's studies do not show this. On the contrary, they show that there is a reduction, not alone in the urea, but also in ammonia and in the total nitrogen. The administration of ammonium citrate showed, moreover, that the ability of the liver to transform this salt into urea was not impaired. If the liver formed urea out of ammonia salts carried to it, a reduction in the quantity of urea ought to go hand in hand with an increase of ammonia in the urine. Pick therefore believes that while the ammonia salts may be the antecedents of urea, they are not brought to the liver as such, but that the waste nitrogen reaches the organ in some other form that does not pass over into the urine. Whether intermittent hepatic fever is a distinct nosologic entity, cannot be definitely decided. In Pick's opinion the name may be used to indicate a particular kind of infection of the gall-passages, which has the following characteristics: (1) Paroxysmal, intermittent fever of prolonged duration; (2) a non-suppurative character of the inflammation of the gall-passages, and the absence of any demonstrable inflammatory or suppurative focus in the liver or elsewhere in the body, despite the persistence for months of severe febrile paroxysms, with chill and stupor. (The absence of leukocytosis in the intervals and in the beginning of the paroxysms may be a diagnostic point against the presence of a purulent infection); (3) a marked diminution in the nitrogen and urea elimination in the urine, which, on the one hand, contrasts with the increased urea elimination in fevers in general, and, on the other hand, while indicating the importance of the liver for urea formation, tells against the accepted theory, in view of the absence of increase in the ammonia elimination, that the liver forms the urea from ammonia salts. The prognosis is dependent upon the cause. If the obstruction persists, the result is fatal. Therapeutically, the possibility that the disease may eventuate in biliary cirrhosis must be remembered; hence, the obstruction should be removed. If its removal does not speedily follow the use of internal remedies, operation should be undertaken. [D.R.]

2.—Kerschensteiner reports a case of "foam liver" in which the gas-production seemed to be due to *Bacillus coli*. [D.R.]

3.—A study of the elimination of methylene-blue and of the relative quantities appearing in the different excreta. The colorimetric method was used, the solutions from the excreta being compared with standard solutions of methylene-blue. It was not possible to obtain in the urine all of the methylene-blue ingested the portion eliminated varying between 40 and 60 % of that ingested. The elimination continued for from 2 to 4 days after the ingestion ceased. When the methylene-blue elimi-

nated in the feces was added to that found in the urine, a total of about 68 % of the amount ingested was obtained. The same percentage is maintained when the dose ingested is doubled or halved. It is probable that some of the methylene-blue is eliminated in an altered state, which escapes the usual methods of investigation, although it is not impossible that in pathologic conditions some is retained in the system. [D.R.]

5.—A case of progressive muscular dystrophy complicated with neuritic paralysis of the serratus magnus in a man of 30. The muscular dystrophy came on after an attack of spasms when the patient was 3 years old. It progressed for many years, and then remained stationary. Six years before coming under observation the man acquired syphilis. The paralysis of the serratus had set in acutely, with fever and tenderness on pressure; under antirheumatic, and later antisyphilitic treatment, it improved very much. The chief feature of the paper is a study of the paralysis of the serratus by the method of Mollier, a system of measurements in affections of the shoulder girdle, 5 points being taken as guides: 1 The point where the posterior edge of the clavicle meets the acromion, called the upper point (U.P.). 2. The point on both sides where the lower margin of the scapular spine passes into the vertebral margin, called the middle point (M.P.). 3. The lower tip of the scapula, called the lower point (L.P.). 4. The middle point of the upper border of the sternum, called the sternal point (S.P.). 5. The point on the spinal column opposite the sternal point, called the spinal point (Sp.P.) The method of using these points as guides in determining serratus palsy must be read in the original. [D.R.]

6.—A case of acne telangiectodes (Kaposi), also known as disseminated follicular lupus simulating acne, acne luposa, lupus miliaris, colloid milium, lupus follicularis acneiformis and acute disseminated nodular tubercular lupus. The patient was a woman of 56, and presented 3 types of lesions:—(1) Nodules and nodes of pea and cherry-stone size, sharply circumscribed, hemispheric, of a reddish-brown color, with a peculiar jelly-like luster, of a doughy or tense consistence, and with a smooth surface. Examined in profile, the lesions appeared vesicular or drop-like. (2) Flat, brownish-red, rounded or oval papules. (3) Very minute nodules, scattered irregularly, reaching the size of a pinhead, pale pink in color, and pointed. They seemed to have their origin from the hair follicles. There were no pustules; no inflammatory reaction. The hairy scalp was involved, and a few lesions were found on the mucous membrane of the soft palate. After an interval of several weeks, the small and medium-sized nodules disappeared, leaving concave, pigmented spots. There were no subjective sensations. Under ether more than two-thirds of the lesions were removed with the sharp spoon, the wounds being cauterized with the galvanic cautery. The lesions peeled out very easily, and seemed to be of a soft, spongy, lupus-like character. The cauterized places were dusted with eorform, and the patient received a prolonged warm bath every 5 days. Microscopic examination showed a tumor-like infiltration, extending from the middle of the corium up to the epidermis, and consisting of confluent foci of cells, which were largely lymphoid in character, although there were here and there epithelioid cells and giant cells; nowhere, however, was there any typical tubercle arrangement. Tubercle bacilli were not found on staining, nor in guinea-pigs that had been inoculated and had been killed after 4 or 5 weeks. [Four or 5 weeks is hardly long enough to warrant the conclusion that the lesions were not tuberculous, as several months are sometimes required for guinea-pigs to show tuberculosis after inoculation of dermal nodules.] A peculiarity of the lesions was the presence of numerous milium-like epithelial cysts. Touton considered acne telangiectodes among the tuberculids. Although in the present case the tuberculous character was not demonstrated, the author is apparently inclined to agree with this view. [D.R.]

7.—Reineboth subjected rabbits to various injuries designed to bring about contusions of the chest, in order to determine the effect upon the lung. He found that the lung-tissue was not very vulnerable [D.R.]

8.—The gist of the article is that there is in gout an excessive formation of uric acid, and that by reason of the constant surcharge of the blood with the acid the organism is inclined to

local inflammations. Necrotic tissue has no affinity for uric acid, while acutely inflamed tissue has a strong affinity. When the acme of such inflammation coincides with the maximum content of uric acid of the body juices, the uric acid is precipitated in crystalline form in the inflammatory exudate; in that way a typical gouty node is formed. The elimination of uric acid temporarily relieves the system of the excess, and new attacks remain in abeyance until again acute local inflammation and maximum uric acid content coincide. In addition to being deposited in inflammatory foci, uric acid deposition may occur in certain noninflamed tissues which by changes in the quantity of their salts offer unfavorable conditions for the solubility of the circulating uric acid. This is true of cartilage. Lessened alkalinity, at least in experimental animals, does not favor deposition of uric acid. A purely local formation of uric acid, independent of an excess of the acid in the blood, does not occur. It may then be said that the characteristic feature of gout is the presence of an increase of uric acid in the blood, and that the essence of the disease must hence be sought, not in the body juices and not in the gouty nodules, but in those places where uric acid is formed. [D.R.]

9.—A brief report of 2 cases of fat necrosis of the pancreas associated with septic complications; in the first, with acute verrucose and ulcerative endocarditis; in the second, with suppurative internal pachymeningitis. An interesting point in the second case was the absence, despite the evidences of sepsis, of a splenic tumor. In simple, uncomplicated pancreatic necrosis the spleen is not enlarged; indeed, Katz and Winkler were able to demonstrate a diminution in the size of the organ in experimental fat necrosis, and attributed this to reciprocal relations between the spleen and the pancreas. In Struppler's first case the spleen was enlarged; in the second, as already stated, it was not. The possible existence of septic complications should be taken into account when an operation for the relief of pancreatic necrosis is considered. [D.R.]

8. Alternating Mydriasis. GESSNER.

1.—Gersuny recently recommended paraffin injections for cosmetic purposes, *e. g.*, to restore shape to the mammas and to contract relaxed scrotums; but Meyer thinks that there may be some danger connected with the practice, as it may cause obstruction of the lymph spaces. Experimental animals at times die in cachexia. Regarding the fate of paraffin, he found that part of it disappears, although very slowly, probably owing to an oxidation process. [D.R.]

2.—Bertelsmann reports a successful operation for the relief of cerebral pressure due to rupture of the superior longitudinal sinus in a woman 40 years old, who was knocked down by a wagon and rendered unconscious by a blow on the back of the head. [H.H.C.]

3.—In a very interesting article, Bender contributes the report of a case of chronic inflammation of the spinal column, resulting in a complete ankylosis, uncomplicated by affection of any other joints. The case resembles very closely the 2 described by von Bechterew, and is that of a 24-year-old seamstress who for 2 years suffered from pain and gradual stiffening of the vertebral column. Bender found total ankylosis of the spinal column, the cervical region being in a state of kyphosis, the thoracic in extension and the normal lumbar lordosis almost entirely lacking. No distinct scoliosis. Purely abdominal type of respiration, with no movement whatsoever of the spinal column. There were no traces of arthritis or spondylitis deformans, as in the cases of Strümpell and Marie. [H.H.C.]

4.—A case of multiple neuritis of unknown origin, in a woman aged 32 years, with well-marked psychic symptoms, consisting in irritability and pronounced failure of memory for recent events. The paralysis of the affected parts improved, but contractures had developed, which rendered the patient's life miserable. She died of an intercurrent disease, and the microscopic examination of the nervous system showed an intact spinal cord and very slight degeneration in the anterior crural nerves. The brain was not examined. [D.R.]

5.—For forensic purposes, the Marsh test for arsenic is still the most practicable, although the biologic test (the development of a characteristic garlicy odor through the action of fungi) is a valuable subsidiary method. The biologic test must be carefully interpreted, as it seems that arsenic is at times found in normal bodies. Stich has made comparative studies upon the effects of arsenic in man, the lower animals, and plants. He finds that, in animals, it is the highly specialized cells of glandular organs and young connective tissue; and in plants, the young parenchyma near the sap conductors, that are affected by arsenic. The bloodvessels and the supporting and connective tissue of animals, and the conducting channels and cell-walls of plants, are less sensitive. The arsenic may be transformed into gas, among animals, by some snails; among plants, by moulds. In cases of intoxication in man, it is noteworthy that arsenic may be carried through the placental circulation to the fetus, and deposited in the organs of the latter. Higher plants take up but little potassium arsenate; more, if the poison enters the water channels. [D.R.]

6.—A very dangerous but fortunately very rare cause of postpartum hemorrhage is the paralysis of the placental site which prevents a proper contraction of the uterine muscles. A characteristic of this condition is that the contracted parenchyma is drawn into the uterine cavity appearing as a knoblike tumor, while there is a corresponding depression perceptible in the external uterine wall. Gerlach reports a case of this kind in his own experience, occurring in a primipara aged 21 years. Delivery by forceps was followed by spontaneous expulsion of the placenta, and then by hemorrhage which neither massage nor hot irrigation with lysol solution availed to check. Examination showed the cervix intact and that the hemorrhage was from the uterus itself. Through the thin abdominal wall he could feel a funnelform depression in the uterus, and internal examination showed a spongy tumor-like mass at a corresponding point within. The patient was now almost pulseless and tampons of iodoform gauze and ergotin injection being tried and found ineffectual, gauze saturated in chlorid of iron solution with an equal part of water was introduced into the uterus. This effectually checked the flow of blood and the uterine depression was no longer perceptible. Recovery followed. Throughout the whole of the treatment there was a free use of normal salt solution. Gerlach thinks this case was without doubt an instance of a high degree of paralysis of the placental site. Opinions differ as to the use of tampons saturated with liq. ferri.; but he believes that when, as in this case, Dührssen's tamponade proves ineffectual, the use of chlorid of iron solution is to be recommended as a last resort. [W.K.]

7.—As a result of his experience in the treatment of felon, Schulze recommends a more conservative action than that usually adopted by the majority of physicians. In 5 cases he found that medicinal treatment yielded good results, the lost phalanges or portions of phalanges being soon replaced by a new growth of bone. [H.H.C.]

8.—Gessner reports a case of alternating spastic mydriasis in a 32-year-old woman suffering from chronic myelitis of the cervical region. The etiology was obscure. [H.H.C.]

1.—Sorgo details his experience in the **diagnosis and treatment with subcutaneous injections of gelatin of 6 cases of aortic aneurysm**. The patients during the entire treatment were confined to bed, and when possible they were limited to a strictly milk diet. No other medication was given. The gelatin was given at first in a 1% to 2% solution, but later (and this is preferred) a 4% to 5% solution. The injections, each consisting of from 100 to 150 grams of the solution, were made with a 150 cc. syringe into the thigh or abdominal wall, at intervals of from 3 to 5 days. He concludes from his experience and a study of the literature that in a large percentage of cases of sacular aneurism (13 of 18 cases), but not in cases of simple dilation of the vessel (none of 16 cases), the subcutaneous injection of gelatin is followed by coagulation of the blood, and that in many cases of hemorrhage of different sources, the bleeding may be checked by the local or subcutaneous use of gelatin. Whether these results are to be attributed to the action of the gelatin, cannot be definitely stated, because they may be due to rest and the diet of the patient; because in many cases no such results occur and in some cases the results may be merely coincidence; but especially because we as yet have no experimental proof of the coagulating action of gelatin administered subcutaneously. The injections, however, even if highly concentrated, are devoid of danger, provided asepsis be observed. The pain can only be of service in that it necessitates quiet on the part of the patient. Kidney affections are no contraindication to the internal administration of gelatin; as regards its subcutaneous injection, however, the question is still open. In addition to pain, fever is a common symptom after the injection, more particularly after the first injection. Other unpleasant manifestations, though they have been observed, are infrequent. The beneficial results of the treatment are to be gauged, not by the subjective, but rather by the objective, manifestations of the patient. Of the latter, the most important are disappearance of a pulsation previously present over a circumscribed area of the chest, or lessening in size and hardening of a palpable and pulsating tumor, lessening or disappearance of pressure symptoms (tracheal stenosis, bronchial stenosis, recurrent paralysis, dilation of veins, dyspnea); diminution of the area of dullness and of the radiographic shadow, etc. With regard to the **diagnosis of aneurysm of the aorta and the innominate artery**, Sorgo refers to a marked slowing of the respirations (to 12, 10, and even 9 a minute), and a markedly prolonged and cogwheel expiration presented by one of his patients. The slowing of the respiration was due to the marked stenosis of the trachea; the expiratory stridor, which was greatly increased during the cardiac diastole, is ascribed to the fact that, whereas during the cardiac systole the aneurysm filled and compressed the trachea to a maximum, thus interrupting the expiration and reducing the exit of air to a minimum, during the cardiac diastole the aneurysm emptied partially and the tracheal stenosis was lessened; but as it was not entirely relieved, the exit of air through the stenotic passage resulted in production of a loud murmur. Attention is also directed to the diagnostic importance of 2 loud sounds or a single loud second sound over the site of a suspected aneurysmal dilation. The second sound he believes with V. Schrötter, is not the transmitted second aortic sound, but a sound produced in the aneurysm itself. Finally it is believed that the presence of a diastolic murmur, with its point of maximum intensity beyond the second right intercostal space, associated with celerity of the pulse (and possibly sounds in the arteries and capillary pulse) exclusively in the distribution of the

innominate artery, renders the diagnosis of aneurysm of the innominate artery very probable. [A.O.J.K.]

2.—Aron, as the result of an experimental investigation conducted on man, concludes that the **cause of illness or altered breathing in rarefied atmosphere**, consists of 2 components—the chemie and physic, both due to the rarefied air as such. The former results from deprivation of oxygen, the latter from diminution of atmospheric pressure. Thus is understood the reason that aeronauts can endure the influences of rarefied air in high altitudes when they inhale pure oxygen from time to time. While they cannot relieve themselves of the discomforts of the physic alterations they thus reduce the unpleasant effects of the chemie changes in the air. He suggests that when railways to high altitudes (such as up the Jungfrau) are constructed, the officials should see to it that canisters of pure oxygen are provided at the stations, so that in cases of sudden illness immediate relief may be at hand and possible fatalities prevented. [A.O.J.K.]

3.—Thomas, in a study of the **late form of cyanosis of peripheral origin**, directs attention to the earlier publication by Bard, in which the latter attributes this so called late form of cyanosis to a mixing of arterial and venous blood in consequence of incomplete closure of the foramen ovale, the opening of the previously closed foramen being brought about by a reversal of the normal pressures in the 2 auricles. Bard later reported another case that was similar clinically, but which at necropsy revealed the foramen closed. The left lung, however, was the seat of extensive bronchiectasia, each dilated bronchus being accompanied by a distended artery and vein. Thomas reports a somewhat similar case—one in which the foramen ovale was found closed, but in which the apex of the right lung was converted into a multilocular cavity communicating with a bronchus, and the remainder of the lung markedly bronchiectatic. Thomas concurs with Bard in the belief that in these cases the cyanosis resulted from deficient oxidation of the blood, the consequence of lessened lung parenchyma and increased pressure in the pulmonary circulation. This view is confirmed by the marked dilation of the vessels in the neighborhood of the bronchiectasias and the hypertrophy of the heart, especially of the right ventricle, as in Thomas' case. Analogous cases in the literature are referred to. [A.O.J.K.]

4.—Bönninger, criticizing several **methods for the estimation of fat in the blood**, expresses a preference for a modification of the Hoppe-Seyler alcohol-ether extraction method. As a result of investigations conducted with animal blood and human blood, the latter in health and disease, he concludes that **normally human blood contains 0.75 to 0.85 % of fat**. High percentage was found in a case of nephritis and another of diabetes. The highest percentage (1.4 %) was found in a case of esophageal carcinoma, and was attributed to starvation—high percentage having been found in the lower animals in conditions of starvation. The same is also probably true with regard to a case of pneumonia in which the examination was made shortly prior to death. The kind of nutriment is of undetermined influence on the quantity of fat in the blood. In human blood the red corpuscles are believed to contain cholesterol and lecithin, but no neutral fat—the cholesterol being free; the serum contains neutral fat, lecithin and cholesterol, the latter combined with fatty acids (oleic acid). [A.O.J.K.]

5.—According to Adamkiewicz there are 3 diseases of the posterior columns of the spinal cord that resemble each other clinically but the material basis of which is different in each instance. He first of all distinguishes between **nerve-tubes and vessel-tubes**. The former is the well-known *tabes dorsalis*, the result of parenchymatous degeneration of the posterior columns; of the latter there are 2 varieties: the one is characterized by a primary proliferation of the neuroglia, the consequence of slow and chronic thickening of the bloodvessels supplying the posterior columns—**interstitial tubes**; the other the consequence of obliterative endarteritis, results from sudden closure of a principal arterial branch supplying the posterior columns and the paralysis of nerve elements that thus ensues. This because of its peculiar clinical manifestations and acute course is designated **acute tubes**. The last named is susceptible of cure; the interstitial tubes may remain stationary and

does not directly threaten life; the parenchymatous tabes is a progressive disease that ends with death. It is believed that the 2 varieties of vessel-tabes are always the result of syphilis, to which, however, the parenchymatous tabes does not owe its origin. Further peculiarities of the 2 varieties are that the parenchymatous tabes is characterized by ataxia and preserved muscle power; vessel-tabes, by motor weakness with slight ataxia. The present article deals especially with the **disturbances of sensation** that characterize the 2 conditions. In the nerve-tabes or parenchymatous tabes, in conformity with the anatomic situation of the lesions, the patients are unable to feel irritations that affect the lower extremities, and in consequence they no more appreciate pain and temperature variations than they are well oriented concerning the position of their lower extremities and the state of contraction of their muscles. In the vessel-tabes, on the other hand, in consequence of the mechanic irritation produced by the proliferating neuroglia, there is an abnormal irritability of the sensory apparatus, and the patients in consequence complain of unpleasant, even painful sensations, tinglings, "pins and needles," which as the interstitial process in the spinal cord progresses from below upward, involve corresponding portions of the body. These paresthesias, while not unknown in nerve-tabes play an unimportant role as contrasted with the characteristic anesthetics; on the contrary, they are peculiar to vessel-tabes in which anesthetics do not occur. In some cases of nerve-tabes there must ultimately occur anatomic appearances similar to those found regularly in interstitial tabes—thus is explained the occurrence in nerve-tabes of paresthesias in addition to anesthetics. To explain the variations in irritation perceptivity of tabetics that occurs *pari passu* with the intensity of the paresthesias, Adamkiewicz employs the metaphor of 2 antagonistic waves, each with its ebb and flow. [A.O.J.K.]

6.—Runeberg narrates some historic data in reference to percussion and auscultation and their combination known as **auscultatory percussion** (*percussorische Transsonanz*). He writes also of the value of the method of investigation, of the proper procedures to be carried out, and of the results to be attained. [A.O.J.K.]

7.—Neisser reports an instance of **extreme atrophy of left lung** in a man aged 42 years. There were enormous hypertrophy of the right lung, marked displacement of the heart and the mediastinum, and elevation of the diaphragm, but, and this is especially noteworthy, no deformity of the thorax. He refers to similar cases in the literature and discusses the occurrence of atrophy of the lung with and without thorax-deformity. He believes that the conditions are totally different depending upon whether the lung atrophy occurs in infancy or adult life. In infancy when the bodily tissues are susceptible of active growth, the conditions result in altered growth of both the healthy lung and the thorax, so that the thorax, following as it were the hypertrophy of the healthy lung, acquires a form differing from that which would have been its, had there been no lung atrophy, but there occurs no deformity. Referring to a few cases in which lung atrophy occurring in infancy resulted in some deformity of the thorax, and to a few occurring in adult life without thorax deformity, he concludes that all cases of extreme lung atrophy observed in adult life without thorax deformity date from fetal life or the earliest days of extrauterine life. He reports also several cases of adults with **extreme atrophy of the left lung and bronchiectasia**, with displacement of the heart and elevation of the diaphragm, but no deformity of the thorax. These also he believes to be congenital. [A.O.J.K.]

8.—Edel as the result of a series of investigations to determine the **influence of artificial sweating upon the gastric secretion** found as regards the immediate effect of the sweating (4 hours after the sweat), that in most of the cases (5) there occurred no difference as contrasted with the condition in the same patient before the sweating; in 1 case there occurred an increase in the degree of acidity. Of greater interest, however, is the remote effect of the sweat (20 to 68 hours after the last sweat). In 2 cases there occurred a slight diminution in the acidity; in 2 cases the acidity was the same before and after the sweat; and in 7 cases there occurred a slight increase in the

acidity. The sweatings were produced by warm baths. Edel being unable to confirm the results of the previous investigations of Simon, who found a general decrease in the gastric acidity following artificial sweating, criticises Simon's work and his theoretic conclusions. [A.O.J.K.]

9.—Rosenfeld groups together the views of different authors concerning the nature of **chronic lymphemia or lymphatic leukemia** as follows: (1) Chronic lymphemia is a primary disease of the lymph glands which of itself results in the production of the characteristic blood-picture. The disease of the liver, spleen, and bone-marrow is secondary—the result of metastasis; (2) chronic lymphemia is indeed a primary affection of the lymph glands, but it gives rise to the characteristic blood-picture only when the bone-marrow has become the seat of lymphadenoid degeneration; (3) chronic lymphemia is a primary disease of the bone-marrow consisting in a lymphadenoid degeneration. It may remain localized to the bone marrow, or by metastasis it may secondarily involve the lymph glands, spleen, etc.; (4) chronic lymphemia is a disease of all the lymphadenoid tissue that preexists in the body. He reports 3 cases and concludes as a result of his observations that the primary disease of the lymph glands, the existence of which cannot well be doubted, gives rise either to an aleukemic prodromal period, or to an exclusive or predominating increase of the small mononuclear leukocytes when the disease is far advanced. The development of disease of the bone-marrow, if marked, results in some alteration of the blood-picture, or the occurrence of severe clinical symptoms. A diffuse disease of the bone-marrow seems always to be associated with a progressive course of the disease. He believes that there is no reason for the opinion of Pappenheim that every case of leukemia, even the lymphemia, is primarily myelogenous. [A.O.J.K.]

- 1.—Continental Progress in Practical Radiography and Apparatus. A. W. ISENTHAL. (Archives of the Röntgen Ray, March, 1901.)
- 2.—Uterine Retraction with Special Reference to the Mechanism and Management of the Third Stage of Labor. D. BERRY HART. (Scottish Medical and Surgical Journal, April, 1901.)
- 3.—A Case of Erythema Multiforme Closely Resembling Smallpox. NORMAN WALKER. (Scottish Medical and Surgical Journal, April, 1901.)
- 4.—Notes on Blackwater Fever in Southern Nigeria. R. A. BENNETT. (Scottish Medical and Surgical Journal, April, 1901.)

1.—Isenthal notes the general use on the Continent in **radiography of the electric light mains** in working the apparatus, the early abandonment of the platinum interrupter and later of mercury, the popularity of the Wehnelt break, and the use of very powerful coils. The continental tube maker does not use highly refractory material for the anticathode, but deflects the heat by conduction or artificially cooling the target. Regeneration has lately been effected by osmosis of hydrogen through a red hot platinum tube which has been suitably fused into the tube, thus lowering the vacuum. An intensifying screen is largely used with the film, frequently 2, whether only one or both sides are coated with emulsion. A short exposure prevents foggingness from diffusion rays, and stand development gives the best results. Moritz' orthodiagraph makes it possible to outline the true size and shape of internal organs and objects by using only the ray vertical to the screen and moving it about to include the outlines of the object to be traced. This is done by bringing certain lead marks into register. The article concludes with a reference to the action of Becquerel rays on the photographic plate and fluorescent screen. These rays can be neither refracted nor polarized, and have the property of ionizing air, but as yet are not of value in medical diagnosis, because of the diffusion and absorption they suffer in passing through bodies of low atomic weight. [H.M.]

2.—The placenta is not separated by **retraction of the placental site**. This is brought about by **disproportion** between the area of the site and the uterine surface of the placenta. During the first and second stages of labor the wall and the placenta act as one, decreasing in area during a pain and increasing again when the pain stops, owing to the "elastic recoil" of the uterus. In the **third stage** after a pain the increase in area of

the placental site is not accompanied by a similar increase in the placenta itself, owing to the cutting off of the influence of the fetal heart. In consequence, the microscopic filaments of attachment are torn away. An expectant management is the only safe one. It is an open question whether it is a consequence of hemamebiasis. [H.M.]

3.—Walker describes the only recorded case in which the diagnosis between smallpox and erythema multiforme was difficult, and a cut shows the papules which were stony hard, with exudation resembling commencing umbilication. [H.M.]

4.—Blackwater fever is on the increase. Most cases occur between the second and fifth years of residence. It is commoner in the dry season. No case has been recorded in a native. The symptoms are a sharp rigor, porter-colored urine, painful micturition, temperature of 104° to 105°, jaundice, persistent vomiting, inability in 12 hours to lift the head. The temperature curve is indefinite. The urine begins to clear on the third day and may be free in 6 hours from hemoglobin. The pulse respiration ratio is 3 or even 2 to 1, with breathlessness. The liver is normal, the spleen enlarged; there is anxiety, restlessness, insomnia and, in unfavorable cases, muttering delirium. Anemia is profound. The urine deposits a brown sediment of blood casts, blood corpuscles and debris. One hundred ounces may be passed daily. In other cases suppression gradually sets in. A large initial dose of calomel is given, followed by a saline and a mixture of sodium salicylate and bicarbonate. Frequent feeding and symptomatic treatment are advised. No one who has had the disease should ever return to West Africa. [H.M.]

2. Some theoretical conditions upon the nature of agglutinins, together with further observations upon *Bacillus typhi abdominalis*, *Bacillus enteritidis*, *Bacillus coli communis*, *Bacillus lactis aerogenes*, and some other bacilli of allied character. By HERBERT E. DURHAM. (Journal of Experimental Medicine, Vol. v., No. 4, January, 1901.)
3. The Influence of Bile on Metabolism, by ELLIOTT P. JOSLIN. (Journal of Experimental Medicine, Vol. v., No. 5, March 25, 1901.)

1.—In this article of 180 pages with 67 photomicrographs, the results of a bacteriologic and pathologic study of 220 cases of diphtheria are described.

Bacteriology.—A general infection of some kind was found in about one-fifth of the cases, being most frequently an infection with *Streptococcus pyogenes*. The diphtheria bacillus was the next most common microorganism; the staphylococci and the pneumococci were found less frequently. In acute inflammations of the pericardium, pleura, mediastinum and lymph-nodes, the streptococci was found most frequently. In one case of acute ulcerative endocarditis the diphtheria bacillus was found in pure culture. Bronchopneumonia occurred in 131 cases; the diphtheria bacillus being found in 69, streptococci in 67, and pus cocci in 37. The diphtheria bacillus was found alone in 19 cases, but was generally associated with the pyogenic cocci or the pneumococcus. In an examination of the accessory sinuses of the nose in 63 cases inflammatory changes of varying degree were found in 39. The inflammation was sometimes catarrhal, more frequently purulent, occasionally fibrinous. The antrums of Highmore were involved in 36 cases; the frontal, sphenoid and ethmoid sinuses each a small number of times. In most of these cases *Bacillus diphtheria* was found, although usually associated with the pus-cocci or the pneumococcus. The writers believe that the slow drainage of these cavities may explain the persistence of diphtheria bacilli in cultures from the throat, after the disappearance of all local evidence of inflammation. The middle ears were examined in 144 cases. Inflammatory changes were found in 86. The results of the bacteriologic examinations in these cases were similar to those of the accessory sinuses of the nose.

Histology.—Diphtheria bacilli are found usually in the necrotic tissue and in the exudation; never in the living tissue, or in connection with the primary degenerative

lesions of the epithelium. It seems probable that the primary lesion is due to the toxic substance produced by bacilli growing in the fluids of the mouth or throat. When necrosis or injury of the epithelium is produced by this toxic substance, the tissue is invaded by the bacilli. Other microorganisms, particularly the pyogenic cocci, are frequently found associated with the diphtheria bacilli. The first step in the production of the false membrane is degeneration or necrosis of the epithelium, often preceded by direct division of the nuclei of the epithelial cells. An inflammatory exudate rich in fibrin coming into contact with this epithelium, forms a definite fibrin network. Associated with this, especially on epithelial surfaces having several layers of cells, a hyalin membrane is also frequently formed. This hyalin membrane may be formed from the fusion of the protoplasm of the cells undergoing hyalin degeneration—the nuclei of the cells disappearing, and leaving spaces which give the membrane a reticular appearance. This hyalin membrane may also be formed by a hyalin degeneration of exudation-cells. The most typical membrane is found in the larynx and trachea. The membrane never forms an intact epithelium, but may extend over it. In the connective tissues and bloodvessels beneath the membrane, a hyalin fibrinoid degeneration may occur. Degeneration of the mucous glands is pronounced.

Fatty degeneration of the muscular fibers of the heart was found in 46 of 67 cases examined. It was most marked in the vicinity of the endocardium. In cases of great severity, fatal shortly after entering the hospital, this degeneration was the only lesion of the myocardium. Segmentation and fragmentation of the myocardium was not observed. In 13 cases, very extensive degeneration leading to complete destruction of the muscle fibers was found. This consisted of a fatty degeneration with disappearance of the contractile elements. The sarcous elements disappeared, their place being taken by a granular material with the formation of large irregular vacuoles which could be readily distinguished from those of fatty degeneration by their size and irregularity. A further form of degeneration consisted of a complete destruction of the fibrils with the formation of large, irregular, hyalin masses. This was found only in the latter stages of the disease, the average duration being about 15 days. It was always more marked near the endocardium. Various degenerative changes of the nuclei of the muscle-fibers were noted. **Interstitial lesions** occurred in 2 forms: (1) in 6 cases an acute interstitial myocarditis, characterized by a large number of plasma cells between the muscle-fibers was found. Lymphoid cells were occasionally seen, but polymorphonuclear leukocytes were rare. This condition may or may not be accompanied by degeneration of the muscle-fibers. The accumulations were sometimes circumscribed and sometimes diffuse. This condition is analogous to the acute interstitial, nonsuppurative nephritis of the kidneys. The average duration of this condition was 10 days. (2) A form more chronic in its character and evidently secondary to degeneration, in which the interstitial tissue was swollen and infiltrated with large cells of an endothelial character, with considerable formation, in some cases, of connective tissue. The average duration of this condition was 17 days. Heart-thrombi were found in 8 cases. There seems to be some relation between thrombi and the acute interstitial changes of the heart-muscle. In 7 of these 8 cases, acute interstitial myocarditis was found.

Bronchopneumonia was present in 131 cases, of which 76 were discrete and 55 confluent. The process begins as an infection of the atria and from there extends; it may be limited to a single acini, to lobules, or to groups of lobules. To the condition in which only single acini are involved, which is essentially the primary lesion, the writers have given the name acinous pneumonia to distinguish it from the condition in which the entire lobule is involved. There is little lateral extension of the infection through the walls of the alveoli. Inflammation of the terminal bronchi is also present, but not necessarily of the larger bronchi. Small areas of atelectasis and emphysema were frequently found. Acute lobar pneumonia did not occur in any of these cases. Inflammatory edema was common, but a general edema of the lungs, comparable to the circulatory edema of

adults, did not occur. The character of the exudation varies greatly; it may be fibrinous, hemorrhagic, serous, or almost entirely cellular. The cells of the exudation are mainly leukocytes, and in part, cells derived from proliferation of the lining epithelium. Lymphoid and plasma cells are found not only in the exudation, but in many cases infiltrating the interstitial tissue. Necrosis leading to abscess was not an uncommon feature. Dilatation of the lymphatics was very common. No definite relation could be demonstrated between the character of the exudate and the infecting microorganisms. Pneumococci, streptococci, and diphtheria bacilli were found in connection with serous, purulent, fibrinous, and hemorrhagic exudates, and with necrosis and abscess formation. Diphtheria bacilli were very frequently found, and may be the cause, without the aid of other microorganisms, of bronchopneumonia, necrosis, and abscess-formation.

The most obvious lesions of the spleen consisted of the formation of foci of epitheloid cells in the lymph nodes. These epitheloid cells are phagocytic, and the nuclear detritus found in the foci comes generally from the lymphoid cells, which are engulfed and destroyed by the phagocytic cells. Large numbers of plasma cells are found throughout the pulp of the spleen. In the veins, an accumulation of lymphoid cells was occasionally found beneath the endothelium of the intima.

In the stomach and intestines, aside from an occasional extension of the membrane, the only important change is the hyperplasia of the lymph-nodes with a proliferation of the endothelial cells.

Lesions of the liver in diphtheria are not characteristic and do not differ from those found in other infectious diseases; they are due to the action of soluble toxic substances, and not to the diphtheria bacillus. The most common lesions are fatty and granular degeneration of the liver-cells with necroses, which are chiefly found in the centers of the lobules. A slight hyalin degeneration of the capillary walls is occasionally seen, as is also a proliferation of the endothelium.

Degenerative changes of the kidneys were found in 112 cases, being chiefly cloudy swelling, fatty degeneration and hyalin degeneration. Hyalin degeneration was found very commonly, and was most marked in the proximal convoluted tubules. Acute interstitial nonsuppurative nephritis was found in 43 cases. The infiltration was made up chiefly of plasma-cells, with numerous lymphoid cells, and a few polymorphonuclear leukocytes, and occasionally phagocytic and endothelial cells. Various cells were observed, which seemed to indicate stages of transition between the lymphoid and plasma cells. The accumulations of cells were generally focal and were most numerous at the base of cortex adjoining the pyramids, just beneath the capsule, and around the glomeruli. Degenerative changes of the tubules generally accompanied this infiltration, but were not constant. In many of these cases, large numbers of the infiltrating cells were found in the bloodvessels. They frequently showed mitotic figures, but not so frequently as did those outside the vessels. Omitting 3 cases, in which death occurred after the forty-second day, the average duration of the cases in which this condition occurred was 16 days. In the cases in which the lesion was most marked the average age was 11.5 days. In younger children, infiltration was less marked. Glomerulonephritis was found in 11 cases, in 9 of which the chief lesion was a proliferation of the cells of the glomerular tuft and Bowman's capsule, with more or less lobulation of the glomerulus. It was not possible to resolve any of these cases into the distinct types of intracapillary and capsular glomerulitis; the 2 conditions were generally combined. In all of these cases there was more or less granular material, evidently coagulated serum in the capsular space. In the tenth case there was extensive necrosis of the glomeruli, with hemorrhage into the capsule, and in the eleventh the capsule was filled with hyalin material, in which both fibrin and red blood-corpuscles were contained. The average duration of these cases was greater than that of those with the interstitial form.

Bronchial, cervical, mesenteric, axillary and inguinal lymph-nodes were examined. The most marked lesions were found in the cervical and bronchial lymph-nodes. Two types of

lesions were observed: (1) those which may follow an injury of almost any sort, consisting of congestion, hemorrhage, diffuse and circumscribed necrosis; (2) lesions which belong distinctly to diphtheria, but which may also be found, in a less marked degree, in any other acute infectious disease of children. These consist of a proliferation of the endothelial cells of the lymph-nodes, and of the endothelial cells lining the sinuses. These cells are phagocytic, engulfing and destroying principally the lymphoid cells, thus giving rise to the nuclear detritus, which is so characteristic a part of the lesion. These lesions are due to the toxic products of the diphtheria bacilli, the bacilli themselves seldom being found in these structures. Changes in the lymphoid tissue of the tonsil are similar to those of the lymph-nodes generally. The principal change in the thymus was degeneration of the lymphoid cells, especially about Hassall's bodies. The degenerated cells were frequently contained in large cells of the endothelial variety. Eosinophilic cells were very numerous.

Marked hyperplasia, with great increase of cells resembling plasma cells was the constant lesion. In the bone-marrow lymphoid cells were comparatively few in number, and polymorphonuclear leukocytes still less numerous. Eosinophilic cells were very abundant in early cases, less frequent in late cases. Apparent transition forms between the cells resembling plasma cells, and the eosinophilic cells were seen. A few endothelial cells with phagocytic properties were found. The so-called plasma cells were frequently found in the veins. "It is possible that the ordinary marrow cell is the same as the plasma cell." Examination in a small number of cases showed local and diffuse fatty degeneration of the central nervous system and skeletal muscles. The pancreas, adrenals, testicles, thyroid gland, salivary glands and pituitary body showed no changes of importance. [R.M.P.]

2.—Gruber and Durham found that within the "species" *Spirillum cholerae asiaticae* the serum-reactions were not uniform, in that the serum obtained by immunizing with one race did not necessarily give more than a trace of reaction *in vitro*, and none whatever *in vivo* when tested with another race, although it was capable of giving complete clumping and positive Pfeiffer reaction when tested upon the first race. This fact was ascribed at that time to differences in virulence of the races. The suggestion then advanced, however, would seem erroneous when considered with reference to the findings which Durham now reports. Durham's present work shows that many members of the *Bacillus enteritidis* group, although apparently identical so far as cultural and morphologic tests are concerned, reveal marked differentiation when tested by serum for agglutination. He finds for example the races "Gartner" and "Morselee" are both strongly affected by "Gartner" serum, whilst the races "Hatton," "Morbificans bovis," "psittacosis," "aertrycke," "Calmpthout," "Gand," "Sirault," "hog cholera," "typhi murinum," "Sheffield," are not very markedly affected by this serum. Taking the reverse view he finds that the serum of Hatton has comparatively slight effect upon the races "Gartner" and "Morselee;" thus a serum that gave good reaction at 1 in 200,000 upon "Hatton," practically gave but a minimal reaction upon "Gartner" and "Morselee" at 1:2,000. Thus it would seem that the lack of mutual agglutination within a definite group of bacilli would emphasize the view that the word "specific," when applied to these tests is erroneous. At the same time Durham shows that the "Gartner" type has a distinct tendency to be affected by the serum derived by the use of typhoid bacilli. Differences between the typhoid bacilli in this respect are also found, and they at once cause inquiry whether the instances in which failure to obtain the agglutination phenomenon in typhoid fever has occurred may not be explained by the employment of a race of typhoid bacillus unsuitable for the testing of that particular typhoid serum. He also discusses and endeavors to explain the partial and mutual reactions of agglutinating serums upon different races of bacteria. The next section of the work is devoted to the technicalities of preparing serums for agglutination-tests. The suggestions offered are good and are given in sufficient detail to permit of employment by those who may find them desirable. Durham gives various means of differentiating *Bacillus typhi abdomi-*

nalis, *Bacillus enteritidis*, *Bacillus coli communis*, *Bacillus lactis aerogenes*, and other bacilli of allied character; but foremost among these he places litmus milk-whey. He believes that more can be gained in the differentiation of these bacilli with this medium than with any other single medium. It is largely upon it as a basis that his present grouping or classification of the above organisms has been made. In conclusion, he gives briefly the incomplete results of his search for substances of carbohydrate nature which would serve for further differentiation of these and other bacillary groups. [R.M.P.]

3.—Joslin's research is a study of the power of the intestinal tract to assimilate the various elements of food under the influence of bile administered by mouth, and also of the cholagogic action of this secretion. The subject of his experiments was a woman who came to operation for gallstone. At operation it was found impossible to remove the stones from the common bile-duct because of the patient's condition, so that a biliary fistula was established from which bile was discharged constantly after operation. Repeated tests for bile in the stools were negative. His experiments were divided into 3 periods, similar in all respects, except that in the middle period the patient received 30 gm. of dried ox-bile. Analyses of stools taken during these 3 periods show the average digestion of fat in the periods without bile was 40%; in the period with bile 60%, *i. e.* bile increased the digestion of fat relatively by 50%. The digestion of nitrogenous food was found to improve with the use of bile pills when the amount of fat in the stools was large. Instead of an average of 15% being lost in the feces, but 7% escaped digestion during the 4 days the patient took bile. The amount of bile-solids secreted in the bile period was 47% greater than in the periods before and after. This once more demonstrates that ox-bile is a cholagogue and confirms the work of Pfaff and Balch. The effect of bile on the bowels was not remarkable, although in this case their action was more satisfactory during the bile period. The research was also extended to dogs, but with results not so satisfactory as in the human subject. [R.M.P.]

1.—Thompson presents conclusive evidence as to the mode of spread of bubonic plague in epidemic form, based upon observations made during the outbreak at Sydney, N. S. W. There was no ground for supposing that the infection was spread with food and taken by ingestion, but the observations show "that as soon as plague occurs among a wholly civilized white population, it appears at once and clearly that this disease is diffused by none of those means which are effectual in causing (for instance) epidemics of influenza, or of cholera. In its mode of spread it plainly resembled in some important respects the epizootic tick-fever. No theory could be devised I think, which would coördinate with the observed facts unless it assumed at all events an animated host which should not be human for the infection. In fact 2 such hosts are requisite; one to diffuse the infection in place, the other to communicate it to man. . . . They are the rat, and a suctorial parasite," (the flea). In support of the assumption that the epidemic was a consequence of an epizootic it was demonstrated that plague-rats were infested over the several areas in sufficient numbers to

account for their infectivity; "briefly, the area over which the epizootic extended coincided with the area over which epidemic was seen to have extended after all cases had been referred to their probable place of infection, a locality fixed upon after carefully considering the separately recorded facts concerning each of the 303 cases in man."

The evidence regarding fleas consists of the isolation of *Bacillus pestis* from the phlyctenulas or blebs resulting from the bites of fleas, and by inoculation of a guineapig with *Bacillus pestis* found in narcotized fleas taken from plague-rats. The fleas were identified as *Pulex serraticeps* and *P. fasciatus*, the latter described as the rat-flea as far back as 1801. [C.S.D.]

2.—Tunnicliffe and Rosenheim present the results of an extensive series of experiments to demonstrate the influence of boric acid and borax, used as food preservatives, upon the nutrition of the consumer, especially children.

Their conclusions are that continued doses of 1 gram of boric acid or of 1.5 gram of borax per diem have no influence whatever upon the proteid metabolism, either in healthy or delicate children. Phosphorus metabolism is not affected, nor the assimilation of fat. The body weight increased in all cases. Contrary to the observations of Foster, they found that boric acid had no effect in increasing the quantity of feces, or in their nitrogen or phosphorus percentage; neither were they able to confirm his statement that boric acid exerts an inhibiting effect on intestinal putrefactive action.

Evidently borax and boric acid may be utilized as food preservatives in moderate amounts without danger or inconvenience to the consumer. [C.S.D.]

3.—Buchanan's observations lead to the *prima facie* presumption that dust may be one of the vehicles of the specific germ of cerebrospinal meningitis. He concludes that "the identity of what in India is called cerebrospinal fever with epidemic cerebrospinal meningitis is established, not only by finding of the *Diplococcus intracellularis* in the Indian cases, but by the clinical and epidemiologic aspects of the outbreak, which exactly resembles outbreaks recorded in other countries." A strong case appears to have been made out in the present instance for connecting this disease with dust, either wind borne, accumulated on roofs, etc., or produced in various processes of grain cleaning the fact that 44 out of 47 cases came from farms of labor where there was great exposure to dust, and only 3 cases from persons who were not so exposed, is difficult of explanation, unless we believe that dust either renders men more susceptible, or, as is more probable, is the actual vehicle of the specific germ of the disease. [C.S.D.]

9.—Ford has with the aid of modern methods and technic gone over the question of the occurrence of bacteria in normal organs, first investigated by Burdon Sanderson in 1878, by Neneki and Giacosi in 1880 and by many others since then, and with practically the same results, *i. e.*, the demonstration of bacteria in abundance. However, Ford's conclusions that each species of animal, each animal, and each organ preserves its own bacterial flora is interesting. [C.S.D.]

THE PUBLIC SERVICE

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine Hospital-Service, during the week ended April 26, 1901:

SMALLPOX—UNITED STATES AND INSULAR.

		Cases	Deaths
Delaware:	Newcastle.....Apr. 1-15.....	4

Changes in the Medical Corps of the U. S. Navy, for the week ended April 27, 1901:

DENNIS, J. B., assistant surgeon, detached from the Naval Academy, May 1, and ordered to the Chesapeake, May 1.
 BOGERS, F., medical inspector, ordered to the Brooklyn for duty as fleet surgeon of the Asiatic Station.
 ARNOLD, W. F., surgeon, detached from duty at Olongapo, P. I., and ordered to the New Orleans.
 STOKES, C. F., surgeon, ordered to the Cavite Naval Station to await the Solace.
 SMITH, C. G., assistant surgeon, ordered to the Vermont, April 25.
 HENRY, H., pharmacist, ordered to the Independence, April 29.

Changes in the U. S. Marine-Hospital Service for 7 days ended April 25, 1901:

MEED, F. W., surgeon, Department letter of January 11, 1901, granting Surgeon Meed leave of absence for 60 days, amended so that said leave shall be for 1 month and 24 days—April 19, 1901.
 GLENNON, A. H., surgeon, to proceed to Tallahassee, Florida, for special temporary duty—April 22, 1901.
 MCINTOSH, W. P., surgeon, to proceed to Ducktown, Tennessee, for special temporary duty—April 19, 1901.
 PETTUS, W. J., surgeon, Department letter of January 11, 1901, granting Surgeon Pettus leave of absence for 2 months, amended so that said leave shall be for 1 month and 27 days—April 6, 1901.
 WORTENBAKER, G. P., passed assistant surgeon, to represent the service at meeting of Texas Medical Association, Galveston, Texas—April 22, 1901.
 NYDEGGER, J. A., passed assistant surgeon, to proceed to Cape Charles Venture, Va., for special temporary duty—April 19, 1901.
 MATHEWSON, H. S., passed assistant surgeon, to proceed to Ponce and Guayannilla, Porto Rico, for special temporary duty—April 24, 1901.
 KING, W. W., assistant surgeon, to proceed to Guayannilla, Porto Rico, for special temporary duty—April 24, 1901.
 GIBSON, L. P., acting assistant surgeon, granted leave of absence for 7 days—April 25, 1901.
 RODMAN, J. C., acting assistant surgeon, granted leave of absence for 7 days from April 24—April 23, 1901.
 WETTERS, MARK H., hospital steward, relieved from duty at Chicago, Ill., and directed to proceed to St. Louis, Mo., and report to the medical officer in command for duty and assignment to quarters—April 19, 1901.

Changes in the Medical Corps of the U. S. Army for the week ended April 27, 1901:

STRAUB, Captain PAUL F., assistant surgeon, is granted leave for 30 days.
 SARGENT, E. H., acting assistant surgeon, now at Vancouver Barracks, will proceed to Fort Flagler, for temporary duty during the absence, on leave, of Acting Assistant Surgeon, J. P. Truax. Upon completion of this duty Acting Assistant Surgeon Sargent will return to Vancouver Barracks.
 TRUAX, J. P., acting assistant surgeon, is granted leave for 20 days.
 PLUMMER, Captain GEORGE R., assistant surgeon, now temporarily on duty at Hamilton Barracks, Matanzas, Cuba, is assigned to duty at that post.
 SUMMERALL, Captain W. B., assistant surgeon, is relieved from further duty at Hamilton Barracks, Matanzas, Cuba, and will report to the commanding officer, artillery defenses, Havana, Cuba, for duty.
 RAYNOR, Captain WILLIS J., assistant surgeon, recently appointed, is granted leave for one month from about May 10.
 GILL, Captain CHARLES R., assistant surgeon, is granted leave for two months on surgeon's certificate.
 BUSHNELL, Major GEORGE E., surgeon, is granted leave for 14 days, to take effect upon the expiration of his present sick leave.

BAILEY, Captain GUY G., assistant surgeon, is relieved from further duty with the 1st battalion, 30th Inf., Presidio, and assigned to temporary duty with troops on the horse transport Thyra during the voyage to the Philippine Islands. Upon arrival at Manila, Captain Bailey, assistant surgeon, will report for assignment to duty.
 PURCELL, Captain FRANCIS J., assistant surgeon, is assigned to temporary duty with troops on the army transport Thomas. Upon arrival at Manila, Captain Purcell will report for assignment to duty.
 PALMER, FRED W., acting assistant surgeon, will proceed to his home, Jackson, Mich., for annulment of contract.
 HORNE, WILLIS S., acting assistant surgeon, is assigned to temporary duty with troops on the army transport Thomas. Upon arrival at Manila, Acting Assistant Surgeon Horne will report for assignment to duty.
 DAYWALT, Captain GEORGE W., assistant surgeon, is relieved from temporary duty at the Army and Navy General Hospital, Presidio, and assigned to temporary duty with troops on the army transport Warren, to sail for the Philippine Islands.
 CHALMERS, Major THOMAS C., surgeon, recently appointed, will report for transportation to Manila, P. I., where he will report for assignment to duty.
 WING, FRANKLIN F., contract dental surgeon, will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
 GRAVES, Captain LEONARD K., assistant surgeon, recently appointed, is granted leave for one month.
 VAUGHAN, Captain MILTON, assistant surgeon, recently appointed, is relieved from duty in the department of Cuba, when he will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
 HEARD, GEORGE P., contract surgeon, will proceed from Birmingham, Ala., to Fort McPherson, Ga., for duty.
 DILLON, G. PARKER, acting assistant surgeon, is granted leave for 15 days.
 MASON, Major CHARLES F., surgeon, 26th Infantry, U. S. volunteers, is relieved from further duty with that regiment and will repair to Washington, D. C., and report to the surgeon general of the army for instructions.
 GRAVES, Captain LEONARD K., assistant surgeon, now in Brooklyn, N. Y., will upon the expiration of leave granted him April 22, proceed to San Francisco, Cal., for transportation to Manila, P. I., where he will report for assignment to duty.
 SPARENBERGER, Captain FREDERICK H., assistant surgeon, recently appointed, now in San Francisco, Cal., will report for transportation to Manila, P. I., where he will report for assignment to duty.

AMERICAN MEDICINE

1321 Walnut Street

Philadelphia

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free: foreign postage, \$2.50. Subscriptions may begin at any time. Volumes begin with the first issue of April and of October.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles, will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is one dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to American-Medicine Publishing Company. Address all correspondence to 1321 Walnut Street, Philadelphia.

Responsibility for Typhoid is, of course, illustrated by every epidemic, but in a striking manner by that of New Haven. The excreta from a single patient in a neighboring town were carelessly allowed to pollute the city's source of water-supply, and the result is that about 500 people have had typhoid fever—the largest epidemic ever known in the state. The fact, again, shows how civilization means the interdependence of each upon every other, the well-being of the social organism being bound up with that of its units. But more than all else does the epidemic demonstrate professional responsibility. Each physician may have in his hands the health of the entire community. Thousands of cases of disease may be due to his carelessness as to the disposal of the excreta of his patients. The legalization of Unchristian unscience, or any form of pseudopathy will tremendously increase this danger. The legislative non-support of medical science will increase it. Political jobbery in our health boards and in the care of our water-supplies will also do the same.

Rabies; Its Cause, Frequency and Treatment, is the title of an article by Dr. D. E. Salmon, the efficient Chief of the Bureau of Animal Industry, Washington, D. C. All who have an interest in the subject—and who has not?—should secure a copy. We especially commend it to the antis. Partial statistics from only 73 cities show that there were 230 deaths from the disease from 1890 to 1900. In many other countries the disease is very prevalent. The official reports of Germany show 1,202 cases of rabies in animals (mostly dogs) in 1898. In France there were 2,374 animals affected in 1899. In Belgium there were 444 cases. In Great Britain there were 727 cases in 1895, and in Hungary 1,397 cases in the same year.

For the eradication of the disease it is only necessary that all worthless, ownerless, and vagrant dogs shall be killed, and that all dogs allowed in public places shall be muzzled. Dr. Salmon cites the following as one of many instances demonstrating the value of muzzling:

In Great Britain the number of rabid dogs officially reported was, in 1887, 217; 1888, 160; 1889, 312. In the last-mentioned year muzzling was adopted, and the number of cases fell to 129 in 1891, and 38 in 1892. Then, owing to persistent opposition, muzzling was stopped, and the effect of withdrawing this measure was at once seen in the increase of rabies. In 1893 there were 93 cases; in 1894, 248, and in 1895, 672. At this point, owing to public alarm, muzzling was again enforced, reducing the number of cases in 1896 to 438, in 1897 to 151, in 1898

to 17, in 1899 to 9. As no case was discovered from November, 1899, to March, 1900, it was believed by the veterinary officer that the disease had been extinguished from Great Britain. It may be added that in countries like France and Belgium, where muzzling has not been adopted, the disease continues to prevail to a very serious degree.

The Number of the Tuberculous.—At the recent meeting of physicians in Washington, Dr. Trudeau alluded to an investigation in which, if we do not err, it was demonstrated that there was the tuberculous reaction in 18% of supposedly well persons. Dr. Councilman also said that his postmortem records proved that in about 17% of cases there was tuberculous infection, although no history or symptoms indicated the existence of the disease. If to this showing is added the proportion of deaths due to tuberculosis we are astonished to find that in all probability about one-third of civilized people are tuberculous. This emphasizes several points:

1. The early diagnosis becomes of exceptional importance.
2. Is tuberculosis really increasing, or are we discovering more cases?
3. Is there, in modern times, a lengthening of the lives of the tuberculous or, in other words, a lessening of the virulence or fatality of the disease?
4. If so, is this due to hygiene and the progress of civilization, or to an acquired immunity?

Whatever the answer to such questions may be, they still confirm the experience of all physicians, that when cases are taken sufficiently early, and are treated with intelligence, tuberculosis is a curable disease.

Local Influences at the Meetings of the American Medical Association are almost certain to be exercised in an undue degree by the present method of choosing the delegates. The majority of those chosen are necessarily from communities lying comparatively near the meeting place. It is only natural that, without conscious purpose, the work of the delegates should result in injustice to certain parts of the country not so well represented, or in overgenerousness to those with a powerful or full corps of delegates. The essential vice of the present method is that it is not democratic, not strictly representative. In a national organization the representation should be as assured and as effective for the few and the distant as for the many and those favored by the luck of contiguity. With the continuous growth of the country proper representation becomes every year

a more important concern. If this representation could also be reduced so that the entire business of the Association could be lodged in its hands and transacted in a workmanlike way, leaving the general meetings free for purely professional purposes, it would be a great means of progress.

The Combined Medical and Surgical Clinic.—There are many diseases which must first be treated by the physician, and which must afterward come under the surgeon's care, and there are conditions which demand the expert knowledge of both physician and surgeon. This is especially true of diseases of the thoracic and abdominal organs. The decision as to the proper differentiation, diagnosis, and treatment, is often puzzling to the student and young practitioner. At the meeting of the Philadelphia County Medical Society, on May 8, 1901, Dr. R. G. LeConte, of Philadelphia, read a paper urging that there should be instituted combined medical and surgical clinics, in which the student would have placed before him by two experts the various phases of the disease under consideration. He recites the experiences of Dr. Frederick A. Packard and himself, carried out last fall at the Pennsylvania Hospital. Dr. LeConte said:

"We were associates on the wards of the hospital during October and November, 1900, and gave eight clinics in the two months. We arranged seven combined lectures, but at the last moment one patient refused further treatment and left the institution, so that only six combined clinics were given. These were on gangrene of the lung, cirrhosis of the liver, epilepsy, Graves' disease and goiter, diseases of the lymphatics and diseases of the pleura. The lectures varied from an hour and three-quarters to possibly two hours and a quarter in length. An attempt was made to trace these diseases from their incipency to their various terminations. The pathology was freely discussed and illustrated with such specimens as could be secured. The patients themselves were examined before the students and the diagnoses made. They were then removed from the clinic and anesthetized, while the various surgical procedures were discussed and then illustrated on the individual case. At some time later the results of our treatment were shown and discussed, whether the case terminated favorably or fatally.

"At the opening clinic less than forty students were present; at the second about 100, and thereafter 150 or 160 would probably represent the average attendance. Neither Dr. Packard nor myself held positions in medical schools, so the personal element did not influence the attendance, and we may fairly attribute the increase alone to the system pursued. Several students told me that these two hours saved them days of reading, and that the mental picture retained was worth volumes of type. Two physicians also told me that it was their custom to rise at six o'clock on our clinic days, in order that they might save the two hours to hear our lectures. I trust that you will understand that my quoting such remarks is not done in a vainglorious spirit, for I know full well that my qualifications as a surgical teacher are extremely limited, but I wish to emphasize the fact that with this system our lectures proved very valuable to the students, although the surgical instruction was possibly of an inferior nature.

"The drawbacks to such a system are, (1) the material at one's disposal will not always lend itself to this method of instruction, and (2) the increase of time given by the instructors, for it is expedient that both teachers be present during the whole of the lecture, the surgeon to know thoroughly the medical status of the case he is about to operate upon, and the physician to see the advantages or disadvantages that result from the operation. To the first objection, of course, there is no answer, for if one has not the material he cannot arrange the lecture. But to the second objection I would say that an

instructor who cannot afford an extra hour for the purpose of saving hours of work to each individual student is of little value as a teacher, no matter how prominent his name may be in the profession.

"The benefits derived from such a system seem threefold: to the student; to the patient who has the advantages of the thoughts of two minds instead of one; to the instructors, for it cultivates in them qualities of the highest value in the practice of medicine."

The scheme appears most commendable, and admirably planned to aid the student and postgraduate in a perplexing class of cases.

The Role of the Water Meter in Public Sanitation.—At first one might naturally suppose that as a free supply of water is so necessary to cleanliness, the meter, by lessening the use of water, would increase disease. In some cases and temporarily this might be true, but in the long run there would doubtless be a lessened death-rate, due to the fact that, according to the wise suggestion of the *Yale Medical Journal*, by means of the water-meter we could secure a purer, if not so copious, a supply of water. The method whereby this may be brought about is through sand filtration. With our present lavish wastefulness of water, sand filtration is an enormously expensive thing, almost amounting to preventing its general introduction. The water-meter would not prevent the use of a healthful and necessary supply, but would check the present absurd extravagance. The meter would therefore permit of universal sand filtration.

Grave pseudoparalytic myasthenia or asthenic bulbar paralysis, a disease happily of uncommon occurrence, is still of sufficient frequency to merit the attention that recently has been devoted to it. According to the statistics of Campbell and Bramwell published in *Brain*, summer, 1900, since the first report by Wilks in *Guy's Hospital Reports*, 1877, there have been recorded 60 cases with 23 deaths and 17 necropsies. At a winter meeting of the College of Physicians of Philadelphia, Burr and McCarthy reported an additional case—if we mistake not, the first case with necropsy reported in this country. The disorder is especially characterized by lack of vigor, by weakness on slight exertion, amounting to veritable paralysis of the muscles concerned in swallowing, chewing and speaking, of the palatal and ocular muscles. Originally thought to involve only the muscles within the sphere of influence of the motor nerves of the pons and medulla, it was later ascertained that the entire muscular system of the body may present the peculiar lack of vigor with very rapid exhaustion on voluntary effort; the original view justified the designation asthenic bulbar paralysis, later studies, the designation grave myasthenia. Though the etiology and pathogenesis of the disorder are not well understood, the weight of opinion seems to favor the idea of its being of toxic origin. In this connection we recall the observations of Jolly who, contrasting grave myasthenia with Thomsen's disease, pointed out that there exist certain poisonous alkaloids, such as physostigmin, veratrin, digitoxin, capable of producing a condition similar to congenital myotonia, whereas another, protoveratrin, gives rise to a condition not unlike grave myasthenia. The struc-

tures implicated in the disease are the peripheral motor neurons, but whether the muscular end-plates, the axons, or the cell-bodies are primarily or especially involved is still to be determined. In the very few cases in which postmortem investigations disclosed any deviations from the normal, the lesions which were inconspicuous, were found in the bulb and in the cranial nerves. These lesions, though inconspicuous as remarked, may nevertheless represent the only tangible evidences of the action of a poison whose other deleterious effects and the concomitant structural alterations elude detection by our present methods of investigation. That which concerns us especially as practitioners is the diagnosis of the disease and the knowledge of the fact that with appropriate management some of the patients may recover. From true bulbar palsy, grave myasthenia usually may be distinguished with facility, and the same may be said with regard to multiple neuritis of the cranial nerves, various syphilitic disorders, and gliosis of the pons and medulla. Another extremely important point was accentuated by Bramwell at the March meeting of the Edinburg Medico-Chirurgical Society—the resemblance of the affection to hysteria. In differentiating grave myasthenia from hysteria, Bramwell directs attention to the significance of the presence of muscular weakness which may be slight in degree and is unassociated with atrophy; the facility with which the muscles become exhausted both by faradism (myasthenic reaction), and by voluntary effort, a condition to which he applies the designation “myasthenic state”; and the absence of sensory symptoms apart from the fatigue of exhaustion, of sphincter trouble, and mental disturbances. With regard to treatment, Bramwell recommends that muscular exertion and mental excitement be avoided since both augment the severity of the symptoms. Solid food should be as finely divided as possible so as to remove all undue exertion from the muscles of mastication. It seems worth while also to bear in mind what may prove to be an extremely valuable suggestion of Bramwell, namely, that in severe cases with great muscular weakness and danger of death, inhalations of oxygen and transfusion of normal salt solution may be of service. Burr and McCarthy, while they found massage useful, believe that arsenic is the only drug that seems possessed of any efficacy. Strychnin, however, would appear to be indicated.

How to Treat “Christian Science.”—According to the *New York Herald* the following statistics summarize the condition of the “Christian Science” sect:

	1890.	1891.
Number of church societies	94	623
Number of chartered educational institutions	33	79
Number of public reading-rooms	27	283
Copies of Christian Science textbooks in circulation	50,000	205,000
Estimated value of church property now held in the United States		\$12,000,000

The churches are awakening to the hugeness of this eruption of unchristianity, and ministers everywhere are anathematizing it in the plainest of old English words. One says of it in a public address that it reminds him of the guineapig—“it does not come from Guinea, and it is not a pig.” There has arisen a class who,

frightened by its onrush, say that its phenomenal progress is due to the very opposition it has encountered; that dogmatism and ridicule help and not hinder it. That veteran fighter of shams and frauds, Dr. Buckley, of the *New York Christian Advocate*, flatly disagrees:

“Christian Science has been let alone long enough. Its principles or want of principles should be exposed, its tendencies traced, its unfulfilled promises enumerated, held up to the light. This may lead to the loss of some nominal members to the churches, but to allow this leaven to enter those churches would poison the whole lump. The situation calls, not for persecution, but for instruction and warning. Christian science is *not* dangerous if *exposed*; it may *become* so if *ignored* or if *treated* as if it were either rational or Christian. We shall soon place in the possession of Methodists the material for aggressive and defensive warfare against this insidious foe to Christianity, science, and common sense.”

One excellent result comes from it all: the lesson to the churches that any alliance with quackery is irreligious folly. It was a needed lesson. We hope they have learned it well.

We would suggest that the eradication of the disease will come in a professional way through prophylaxis, disinfection, and antisepsis. All must unite to carry out the law where it exists or to secure the passage of beneficent medical practice acts where they do not already exist. Disease is a fact. The American people are not such fools as to deny this, and to assent to the idiocy that they can treat disease who know nothing about it, and who deny its existence.

The best results from urotropin have been in those diseases of the bladder and pelvis of the kidney in which bacteria are found free in the urine. Thus, it has proved very effective in typhoid cystitis, cystitis accompanying enlarged prostate and urethral stricture, and in simple bacteriuria. On the other hand, when the bacteria, instead of being free in the urine, are chiefly in the tissues of the bladder, as they are in tuberculous and gonorrhoeal cystitis, urotropin is little value. As the urine of typhoid patients frequently contains typhoid bacilli in great numbers, Horton-Smith, Richardson, Cammidge, and others have advocated as a routine treatment the administration of urotropin during the last weeks of the disease in order to render the urine sterile, but such a procedure seems entirely unjustifiable. The bacilli are found in the urine in less than one-third of the cases. When present they are not always provocative of harm to the patient; urotropin is not always effectual in removing them, and finally, so far as the safety of the community is concerned, it is far more rational to disinfect the urine in every case after it has been voided.

Educational Statistics.—In the recent report of the Commissioner of Education the professional man may find food for thought, and the educational philanthropist cause for gratulation. His statistics for the year 1898-99 show a general increase in the number of those attending professional schools, although there has been a decided decrease of theological students enrolled in the United States, 110 less than the previous year. Balzac, speaking of the priest, the lawyer, and the doctor, said they repre-

sented the three principal elements necessary to the existence of society, conscience, property, and health. Does this decrease in the number of clerical students indicate a loss of conscience, or of the desire of conscientiousness? Or does it mean that our progress has been so great that the necessity for moral instructors is less, and that the supply exceeds the demand? However, the medical man will be more interested in the fact that there are 23,778 medical students enrolled in the United States, an increase of 345 over the previous year, those in the regular schools numbering 21,401; in homeopathic schools 1,802; in others 575. All of the medical schools which give full courses of instruction report that they have a course of four years except fifteen schools, and some of these are preparing to enter upon a course of that length; and in several the time of attendance now required for one year is equal to the whole time of attendance required twenty years ago. During the ten years from 1889 to 1899, the number of students in theology increased 18%; in pharmacy 26%; in homeopathic medicine 55%; in regular medicine 75%; in law 204%; and in dentistry 301%.

There are in the United States 151 medical schools, with a total of 4,389 instructors; and in the year 1898-99, 4,911 students were graduated. The progress of medical education is indicated by the lengthened school term in many institutions; by the higher standard required for admission; and by the increased number of men having college degrees who are studying medicine. About 9.5% of all medical students have either an A.B. or B.S. degree. This constant yearly influx into the ranks of the professional of more thoroughly educated men means keener competition, better work, and the survival of the fittest.

Politics in the Ohio Hospital for Epileptics.—

Another instance of the pernicious influence of bad politics in medicine comes to our knowledge in the attempt to force Dr. A. P. Ohlmacher from his office as Director of the Pathological Laboratory of the Ohio Hospital for Epileptics at Gallipolis, Ohio. We cannot learn what reasons for this wretched blunder may exist, but in the letter of Dr. H. C. Rutter, manager, summarily discharging Dr. Ohlmacher, no reasons are assigned. This fact is alone more than enough to justify the demand of the profession that such an outrage shall not be permitted upon a man of the high character and scientific attainments of Dr. Ohlmacher. During the past year seven contributions of value have been made by Dr. Ohlmacher and his associates in connection with his work, besides others completed but not yet published. But, as in all such affairs, it is not the personal aspect of the case that should be decisive. Professional interests are most deeply involved. Positions of trust such as this one, where professional and scientific concerns are in the balance, dare not be treated as the puppets of arbitrary power. In such cases the professional honor and interest are supreme. Men must not be discharged as if they are the slaves of money or power. We learn that the final decision will rest with Governor Nash, and physicians should use their influence to secure a reversal of an act so repugnant to the

feelings of honorable medical men. The rational, humane, and scientific treatment of epileptics, for which the Ohio and New York institutions stand, must not be endangered.

Progress in the Sanatorium Treatment of Tuberculosis is shown in the third annual report of *the Free Hospital for Poor Consumptives of Pennsylvania*, from which we epitomize the following:—

In Germany, there have been established during the last few years nearly 100 sanatoriums for the treatment of consumptives, with a combined capacity of 5,000. This has been established partly through the Government, partly through private charity, and largely through the life insurance companies. In Germany, the life insurance companies find it profitable to send their insured who have tuberculosis to sanatoria for treatment, because of what they can save in the payment of insurance money with those who get well, and the deferment of such payment with those whose lives are prolonged. They also profit by the prevention of the spread of the disease.

In England, prior to the present movement on behalf of consumptives, there were already hospital accommodations for consumptives to the extent of about 2,000 beds. Since this movement began many new sanatoriums have been opened, and the old ones have been improved. England has probably 3,000 beds for consumptives at the present time.

In France, about 2,800 beds for tuberculous subjects existed when the present movement began, and sanatoria either have been built, or are being built, since then at Lyons, Paris, Orleans, Bordeaux, Nancy, Lille, Havre, Canet, and Cimiez. The French Government is about completing a sanatorium at Agincourt, at an outlay of over a million francs.

In Russia, under the leadership of the Tsars, 5 sanatoriums have already been established and a number are under way.

In Italy, sanatoriums are being established at Arizanno, Padua, Umbria, Naples, Messina, Tarent, Cadore and Milan. A law has also been passed requiring existing hospitals to set aside wards for the treatment of consumptives.

In Norway, since 1897, 3 sanatoriums have been established, and 2 are under way—all under the government. A number of private sanatoriums have also been opened.

In Denmark, a hospital for consumptives with 94 beds was opened in 1900 for the use of the entire country, and another with 110 beds for the use of the city of Copenhagen only.

In Sweden, a large sanatorium for consumptives is at present being built as a Jubilee memorial.

In Switzerland, there are already 7 sanatoriums for poor consumptives, and a number of others have been projected.

In Austria, a sanatorium has been established at Alland, and similar institutions are projected in Bohemia, at Maehren, and at Steiermark.

In Hungary, a sanatorium for consumptives is at present being erected as a memorial to the late Queen Elizabeth.

In Poland, 3 sanatoriums for consumptives have recently been erected.

In Spain, under the leadership of the royal family, a large national sanatorium for consumptives has been opened at Porta Coeli.

In Portugal, Queen Amelia has recently given 20,000,000 reis for the establishment of a tuberculosis hospital.

In Holland, the popular young Queen of Holland within a year has given a large sum of money for the establishment of a sanatorium for consumptives.

In Canada, there are as yet but 2 sanatoriums for consumptives with a combined capacity of 75 beds. The Government of the Province of Toronto has, however, recently passed a bill encouraging the establishment of sanatoriums by providing legal machinery for raising revenue for the same. Under this act any municipality can, with the consent of the general government, establish a sanatorium, and raise revenue for its maintenance.

United States.—The National Government has established

sanatoriums in New Mexico for the treatment of tubercular marine hospital patients, and for consumptives of its army.

The State of New York has at present 10 sanatoriums for consumptives under private management, and one projected sanatorium to be supported by the State. These have an aggregate capacity of about 600 beds. The State of New York appropriated \$50,000 during the last session of the legislature for a hospital site, and is asked to appropriate \$100,000 during the present session of the legislature for buildings and maintenance. The City of New York appropriates \$75,000 annually for maintenance of consumptive patients in the Spuyten Duyvil Hospital on the Hudson.

Massachusetts has 5 hospitals for consumptives, 1 of which has been established by the State. The combined capacity of the 5 hospitals is about 350 beds. The State of Massachusetts appropriated \$150,000 for the establishment of its hospital.

Illinois has 1 hospital for consumptives in operation, and 2 projected—all in Cook county. The 3 will have a combined capacity of about 500 beds.

Colorado has 3 private sanatoriums for pay patients.

Maryland has 1 hospital for poor consumptives with a capacity of 100 beds.

Ohio has 1 hospital for poor consumptives with a capacity of 100 beds.

North Carolina has 2 pay sanatoriums for consumptives.

Alabama has 2 sanatoria for consumptives, 1 for pay patients and 1 for consumptive prisoners of the State.

New Mexico has 3 small pay sanatoriums for consumptives, and 1 large one projected.

Connecticut has 1 small pay hospital for consumptives.

Pennsylvania has 3 tuberculosis hospitals with a combined capacity of about 120 beds, and nearly $\frac{1}{2}$ of these beds are in wards of general hospitals, supported by the Free Hospital for Poor Consumptives.

Other States.—Sanatoriums for consumptives have been projected in New Jersey, Ohio, Minnesota, Michigan and Rhode Island, and probably in many other States. Rhode Island has under consideration a bill appropriating \$200,000 for a tuberculosis hospital.

The contagiousness and the prevention of pulmonary tuberculosis are as certain as that the hospital treatment of the poor afflicted with this disease is at once the scientific and the humane way of preventing the spread of the disease. The late Professor J. M. DaCosta, shortly before his death, wrote:

"The lot of the consumptive poor is indeed a terrible one. Constantly losing strength and power; feverish and in distress; shut out from hospitals because their accommodations do not permit them to receive any large number of cases likely to be of very long duration, because, too, it is now recognized that it is not fair to others to admit into the wards what will be a source of infection; shunned and neglected, and ever growing weaker, while yet obliged to labor incessantly for the daily bread of himself and family—the poor consumptive is the most pitiable figure in our midst. Help him where you can; labor for him."

EDITORIAL ECHOES

A New Light on Pernicious Anemia.—The *Medical Press* is very enthusiastic over what it considers a great discovery made by Dr. W. Hunter. This is that pernicious anemia is a septic affection, the poison being derived from the suppuration about the teeth or in the mouth and its dependencies. The poison passes into the stomach where it sets up a special form of gastritis, finally resulting in peripheral neuritis and blood-disturbances.

Cyclic Albuminuria.—The *Medical Record*, epitomizing the researches of Drs. Hawkins and Sutherland, says:

"It is certainly in some degree curious that after all these years of investigation a more accurate knowledge of cyclic albuminuria has not been attained. At present no one knows with certainty whether it is physiologic or functional or tending toward organic change in the kidney. It is self-evident that the subject is of the very first importance, and its final settlement would take rank almost with the greatest medical discoveries of this or any age."

Osteopathy vs. Massage.—"Whatever is of value in osteopathy is massage; in spite of their denials the osteopaths are simply masseurs, but using their methods with an ignorance and presumption that is liable to make their manipulations perilous in some of the graver cases they too often venture to treat. It speaks ill for the scientific culture and general intelligence of the country that such palpable pseudoscience as the utterances of the Still propaganda should find so many dupes."—[*Jour. Am. Med. Assoc.*, April 6, 1901.]

Postgraduate Study, the *Journal of the American Medical Association* thinks, may be justified by the present state of medical education, and that the postgraduate medical schools constitute a poor comment on our system of education. Such study should be rendered unnecessary by rapidly raising the general standard of undergraduate work. The *Journal* urges that kind of postgraduate study which fits one for the task, as Sir Michael Foster says, "of inquiring after new truths, of grappling not with the known but with the unknown."

Forced Feeding Follies.—The physician who undertakes to give a patient the "Rest-Cure" should be endowed with a fair amount of common sense and judgment. He must study the individual as well as the technique of his treatment, and keep in mind the fact that not all of his patients can be subjected to the same routine * * *

A patient who has spent 3 months under mismanagement, discharged with a 2 or 10-pound gain, perhaps, who suffers from indigestion and autoinfection, and is still a broken-down neurotic, is an unprofitable advertising agent who might have done the physician much credit, and saved the reputation of the "Rest-Cure," if a more careful study had been made of individual requirements. * * *

There is much folly in forced feeding.—[*Northwestern Lancet.*]

The South African Hospitals Question.—The alleged abuses, says the Royal Commission (of England), do not constitute anything in the nature of a scandal. "The undermanning of the Royal Army Medical Corps," says *The Practitioner*, "has been the main cause of such failure in the medical arrangements," but "this is not the whole truth. The real responsibility for the deficiency of medical officers must rest on the military advisers of the Secretary of State for War, who apparently out of mere caste prejudice have systematically snubbed and starved the service regardless of possible consequences. It is to them that the responsibility must be pushed home. If Mr. Burdett-Coutts would help us in doing this, he would be doing better service to the country than by striving to upset the findings of a commission of competent and impartial men because they were led by the force of evidence to the conclusion that his sensational descriptions conveyed a false impression of the state of things. The fact is that it is so long since we have had personal experience of a great war that the plain, unvarnished tale of its inevitable horrors came upon us with an appalling shock. The British public has got to realize that war is, as the American general said, simply hell. But Mr. Burdett-Coutts apparently expected it to be a kind of game in which those who were hurt were to be sprayed with rose-water and fed on chocolate creams by smart ladies who found a new sensation in playing the part of ministering angels."

AMERICAN NEWS AND NOTES

GENERAL.

"American Journal of Nursing," is the title of a new periodical under the direction of Miss Sophia F. Palmer, of Rochester, N. Y., published monthly by J. B. Lippincott, Philadelphia.

Alexander Agassiz, of Cambridge, Mass., has been elected president of the National Academy of Science. He succeeds Dr. Wolcott Gibbs, of New York, resigned. The term of the president is 6 years.

Grip is reported as prevalent in Agana, Island of Guam, from advices dated March 14, and many native children and adults are dying from the effects, mainly because of the existing ignorance among the natives of the necessity of caring properly for the sick.

Appointment Revoked.—Owing to the development of tuberculosis following grip the appointment of Brigadier-General William Ludlow to be military governor of the department of the Visayas has been revoked and he will return to the United States.

Crusade Against Mosquitos.—The sanitary department of Havana in its campaign against mosquitos, it is stated, purpose planting eucalyptus trees in all the marshy and malarial districts in and around Havana, and \$1,000 have been appropriated for that and for buying seeds.

Sanitary Treaty.—Argentine and Uruguay have entered into an alliance of sanitary protection against plague and other infectious diseases. It provides for mutual inspection and quarantine sufficient to protect either country from invasion of disease from the other without any undue interference of commerce.

To Introduce the Metric System.—The main subject discussed at the annual meeting of the American Meteorological Society, was the introduction of the Metric System into this country. The society decided to use its influence to promote its adoption. Dr. Seaman read a paper on the use of this system by physicians and pharmacists.

Minnesota State Medical Society.—The *St. Paul Medical Journal* urges all physicians in that State who are eligible to membership, but who are not members of the State Society, to apply for membership at once, so that when the American Medical Association meets there in June every reputable physician in the State may feel himself one of the hosts of the occasion.

Typhus Fever situation in Mexico is reported improving owing to good rains, and Consul-General Barlow at the City of Mexico has telegraphed the State Department his opinion that there is no reason for quarantining against that city on account of the disease. He reports that for the week ended May 1 there were 53 deaths from it, mainly among the very poor and about the same number for each of the 2 preceding weeks.

Yellow Fever (2 cases) is reported at Havana and the order of the Secretary of the Treasury, suspending the quarantine regulations until May 15, has been revoked. These regulations which go into effect immediately require certificates of immunity from persons coming from Cuba to the United States through southern ports, and 5 days' absence from Cuba on the part of persons coming from that island through northern ports.

Photographs in Surgery.—To obviate the difficulty experienced by students in surgery in securing satisfactory instruction in practice, because during an operation the surgeon is too absorbed to teach, it is suggested that a series of photographs shall be taken illustrative of the important stages of surgical procedure and used as a basis for a course of lectures that shall embrace all the common operations and also the remarkable and exceptional ones.

Anticigaret Law.—Bills prohibiting the sale, presentation of, or bringing into the State, of cigarets, cigaret paper, or any substitute thereof have been passed by the Lower Houses in both Illinois and Michigan. In West Virginia the new law of imposing a tax of \$100 on all dealers has become operative May 1. In Pottsville, Pa., cigaret smoking is so prevalent among the schoolboys that the authorities have concluded to enter suit against all dealers found selling cigarets to boys under 16.

Dead Soldiers from the Philippines.—The transport Logan recently brought the bodies of 250 officers, soldiers, and civilian employes, who died or were killed in the Philippines. Of this number 102 have been claimed by relatives, 8 will be buried by request in the Presidio cemetery, and 4 in the Arlington cemetery. Seven unknown bodies, and 34 of men who died

of smallpox, will also be interred in the Presidio, and the remainder will be buried there if not claimed by relatives within a short time.

A Case of Typhoid.—The investigation of the relationship between typhoid and the consumption of raw vegetables carried on by the Department of Agriculture is stated to lead to the conclusion that the prevalence of such diseases at certain seasons of the year may often be traced to the eating of raw vegetables that are grown near cities, on soil fertilized by refuse from sewers and by other city offal. The danger from this source is considered important enough to call for the sterilization of such fertilizing matter by oil of vitriol, or the sterilization of the raw vegetables by washing them in a 3% solution of tartaric acid, and then rinsing them in pure water.

Lack of Quarantine Facilities.—The attention of the Marine-Hospital Service has been called to the lack of quarantine facilities of the Central and South American ports. A case is cited of the steamer Chili which, having yellow fever aboard, was turned away from port after port on the west coast of South America. They were not allowed to secure medicines, disinfectants or medical attention. After a number of deaths had occurred from the disease, the vessel reached Valparaiso, and after a careful inspection the passengers were allowed to land after being imprisoned on the ship for 1 month.

Dental Surgeons in the Army.—Of the 14 candidates appearing before the Examining Board of Dental Surgeons of the United States Army, only 2 received appointments: Siebert Davis Boak, of West Virginia, and Edward Clarence Lauerdale, of New York. The Board expressed disappointment in the qualifications of the young men who presented themselves, believing the examination to have been fair. It has been officially announced that before an applicant can secure a position as Dental Surgeon in the Army he must pass examinations in the following: Histology, anatomy, physics, chemistry, metallurgy, physiology, dental anatomy and physiology, dental pathology and bacteriology, dental materia medica and therapeutics, oral surgery, orthodontia, theoretic operative dentistry, theoretic prosthetic dentistry, practical and operative, and practical prosthetic dentistry. In the theoretic examination 75% is required in each branch, while in the practical 85% is the passing limit.

Obituary.—ROBERT W. GREENLEAF of Boston, April 28, aged 46. THOMAS CONRAD PORTER, Professor of Botany and Zoology at Lafayette College, Pa., April 25, aged 79. WILLIAM WALLACE WELCH in Quincy, Ill., April 25, aged 80. JOHN T. THOREN of Chicago, April 29, aged 36. S. G. DORR of Buffalo, N. Y., April 28, aged 61. C. A. BLACK of Bay Verta, N. B., April 29. POLK WATKINS of Hattiesburg, Miss. JACOB A. SHERMAN of Plainfield, N. J., April 29, aged 81. WILLIAM F. CRIGHTON of Alexandria, Va., May 2. IRVING C. ROSSE of Washington, May 3, aged 54. DAVID H. BARTINE of Merchantville, N. J., May 3, aged 59. JOHN THRUSTON of Louisville, May 2, aged 75. HAROLD SNOWDEN of Alexandria, Va., May 4, aged 55. CHARLES Q. COCKE of Roanoke, Va., May 4, aged 83. CHARLES D. COVERNTON of Toronto, Can., April 28, aged 88. W. D. JESSOP of Pittsburg, Pa., May 2, aged 32. E. HUMPHREY of Akron, O., May 4, aged 50. H. S. PELTON of Oakland, Cal., at Nome, Alaska, in January. N. F. BANKS of Opelika, Ala., May 1, aged 70. SAMUEL K. LYON of New York City, May 4.

Smallpox in New York City is reported as having a stronger foothold than at any time since last November. More than 80 cases were reported to the Board of Health in the first 3 days of this month, and recently there were 30 cases in 1 day. Dr. Dillingham reports that in the hundreds of cases not one patient has been vaccinated in recent years. Two steamers from Italian ports, one from Marseilles and one from Hamburg, have had cases of smallpox in the steerage. In New York State the monthly bulletin of the State Board of Health reports the existence of the disease in 19 municipalities. An investigation is being made of a reported epidemic of it at Newark, N. J. A case has been discovered in the Camden county jail, and it is reported, May 7, epidemic in Gloucester City, where it has existed for 2 weeks scattered through the city and was diagnosed as chickenpox. New cases are reported from Hagerstown, Md., and from Pendletonville, Greenville, Lufkin and Navasato, Texas, from Hickman, Huntingdon, Crossville, Tenn., and from Florence, Ala., and a very serious epidemic which is spreading exists in Snohomish county, Washington, as no effort has been made to check the disease and no quarantine on affected persons has been established. In each of the towns of Wallace, Sultan and Monroe, there are from 50 to 75 cases. The matter has come to the notice of authorities and an effort will be made to check the advance of the scourge. An epidemic of smallpox is also reported in a township in Vanderburgh county, Indiana, among the farmers. In Hampton, N. H., the order to vaccinate all children who have not been vaccinated is meeting with opposition, and it is considered a very arbitrary measure on the part of the State Board of Health. In Ontario, Canada, many new cases are reported from scattered localities, and the outlook for freeing the province from smallpox or for preventing new cases is discouraging, owing to the fact that in so many of the back townships where the disease has been most active the majority of the people have never been vaccinated.

EASTERN STATES.

The Eastern Maine Insane Hospital, located at Bangor, will probably be ready for occupancy by June 1.

Yale Medical School.—An unknown benefactor has donated \$100,000 for a new building and the contract for it has been awarded at \$96,000.

The New Jersey State Board of Health is obliging New York physicians to obtain a license to practise in New Jersey if they practise on the New Jersey side of the Hudson river.

A Newark Midwife.—Mrs. Charlotte Bergmann will receive a medal from the City Clerk to commemorate the fact that she has assisted in introducing nearly 5,000 infants into the world.

A Hospital Donation.—In memory of his 2 grandsons, J. Howard Wright has offered to give the sum of \$10,000 to the Muhlenberg Hospital authorities to assist in the erection of a new hospital in Plainfield, N. J.

Inveterate Drunkards.—A study of the records of 140 inebriates committed to the House of Correction on Deer Island, Boston Harbor, between July 1 and December 31, 1900, showed that on an average each had been committed to that institution at least 15 times.

To Prevent Typhoid.—The Board of Health of Worcester Mass., are taking action for the investigation of the sanitary condition of towns bordering on the streams which constitute the water-supply of that city, to guard against conditions similar to those which have been in evidence in New Haven, Conn.

Dr. James Sanford, of Bennington, Vt., has practised medicine in Rutland County for more than 60 years, and although he will soon celebrate his eighty-fifth birthday, there is scarcely a day when he does not make a professional call on from one to a dozen patients. Who is the oldest actively practising physician in the United States?

The Abuse of Cattle in Transportation has been the subject of a complaint to Governor Odell from a resident of Evans Mills, N. Y. It has resulted in the notification being sent throughout northern New York that it is unlawful to keep livestock in transit without food for more than 24 hours and that a test case in prosecution will be made at the earliest opportunity.

A Medical Society in Fletion.—In an entertaining address delivered before the Fairfield County (Conn.) Medical Society recently, the President, Dr. L. T. Day, of Westport, discussed the fact that William Dean Howells had founded one of his novels, "Dr. Breen's Practice," upon a decision made by the society in reference to consultation between homeopaths and the regular school.

Charitable Bequests.—According to the will of the late Matilda Goddard, of Boston, Mass., \$30,000 is to be distributed among a number of charitable institutions. The bulk of this amount (\$20,000) is given to the Gwynne Home for Destitute Children. Among those mentioned for small bequests are the New England Hospital for Women and Children and the Homoeopathic Hospital, each to receive \$300.

The Smoke Nuisance.—The Massachusetts Committee on Cities will report the bill of Representative Gale of Natick which provides that the emission into the open air of dark smoke or dense gray smoke for more than 2 minutes continuously, or the emission of such smoke during 12% of any continuous period of 12 hours within quarter of a mile of any dwelling, except under a license granted as herein provided, is hereby declared a nuisance.

Bacteria in Modeling-clay.—M. O. Leighton, Health Inspector of Montclair, N. J., declares that he has found bacteria to be quite abundant in clay that has been used and reused for modeling in schools. An attempt to sterilize the clay showed that the only efficient way of accomplishing this was by the use of superheated steam under a pressure of 15 to 20 pounds for 45 minutes. The species of bacteria identified were those which occur in pus-formations. Sterile clay was then inoculated with the bacilli of typhoid, diphtheria and tuberculosis. A study of the clay showed the typhoid germ to be alive after 32 days and the diphtheria and tubercle to be still alive in 18 days.

Society for Prevention of Consumption.—At a complimentary dinner given to Dr. William C. Bissell, Bacteriologist of the University of Buffalo, the suggestion was made by Dr. Benjamin G. Long that organized work ought to be done for the suppression of consumption. Dr. Bissell favored the motion, and every doctor present agreed the idea should be carried out. They decided on the formation of a Society for the Prevention of Consumption, the principal function of which would be the spreading broadcast of information concerning tuberculosis. Dr. Long was made chairman of a committee appointed to effect an organization; it is believed that Buffalo and Western New York will derive much benefit from the new society.

NEW YORK.

Dr. Heinrich Stern has been elected Professor of Internal Medicine in the New York School of Clinical Medicine.

The Geneva City Hospital has been freed from debt amounting to \$7,200 by the gift of Thomas C. and Joshua J. Maxwell.

Dr. Roger S. Tracy, registrar of the Bureau of Vital Statistics, who has been connected with the New York Board of Health longer than any other now in its service, has resigned his position.

Charitable Bequest.—Mrs. Elizabeth R. Grafton of New York has left by will \$10,000 to the Sheltering Arms and \$10,000 to St. Luke's Home for Indigent Christian Females of the Protestant Episcopal Church.

Diphtheria in Horses.—A disease which veterinarians have diagnosed as diphtheria is said to be prevalent among the horses of farmers living between Geneseo, N. Y., and Cane-sus Lake. It is of a severe form, proving fatal in every case.

The Medical Aspect of Heredity is the subject of the address which will be delivered by Prof. J. George Adams, of McGill University, Montreal, under the auspices of the Brooklyn Medical Club, May 17, 1901, 8 p. m., in the Medical Library Building, 1313 Bedford avenue.

Protective Organization.—An association to protect physicians from bogus malpractice suits is under consideration in New York City, the County Medical Association having referred the matter to executive committees. It is said that blackmailing schemes of this kind to extort money from medical and surgical men are numerous.

Buddhist Dwarfs.—Two professional actors, a sister and brother from Burnah, of Indo-Chinese origin, arrived recently in New York. Smaura, the brother, is 18 years old and 19½ inches in height, and Fatma, the sister, 19 years old and 20½ inches in height. They are perfectly and symmetrically developed and are bright and intelligent.

Nonintoxicating Drinks in Saloons.—Senator Raines has introduced a bill to compel holders of liquor tax certificates which entitles them to sell liquor to be drunk on the premises to have also for sale in like manner the nonalcoholic beverages milk, coffee, tea, cocoa and chocolate which, on demand of the buyer, shall be served hot or cold as may be desired, in the same place and manner as intoxicating drinks are sold.

Health Authorities in a Dilemma.—The Bureau of Contagious Diseases, of the Health Department of New York, has recently been besieged by tenants and landlords. The former claim that, owing to contagious disease in their homes, the landlords wish to dispossess them. Frequently the landlords have paid the expense of moving in order to get a stricken family out of their premises. This, of course, but spreads the infection. On the other hand, the landlords claim that some families are using similar pretenses as excuses for not paying the rent.

Zoological Park Pathologist.—Dr. Harlow Brooks, pathologist to Harlem and Montefiore Hospitals, has been appointed pathologist to the New York Zoological Park. In creating this position the New York Zoological Society has defined the attendant duties: "To make regular visits to the park, to examine into the hygienic condition of the animals and to recommend such treatment and to make such autopsies and microscopic studies as will advance the knowledge of the prevention and treatment of the diseases incidental to captive animals." A laboratory will be at his disposal and by systematic bacteriologic examinations it is anticipated that the knowledge of animal diseases and their causes will be greatly enhanced.

The Medical Society of the State of New York, at the ninety-fifth annual session held at Albany, January 29, 30 and 31, 1901, unanimously agreed that each County Society should be allowed to send 5 times the number of delegates it had formerly sent to the State Society. These delegates are elected for a term of 3 years, and are eligible for permanent membership if they register twice during that time. This will make the number of delegates from the County Societies to the State Society 750 in all, or 1 delegate for every 8 or 9 members of County Societies, without increase of expense to the County Societies. It was further agreed that a semiannual meeting shall be held in the New York Academy of Medicine, New York City, October 15 and 16, 1901, for scientific work and social intercourse. Members wishing to read papers are requested to communicate with Dr. Nathan Jacobson, 430 South Salina street, Syracuse, New York; and information of any other nature can be obtained from Dr. Frederick C. Curtis, Secretary, 17 Washington avenue, Albany, New York, or from Dr. Frank Van Fleet, Associate Secretary, 63 East Seventy-ninth street, New York City. Tickets of admission to a reception which will be given by the Society to its members, delegates and guests on the evening of October 15, at Delmonico's, will be furnished without cost to all who register at the semiannual meeting, as well as to the Society's guests.

PHILADELPHIA, PENNSYLVANIA, ETC.

Medico-Chirurgical Hospital.—The trustees of the Medico-Chirurgical College have asked the State for an appropriation of \$334,000 to complete improvements now under way, and to erect new necessary buildings.

Sugarcoated Pills.—William H. Warner, whose death recently occurred in Philadelphia, was the first to introduce licorice tablets into the drug trade, and was also one of the pioneers in the introduction of the sugarcoated pill, though not the very first. Bullock & Crenshaw's sugarcoated pills were introduced some months before those of the Warner make.

A Plea for Poor Consumptives.—Dr. Lawrence F. Flick, of the Free Hospital for Poor Consumptives, has issued a circular letter asking the public cooperation in an effort to get a State appropriation of \$110,000 for the tuberculous poor of Pennsylvania. He states that there are about 5,000 of this class in the State—probably $\frac{1}{4}$ of all the sick poor—and they are excluded from the general hospitals. A letter written to Hon. Ward R. Bliss, Chairman of the Appropriation Committee, and Hon. William A. Stone, Governor of Pennsylvania, urging them to give support to the bill, will probably largely influence the making of this appropriation.

College of Physicians.—Abstract of the monthly report of the honorary librarian, Library of the College of Physicians of Philadelphia, April, 1901:

Books, pamphlets and journals received:

General Library,	447	volumes	806	pamphlets	3415	journals
Lewis Library,	11	"	0	"	0	"
S. D. Gross Library,	1	"	0	"	0	"
	459		806		3415	

Accessions, 378 volumes. Duplicates, 81 volumes.
Donors, General Library, 67.

The college has acquired, by purchase, the valuable and perhaps unique collection of books and pamphlets known as the "J. Stockton Hough Library," about 3,000 volumes, valued at \$8,000.

SOUTHERN STATES.

Dr. L. H. Stick has been appointed resident physician of the Baltimore City Hospital.

Leprosy.—In Baltimore 2 cases of leprosy are reported, both the victims being women, one of whom is isolated, the other at large.

An Army Appointment.—The President has appointed Dr. Percy L. Jones, of Nashville, assistant-surgeon with the rank of captain.

The College of Physicians and Surgeons of Baltimore, has announced that 61 young men have successfully passed the final examinations.

Insanity and Divorce.—A bill has been introduced into the Florida Legislature asking for a repeal of the recently enacted insanity divorce law.

Compulsory Vaccination.—A bill before the Florida Senate and House to enforce and compel the vaccination and revaccination of citizens and residents of the State, was attacked and finally postponed indefinitely.

Retired.—The withdrawal of Dr. James B. McGaw of Richmond, Va., from practice after 57 years of active service was marked by manifestations of the deep esteem in which he is held by his professional associates.

The Triple State Medical Association, composed of members from Ohio, Kentucky, and West Virginia, was organized in Ashland, Ky., on April 18. Dr. Lester Keller, of Ironton, O., was elected President of the Association.

Dental Abnormality.—A citizen of Baltimore, aged 78, recently cut 3 new teeth in his lower jaw. They grew to such a length that he broke them off to prevent their lacerating his tongue. His teeth had never troubled him and he had never been in a dentist's chair.

To Drain New Orleans.—At a recent meeting, the Drainage Commission of New Orleans expressed its intention to complete at an early date, the system whereby all New Orleans will be thoroughly drained. A resolution was also adopted promising cooperation if the city would make the attempt to establish and operate its own electric light system.

Salt Sickness.—This disease of cattle is considered one of the greatest drawbacks to the Florida stock business and in response to a petition of the State Convention of Stockmen to the State Legislature to request the Government to investigate it, Victor A. Norgard, representing the United States Bureau of Animal Industry, has been sent to Florida to study the disease.

A Garbage Disposal System has been adopted in Washington whereby the food refuse becomes a valuable commodity and the contractors, urged by consideration of profit, require of their employes faithful collection from all houses, as every pound of it has a distinct value. The commissioners have been wise enough to make no exception to the rule that all garbage shall be collected by the contractors.

The Indigent Insane.—Coroner M. V. Richard, of New Orleans, proposes a plan to care for the insane poor until the city or State could take charge of them. His idea is to raise a fund by means of 20 public-spirited citizens contributing each \$100 toward that end, and heads the list with his own contribution, followed by that of a nameless friend. The scheme is under the consideration of the Prison Commission of that city. The secretary of the board intimates that the favoring of such a plan would establish a bad precedent.

Insane Delusion no Defense.—Great interest is excited at Paris, Texas, as to what decision will be rendered in the case of Solomon Hotema, arrested for killing alleged witches. The majority of the physicians who examined him as to his sanity declared him insane and stated he was suffering from an insane delusion when he committed murder; they therefore argue he should not be held morally or legally responsible for his acts. The prosecution contends that insane delusion is no defense, that when a man reasons the law demands that he reason correctly. The case of Charles J. Guiteau, who was tried and executed for the assassination of President Garfield, is cited as an example.

Dr. Irving C. Rosse, who died in Washington, May 3, was born on the eastern shore of Maryland about 54 years ago of one of the oldest families in the State and of Scotch descent; for 20 years he has occupied a prominent position in medical circles. He was the author of several textbooks on medical jurisprudence and neurological diseases and of many pamphlets on special nervous diseases. He had held official positions in important medical societies in Great Britain, Germany and Austria, as well as in this country; served as a surgeon in the United States Navy for about 10 years and was a member of the Jeanette Relief Expedition. Owing to his familiarity with every phase of insanity he was called upon to serve as expert witness on the Guiteau trial, the Bean murder trial, that of Benjamin Snell and the Howard Schneider trial.

WESTERN STATES.

Dr. C. R. Holmes, of Cincinnati, has been elected president of the Western Ophthalmologic and Otolaryngologic Association.

Glanders.—Despite precautions, this disease seems to spread, and 65 horses of the Ninth Cavalry at the Presidio have been shot.

Dr. Kate Post Van Orden has been appointed a member of the Board of Health of Alameda, Cal. This is the first time a woman has served on any official board in this city.

Hospital Donation.—John E. Dubois, of Pennsylvania, has presented to the Dunham Medical College of Chicago \$1,000,000, as an act of appreciation for the benefits received by his wife while a patient in that institution.

Leprosy.—The case of a young man afflicted with leprosy for 5 years has been discovered by the Rush Medical College, Chicago, and is being investigated by the physicians there. About 19 years ago he had spent 2 years in the Sandwich Islands.

Measles prevail among children and adults in Portland, Oregon, and are reported as an epidemic in Spokane, Wash., in Two Rivers, Wis., and among the members of the Fourteenth Cavalry at Fort Leavenworth; 40 men now in hospital and new cases occurring daily.

Walla Walla Hospital, of Washington, will hereafter be known as the Joseph Conatser Walla Walla Hospital, as Joseph Conatser, who died there recently, has bequeathed \$10,000 to it in consideration of the excellent care he received, provided the name should be changed as indicated.

Medical Inspection of Schools in Chicago, 1901.—Number of pupils examined in January, 15,077; number excluded, 882. Number of pupils examined in February, 18,488; number excluded, 798. The causes of exclusion were chicken-pox, diphtheria, eczema, impetigo, measles, mumps, ophthalmia, pediculosis, ringworm, scarlet fever, tonsillitis, whooping cough, and other diseases.

The Excursion to Yellowstone Park for the members of the American Medical Association seems to be an assured fact, as the Committee on Arrangements has finally succeeded in persuading the officials to open the park a week earlier than usual to accommodate the Association. A special train will be run from St. Paul to Yellowstone Park, and the rates will be very low, but just the amount of charge is not yet definitely stated.

Increased Death Rate Due to Speculation.—The Chicago Health Department, in a report of May 6, attributes an accelerated death rate to the craze for speculating in stocks, the excitement occasioned either by loss or gain having proved fatal to persons more than 60 years old. Of 566 deaths in that city the week before, 124 were persons of 60 or older, an increase of 26% over the previous week, and of 24% over the corresponding week in 1900.

Filthy School Buildings.—The school teachers of Cleveland, Ohio, have entered a protest against the dirty school houses. They say the buildings are never scrubbed, and dust an inch or more in thickness is allowed to settle on the floors; consequently the health of the children is endangered, and a great degree of personal discomfort suffered. The matter will be taken before the school council and an effort will be made to provide the money necessary to have the buildings thoroughly scrubbed at least once a month.

Colonization of Epileptics.—Minnesota claims very restricted facilities for the care of her epileptics. Apart from 145 patients in the hospitals for the insane, and 167 in the school for feeble-minded at Faribault, no provision is made for this class of sufferers. Arrangements are being made for the separate care of 150 epileptics at the Faribault school, and so far as it goes this is admirable but fails utterly to meet the needs of numbers thus afflicted. Influence is being brought to bear upon the State Legislature to establish colonies having their own schools, shops, hospital-chapels, etc., its own interests and industries and in every way separate and distinct from the life about it. This method develops sympathy and helpfulness and does much to overcome the selfish, introspective mood and obstinacy which characterizes this disease.

Foreign Body in the Brain.—A case puzzling the surgeons of Cleveland, Ohio, is that of a man, the victim of burglars, in the St. Clair Hospital with a 32-caliber bullet in his brain which causes him no inconvenience whatever. The bullet struck the center of the forehead near the hair, penetrated the skull, and plunged downward, making a path through a portion of the brain whose function is not well understood. The surgeons have not dared to probe for the bullet, but it is thought to be lodged near this portion, for had it taken another course it would have reached and paralyzed a nerve center. No paralysis of any function has occurred, but a sudden death or an equally sudden attack of insanity would not be altogether unlooked for. The patient is kept in bed with difficulty, as, feeling as well as he does, he does not understand why he should be restrained from going to his work.

Association of American Medical Colleges.—The next regular meeting of this association will be held at the Hotel Ryan, St. Paul, Minn., June 3, 1901. It will consist of 2 sessions, an educational session and a business session. The educational session will be opened at 2 p. m. by the President's address followed by several papers of medical pedagogic interest. To this session all persons interested in medical education are respectfully invited. The representatives and associates of the Association of Southern Medical Colleges have received a special invitation. The members of the Confederation of State Examining and Licensing Boards are also invited. There will also be an exhibition of work done in medical colleges. At 8 p. m. the business session will be held at which the amendments to the constitution proposed by several colleges will be considered. The report of the judicial council, the election of members and the election of officers for the succeeding year will close the program.

CANADA.

Winnipeg General Hospital shows by its annual report that 2,849 patients have been treated there the past year. A deficit of \$4,510.50 is due to an outbreak of smallpox within its walls early in the year.

A Metric Association.—The work begun by the Canadian Government to prepare the people for the adoption of the metric system is being extended by Lieutenant-Colonel Burland, of Montreal, by the formation of a metric association.

Dominion Medical Council.—A bill has been introduced for a medical council for the whole Dominion of Canada, providing that each of the 7 provinces and the North-West Territories shall have each 3 members on this board—in all 24 regular physicians. As there are some homeopaths who are represented on the Ontario Medical Council these will also be allowed 3 members on the Dominion Board who shall be elected by themselves.

Tuberculosis.—A law which became operative June, 1900, in Quebec, provides that every householder in that province, in whose house there occurs a death from tuberculosis, shall notify the local Board of Health within 48 hours, and upon the event of such notification the municipality is obliged to have the contaminated apartments disinfected. Official statistics show that the death-rate in Quebec City from tuberculosis is 1.99 per 1,000 of the population; that of Ottawa is 3.12, of Montreal 2.87, of Kingston 2.17, of Toronto 2.41, and of London 2.67.

FOREIGN NEWS AND NOTES

GENERAL.

A Serious Famine affecting 11,000,000 population is spread over the Shan-shi province, China.

Fever is Reported as committing frightful ravages in the Delagoa Bay district of Portuguese East Africa, where in the last 3 months there have been 500 deaths.

Famine in Siberia.—Famine has overtaken the greater portion of Siberia, and the suffering is terrible. Scurvy, diphtheria, and typhus fever are likewise ravaging the country.

Plague.—From Cape Colony, under date May 3, Sir Walter F. Hely-Hutchinson, the Governor, has telegraphed to the Colonial Secretary, England, that the total of deaths from plague up to April 27 was 217. This number includes 41 Europeans. If the cases at Mafeking which present plague symptoms are embodied in the report the total of cases would number 519, including 105 Europeans. A case of illness has occurred at Galata, the largest suburb of Constantinople, which is announced officially to be bubonic plague.

Malarial Fever.—The etiology and prophylaxis of this disease occupied 2 sessions of the Hongkong branch of the British Medical Society during the winter, and 4 means of prevention were outlined as adaptable there: the destruction of breeding places by repairing drains, the use of kerosene, the use of mosquito nets and the use of quinin. The quinin given in the manner recommended by Koch was used among the local police stationed in the new territory, and these men enjoyed marked immunity although stationed in malarial districts.

Plague.—Advices from Cape Town report fresh cases of the plague, and a resistance on the part of the Malay population to have patients removed from among them. Near Sialkote, India, a serious riot occurred, due to plague inspection of women, and a force of cavalry was summoned to quell the disturbance. Plague has broken out in an Australian asylum in which there are 1,000 inmates, and is reported at Brisbane, Perth, Adelaide and 1 case at Sidney was introduced on a troopship from Cape Town. The destruction of rats has been going on steadily.

Extermination of Rats.—According to Dr. Nagusha, a prominent Japanese bacteriologist, now a visitor in Chicago, who has made a study of the plague in Hong Kong, Bombay and in his native country, Japan has made an exhaustive investigation of the role played by rats in the spread of disease and that nation may appeal to civilization to wage a war of extermination on these most active of all propagators of contagious diseases. In the opinion of some this may be taking a step in the dark, as the rat is a scavenger and in the economy of nature is supposed to fill its place.

Medical Study for German Women has not met with the approval of the authorities. Until quite lately very few of the courses were open to women and those who did undertake medical study, whether at home or in Switzerland, were not permitted to take the State examinations giving license to practise. Of late some concessions have been granted, however, and the German daily papers announce that the first State examinations for women have been recently passed by Fraulein Mathilde Wagner at Freiberg University, and by Fraulein Democh at the University of Halle, both graduates at Zürich. Fraulein Martha Wygodzinski has passed recently the first physician preliminary medical examination that has ever been given to a woman at Berlin University.

Obituary.—HENRY VEVERS, of Hereford, England, April 5, aged 80. JAMES MARE TAYLOR, of Burslem, England, April 12, aged 57. JAMES WILDING, of Bristol, England, aged 41. GEORGE STONE, of Liverpool, April 21, aged 52. WILLIAM MOORE, of Dublin, Ireland, April 17, aged 67. JAMES BAMPFYLDE, of Bath, April 22, aged 36. JOHN BARCLAY, of Summerplace, S. W., April 17, aged 81. ARTHUR W. OGLE, at Charleston, Natal, April 19, aged 48. MICHAEL KEMBLE-TEBY, of Surrey, England, at Manaus on the Amazon river, S. A., March 25. EDWIN THOMAS WATKINS, of Cambridge-gardens, Wales, April 21, aged 76. RICHARD PRIOR WINTLE, of Oxford, April 16, aged 61. THOMAS WILSON, of Scarborough, England, aged 82. GEORGE FLEMING, of Combe Martin, Devonshire, England, April 13, aged 68. HORMAH RUBITSA, of Merida, Yucatan, April 24. Prof. KOHLSTOCK, in Tientsin.

Sanitation of West Africa.—A deputation on the sanitation of West African coast towns from the Chambers of Commerce of London, Liverpool and Manchester and the Liverpool School of Tropical Medicine, were received recently at the Colonial Office, Liverpool. The points submitted included proposals that the governments of the various colonies on the west coast of Africa should be invited to prepare schemes, with estimates, for the organization of sanitation in the coast ports of

regions occupied permanently by any considerable number of Europeans, especially with regard to disposal of refuse, drainage, removal of native huts when menacing health, and the institution of sanitary regulations for observance by the public, and at the same time the appointment by the Colonial Office of a sanitary commissioner to visit all the colonies and report to the Secretary of State the condition of each one and the measures of improvement taken by the local authorities; and that where new settlements are being planned, quarters for Europeans shall be arranged on the Indian cantonment model, and strict measures taken to prevent the overcrowding of these by the general public. In reply, it was stated that these subjects were receiving the careful consideration of the Government, but the question of cost was a serious one. It was proposed that the 3 chambers of commerce should each appoint one of their number to be a member of a committee of sanitary inspection, and that a representative from the Colonial Office should accompany it, and in addition they should have a scientific expert whom the 3 gentlemen should nominate. If the deputation accepted that view, the Colonial Office would refer to this commission certain questions, the first and most important being the sanitation of the colonies and its cost.

CONTINENTAL EUROPE.

Typhoid Fever in an epidemic form has broken out in several of the forts and villages in the neighborhood of Metz. The Eighth Bavarian regiment is reported to have 281 men sick with the disease and 16 have died.

Typhus in South Russia is reported as increasing among the village population of Bessarabia, due to famine arising from failure of the last harvest. Owing to lack of forage 70% of the farmers have lost their horses, and they lack seed for the spring sowing.

A Cooking School for Doctors under the management of Frau Hedwig Heyl is said to be in operation in Berlin and more than 100 prominent physicians from France, Russia, Italy and Germany have already taken the course. Branch schools are to be operated in other European capitals.

Long Skirts.—A campaign has been opened against trailing skirts by the medical profession of Munich, and in Dresden a similar movement is afoot, and it is reported that a Committee of the Town Council has ordered the police to fine any woman appearing in the streets with trailing skirts.

The Stuff Whereof Dreams are Made is reported to have been discovered by M. Vergson, a professor at the College de France, who claims that the circulation of the blood in the retina and the pressure of the eyelid on the optic nerve causes a color-sensation and the colors assume phantom shapes, which stir the memory.

The Discoverer of the Laryngoscope, Señor Mannel Garcia, is now 96 years old. He was a singing master, and in 1854 he presented a paper to the Royal Society of London, entitled, *Physiological Observations on the Human Voice*. His observations were carried out upon himself by the aid of 2 mirrors, essentially the same as now used by laryngoscope.

Camillo Golgi, Professor of General Pathology in the University of Pavia, has been unanimously invited by the medical faculty of the University of Turin to fill Dr. Bizzozero's vacant chair. His great work in histology, his studies in malaria and his reputation as Bizzozero's most distinguished pupil were recommendations not found united in other candidates.

Preliminary to Medical Course.—The German Government has been petitioned by the *Medicinische Gesellschaft* and 70 other medical societies to require a classical training as heretofore as a preliminary to a course in medicine. An effort is being made to prevent the graduates of the technical schools from being admitted to the medical course without further training.

Prof. Koch, of Berlin, who for several years has been studying various infectious diseases in other countries, has been called back to Germany to undertake the study of some serious epidemics of typhoid fever which have been prevailing in East Prussia during the past year. The investigation will be carried out in conjunction with Prof. Flügge, of the University of Breslau.

Röntgen Rays.—L. Benoist has announced to the Paris Academy of Sciences the law that the capacity of substances for Röntgen rays depends on their atomic weight, the greater this weight the higher the capacity. It is not affected by temperature, being the same for ice as for water, and is independent of atomic arrangement and chemie combination, and depends only on atomic weight.

Influenza in Germany.—Deaths from influenza seem to be very common in Germany, or else the causes of death are incorrectly reported. Influenza was first mentioned as a cause of death in the Kingdom of Prussia in 1859, in the last 2 months of which year 314 persons died from this cause. In 1892 the maxi-

mum number thus far reported in 1 year was reached, with 15,911 deaths. Of late years the number has been considerably smaller, amounting to 77,282 deaths in the past 10 years, however.

University of Berlin.—Dr. Fedor Krause, who has recently come to Berlin from Altona to take charge of the Surgical Clinic of the Augusta Hospital, has just been appointed *ausserordentlich Professor* in the University of Berlin. Dr. Krause is known in America from his operation (also suggested independently by Hartley of New York) of excising the Gasserian ganglion by the temporal route, and his exhaustive paper on joint tuberculosis. He was a pupil of Volkmann at Halle and before he was called to take charge of the surgical clinic at Altona, in 1892, he was for 3 years a professor at the University of Halle.

The Needle Swallower of St. Germain.—The Paris papers report the interesting case of a nurse maid, aged 16, named Julienne Landrieux, who since 11 years of age has given exhibitions of swallowing sewing needles. An apothecary of St. Germain-en-Laye has removed 120 needles from various parts of her body during the past 3 months, and according to the girl's estimate there should be several hundred still left in her body. She visited the Salpêtrière clinic, where her case was considered unique, but refused to enter the hospital, preferring to have the needles removed by her apothecary by means of a magnet and forceps.

Doctors Protest.—The sick funds in Leipsic have so lowered the doctor's fee that many of them have arisen in protest. These sick funds supply physicians to attend their members at a reduced nominal and inclusive fee. The doctors found their regular patients grow less as the sick funds increased. Some physicians had treated so many as 100 cases a day and received but 7 marks (\$1.75) in payment. For their protection they organized committees and quarrels arose between the representatives of the sick funds and these committees, resulting in the strike of the physicians. They have the sympathy of their brother doctors throughout Germany.

Antialcohol Congress.—In a report read before the Antialcohol Congress, opened at Vienna, April 9, Dr. Koerber, the president, stated that Austria paid twice as much for drink as it did for its army, that 50% of the lunatics in their asylums and 60% of their criminals owed their downfall to the use of alcohols, and that 50% of the children were in the habit of using strong drink. Dr. Meimert, of Dresden, said the mortality among medical men addicted to the use of alcohol and morphin, was greater than any other profession, and that drink was even a worse enemy to women than tight-lacing. Professor Forell held that the Boers of South Africa were better able to endure the hardships of war because of their almost total abstinence. All the governments, with the exception of England, were represented at the Congress.

Improved Milk Supply.—One of the largest examples of an extensive milk-supply station in which the production of milk is dealt with scientifically, both as regards hygiene and economy, is that of C. Bolle, in Berlin, who supplies milk at the rate of 7,000,000 gallons to about 50,000 families. This firm supplies milk, cream, milk from a special farm for infants, sterilized milk, Kefyr machine-skimmed milk, buttermilk, butter and cream cheese obtained from 130 farms with their 14,000 cows which supply the central establishment. Special officers supervise these farms, and the control and observation of the health of the cows is allotted to 4 veterinary surgeons. With the exception of the milk which comes from one of their own farms all the milk received is subjected to an improved Pasteurizing process which they claim does not interfere with the taste or chemical composition of the milk, but destroys all pathogenic microbes. The central station is furnished with a bacteriologic laboratory, a chemical analytic laboratory and a chemical technic laboratory. In 1899 over 30,000 tests were made in the chemical analytic laboratory alone, and 1,500 guinea pigs were used in the bacteriologic laboratory, mainly in testing for tuberculosis.

GREAT BRITAIN.

Cost of Vaccination.—The Falmouth Board of Guardians reported April 19 that the cost of vaccination by them during the past 12 months has amounted to £527.

Measles and Chickenpox should be removed, it was decided, from the schedule of diseases notifiable under the Infectious Diseases Notification Act, at a late meeting of the Dartmouth Town Council, England.

Smallpox has been introduced into Nottingham among the Mormons there by letters, it is thought, from Salt Lake City, and this outbreak has been the means of spreading the disease through a Mormon conference held in Nottingham to 6 other places; though in single cases only.

Smallpox.—The new cases admitted to the Glasgow Hospital are being steadily reduced. The total under treatment in hospital on April 17 was 185. Since the beginning of the outbreak there have been 1,720 cases and 222 deaths. At Newcastle,

England, 23 cases of smallpox from 9 households have been reported. Smallpox is reported at Cardiff, Wales, and the sum of fourpence has been offered for every rat caught within the sanitary district there.

Exclusion of American Beef.—The report that the English Government intends to depend exclusively for 6 months on homebred beef for the British Army supplies after the beginning of June has been confirmed by the British War Office. This new rule applies only to refrigerated beef, of which the total weekly supply for the army is only 200,000 pounds; this is barely 2% of the weekly imports of refrigerated beef into England from the United States.

Destruction of Rats on Ships.—Some successful trials have been made recently in England for this purpose, with an apparatus for extinguishing fires which generates and floods the hold with sulfurous dioxide gas (SO₂). This gas, being much heavier than air, diffuses slowly, and experiments show that the rats retire before it, and when the hold is opened they are found dead at the highest parts near the exit pipes, an important point, as in other methods they might die in inaccessible places. The only ill effect noticed was the tarnishing of the gilding.

SOCIETY REPORTS

XIX GERMAN MEDICAL CONGRESS.*

HELD AT BERLIN, APRIL 16, 17, 18, 19, 1901.

The Nineteenth German Congress for Internal Medicine met in Berlin April 16-19, inclusive. The sessions, 7 in number, were of considerable interest as may be seen by a glance at the program. Unfortunately the limited time allowed the presentation of but 48 of the 70 papers announced. About 450 physicians were present.

FIRST SESSION.

Address of the President of the Congress, PROF. SENATOR (Berlin) reviewed the progress in internal medicine during the nineteenth century, and showed that it was in the sphere of diagnosis that the advance was most marked. As evidence of this he contrasted the very extensive exhibition of scientific instruments in the adjoining rooms with those in use at the beginning of the century, the entire collection of which the physician could carry to the bedside with him. But has the progress in the treatment of disease been comparable to that in its diagnosis? He answered that the period following the revelations of pathologic anatomy during which time physicians despaired of the efficacy of their treatment has been followed by one extending over the past 25 years during which the advance in therapeutics has been very great. This has been due to the development and application of the scientific methods of studying diseases, allowing deeper insight into their nature and recognition of their earlier stages. The treatment of the parasite diseases, myxedema, locomotor ataxia, of tuberculosis especially, the use of antitoxic serums, and the advances in the sphere of prophylaxis, were cited as some of the most striking illustrations of the progress made in the treatment. He reminded his hearers of the value of symptomatic treatment and of the danger of treating the disease well but the patient poorly.

The President then greeted the Honorary Guests, Dr. Von Cöler, Physician-in-chief of the German Army; Dr. Plstor (Berlin), of the Prussian Ministry, and others.

Prof. Naunyn (Strassburg), chairman of the committee in charge, then read the official notices.

General Topic, Cardiac and Vasomotor Therapy.—(Mittel.) GOTTLIEB (Heidelberg) considered the question from the point of view of experimental pathology—any disturbance of the circulation results in a pathologic distribution of the blood. To restore to normal this distribution is the office of cardiac and vasomotor drugs, and the choice of a drug should be governed by the cause producing the disturbance. In vasomotor paralysis of central origin such as occurs in acute infectious diseases, following chloral, alcohol, and other narcotics there results congestion in the splanchnic area, anemia in the brain and peripheral vessels; the pulse is small, the heart feeble. The proper drug in such a case would not be a cardiac stimulant since the heart lacks not ability to work but blood to work upon, but a drug causing vaso constriction in the splanchnic area, thus furnishing the heart with blood to pump into the anemic areas, thus restoring the distribution to normal. Such drugs are strychnin, caffeine and camphor. Local cold is also an effective measure. These drugs differ considerably in their action; strychnin, e. g., dilates the vessels of the brain and skin.

Cardiac Stimulants increase the ability of the heart to do its work, the pulse volume is increased, the overdistended veins are relieved and more normal distribution of blood

*Specially reported for AMERICAN MEDICINE by DR. CHAS. P. EMERSON with grateful acknowledgment of indebtedness to PROF. EWALD, editor of the *Berliner Klinische Wochenschrift*, for his assistance in the preparation of this report.

results. Of these drugs **digitalis** is most important, and its introduction was justly considered by Kursmanl to equal in importance that of vaccination. G. described carefully the therapeutic and toxic stages of the action of digitalis. In the therapeutic stage the increase in work done by the heart is the important factor; its action on the vessels (constriction) less so; the pulse becomes slower, the blood pressure rises. G. then described the experiments upon the hearts of warm-blooded animals performed during the past 2 years, both by the method of isolating the heart (*überleben des Herz*) and by cutting the peripheral vessels out of the circulation. In the latter case the carotid artery and jugular vein on the right side were united; a manometer was connected with the left carotid; the aorta was then tied. In such an animal all vasomotor phenomena were excluded since the pulmonary vessels do not respond to such stimuli. He showed blood-pressure tracings from such experiments showing the work done after digitoxin was increased 3 or 4 times. This, G. claims, is the result of stronger contraction of the ventricle which thus empties itself more perfectly—the absolute strength of the heart is not increased, but it uses its strength to better advantage. It is aided somewhat by the stimulation of the vagi, causing a slowing of the pulse, allowing better filling of the heart. The result to be striven for by the use of digitalis is therefore a moderate slowing of the pulse allowing complete filling of the ventricle during diastole, followed by a complete systole. All substance resembling digitalis in action produce also some vasoconstriction. G. described his experiments to prove this point. Therapeutically this action is favorable, although of minor importance, but when extreme may, by increasing the peripheral resistance to too high a point, burden the heart considerably. He then briefly considered other drugs.

Camphor not alone is a vasomotor but a direct cardiac stimulant increasing its irritability, tiding it over crises as was beautifully shown in one chart exhibited. It has little effect on the normal heart.

Caffeine also is a direct cardiac stimulant but by no means a substitute for digitalis as some French writers claim. On the isolated heart its action is much less marked. It increases the ability of the heart to work against pathologic resistance and may be of use in conditions associated with increased arterial pressure. It shows no action by normal blood pressure.

Alcohol has no direct cardiac action unless in large doses in which case it is directly toxic, but in smaller doses it favors the heart's action by producing vasodilation thus diminishing peripheral resistance, and as a specific vasomotor drug is of value in heart cases where the increased arterial pressure prevents complete emptying of the left ventricle. In conclusion he emphasized the value of experimental pharmacology clinical medicine by discovering the reason for the pathologic blood distribution and indicating the proper drug to restore this to normal.

2. SAHLI (Bern) considered the above topic from the clinical side. In the introduction of his paper he emphasized the point that in the future the physician should study the disturbances of function rather than limit himself to pathologic anatomy as was the tendency at present, since in the former field was more to be gained than in the search for specific remedies. After the exact diagnosis of the disturbance in function had been made the treatment should then be directed with a view to restore the normal functional conditions. It was from this point of view that he approached his subject, the general pathology and diagnosis of disturbed function in the different congestions of the circulation with respect to the indications for cardiac and vasomotor stimulants. The result of disturbed function is always a congestion of blood somewhere in the vascular system. He separated (1) **Cardiac congestions** resulting as well from insufficiency of the heart's systole as from disturbance of its diastole. (2) **Respiratory**, from diseases of the respiratory organs and intrathoracic exudates. S. believes this group really is a subdivision of the first. (3) **Vasodilator congestions** from paralysis of the smaller vessels of the greater circulation. The cardiac congestions were further subdivided according to the arterial pressure into those with **high tension** and those with **low tension**. S. described at length the congestion of the splanchnic area which is important since there may be no external symptoms and in its early stages is often overlooked. He pointed out the importance of, in all these congestions, recognizing the incomplete as well as the complete picture, since in either case digitalis may be indicated. He discussed at length the use of digitalis, which he considered had the same importance in a physician's practice as Sydenham had claimed for opium. He emphasized the point, however, that its proper use was, in itself, considerable of an art. It is indicated in cases of very slight congestion, and in many cases the best results from its use are not obtained, since the physician prescribes it too late. In the congestion with high arterial tension it is not contraindicated, since it not only removes the congestion, but diminishes also the pressure. It is contraindicated in but one type of congestion that in extreme noncompensated valve disease where the muscle-strength is exhausted. In many cases the heart drugs are combined with advantage. He considers the dangers of long-continued use of digitalis overestimated; cumulative action need be feared only when the case is poorly watched; with careful attention digitalis can be prescribed for

long periods of time, thus prolonging the patient's life for years. The curative action of digitalis, that is, the fact that its beneficial results continue even years after its use is discontinued, S. explains by saying that the drug breaks the *circulus vitiosus* produced by the effect of the congestion upon the heart's muscle itself. Digitalis forces the heart to greater activity, thus improving the coronary circulation. He next mentions the factors hindering the action of digitalis, one of the most important of which is *essential* congestion, as opposed to that resulting from disturbed compensation. By essential congestion he understood one due to a cause which cannot be compensated for even though the heart had very good muscular power and the systole perfect; such a condition as may result from extreme insufficiency of a valve. The action of digitalis in such a case is insufficient and transitory. Failure to recognize essential congestion has resulted in incorrect ideas concerning the difference in the action of digitalis in the various valve lesions. S. does not believe that the difference in the results of the use of digitalis in lesions of different valves is based on the hydraulic relations of the valve, but that the cases of aortic insufficiency after years of comfort come to treatment with the condition of essential congestion and many complications.

In discussing dosage S. distinguished large doses which affect both systole and diastole, and small doses affecting systole alone.

Then followed a brief discussion of other drugs. **Caffein** and **camphor** have clinically little if any action on the heart but are valuable in congestion due to vasodilation. They aid also by improving respiration and the former by its diuretic action. **Alcohol** lightens the work of the heart by diminishing peripheral resistance, but owing to its only transitory action cannot be relied upon as the only drug in high tension congestion. S. considers alcohol useless in circulatory disturbances of infectious diseases since its action on the vessels is similar to that of the toxin of the disease, but it is valuable in the chills during fever and after exposure to cold. In conditions of collapse also alcohol is not useful except the condition be one accompanied by normal or high pressure. **Ether** has an action similar to alcohol. Mention was also made of **atropin**, **strophanthus**, et al. Combinations of cardiovascular drugs were recommended and also the necessity of applying all useful therapeutic measures of whatever nature in the treatment of the case.

SECOND SESSION.

Discussion on the Preceding Two Papers.—This discussion was of special interest since so many took part, and the points were so thoroughly debated.

SCHOTT (Nauheim) claimed that it was not easy to separate vasomotor and cardiac stimulants—the essential thing is to stimulate the heart which will, when more forcibly contracting, arouse the vasomotor nerves to action. The latter are a subordinate factor.

JACOB (Cudowa) discussed the question why digitalis has so little effect in severe aortic insufficiency. He thought that the heart had already exhausted its strength and was therefore unable to respond to the added stimulus.

LANG (Marienbad) considered the poor preparations and the deterioration from age, especially of the infusion, responsible for many cases where digitalis apparently fails. He recommends combining alcohol with digitalis.

HEINZ (Erlangen) reported animal experiments which showed the finely powdered digitalis is more efficient than the coarsely ground leaves.

GOLDSCHIEDER (Berlin) believed in long-continued administration of small doses of digitalis, *e. g.* 0.1–0.2 gms. daily for months. In cases with frequent breaks in compensation the doses should not be suddenly stopped but gradually during weeks diminished. He considered digitoxin worthy of more extensive use.

HIRSCH (Leipzig) reported his experiments in conjunction with **BECK** upon the **Viscosity of the Blood and the Clinical Importance of its Determination**. Viscosity and specific gravity do not always run parallel. The former depends on the serum as well as the corpuscles. When fluid flows through a tube the central portion moves fastest, the peripheral portions in contact with the tube not at all; hence the fluid moves through a tube of its own substance, and its viscosity depends on its nature (the fluid's) and the temperature. Former investigators made the mistake of using defibrinated blood. Hirsch and Beck had studied the viscosity of the unchanged blood, its relation to food, to temperature, but especially to changes in the heart's muscle. The cardiac hypertrophy in nephritis is seen in the right ventricle as well as the left; its cause must be either a directly increased stimulation of the heart's muscle or an increase in the viscosity of the blood.

EWALD (Berlin) mentioned the importance of relieving the congestion in the vessels before the digitalis can exert its best effect. To accomplish this it is useful to remove, by puncture or scarification, the fluids in the tissues. He exhibited a rubber apparatus introduced by **Dehio** (Dorpat), and recommended it for this purpose. Ewald emphasized the fact that after all heart drugs gastric disturbance may follow, even when the same are given per rectum. **Adonis vernalis** cannot replace digitalis. He has often seen digitalis manifest the desired action only when preceded by morphia. The latter he considers a very valuable drug in heart disease.

PICK (Prag) stated that the vasoconstriction following the use of digitalis results in a diminution of edema. He recommended **hydrastis** as a good drug to constrict the peripheral vessels.

UNVERRICHT (Magdeburg) emphasized the importance of the preparation of digitalis. He recommended preparations made from digital. grandiflor. as richer in digitotoxin than those from digital. purpur., and considered the **Golaz dialysate** excellent, since it could be considered to have a constant content of the glucosid. Best of all he thought was digitotoxin. He could not recommend long continued use of digitalis, but thought what a short course of the drug would not accomplish could not be accomplished. He characterized the results of long use as digitalismus, and considered the gastric symptoms, present also after administration of the drug per rectum as of central origin.

ROSENSTEIN (Leyden) recommended **strophanthus** as next in importance to digitalis. He had used it with excellent results. Also it can be used in smaller doses than digitalis and without the gastric disturbances. Camphor, since its effects are so transitory, is suitable at critical periods. He suggested that **Hirsch** see if the changes in viscosity of the blood could explain the heart murmurs heard in anemia; he doubted that viscosity could explain heart hypertrophy.

NAUNYN (Strassburg) stated that according to his experience the infusion of digitalis was the most reliable preparation. He could not at all recommend digitoxin. He had obtained excellent results from the long-continued use of small doses (0.2 gms. per day) of digitalis, and if proper care were exercised, considered the dangers of digitalismus and the gastric disorders slight.

GRÖDEL (Nauheim) agreed with the last speaker. He had never seen digitalismus either in the sense of a condition comparable to morphinismus, or of a blunting of the faculties.

ROSENFELD (Stuttgart) has returned from the use of digitoxin to that of infusion of digitalis. To continue the effects of a course of digitalis he uses **Adonis vernalis**.

BÄLTZ (Tokio, Japan) recommended the infusion of digitalis. **Strophanthus** he considered next in value. The latter is very serviceable where rapid action is desired. He recommends **Adonis vernalis**.

OTT (Prag) mentioned the fact that digitalis varies according to its source.

The discussion was then closed by short remarks by **GOTTLIEN** and **SAHLI** answering the objections raised in the course of the discussion to points in their papers. **Sahl** repeated the advantage of using all the drugs discussed. **Strophanthus** he had used with good results, but its preparations are inconstant and it can cause diarrhea. He could not consider digitoxin a complete substitute for digitalis.

Testing the Functional Ability of the Heart and the New Points of View Resulting. **SMITH** (Schloss Marbach) determines the size of the heart to test its functional ability. He spoke at length on the causes of the dilation, and mentioned several functional neuroses as results.

The Objective Effects of Modern Heart Drugs on the Cardiac Function. **HOFMANN** (Schloss Marbach) exhibited many charts showing the effects of many drugs on the normal heart, on the pulse and blood pressure (measured with **Gärtner's** tonometer).

Blood Pressure in the Treatment of Chronic Heart Disease. **SCHOTT** (Nauheim) found in the cases where gymnastic treatment was indicated an increase in blood-pressure following the same. (Used **Gärtner's** tonometer.) In cases of arteriosclerosis, advanced myocarditis, aneurysm of the heart or aorta a fall in pressure followed the baths and exercises, proving them contraindicated in such cases.

THE AMERICAN ASSOCIATION OF GENITOURINARY SURGEONS.

HELD AT OLD POINT COMFORT, VA., APRIL 30, MAY 1 AND 2, 1901.

[Specially reported for AMERICAN MEDICINE.]

Address by the President.—**DR. SAMUEL ALEXANDER**, of New York, delivered his address, in which he called the attention of the Association to the death of **DR. FESSENDEN F. OTIS**, a former president of the Association. He then presented the subject "**The Treatment of Intra-peritoneal Traumatic Rupture of the Bladder by Laparotomy and Suture.**" His report consisted of 45 cases, with 23 deaths and 22 recoveries. After taking up the critical examination of the cause of death he considered the etiology. He condemned the routine methods of diagnosis, especially the injection and the inflation tests. Both conditions required operation and he advised that the operation should be begun by exploring the prevesical space, and if this was found to be healthy the incision should be extended upward and the abdominal cavity opened. He advised most thorough irrigations of the cavity with hot normal saline solutions. To effectually close the bladder wound it was not so much a question of the material used as of the manner in which it was introduced. In the case he reported silk was used and the rent was closed by a layer of interrupted **Lempert** sutures and **matrass** sutures.

Report of a Case of Nephrectomy for Adenocarcinoma, with remarks on Combined Cystoscopy and Segregation as a Guide to the Earlier Surgical Intervention.—Dr. JOHN P. BRYSON said that in this case there was only the absence of a vesical symptomatology to justify exclusion of the bladder as a source of the hemorrhage, and this was far from exclusive. A vesical papilloma situated behind and above the trigone may have produced the same kind of manifestation. Urethral and prostatic hemorrhage were easily excluded and the vesical symptoms accompanying the entire hemorrhage were referable to the clotting of blood in the bladder. There was entire absence of a history of renal symptoms during the entire attack. The first satisfactory step in the location of the source of mischief was in cystoscopy. This revealed a normal bladder and 2 normally situated ureteral orifices. While it was true that the injection of the left orifice and the gradual clouding of that part of the cystoscopic field as the observations progressed raised strong suspicion of the source of the bleeding, and while it was equally as true that subsequent and more extended observation might have given more conclusive evidence in the way of a blood spurt when the bleeding was more active, the real and practical value of the cystoscopy was in excluding that viscus as the source of the bleeding and preparing the way for a segregation. Segregation with the Harris instrument was easily and almost painlessly done and gave evidence of the highest value in determining the justification, not to say the necessity, for doing an exploratory operation. In looking at the tables presented he thought that one could easily conclude that (1) the 2 specimens came from the same kidney; (2) the right kidney was functioning normally; (3) the left kidney was the source of the hemorrhage, and (4) the left kidney was in such a state of irritation as to determine a unilateral polyuria, albuminuria, mild bacteriuria and pyuria.

The lower specific gravity, the greater quantity and the amount of albumin out of proportion to the amount of pus and blood, tended strongly to eliminate the ureter and pelvis as the seat of the mischief and thus to carry it quite into the renal parenchyma. It will be noted that no tests were made to determine this epithelial adequacy and the renal permeability; omissions which might today be open to criticism. Of cryoscopy he had not yet had much experience but he instituted a phloridzin test with a lively appreciation of its practical value. In at least 3 cases it had been of excellent service and it was impressed upon him that it is, in connection with the separation of the urines, capable of greatly enlarging our field of direct observations of renal capability. In the effort to determine the relative adequacy and permeability we have been accustomed to give the greater weight the quantity and specific gravity of the separated urines. The ascertaining of the relative fractional capabilities of the 2 kidneys, does not give us all the information required in regard to the kidney which is to remain and do the whole work of excreting. The matter of the relative excretion of urea may have been too much overlooked but we cannot well tell how well a kidney may be doing until we know what the blood brings to it and the antecedents of urea in the blood are, so far as we know, influenced by so many and varying conditions that it is difficult to bring it within a working formula.

The Value of the X-ray in the Diagnosis of Renal Stone: Report of 4 Cases.—Dr. PAUL THORNDIKE, of Boston, made a brief report of these 4 cases, not in order to show beautiful x-ray plates of kidneys containing calculi, but because the cases were studied by the same people under the same conditions and show results partly negative in character, which he deemed of enough interest to justify their presentation. It seemed to be true that stones which contained mineral salts are much more readily photographed than others, and yet 2 of these cases were made of layers of uric acid and in both distinct shadows were evident, while in 1 of them the stones were shown with considerable clearness, probably due to the admixture of urates in the former and of calcic phosphate in the latter case. It would seem that there was something to expect from x-ray photography in connection with the diagnosis of renal stone, for in those cases, even when there is every clinical reason for thinking that a stone, if present, is composed of uric acid, it evidently needs only a small amount of urates or some other mineral salt to give a shadow which, although it does not show for much on the plate, is still capable of being recognized with some degree of precision by properly experienced observers.

Rupture of the Urethra: A Report of Cases.—Dr. JAMES R. HAYDEN, of New York, stated that the treatment of rupture of the urethra was either operative or non-operative, depending upon the nature and extent of the injury. If there is a marked hemorrhage from the meatus, with complete retention of urine or difficult and painful urination and bloody urine, associated with difficulty or inability to enter the bladder with instruments, and also if there is a fluctuating perineal tumor with perhaps a rise of temperature, then immediate perineal section and bladder drainage are indicated. If, on the other hand, hemorrhage is slight, urination free but somewhat painful, the urine tinged with blood or containing light, bloody flakes, and catheterization normal, except perhaps causing some pain at a local spot, which feels slightly roughened or thickened, and little or no perineal tumefaction, then catheterization, irrigation and urinary antiseptics should be resorted to, with rest in bed, and the first sign of urinary extravasation looked for, in which event external urethrotomy with vesical drainage should be resorted to. Partial suture of the urethra must always be

employed in cases of complete rupture, in which the divided ends of the canal are widely separated, otherwise it is not essential.

Inversion of the Tunica Vaginalis for Hydrocele.—Dr. R. H. GREENE, of New York. He stated that within the last 10 years a new operation for the radical cure of hydrocele had originated in France, and its use was being advocated by a large number of surgeons at the present day. About 1 month ago he had operated upon a patient by this method, which was as follows (according to the description by Winklenan): "Incision down to sac of hydrocele. Incision of sac $\frac{3}{4}$ cm. long from above downward, more toward the upper than the lower pole. After the hydrocele fluid has escaped, the testicle is drawn completely out, so that the entire tunica vaginalis is turned inside out. The incision in the tunica then comes in relation with the insertion of the spermatic cord into the testicle, which incision may be shortened by a suture or two so that the testicle cannot return through the opening in the tunica. The tunica and testicle are replaced in the scrotum with the result that the entire serous surface of the tunica vaginalis proper faces toward the loose connective tissue of the tunica vaginalis communis, with which it may soon become fused, the testicle lying outside the tunica, between the tunica and the scrotal wall. This bloodless operation is concluded by closure of the external wound in the scrotum. In the majority of cases the testicle is dislocated upward as the result of the operation." Drainage is not required. The only complication mentioned by any writer is "a slight periorehifc swelling, due probably to the saturation of the loose connective tissue interspaces with the secretion of the serous membrane, and which may persist for some time." This operation can be performed for double hydrocele by means of a single scrotal incision, followed by an incision through the membrane separating the 2 sides of the scrotum.

A Case of Unusual Bacillus or Abnormally Behaved Gonococcus.—Dr. J. P. TUTTLE, of New York, related the case of a patient, 50 years old, who gave a protracted history of urethritis and who was taken with symptoms of a severe cystitis, and who discharged large quantities of pus and mucus in the urine. No results were obtained from inoculation experiments. In culture experiments a mixed form of coccus, similar to gonococcus but resembling more the diplococcus found in cerebrospinal meningitis, was found. It differed from the gonococcus in that it was rapidly destroyed in an acid media but thrived in an alkaline one.

Partial Excision of the Bladder and Urethra for Carcinoma.—Dr. TUTTLE reported this case of cancer of the rectum which involved the urethra, the prostate and possibly the wall of the bladder.

Clinical Observations in Syphilis.—Dr. JOHN A. FORDYCE, of New York, had recently seen gangrene of the initial lesion in a patient who presented no phimosi or paraphimosi, who was not addicted to alcohol and who was in good health. During this process the induration disappeared only to return upon cessation of the process. Chlorinated soda solutions he had found to be rapidly beneficial, probably due to the penetration into the tissues of the chlorine which was set free. The cure was facilitated by the use of iodoforn. Certain forms of lichen planus may readily be mistaken for the popular or papulo-aquamous syphilide, as in a case reported by him there were grouped papules with circinate or gyrate outlines having a pigmented center and surrounding areas of pigmentation. This resembles in a very striking manner the relapsing syphilide. He related a case of a patient in whom a very careful examination showed a pronounced thickening and exquisite sensibility of both ulnar nerves and atrophy of the muscles of the ball of the left thumb. These conditions together with the eruption which one would not expect to encounter in syphilis pointed strongly to lepra, an opinion which was confirmed by the presence of lepra bacilli in a piece of tissue excised from one of the infiltrated patches. Mercury administered intramuscular, caused a disappearance of the eruption. Crocker and others have noted a rapid disappearance of leprosy nodules after intramuscular injections of mercury.

A Case of Prostatectomy.—Dr. JAMES BELL, of Montreal, cited this case which was of interest because of the atrophy of the testicle 50 years before operation and the demonstration at the time of operation that practically the whole of the prostatic enlargement was in the left side of the prostate and, therefore, the Bottini incision could not have had any effect upon this enlargement.

What I Have Learned from 161 Operations for the Relief of Benign Hypertrophy of the Prostatic Gland.—Dr. ORVILLE HORWITZ, of Philadelphia, read this paper. The various operations he performed were classified as follows:

Vasectomy.—Twenty-eight cases with no deaths. The results obtained lead him to make the following conclusions: 1. As a curative measure vasectomy is of little value, and is not to be recommended. 2. The operation appears to be most effective when performed on patients between 50 and 60 years of age, in whom the prostatic enlargement is of the soft glandular variety. The genital organs of patients of this age are usually in a healthy condition, and the individuals usually object to any operation that is liable to interfere with their sexual functions. 3. The operation is serviceable in those cases where the physical condition of the patient renders him unfit to undergo surgical procedure, who will not submit to a mere serious proceeding, who has to depend upon the frequent use of the cath-

eter, or who suffers from periodic attacks of orchitis. 4. Sexual vigor is not diminished by the division of the vasa deferentia. 5. Atrophy of the testicle does not result from the operation.

Castration.—Forty-four cases, 2 deaths. The following deductions he thought were warrantable: 1. In selected cases, bilateral castration will always hold a place in genitourinary surgery as a means of removing the obstruction caused by prostatic hypertrophy. 2. The operation is indicated in men of advanced years, whose sexual powers are lost, the overgrowth of the prostate being glandular in character, or who have reached that period of life where the passage of a catheter becomes difficult and retention of urine not uncommon, or if advanced disease of the bladder and kidneys does not preclude a serious operation. 3. The primary effect of castration on the glandular prostatic hypertrophy is first to relieve congestion, and secondarily to cause atrophy. 4. When the prostatic enlargement is fibrous in character no benefit is derived from the operation, and the employment under these circumstances is not to be recommended. 5. Orchidectomy in very old subjects with extensive disease of the bladder and kidney is attended by a large mortality, and is a very serious operation.

Suprapubic Cystotomy.—The indications for a suprapubic cystotomy in prostatic hypertrophy may be summarized as follows:

1. When retention exists, and it is found possible to evacuate the urine by the usual methods that are employed for the purpose. 2. As a temporary palliative means in those patients who have reached the "break-down part of catheter life," whose resisting powers have disappeared, and who suffer from secondary involvement of the bladder and kidneys, and whose condition is such as to preclude the resorting to any more serious operation, but require immediate relief from the symptoms caused by the obstructing prostate gland. 3. In feeble old men, in whom the enlargement of the prostatic growth is fibrous in character, which renders the introduction of a catheter difficult, and the passage of the Bottini cautery knife impossible, in whom there is long-standing chronic cystitis, with probably diseased kidneys, which precludes a prostatectomy, suprapubic cystotomy may be selected as the least dangerous and most satisfactory operation which can be employed.

Prostatectomy.—His conclusions he summarized as follows: 1. With the exception of ligation of the internal iliac arteries, prostatectomy is the most dangerous of any operation that has been recommended for the relief of prostatic obstruction, due to hypertrophy. 2. Suprapubic prostatectomy is the safest method, especially if combined with perineal drainage. 3. The best period to select to perform this operation is early, before the breakdown of catheter life and serious complications have supervened. 4. Either an atonied or contracted bladder of long standing, associated with chronic cystitis, attended by the formation of sacs or pouches, are contraindications for the operation. 5. A partial prostatectomy is indicated in those cases where a valve-like lobe exists, which interferes with urination, or where there is partial hypertrophy of one of the lobes. 6. A complete prostatectomy is indicated where a hypertrophy of the 3 lobes has taken place, especially if the condition is associated with tumor formation, projecting well back into the bladder, or has given rise to a stenosis of the prostatic urethra. 7. Perineal prostatectomy is best suited in those cases where the enlargement of the lateral lobe has a tendency to grow toward the rectum or obstruct the urethra. 8. When performing a perineal prostatectomy, the semicircular incisions advocated by Pyle, or the transverse cut of Nicoll is the most satisfactory. 9. The removal of a portion of a small, hard fibrous prostate gland by means of the perineal route is a very difficult operation. There is danger of not only extirpating the entire gland, but the prostatic urethra as well.

Bottini Operation.—From the results obtained by the experience that he recorded in his paper, he felt warranted in forming the conclusions as follows: 1. Success following the Bottini operation depends on having perfect instruments, a good battery, the necessary skill, and the employment of a perfect technic. 2. In suitable cases the Bottini operation is the safest and best for the radical cure thus far devised for the relief of prostatic hypertrophy. 3. It is often very efficacious in advanced cases of obstruction as a palliative measure, rendering catheterism easy and painless, relieving spasm, lessening the tendency to constipation, and improving the general health. 4. It is of special service in the beginning of obstructive symptoms due to hypertrophy of the prostate gland, and may be regarded as a means of preventing catheter life. 5. It is indicated in all forms of hypertrophy, except where there is a valvular formation, or where there is an enormous growth of the 3 lobes, associated with tumor formation giving rise to a pouch, both above and below the prostate gland. 6. Where the bladder is hopelessly damaged, together with a general atheromatous condition of the blood vessels, associated with polyuria, results are negative. 7. Pyelitis is not a contraindication as a resort to operation. 8. The character of the prostatic growth has no bearing on the results of the operation.

Some of the Conditions Following the Bottini Operation for Prostatic Obstruction.—Dr. L. BOLTON BANES, of New York, brought out the following points which he considered of importance: 1. The muscular impediment which almost immediately followed the removal of the instrument. In order to overcome this difficulty he had made a series of metal cath-

eters patterned after the Trendelenberg searcher, with solid tips in order that the instrument may be sterilized. 2. The process of repair, as witnessed with the cystoscope, begins and proceeds as under ordinary aseptic conditions. A specimen removed from one of his patients was then shown which demonstrated that the grooves made had immediately relieved the mechanical obstruction. It was his opinion that the spontaneous urination which followed the operation was due, not only to the formation of the grooves, but to the contraction of the cicatrices and to atrophy of the gland tissue. 3. The decided necessity for after-treatment. Patients usually come for treatment with chronic catarrh of the prostate, seminal vesicles, bladder and urethra and the after-treatment in these cases should be continued until all the foreign material has disappeared. Out of 42 cases he had 3 deaths. His explanation for these deaths was "bad judgment in operating." A parenchymatous prostatic abscess existed in 1 case and this could not have been diagnosed. In another instance death occurred in an old man who insisted upon the operation.

Officers.—President, Dr. W. T. Belfield, of Chicago; Vice-President, Dr. Paul Thorndike, of Boston; Secretary, Dr. James R. Hayden, of New York; Member of Council, Dr. William K. Otis, of New York. Next place of meeting, Atlantic City.

AMERICAN GASTROENTEROLOGICAL ASSOCIATION.

FOURTH ANNUAL MEETING AT WASHINGTON, D. C., MAY 1, 1901.

[Specially reported for AMERICAN MEDICINE.]

Syphilis of the Liver.—Dr. MAX EINHORN reviewed the literature covering liver disease in connection with syphilis. Up to the seventeenth century the impression prevailed that ulcers of syphilitic origin were the result of bad humors of the body. A review of the pathology of this condition was made, together with a report of 34 cases. Hepatic syphilis was grouped under gummatous, syphilitic cirrhosis and syphilitic disease accompanied by icterus. In a certain case a patient was cured by treatment with sodium iodid and inunctions of mercury. Syphilis of the liver could be absolutely diagnosed when gummatous are present. Gummatous are easily mistaken for malignant neoplasms. Pain is present in the right hypochondrium, constant or spasmodic, sometimes simulating gallstone colic. There are disturbances of digestion with loss of weight, the organ is found swollen. Later there may be evidences of amyloid degeneration; the spleen is not always enlarged; treatment, potassium iodid or sodium iodid, and like preparations. The hygiene of the patient should be well looked after.

Discussion.—J. C. HEMMETER thought the paper was a classic, systematizing as it did so much valuable literature in one article.

Dr. EDWARD QUINTARD reported a case of a small tumor with absence of polymorphonuclear neutrophiles. He believed that Dr. Einhorn's treatment was good.

It seemed to Dr. LICHTY as if, in the diagnosis, one would have to fall back on the therapeutic test. He likewise believed in the iodids and the antiluetic treatment.

Dr. HEMMETER said that out of 3 cases of syphilis of the liver that came under his notice, there was 1 in a man who, instead of having supposed tuberculosis of the lung, had suffered from gumma of the lung which had torn the bronchial tube.

The German Clinics of Today.—Dr. J. C. HEMMETER was of the opinion that every physician should familiarize himself with the *modus operandi* of the disease and its influence on the patient. The study of the patient is paramount. He went over the different processes in the German clinics. He thinks it necessary that there should be established in this country a journal dealing principally with dietetics, medical treatment, and clinical, experimental and pathologic research.

Discussion.—Dr. QUINTARD thought the suggestion a timely one, and Dr. EINHORN spoke of the necessity for a closer study not only of scientific methods, but of curing the patient. Dr. AARON likewise endorsed the proposition.

Dr. HEMMETER's idea is that the paper shall find its birth in this society.

In the absence of the authors, the following papers were read by title: **Etiology of Hepatic Sclerosis**, Dr. A. L. BENE-DICT; **Treatment of Gastric Ulcer**, Dr. D. D. STEWART; **The State of the Gastric Secretion in Chronic Rheumatism and Rheumatoid Arthritis**, Dr. FRANK H. MURDOCH.

Spastic Ileus.—Dr. EDWARD QUINTARD, said that spastic ileus is not so rare as is supposed. The similarity between the spastic and mechanical forms was brought out well, as well as the methods of differential diagnosis. In 2 of his cases there had not been fecal vomiting. He believed in a pathologic antiperistalsis, and related certain cases to prove that such was the case. While he thought that the theory of Hagenet explained many of the cases of fecal vomiting in mechanical ileus, he likewise believed that the theory of antiperistalsis came very nearly covering the ground in spastic ileus.

Discussion.—Dr. ROSE wished for a better understanding of the pathologic condition of the splanchnic nerves. Warm water

and opiates, together with the inflation of the rectum with carbonic acid gas, were remedial measures of merit. With the latter he had good results in dysentery and pertussion.

Some Cases of Tetany.—WILLIAM GERRY MORGAN gave an intelligent exposition of the etiologic factors and referred to the dehydration theory. Tetany is an affection characterized by tonic and occasionally clonic spasms in the hands, arms, forearms, legs and feet, and in dangerous cases, neck, face, larynx and body. He distinguished epilepsy from gastric tetany and reported several cases of interest.

Discussion.—Dr. ROSE remarked that one would find in English literature a great many cases reported in connection with dilation of the stomach. In speaking of compensation in dilation of the stomach, he said that compensation may fail and then there are symptoms of acute dilation.

Report of 2 Cases of Acute Dilation of the Stomach.—Dr. JULIUS FRIEDENWALD. (This will be published in a future issue of AMERICAN MEDICINE.)

Discussion.—Dr. HEMMETER spoke of a case which was operated on for gallstone, and inspection of the stomach revealed that it was normal. After the patient died the stomach was found to be enormously distended.

Dr. EINHORN said that the cases were very interesting, but he should certainly think that they ought to be termed as acute dilation.

Dr. FRIEDENWALD believed that there were but few authentic cases of dilation.

The following papers were read by title in the absence of the authors: **Experiments in Peristalsis**, Dr. FENTON B. TURCK; **Some Clinical Studies in Gastric Secretion**, Dr. G. W. McCASKEY; **Report of a Case of Cancer of the Cardiac End of the Esophagus at a Distance of 21 Inches from the Incisor Teeth in a Man 5 Feet and 3 Inches Tall**, Dr. C. D. SPIVAK. (This will appear in a future issue of AMERICAN MEDICINE.)

Dr. A. ROSE.—**Treatment of Atonia Gastrica and Splanchoptosis by Means of Abdominal Strapping.** Dr. ACHILLES exhibited to the Society the bandage which he used as an abdominal support. He believed that "a number of pathologic conditions of the stomach are caused by insufficient activity of its muscular fibers, diminished activity of its walls, elongation of the suspending ligament of the lesser curvature, the lesser omentum and gastropoptosis." He used the word "gastropoptosis" in place of "gastroptosis." As to causes, hernia, tumors of the spleen and liver and enlargement of the abdominal space were mentioned; also the injurious effects of "tight-lacing, and the tight attachment of skirt-strings aggravate an existing gastroptosis." He had examined 100 patients to ascertain the phenomenon.

Discussion.—The bandage was not successful in the hands of Dr. LICHTY, while Dr. HEMMETER said that the bandage as mentioned by Dr. ROSE "had the advantage of grasping the whole abdomen," and of lifting it up, and, in his opinion, was the best contrivance he had yet seen.

Dr. EINHORN said that there were a few cases in which there was difficulty, but in most instances a bandage could be made well, and the advantage is that the patient can take it off at night. Strapping the plaster on the skin irritates it. He believed that the bandage was more efficacious.

Hyperchlorhydria.—Dr. JOHN A. LICHTY said that indigestion of diet is not given as a causative factor; in the majority of cases suffering from digestive disturbances there is marked hyperacidity. Out of 225 cases 84 were analyzed and found to contain more than a normal amount of acid.

Dr. HEMMETER presented some interesting microscopical specimens, the most interesting perhaps being that of a case of arteriosclerosis in a boy of 10 years.

ELECTION OF OFFICERS.—President, Dr. W. D. BOOKER, Baltimore; first vice-president, Dr. S. J. MELTZER, New York; secretary and treasurer, Dr. CHARLES D. AARON. Dr. MAX EINHORN was elected as a member of Council to serve for 3 years.

ASSOCIATION OF AMERICAN PHYSICIANS.

16TH ANNUAL MEETING HELD AT WASHINGTON, D. C., APRIL 30, MAY 1 AND 2.

[Specially reported for AMERICAN MEDICINE.]

President's Address.—WILLIAM H. WELCH, of Baltimore, called attention to the opportunities enjoyed by students for acquiring a systematic training in anatomy, pathology and physiology as compared with those that were open to them in clinical medicine and surgery. The laboratory side of their teaching had advanced from the weakest to the strongest position in medical education. The conditions in regard to the branches referred to were somewhat like those prevailing in the German Universities. The American schools were only at the beginning of this process of development, but it was gratifying to notice that the path had been opened, and the lines on which they were advancing clearly marked. Much less satisfactory conditions existed with regard to the far larger number of students who wished to fit themselves for clinical medicine and surgery. In short, the training of physicians had not kept pace with that of those who intended to devote themselves to the more purely scientific branches of education connected with

medicine. Dealing with matters more particularly affecting the association, he alluded to the pressure on its doors for admission to membership and expressed approval of a suggestion thrown out by one of his predecessors that, instead of increasing the number of active members, a freer use might be made of the honorary list. In concluding his remarks, Dr. Welch referred to the fact that the association had lost by death during the year 4 of its founders, 3 of whom had filled the presidential chair, Dr. JAMES T. WHITTAKER, Dr. JACOB DaCOSTA, Dr. SAMUEL C. BUSEY and Dr. WILLIAM H. DRAPER, to the memory of each of whom he paid a fitting tribute.

The reading of papers was then proceeded with, the first being one by Dr. H. A. HARE, Philadelphia, entitled **An Undescribed Cardiac Sound**. A contribution by Dr. ROBERT T. EDES, Boston, on **Slow Pulse with Special Reference to Stokes-Adams' Disease** was read by title, the author not being present. Dr. WILLIAM S. THAYER, Baltimore, discussed the **Frequency and the Diagnosis of the Flint Murmur in Aortic Insufficiency**. Dr. ALFRED STENDEL, Philadelphia, followed with a paper on the **Causes and Clinical Features of Cardiac Hydrothorax**. Dr. BEVERLY ROBINSON, New York, dealt exhaustively with the subject of **Myocarditis and Fatty Degeneration of the Heart**. Dr. A. JACOBI, New York, described cases of **Hemorrhage from a Pleural Abscess**.

Dr. CHARLES CARY, Buffalo, presented a case of **Pneumonia Complicated by Pseudo-Membranous Exudate on the mucous membranes of the mouth, tongue, pharynx, nares, conjunctivae, glans penis, anus, etc., caused by Diplococcus pneumoniae**.

Pernicious Anemia was the subject of papers by Dr. FRANK BILLINGS, Chicago, and Dr. F. P. HENRY, Philadelphia. Dr. Billings continued the report he made last year, in which he gave the details of 20 cases. In 10 of these cases the patients were dead at the time referred to. Four had died since; 2 had disappeared, and 4 were still under observation. The results in all the later cases confirmed the conclusions he put forward in his previous paper. Nine new cases had come under observation during the year, and they also presented the characteristic conditions, the blood changes showing waves of improvement followed by a decline. Dr. Henry gave further details of a case he had previously reported.

Under the title of **Acute Miliary Tuberculosis, Primarily Splenic**, Dr. D. D. STEWART, of Philadelphia, reported a number of cases in which signs of disease were seen nowhere except in the spleen until close on the time when they resulted fatally, when the manifestations of general affection usually appeared.

Dr. JOHN H. MUSSER, Philadelphia, presented notes on the **Relapsing Fever of Hodgkin's Disease**. (This will appear in a future issue of AMERICAN MEDICINE.)

Dr. ALFRED STENDEL, on behalf of Drs. C. Y. WHITE and WILLIAM PEPPER, Philadelphia, presented the results of a **Study of Granular Degeneration of the Red Blood-Corpuscles**. He remarked that he had a practical interest in the subject because the cases experimented on were cases of sub-acute lead poisoning which had come under his observation. His colleagues, however, were interested in the experiments scientifically. A large number of lead workers had been examined, and most of them showed the characteristic symptoms, though some of them remained for many years in apparently good health. Dr. JACOBI asked for further information as to the effect on the general system of this supposed lead poisoning, and gave as his reason for pressing the inquiry that he often gave large doses of acetate of lead to stop hemorrhages. If it were really lead poisoning that was produced, he desired to know how the general health was not affected in the cases referred to. Dr. Stengel said he did not care to go into the discussion of the question thus raised. All he could say was that the lead workers referred to presented the symptoms he had described, and yet remained in apparently good health.

Dr. M. ALLEN STARR, New York, presented a paper with the view of showing the **Toxic Origin of Neurasthenia and Melancholia** in certain cases. He by no means said that all cases of neurasthenia and melancholia were of toxic origin, for among common causes of these diseases were anxiety and worry, overexertion (mental or physical), and the degeneration of the neurons on account of diseased conditions. At the same time, however, he did contend that some cases were toxic in their origin. Dr. W. W. JOHNSTON, Washington, dealt with the **Evils arising from Failure to Recognize the True Nature of Neurasthenia and some Causes of this Failure**. (This will appear in a future issue of AMERICAN MEDICINE.)

Dr. JOHNSTON also showed a case of **Addison's Disease**—a young man who had been 2 years under treatment with suprarenal extract, and who was now in very much improved health, being able to work without feeling fatigued on a farm. His color, however, still remained symptomatic of the disease, though not so dark as it was.

Papers were read by Dr. C. A. HERTER, New York, on the **Acid Intoxication of Diabetes and Its Relation to Prognosis**, and by Dr. GEORGE ADAMI, Montreal, on the **Classification of Intoxications from a Pathologic Standpoint of View**. As a supplement to the former paper, Dr. E. P. JOSLIN read a short communication on **Metabolism in Diabetic Coma**, with special reference to acid intoxication.

The proceedings of the first day were brought to a close by an evening session, at which a number of demonstrations were

shown by the aid of the lime light. Dr. CHARLES S. BOND, Richmond, Ind., exhibiting some features of **Photo-Micrography**; Dr. WILLIAM F. COUNCILMAN, Boston, **Renal Lesions in Diphtheria**; Dr. H. C. ERNST, Boston, **Lantern Slides**; Drs. S. FLEXNER and R. M. PEARCE, Philadelphia, specimens of **Experimental Acute Pancreatitis**; Dr. WELCH and Dr. E. L. OPIE, Baltimore, specimens of **Hemorrhagic Pancreatitis**, human and experimental, and of **Filarial Lymph**; Dr. WELCH for Drs. K. C. McCALLUM and BUCKLEY, specimens of **Multiple Myelomata** and of **Epizootic Hemorrhage, Encephalitis**, etc.

SECOND DAY.

The first item on the program on the second day was **A Study of Bubonic Plague Based Upon the Outbreak in San Francisco**, the clinical aspects of the disease being dealt with by Dr. L. F. BARKER, Chicago; its bacteriology, by Dr. F. G. NOVY, Ann Arbor; and its pathology, by Dr. SIMON FLEXNER, Philadelphia. One satisfactory feature noted by Dr. Barker, in regard to the plague in San Francisco, was that there had been no outbreak among the rats as there usually was when an extensive epidemic was to be expected. Thirty-one cases in the Chinese colony at San Francisco had been positively proved to be bubonic plague, and the probability was that there had been a good number more cases which had escaped notice. Of the 31 cases 23 were Mongolians and 3 Caucasians. The ages of the victims were higher than usually noticed elsewhere, the average number being between 31 and 41, whereas it was generally between 21 and 31. This, however, was to some extent accounted for by local circumstances, as was also the fact that most of those attacked were of the male sex, there being comparatively few women and young people among the Chinese in San Francisco. The disease as a rule commenced with a chill and an intermittent irregular fever; the patient had nausea, usually vomiting; followed by severe nervous symptoms, often delirium and coma; within 24 hours a bubo would be found. Thereafter the symptoms generally increased from day to day, death usually taking place on the fourth day. Individuals who lived beyond the sixth day were more likely to recover. The development of the bubo was very rapid, quite different from the enlargement of the glands in venereal and other infections. Sometimes it was as large as one's fist, but sometimes again it was so very small that it had to be carefully looked for. It was not to be regarded as the enlargement of a single gland, a group of glands being usually involved. It was accompanied by a rapid development of edema, and the edema was characteristic, having a marked elastic power of resistance. The patients frequently complained of rheumatism, and the Chinese doctors put on the sticky black plasters which were used for that complaint. Indeed in a district where the plague existed the presence of this plaster might be regarded as evidence that the person wearing it was affected with the disease. In diagnosing a suspected case where the plague had not previously existed, it was all-important to have a bacteriologic examination. Despite the belief entertained by some that bacteriology was too young a science to be allowed to interfere with the interests of business men, it afforded an infallible test of the presence of the plague. As to treatment there was not much to be said, though if he had the disease himself, Dr. Barker added, he would fill himself as full as possible of Roux's serum. Dr. Flexner, after describing the pathology of the disease, stated that the obstacles that had existed so far to the proper examination of plague conditions in San Francisco were likely to be removed in consequence of arrangements that had been made with the authorities.

Discussion.—SURGEON-GENERAL STERNBERG remarked that if such an outbreak had occurred 30 years ago they would probably be reading in the daily newspapers of 500 deaths a day in San Francisco and of the spread of the disease to other parts of the country. That the plague had been so successfully kept under control was due to their having a trained bacteriologist on the spot, and the fact that on discovery of the disease steps had been taken to deal with it. Otherwise the plague might have developed into proportions equivalent to those of the previous century.

Dr. W. H. PARK, New York, described 2 extremely mild cases of plague which had arrived in the harbors of that city in a ship from South America, and Dr. VICTOR A. VAUGHAN, Ann Arbor, gave a detailed report on the case of the student there who had acquired the disease through engaging in laboratory work on cultures from bubonic patients.

Replying on the discussion, Dr. BARKER remarked that Ann Arbor was to be congratulated on the speedy recognition of the disease, and the saving of the patient.

Experimental Yellow Fever.—Dr. WALTER REED and Dr. JAMES CARROLL. This will be published in a future issue of AMERICAN MEDICINE.

Discussion.—Surgeon-General STERNBERG thought that Dr. Reed and his colleague should be congratulated on the success of their experiments, which had cleared up many conflicting facts which had previously puzzled the profession in regard to this disease. He himself had spent some years in trying to discover the microorganism of yellow fever, and he had no doubt that its discovery would yet be effected. He had never doubted that mosquitos might be the means of spreading the disease, though he had criticized Finlay's claims in respect thereto because his report did not support the theory he advanced. The

reason that Finlay failed in his demonstration was evidently that he did not keep his mosquitos long enough. His (the Surgeon-General's) own experiments had shown that yellow fever could not be communicated to the lower animals. The result of the experiments now reported was to demonstrate absolutely that the fever could be produced experimentally, and that a condition of immunity might thus be produced.

The President said it ought to be known that none of the patients experimented on had died. Those who had voluntarily submitted themselves as subjects for experimentalism—young American soldiers and others—were deserving of much credit. They were veritable heroes.

A Case of malarial nephritis with massing of the parasites in the kidney was presented by Dr. JAMES EWING, New York. A paper on **Septic Infection through the Stomach and Duodenum** was read by Dr. WALTER B. JAMES, New York; a report on 2 cases of **Streptothricial Infection, 1 Broncho-Pneumonia, the second Abscess of the Brain**, was presented by Dr. JOHN H. MUSSER, Philadelphia, on behalf of himself and Dr. N. B. GWYN, and Dr. A. C. ABBOTT, Philadelphia, gave a demonstration showing a product of bacillus pyocyanus resembling vegetable gum.

At the afternoon session Dr. WILLIAM A. PARK, New York, discussed the question of the extent to which **Urine is a Suitable Soil for Bacilli Growth**. A paper on **Orchitis Complicating Typhoid Fever** was read by Dr. FRANCIS KINNICUTT, New York. Notes on the **Treatment of Some Forms of Cancer by the X-rays** were contributed by Dr. FRANCIS H. WILLIAMS, Boston. Among the other items on the program were: **Osteitis Deformans**, by Drs. FREDERICK A. PACKARD and J. DUTTON STEELE, Philadelphia; **the Spiral Form of Arthritis Deformans**, by Dr. WILLIAM OSLER, Baltimore; **Certain Tropho-Neuroses and their Relation to Vascular Disease of the Extremities**, by Dr. B. SACHS, New York; a case of **Subcortical Glioma of the Lower Part of the Ascending Frontal Convolution**, a contribution to the nature of the speech disturbance arising from lesions in this situation, by Dr. J. STEWART, Montreal (this will appear in a future number of AMERICAN MEDICINE); **Personal Experiences in Cases of Jacksonian Epilepsy**, with special reference to the question of treatment by operation, by Dr. JAMES J. PUTNAM, Boston; **The Clinical and Microscopical Results of the Examination of 3 Cases of Family Periodic Paralysis**, by Drs. JOHN K. MITCHELL, SIMON FLEXNER, and D. L. EDSELL, Philadelphia; and **Hereditary Appendicitis**, by Dr. F. FORCHHEIMER, of Cincinnati.

The annual dinner of the association was held in the evening at the Arlington Hotel. One of the features of the proceedings was the reading by Dr. W. A. NORTHROP of an unpublished poem by Oliver Wendell Holmes.

THIRD SESSION.

The first paper was read by Dr. FRANZ PFAFF, Boston, and consisted of some observations he had made in a case of **Diverticulum of the Esophagus**.

Dr. EDWARD L. TRUDEAU, Saranac Lake, read a paper on **Tuberculosis**, in which he demonstrated the importance of a recognition of the significance of the disease in its early stage in relation to treatment. Physicians generally, he thought, were far from being sufficiently impressed with the importance of making an early diagnosis, and the consequence was that many patients were not informed of the nature of their malady and advised to make a change of climate until it was too late. So long as the significance of the earlier symptoms was overlooked and treatment postponed until the disease had advanced to a grave state, he was afraid that much disappointment would be experienced in regard to the results obtained by the new open-air methods of treatment.

Dr. J. GEORGE ADAM, on behalf of Dr. J. McCrac, Montreal, reported the results of a series of cases of burns. The general effect of the observations described was to support the suggestion that burns produced toxins bearing a marked similarity to bacteriologic toxins.

An elaborate paper on **Hemolysis** was read by Dr. S. J. MELTZER, New York.

A number of other papers were read by title, among them being: **The Relative Prevalence of Bright's Disease in New York, London and Berlin**, by Dr. HERMANN N. BIGGS, New York; **Lithemic or Recurrent Coryza**, by Dr. B. K. RACHFORD, Cincinnati; a further report on a case of **Presystolic Mitral Murmur, associated with Systolic Triaspical Murmur complicating Pregnancy**, reported to the Association in 1899; **The Extension of Aortic Aneurysms into and between the Walls of the Heart and Dissecting Aneurysm of the Heart**, by Dr. LUDVIG HEKTOEN, Chicago; **A Case of Spondylose Rhizomelique with autopsy**, by Dr. CHARLES L. DANA, New York; **The Relation of the Tracheal Tug to Fixation and Elasticity of the Left Lung**, by Dr. HENRY SEWALL, Denver, and **A Study of Bacteria isolated from Cases of Dysentery**, by Dr. F. F. WESBROOK, Minneapolis.

New Office-bearers.—The election of new officers resulted as follows: President, Dr. James C. Wilson; vice-president, Dr. James Stewart; recorder, Dr. S. Solis Cohen; secretary, Dr. Henry Hun; treasurer, Dr. J. Crozier Griffiths; councillors, Drs. Frank Billings and Francis P. Kinicutt; representative on executive committee of Congress, Dr. William Osler; alternate, Dr. Francis H. Williams.

ORIGINAL ARTICLES

THE NECESSITY FOR GREATER CONSERVATISM IN THE USE OF VASODILATORS IN CERTAIN CASES OF CARDIOVASCULAR DISEASE.*

BY

LOUIS FAUGÈRES BISHOP, A.M., M.D.,
of New York City.

Corresponding Secretary, New York Academy of Medicine; Member Neurological Society, Pathological Society, Society Alumni, St. Luke's and Sloane Maternity Hospitals; Attending Physician Colored Hospital; Assistant Physician French Hospital, etc.

In the career of every form of treatment there are several stages. The first is discussion, skepticism overcome, and adoption. The second is intelligent application in the light of previous discussion and the consequent general information. Third, the routine use of an accepted treatment as a matter of course in a particular disease.

When Brunton applied amyl nitrite to the treatment of angina pectoris he achieved a signal triumph in therapeutics. Not less was the triumph of the more gradual application of the nitrites in general to the treatment of vascular spasm. These were first well used by those who had witnessed their development and were familiar with their philosophy and limitations. Unfortunately the student coming later upon the field of medicine and finding the nitrites in general use for vascular disease, jumped naturally to the conclusion that they were the remedies *par excellence* and used them in a routine way as a matter of form in the treatment of these cases. The observation of this fact makes it useful at this time to emphasize the necessity for some conservatism in this matter. It is a trite saying that we should always treat the patient and not the disease, meaning by this that we must carefully recognize the exact physiologic and pathologic conditions present, and so influence them as to bring about the cure of disease. Patients differ widely in their behavior under the nitrites. For that reason every case requires physiologic study to determine the amount of drug necessary and how it should be applied.

There is no more important function of the physician than the early recognition of that tendency to degeneration and death that comes prematurely to so many of the human race. This shows most often in arterial changes one of the earliest symptoms of which is alteration of blood tension. The tension in the bloodvessels in health is maintained at an even point through the action of the unstriped muscular tissue in the walls of the bloodvessels. The heart is a part of the circulatory tubes, and differs only in arrangement and degree from the mechanism of the rest of the circulatory path. It contains unstriped muscular fiber as do the bloodvessels, and an arrangement of valves as do the veins. Its muscular action is rhythmic while the muscular action of the bloodvessels is only slightly so. Both are subject to the control of the nervous system. It is in the disordered action of all these muscles that the first signs of degeneration appear. The muscles in the vessels act badly, the muscle in the heart is irritated and the result is ten-

sion. To apply vasodilators without also instituting hygienic measures to reduce the irritability of the heart and restore the disordered or exhausted nervous system, is to overlook an important element in the problem of cure.

The necessity for the use of vasodilators is diminished in proportion to the intelligence and success attending these accessory measures. In Bright's disease there is probably some substance circulating in the blood that irritates the muscular coats of vessels and causes contraction. This, with the physiologic attempt of the heart to carry on the circulation, again brings about high blood-tension. When high tension antedates the onset of nephritis it may well be supposed that the tension has something to do with the production of nephritis.

A physiologic increase of blood-pressure is caused whenever there is nervous, muscular or physiologic exertion. Prolonged nervous strain, such as that met with in an exciting business career or in prolonged dissipation, keeps up a tendency to tension that is particularly apt to lead to arterial degeneration. Muscular action is less prone to produce damage and probably does so only in rare instances of long training and severe contests of strength. The reason for this is that exercise is accompanied by natural dilation of the arterial circulation, improved nutrition and relief afforded by perspiration. The physiologic activities of the body are usually accompanied by too slight a stimulation of the circulation to count for much in health, but are worth considering in disease. From this brief review of the natural causes of tension it may be quickly inferred that in a person suffering from abnormal tension it is specially important to do away with mental strain and responsibility. Such a person should not indulge in violent exercise but is benefited by slow exercise. Food should be moderate in amount, taken at frequent intervals. Sugar and alcohol should be done away with entirely if possible, and meat used in limited amount.

When the vasodilators are given it is to produce a definite physiologic effect which is capable of appreciation by the observer.

The dose required to produce this effect differs widely in different individuals and under different circumstances. In a large number of cases they are now so given that no effect whatsoever is produced. Crude therapeutic thought is responsible for this. The idea is picked up that the nitrites are good for kidney and heart-disease, and so they are administered with the hope that the patient may be benefited thereby. If improvement takes place the medicine receives the credit whether or not it has done its work. The word "conservatism" means more than caution, more than small dosing. It means the working out of the possibilities of the remedy and its application in such a way as to fulfil its broadest mission, not be wasted or abused—wasted when used in nonactive doses, and abused when used too often or in too great a quantity. With the vasodilators a careful regulation in doses is of vital importance, for their final action may be dilation and paralysis of the heart through a complete breaking down of that great power called inhibition that moderates all muscular activity.

* Read before the New York State Medical Society, January 20, 1901.

When nitrites are used it is also of the utmost importance that the preparation selected should be reliable. I have known patients to take tablets of nitroglycerin for a long time that were proved afterwards to be inert. When no benefit is obtained in conditions in which the nitroglycerin is clearly indicated this may be fairly suspected. Then one of the tablets may be given to a healthy person who should immediately feel the throbbing in the head due to the dilated bloodvessels and the stimulation of the heart. If no effect is felt a new preparation must be sought and then tested. The 1% solution of glonoin is probably more reliable but is not nearly so convenient for patients as the tablet.

Cases must be studied from time to time by the withdrawal of these drugs and by the substitution of other drugs of a different class. Particularly is it important in every such case to know from actual observation the effect of digitalis in such doses as bring about distinct physiologic phenomena.

But few diseases can be treated by specific measures and cardiovascular disease is particularly remote from such an ideal. What drugs accomplish is to control the circulation so that it shall tend to benefit the condition of the tissues, or prevent the condition of these tissues from working injury to the body as a whole. The management of cardiovascular disease is like the running of an intricate machine. The physician must study the machine itself and learn all its resources. He must know the use of every tool and the effect of the turning of each screw. It is no abuse of the privileges of the physician to study his cases therapeutically by testing from time to time the effect of different classes of drugs though he return after each trial to the original plan of treatment. It is the height of arrogance to assume that his inductive reasoning can plan for each case a permanent course of management. Such action will only lead to humiliation and disappointment. How exasperating it is when for a long period of time, on theoretic grounds, we have abstained from the use of such a drug as digitalis to find some time or other that our patient has taken it through the advice of the corner druggist and has received appreciable benefit from it. Of course, we know very well that the corner druggist had no right to experiment and that there might have been a miliary aneurysm to rupture in the brain and kill the patient, but perhaps the risk was worth taking after all.

There is a particular form of pulse in which nitroglycerin is not as valuable as a number of other drugs. This is a high-tension pulse with persistently rapid heart-action. In these cases I have sometimes seen the greatest benefit from the use of digitalis. Nitroglycerin has a twofold action in stimulating the heart and dilating the bloodvessels. Digitalis has a twofold action in slowing the heart and contracting the bloodvessels. Theoretically, digitalis would not act in these cases, but practically in a case of nephritis with a high tension and a rapid pulse, digitalis will often show its controlling action upon the heart in greater degree than any other of its effects, and in that way bring about a slower pulse with less apparent tension. At the same time digitalis will clear up congestion of the kidneys and cause a better secretion of urine.

Even when tension does exist in cardiovascular disease with nephritis it should be realized that some tension may be desirable. As time goes on, in such a case the greatest danger to be feared is a too great lowering of the blood tension with its accompanying congestions and effusions. In the presence of symptoms indicating disturbances of cerebral circulation, such as numbness or awkwardness of one of the extremities or slight difficulty in speech, the vasodilators are imperatively needed. Sodium iodid has also an undoubted power to control these conditions and to postpone paralytic attacks due to the plugging of bloodvessels.

A word as to the possibility of recovery from cardiovascular degenerative disease. The heart symptoms are those of myocarditis and the kidney symptoms those of chronic nephritis. The tendency of the bloodvessels is to become thickened. Every one knows that under ordinary circumstances a person starting with this form of disease generally becomes worse and finally dies. However, I do not believe that this need always be the case. With a properly planned regimen and the possibility of carrying it out, and with careful medication and other therapeutic measures the heart may recover its tone so that all symptoms of degeneration will disappear and the kidneys may settle down to do their work according to a particular plan, but well enough for the maintenance of health.

It is hard to prove the regeneration of kidney tissue, though the physiologic hypertrophy of one kidney when the other is removed leads to a belief in its possibility. Certainly there are many persons passing a large quantity of urine of low specific gravity and with a slight trace of albumin who maintain year in and year out all the other signs of health. Their hearts, bloodvessels and kidneys have readjusted themselves and though bearing the scars of disease are carrying on the functions of the body in a satisfactory manner. I have pictured this condition because it is extremely interesting to decide in these cases how much we should intervene with drugs to alter the heart action or relax the bloodvessels. It seems to me that in the absence of symptoms sodium iodid will accomplish the best purpose and that the use of the nitrites should be limited.

Smallpox Inoculation in Algeria.—M. Hervieux recently drew before the Academy of Medicine a very somber picture of the danger to which smallpox inoculation is giving rise in Algeria. According to a report by M. Trolard, this abominable practice is making headway more and more among the natives. They refuse vaccination, despite all the efforts of the medical men, and prefer direct smallpox inoculation performed by native practitioners, who inoculate with a lancet charged with virulose pus. Owing to this deplorable habit, which the French authorities try in vain to combat, smallpox is increasing rapidly among the Arabs, and the mortality is going up, to say nothing of the numbers of maimed and blind, who have to be looked after by the state, while, as a final result, the commercial relations of the colony are beginning to be imperiled. M. Hervieux argued that energetic measures must be taken, and proposed that the Academy should lay down a rule that inoculation should be made a penal offence punishable by a fine in every French colony. A discussion, however, took place, M. Chauvel saying that the Academy could not formulate penal laws without going outside its proper role, which was advisory and scientific. M. Gautier considered that a fine was an insufficient punishment, and suggested that compulsory isolation of smallpox patients, which, being at once a kind of imprisonment and a valuable method of prophylaxis, would have greater weight in the eyes of the natives. Finally, the Academy left the choice of the punishment to the Minister concerned, but insisted that smallpox inoculation ought to be sternly suppressed in French colonies.—*London Lancet.*

ANEURYSM OF ASCENDING AORTA OF GREAT SIZE: TREATMENT BY GELATIN INJECTIONS AND ELECTROLYSIS, WITH EFFECT OF COAGULAT- ING MOST OF THE CONTAINED BLOOD.

BY

W. W. JOHNSTON, M.D.,
of Washington, D. C.

R. D. W., aged 40; white; single; occupation, sugar-planter in the Philippines. As a boy he was strong and well developed; at college he engaged in athletic exercises, especially running. In 1884, 16 years ago, he went to the Philippines and engaged in sugar-planting. His life was very active and laborious, the greater part of the time being spent out of doors on horseback. His health improved very much and he gained in 5 years 50 pounds in weight. In 1893 he contracted syphilis and was treated with mercury for 9 months; the symptoms were few, and at the end of this time he considered himself cured.

In 1898, Spanish soldiers destroyed his property and arrested him and his mother on the charge of aiding the native rebels. He was treated with great cruelty and threatened with instant death. But after reaching Cibu, he was protected by the English Consul, who subsequently secured his escape to Singapore. The excitement attending these occurrences may have had something to do with the rapid growth of the aneurysm, for it was in this year that he felt frequent pain in the right shoulder and down the right arm; there was no suffering connected with the heart or with respiration. In December, 1899, a swelling appeared under the right clavicle; this grew rapidly and in March, 1900, had reached the size of an orange, occupying a good part of the right mammary region. He then

went to Hong Kong for treatment, and was in the Peak Hospital under the care of Dr. Alexander Rennel. The following extract from a letter written by Dr. Rennel exhibits his condition when he left Hong Kong in April last:

"The pulsation" in the tumor "is much diminished, but the size of the aneurysm is greatly increased, bulging now more toward the right side. He suffers aching pains, but dyspnea and severe cough are considerably less than one would expect. The treatment I have followed has been injection of gelatin

solution into the axilla every 5 days, and potassium iodid, 20 grains 3 times daily. The gelatin seemed to have a good effect in producing more solidity of the tumor when first used, but latterly I have not seen any benefit, and I do not think it is worth going on with. You will find his general health good, but will observe the great increase in the size of the tumor."

The voyage to San Francisco on a United States transport was undertaken in April. There was no great suffering at first; he took his meals in his cabin, and rested a great deal.

Thoracic aneurysm showing points of insertion of trochar in the effort to find the portion of the sac filled with fluid blood; the successful puncture was at x4.

Towards the last, dyspnea and cough annoyed him greatly, and on reaching San Francisco he was unable to leave the steamer, and was compelled to rest before continuing his journey. He thought that the tumor increased in size while traveling, and in view of the rapid growth after reaching here, I have no doubt that this belief was correct.

I saw him on May 26, the day after he reached Washington. Breathing was not labored, but he had a harsh, frequent cough that gave great distress. The lips were dusky in color; he lay usually on his right side with the head very little raised, and talked without difficulty. Nothing in his appearance or manner indicated that he was very ill. The appetite and digestion were good.

The right chest, anteriorly, was occupied with a tumor (see illustration) having the appearance of a large and distended mamma with tense walls. It reached from the left border of the sternum to the right axillary line, and above to the clavicle; its lower contour was some 6 inches below the nipple. The vertical measurement of the tumor from its highest point to the chest-wall was about 6 inches. The pulsation of the tumor was very forcible, and was the same over its whole area. There was no murmur and no thrill. The pulse was the same in both arms, and there was no edema of the right arm, and no pain. The pulse was 110 and over for the first 10 days; it gradually reduced in frequency, and on May 26 varied from 80 to 90.

The physical signs of the heart were not much altered; the impulse was feeble and displaced to the left, and the heart-sounds were weak. Over the lung, to the left of the aneurysm, there was loud, bronchial breathing; bronchial breathing was also heard over the right scapular region.

The patient was kept at rest, with a simple diet, and potassium iodid was continued for a short time. For the cough

codein and later morphia were given. The patient improved in the first 2 weeks; his cough lessened and finally stopped, and the pulse as stated decreased in frequency. The aneurysmal tumor increased in size, growing most rapidly toward the clavicle and the right shoulder.

The question of electrolysis of the aneurysm was discussed for some time, but it was not until July 10 that this was done by Dr. Finney of Johns Hopkins Hospital. Three unsuccessful attempts were made to reach fluid blood with a cannular needle 4 inches long, passed directly downward into the tumor. The points of insertion were made where the pulsation seemed strongest. In each instance the needle passed into solid tissue and there was no escape of blood. The fourth insertion, at a point near the shoulder, was successful, blood escaping in a jet when the needle had passed its whole length. Ten feet of silver wire was then unrolled from a spool and passed through the tube of the needle. A current of 10 milliamperes from a dry cell battery was then turned on and continued for 1 hour. The operation was attended with very little pain and this was only in the beginning. At the conclusion of the operation there was a noteworthy lessening of pulsation in the region of the last puncture. The pulse was 108 and the patient com-

Heart and aneurysmal tumor showing size of the tumor outside chest wall.

plained of no inconvenience. On July 12, 2 days later, the pulse was 102 and from this time it fell to 92 in a few days. There was no apparent inflammation in the neighborhood of the punctures.

During the latter part of July the patient had an intermittent fever, his evening temperature rising from 100° to 101.5°. Several large blebs formed near the sternal margin of the aneurysm. Two of these finally ulcerated through, revealing necrosed fragments of the ribs and discharging continually a thin bloody serum. This "weeping" continued more or less profusely until the time of his death. Later, little raised spots in the skin appeared over 3 places where the needle had been introduced at the time the wiring was done. These enlarged and ulcerated with remarkable rapidity, a thin bloody serum escaping continuously. Their dimensions varied greatly being at one time nearly healed and again quite large. Granulation tissue formed abundantly around the margin of these little ulcerations. At times the discharge from these openings became bright red in

color and quite profuse. A slight evening rise in temperature continued. August 15 the patient suffered severe pain in the aneurysm, right shoulder, and arm, accompanied by great loss of power in his right arm. A few hours later he felt a giving away in the aneurysm with a whirring noise; a jet of blood about the thickness of a darning needle escaped forcibly from one of the sternal ulcerations. This was controlled by pressure after the loss of considerable blood, but his condition seemed alarming for several days after from the shock, loss of blood and severe pain. At this time he rallied and seemed better in every way than he had been for months. August 20, pain, labored breathing and restlessness reappeared and he predicted another hemorrhage which occurred in the night from one of the sternal perforations and simultaneously from one of those on the dome of the aneurysm. Forceful jets of blood escaped from each, but were controlled with the same result as in the first hemorrhage. After this small hemorrhages recurred from one or several of the ulcerations at intervals of a few days. He gradually gained the use of his arm, overcame the depression of spirits following the first few hemorrhages and felt confident of recovery. These repeated hemorrhages at short intervals, however, began to tell rapidly upon his strength. The majority of the later hemorrhages proceeded from the point at which the wire was inserted in the aneurysm.

The patient died suddenly on September 26, from the sudden loss of about one pint or more of blood from the point of successful puncture.

The autopsy was performed by Dr. Glazebrook.

Necropsy.—The heart, arch of aorta, etc., were removed and examined. The heart was normal except for some thickening and induration at the base of posterior leaflet of aortic valve. The ascending aorta showed a large aneurysmal pouch; the transverse and descending arch were atheromatous. The aneurysm was nearly globular in shape and about 7 inches in diameter in all directions; it projected forward and toward the right, bulging between the first and fifth ribs; the second, third and fourth ribs were absorbed in much of their length. The right border of the sternum was involved in the sac, but the bone was not eroded. Next to the wall of the pouch there were 2 inches of red laminated clot, the next 2½ inches were filled with a ball of dense nonlaminated coagulum through which ran strands of fine silver wire; the posterior 2 inches was an open space with a thin lining of clot and also contained some silver wire which seemed to have passed through the posterior wall of the aorta. The primary branches of the arch were patulous. There were small portions of adherent lung. The trachea and esophagus were normal. The large amount of laminated clot showed that a process of cure had been slowly going on, while the more recent nonlaminated coagulum in which the silver wire was imbedded indicated clearly the effect of the recent electrolysis. Death was due to the blood-current making channels between the clot and the sac and finally making an exit through eroded spots in the outer wall.

Schools for the Deaf.—A substitute bill is before the Wisconsin Legislature which, if passed, will preclude any exercise of authority by the school-board or any municipal corporation in places where public schools for the deaf are located, and will put them under the State Board of Control; it will deprive the State Superintendent of Public Instruction of all power over and relationship to the day schools for the deaf and thus remove them entirely from the public school system, and put them in the same class with the State reformatory, charitable and penal institutions, to which they are not related and from which they should be kept separate. It also empowers the State Board of Control to discontinue any or all of such schools at its discretion.

POSTPARTUM METASTATIC PANOPHTHALMITIS,
WITH A CLINICAL AND PATHOLOGICAL STUDY
OF A CASE.*

BY

WALTER L. PYLE, M.D.,

of Philadelphia, Pa.

Assistant Surgeon to Wills' Eye Hospital, Philadelphia.

Historical.—The suppurating ophthalmia complicating puerperal fever was described early in the nineteenth century in the works of Tenon, Jungken, Velpeau, and Himly. Since then it has been discussed by Jacob, Fischer, Arlt, Hasner, Pilz, Weir, Lee, Szokalski, Müller, Virchow, Nagel, Knapp, Wadsworth, Williams, Schmidt-Rimpler, Hosch, Schöbl, Mitvalsky, Herrnheiser, Kahler, Wagenmann, Litten, and others.

Fortunately postpartum metastatic ophthalmia is very rare in this country at the present day. Since the introduction of antiseptics in obstetric practice, infection of the parturient tract in civilized communities has gradually become less frequent, and when it occurs it is promptly treated in a rational manner. Formerly the mortality after childbirth in many institutions was from 5% to 10%. Today it is not over from 0.3% to 0.4%. However, the affection is still prevalent in some rural and uneducated communities.

Thirty years ago medical literature contained frequent references to metastatic suppuration of the eyeball after labor. In such an enlightened community as Prague, Austria, as late as the period between 1850 and 1870, puerperal infection with ocular complications was common in both hospital and private practice. Schöbl states that within this period he remembers a time during which he saw daily more than 20 cases of puerperal fever, of which 4 or 5 were complicated by metastatic ophthalmia. He also states that he has examined over 100 cases ophthalmoscopically, and beside many eyeballs that he had cut into sections in those days he had 17 or 18 well-prepared but intact specimens of metastatic panophthalmitis. As the adoption of antiseptic and aseptic methods in obstetrics became more universal, the number of cases gradually diminished, until now he states that he has not seen a case in his clinic for many years.

Symptoms and Clinical Course.—The time of occurrence is from the fifth to the fifteenth day after delivery, depending largely upon whether the metastasis follows infection through the lymphatics and bloodvessels near fresh wounds in the parturient tract, or through the open uterine sinuses, going directly into the circulation. Monolateral cases seem to be twice as frequent as bilateral, but as in the latter instance there are generally also bacterial thrombi in the internal viscera or brain, causing profound constitutional symptoms and usually death, it is likely that many cases of bilateral intraocular metastasis have been overlooked. In the bilateral cases one eye is affected within a few days, at the most, of the other.

In postpartum metastatic panophthalmitis there are, of course, the associate local symptoms, such as vulvitis, vaginitis, purulent lochia and pus about lacerations and

suture-openings. Persistent and extreme variation in temperature and pulse, with perhaps a chill, occurring within 48 to 60 hours after delivery, are all indicative of general puerperal septicemia. However, it should be recorded that postpartum ophthalmia may follow an apparently normal labor. A. Hill Griffith has reported 2 such cases, in healthy women, that were characterized by the presence in the fundi of large, rounded, bluish-white, flocculent masses like packed cotton-wool. There were no signs of external inflammation in either case and the eyeball slowly atrophied.

Unless the general condition is so grave as to prevent the complaint of subjective phenomena, an early ocular symptom is loss of vision. This may occur with obscuration of the fundus oculi before external signs of inflammation are noticeable. Usually there is injection of the globe and signs of iritic disturbance, with, perhaps, the formation of synechias. Slight hypopyon may appear in the anterior chamber. There is soon, however, the formidable picture of panophthalmitis—intense inflammation, chemotic swelling of the conjunctiva and lids, protrusion and immobility of the eyeball, and a whitish-yellow reflex from the pupil. There is intense burning pain in the eyeball and orbit and in the surrounding frontal, temporal and malar regions. The globe becomes a virtual abscess cavity, the sclera ruptures, the contents of the eyeball escape, and the orbit becomes infiltrated.

In some cases there is a less acute course, not involving the orbit, and allowing for a time an imperfect fundus-reflex. Such indolent cases are often almost painless, but eventually vision is entirely lost, and even though the sclera does not rupture, the eyeball becomes atrophied.

Diagnosis is based upon the panophthalmitis occurring within a few days of delivery, and the associate local and general symptoms of postpartum infection. Unless the vitreous remains clear enough to permit of ophthalmoscopic examination, it is impossible to decide whether the initial infection is a choroiditis, retinitis or chorioretinitis. In the chronic cases the diagnosis may be in doubt for a time, but it is eventually no less certain.

Etiology and Pathology.—In the early days, postpartum panophthalmitis was thought to be due to milk-metastasis. At present there is abundant proof of its bacterial origin, the septic emboli from the infected genitalia entering the bloodvessels of the choroid or retina. Heiberg was the first to demonstrate in these cases the presence in the choroid and retina of microorganisms. Since then, Roth, Leber, Beck, Litten, Hosch, Wagenmann, Mitvalsky, Schöbl, Herrnheiser, Kahler, Hirschberg and others have reported the discovery of microorganisms in rather large emboli in the intraocular bloodvessels and vitreous. Among the varieties found were *Streptococcus pyogenes*, *Staphylococcus pyogenes aureus*, pneumococcus, a new diplococcus and the leptothrix.

It should be added, however, that it is quite possible for a suppurative panophthalmitis to follow a nonseptic embolism of the central artery of the retina. A. Hill Griffith has seen one case, and quotes J. Adams, who has reported a case in which the suppuration did not appear until 2 months after the arterial blockage.

* Read at a meeting of the Philadelphia County Medical Society, March 13, 1901.

There is always a question of doubt as to the initial ocular lesion. Both the choroid and retina may be the seat of destructive inflammation. Heiberg discovered bacteria in both membranes. Schöbl, Herrnheiser, and Hoesch found the retina generally more involved than the choroid, and a retinitis much more frequently the initial lesion than a choroiditis or chorioretinitis of a similar character.

Hirschberg has seen a case in the early stage, in which, though cloudy, the vitreous was sufficiently transparent to permit an ophthalmoscopic view of retinal embolism and hemorrhages, and he confirmed postmortem the site and nature of the initial retinal lesion.

Leber and Schöbl emphasize the fact that cell-infiltration always begins in the nerve-fiber layer of the retina and spreads to the other layers and into the vitreous. This infiltration is greatest near the bloodvessels, and there is an accompanying perivascularitis and endovascularitis. In advanced cases the retina is detached and may be demonstrated only by a single shred of densely infiltrated retinal tissue and vascular debris. The choroid, vitreous, lens, cornea, sclera, and Tenon's capsule may show similar conditions in a varying degree to those found in traumatic panophthalmitis. It is very often impossible to demonstrate either emboli or microorganisms.

Prognosis as to recovery of the eye is hopeless. Even in the indolent painless cases, vision is eventually lost and the eyeball becomes atrophic. If suppuration has destroyed the contents of the eyeball and they have been mostly evacuated through a scleral opening, the globe immediately becomes very small—a condition known as phthisis bulbi—and usually remains quiescent and harmless, and may be allowed to remain in the orbit. If, on the other hand, the intraocular membranes though greatly altered are not entirely destroyed and the sclera is not extensively ruptured, atrophy of the eyeball results, causing a more gradual and moderate shrinking of the globe, but which on account of the tension on the intraocular membranes by contraction of the exudate, may give rise to repeated attacks of inflammation and even sympathetic inflammation of the sound eye; such an atrophic globe must be promptly enucleated.

The prognosis as to life is good in monolateral cases, uncomplicated by metastasis of septic emboli elsewhere in the body. Bilateral cases are generally attended with a fatal issue.

Treatment includes disinfection of the parturient tract with copious douches of mercuric chlorid solution (1:5,000, at a temperature of about 100° F.) 4 or 5 times a day. Special attention should be given to ulcers and fissures, cleansing them with hydrogen-dioxid solution, carbolic-acid solution, etc., and making applications of iodoform, boroglycerid, boric acid, etc. The bowels should be evacuated at once by a large hot enema. Constitutional alterative and tonic treatment is indicated to combat the febrile process. Alcohol and quinin may be administered. Nutritious and easily digested food should be given. Cold sponging and the administration of antipyretics may be resorted to. The surgical evacuation of pelvic abscesses may be necessary.

The chief local ocular treatment should be directed to

the relief of pain and reduction of inflammation. Instillations of atropin and the application of hot compresses are first indicated. These failing, the sclera should be incised between the tendons of the external and inferior recti muscles, and the pus evacuated. The opening in the globe may be packed with gauze and the cavity irrigated several times a day with a germicidal solution.

Even under the most rigid antiseptic precautions, enucleation during the active stage of inflammation is not free from the danger of purulent meningitis. The bloodvessels and lymphvessels of the orbit being extensively opened invite infection to the brain. Even evisceration of the eyeball has been followed by a fatal meningitis. However, this complication has been known to follow panophthalmitis when no operation was performed. Some ophthalmic surgeons advise the routine practice of operating at any stage of the inflammation; but in view of the possible dangers, and the perfect relief given by simple scleral incision, which may be followed later by enucleation, evisceration or implantation, this treatment has not been adopted by conservative ophthalmic surgeons.

CLINICAL HISTORY OF A CASE.

The patient was a well-nourished woman, aged 27 years, who was delivered of her first child on August 2, 1900. She had been in good health all through her confinement; but she was in labor 56 hours, and was delivered finally by means of the forceps. The day following delivery she was affected by severe pain in the abdomen, and diarrhea, which continued with a dozen or more evacuations daily for over a week. During this period there was high fever, at times accompanied by delirium and followed by falling-out of the hair.

On the tenth day after delivery the right eye became inflamed; although relieved of pain by atropin, hot and cold compresses, etc., ordered by her family physician and a local oculist, the inflammation of the eye became more violent and did not subside for 5 or 6 weeks.

The patient consulted a professional colleague for the first time on October 10, 1900. On account of pain in the affected eye and discomfort in its fellow, enucleation was advised, and the case was referred to me for operation.

When I first saw the patient on October 16, 1900, the right eyeball was atrophic and congested, but the cornea was clear and the iris was quite distinct, and at first glance apparently normal, although immobile, being bound down to an opaque mass in the pupillary space, resembling a calcareous lens. On the following day I enucleated the eyeball, and found the conjunctiva and Tenon's capsule tightly adherent to the sclera. There was a depressed triangular cicatrix in the horizontal meridian, 8 mm. from the sclero-corneal junction—a most unusual location for spontaneous scleral rupture.

A careful microscopic study of the enucleated globe was made for me by Dr. E. A. Shunway, at the William Pepper Laboratory of Clinical Medicine, and I append herewith his report.

PATHOLOGIC REPORT.

The eyeball measured 20 mm. in its antero-posterior diameter; 12 mm. in its horizontal; and 19 mm. in its vertical diameter (Normal measurements, 24.5 x 24 x 24 mm.). The corneal diameters were 11 x 10 mm. Eight mm. posterior to the limbus, in the horizontal meridian was a depression in the sclera, at the bottom of which was a circular opening 2½ mm. in diameter closed by a plug of granulation-tissue. The globe was hardened in alcohol of gradually increasing strength, and then cut in a horizontal meridian through this opening.

Macroscopically the eyeball appears to be undergoing atrophy. The anterior chamber is shallow, the pupil is occluded, the iris is bound down to the partly shrunken lens, and the vitreous cavity is filled with a mass of organizing tissue, which extends into, and plugs the opening in the sclera.

Microscopic examination shows these points in detail. All of the tunics of the eye have been the seat of a suppurative process, and the resulting exudate is undergoing organization, binding together contiguous structures, and distorting them almost beyond recognition.

Cornea. Bowman's and Descemet's membranes are intact, but are somewhat irregular, owing to the wrinkling of the cornea which has resulted from the distortion of the shrinking eyeball. The anterior epithelial covering is missing over a large part of the surface, but this is evidently an artefact, as there are no signs of superficial ulceration. The substantia propria shows a number of newly-formed bloodvessels, which are surrounded by round cells, and the connective tissue corpuscles between the lamellas are increased in number. The episcleral tissues are thickened from long-standing edema, the bloodvessels are dilated, and the tissues infiltrated with round cells. The anterior chamber is shallow, and is filled with an exudate rich in fibrin, in the meshes of which are a few leukocytes and red bloodcorpuscles.

Iris. The surface of the iris is covered with a thick layer of firmly organized fibrous tissue, which occludes the pupil, is adherent to the anterior capsule of the lens, and unites the periphery of the iris to the posterior surface of the cornea, thus blocking completely any communication between the interior of the eye and the outside through the ordinary lymph-channels of its anterior segment. The iris itself is densely infiltrated with round cells—mononuclear lymphocytes, polymorphonuclear leukocytes, and a number of large mononuclear mast-cells with coarse, basophilic (notably gentianophilic) granules. The stroma is condensed, the pigment-cells are destroyed, and the pigment is massed in irregular clumps. The bloodvessels are distended with blood and polynuclear leukocytes; their walls are thickened and show evidences of endarteritis. The posterior pigment-layer is irregularly proliferated and is loosely adherent to the lens-capsules, leaving spaces which are filled with bloodcorpuscles, blood-pigment, and edematous connective tissue cells.

The ciliary bodies have undergone the same changes as the iris, and the ciliary processes are embedded in a cellular exudate, by the organization and shrinking of which they have been drawn out into bizarre forms which are lined with tall cells from which the pigment has been almost completely removed.

The lens is cataractous, and is undergoing absorption. The capsule is swollen and the capsule cells have extensively proliferated, and show degenerative changes; the nuclei stain poorly, in many instances they are fragmented, and the cell protoplasm is filled with vacuoles. The posterior capsule has been eroded, and the capsule-cells are mixed with the cells from the exudate in the vitreous, in which the lens is imbedded. The lens-fibers are absorbing, and the center of the lens is occupied by degenerated fibers, Morgagnian droplets and by a large number of the vesicular cells characteristic of advanced cataract.

The sclera is much thickened, especially posteriorly, and shows the opening in the position already described. The edges of the opening are infiltrated, and are drawn inward, the opening being closed by a mass of young granulation-tissue, which is very cellular, but which shows many well-formed blood capillaries and many spindle-shaped cells.

The choroid can hardly be recognized as a distinct membrane, and its former situation is indicated by the lines of pigment-cells which are widely separated by, and embedded in the exudate which fills the interior of the eyeball. The old bloodvessels which persist, show very marked thickening of their walls, and proliferation of the endothelial cells lining their lumens. Both the ciliary bodies and the choroid have been detached from the underlying sclera and the spaces thus produced are filled with a mass of coagulated transudate, which contains blood-cells and a moderate number of edematous leukocytes.

The retina is represented by a small, folded mass of tissue near the posterior pole, and can be recognized by the lines of cells composing its nuclear layers, and by the stretched-out fibers of Müller; but no trace of nervous element can be

detected. Between it and the optic nerve entrance are the remains of an old hemorrhage. The blood corpuscles stain faintly, and show masses of blood-pigment partly in free clumps, and partly in the bodies of broken-down leukocytes.

The optic nerve is quite atrophic. It exists only as a thin, hypernucleated strand, and shows no connection with the disorganized retina. Its nerve-fibers have disappeared.

REVIEW.

The microscopical examination showed an eyeball which had undergone phthisis, as the result of an acute suppurative process which had disorganized most of its component parts, particularly those in the posterior segment, and had caused rupture of the sclera with a consequent loss of a considerable portion of its contents. The posterior location of this spontaneous rupture is worthy of special mention, as it left a shrunken globe with the anterior segment, on first inspection, comparatively unchanged. Such ruptures usually occur at or near the sclerocorneal junction.

The desideratums of microscopic study of the case were:

1. To locate if possible the initial ocular lesion.
2. To demonstrate septic emboli in the choroidal or retinal bloodvessels.
3. To demonstrate the existence of microorganisms in the eye.

In the advanced stage of disorganization it was manifestly impossible to determine surely whether the process originated in the choroid or retina. No signs of embolism could be found. Sections were stained by the Gram-Weigert method and examined carefully for microorganisms, but none were detected.

A PRELIMINARY NOTE UPON HYDROCYANIC ACID GAS AS A DISINFECTING AGENT.

BY

JOHN S. FULTON, M.D.,

of Baltimore, Md.

Secretary of the State Board of Health of Maryland.

Experiments, which at present I shall report briefly, lead me to suggest that hydrocyanic acid gas may be found a reliable agent for house disinfection by boards of health, especially serviceable in maritime disinfection, and, alone, or in combination with other gaseous germicides, very effective against certain infectious diseases.

In bactericidal power hydrocyanic acid is inferior to formaldehyd, but formaldehyd is not more effective against diphtheria bacillus and the nonsporulating bacilli generally. It offers a slight advantage over formaldehyd for house-disinfection in that it is generated without fire. Reported experience does not indicate that formaldehyd generators are dangerous, but having narrowly missed burning a house in my own first disinfection with a Robinson lamp, I have constantly expected worse luck with lamps of any sort.

Hydrocyanic acid is somewhat more expensive than formaldehyd, and it is undoubtedly far more poisonous. The destructive effects of hydrocyanic acid upon animal life point to its usefulness in disinfection after plague, yellow fever and malaria. At quarantine stations formaldehyd has not found favor in the disinfection of vessels, the chief objection being that it is not very injurious to rats or other ship vermin. Hydrocyanic acid holds undisputed rank as the speediest of gaseous poisons. Indeed, the cyanogen compounds have a reputation so sinister that the proposition to employ the deadliest one in public health work is not likely to be received with enthusiasm. In books on toxicology, hydrocyanic acid and potassium cyanid always appear as the twin demons of sudden death, though no proof is asked or offered of their title to that terrible supremacy. Having inhaled the gas often and in considerable amounts without noteworthy discomfort, I have diminished somewhat my fears of its imputed energies, though its real power must always be respected.

In electroplating works, in photography, in engraving, and in various other industrial arts, enormous amounts of potassium cyanid are handled by working people of all grades; dangerous cyanids enter into the manufacture of certain explosives, and are present in aromatic substances in common domestic use; and yet there is no considerable literature of poisoning by cyanogen.

Since 1897, hydrocyanic acid gas has come into extensive use in the disinfection of orchards and of nursery stock, the dangerous gas being generated on a large scale by inexpert persons, but not a single fatal accident has yet been reported.

The gas has found a wide application in greenhouses, against the enemies of fruits and flowers. In order to avoid injury to plants some caution must be observed as to the amount of gas, as to period of growth of plants, as to surface moisture, and as to exposure to sunlight soon

after fumigation; but the precaution of 10 minutes' free ventilation of the fumigating room seems to be sufficient for the safety of those who are engaged in the work. It has been used in large flouring mills to eradicate the weevil and other insect pests. It has done this work without injury to the grain or flour exposed in fumigation. In South Africa, hydrocyanic acid fumigation is said to be employed to rid railway coaches of bedbugs, which are particularly troublesome in that climate. It has in a few instances been successfully used to kill the rats and mice in farm buildings and mills. Some of the earliest demonstrations of the usefulness of this gas to nurserymen and orchardists were made in Maryland by W. G. Johnson, State Entomologist; and through observation of his work I have been led to look into the effects of hydrocyanic acid gas upon bacteria.

The physical properties of hydrocyanic acid are pretty well known. The gas is lighter than air, and has an agreeable aromatic odor, quite familiar in the flavoring essence of bitter almond.

It is best generated by the action of dilute sulfuric acid upon potassium cyanid. The proportions are: potassium cyanid 1, sulfuric acid 1.5, water 2.25. Potassium cyanid suitable for this purpose costs about 32 cents a pound, and is 98% pure. Sulfuric acid of the best commercial grade, costing about 2 cents a pound in carboys, will do this work very well. The chamber acid used in fertilizer works is unsuitable.

The first step in making the gas is to dilute the sulfuric acid. This must be done slowly, and it is best to add the acid to the water. A good deal of heat is generated, and for this reason glass vessels should not be used for diluting the acid. Vitriified clay jars bear the heat very well. The whole amount of cyanid is put into the dilute acid at once. As the evolution of gas is very rapid, one must be ready to leave the spot immediately, or what is better, the cyanid, tied up in a bag, may be lowered into the acid by a cord passing outside the room.

The amount of gas used for plant fumigation, expressed in terms of cyanid, is about 25 grams per 100 cubic feet. For room-disinfection a greater amount is necessary.

In my first experiments the infected materials were enclosed in a 1500 c.c. hydrogen jar, and exposed to the gas for 24 hours. The organisms used were *B. typhosus* 5 times, *B. diphtherie* 7 times, *B. subtilis* 7 times, *B. coli communis* 4 times, *Staphylococcus pyogenes citreus* 4 times and *aureus* 4 times. The vehicles were glass rods; bits of linen, wet and dry; cotton swabs on iron wire, both wet and dry; cultures of the various organisms upon beef tea, plain agar, sugar-agar, or blood-serum. In all of these experiments, except 2, the amount of gas used was generated from 10 grams of potassium cyanid. Two experiments were made by exposing articles to the residual gas in the jar after the conclusion of a previous experiment.

Without giving the details of these observations it may for the present suffice to say that the resistant organism was *B. subtilis*, which was killed but once in 7 trials. *Staphylococcus citreus* was found alive 3 times, and *Klebs-Löffler bacillus* survived one experiment.

B. typhosus and *B. coli communis* and *Staphylococcus pyogenes aureus* were killed every time.

Iron wire, when wet, was attacked by the gas, and received a thin coat of Prussian blue. Paper labels on the test tubes exposed to the gas were stained brown. Some cotton which remained in the bottom of the jar through several experiments, took on a dark brown color, and the fiber became brittle. Cultures in unstoppered test tubes were inhibited or killed. Sugar agar in tubes took a reddish brown stain to the depth of half an inch or more. In this stained medium *B. subtilis* did not grow, though transfers from the stained area grew. *B. coli* did not produce gas in sugar agar when exposed to hydrocyanic acid gas, but transfers grew in a characteristic manner.

The single specimen of Klebs-Löffler bacillus which resisted the gas, was a beef tea emulsion from a 24-hours' growth on serum, dried upon a glass rod. Another specimen of the same sort exposed at the same time was killed. Linen infected with the surviving Klebs-Löffler bacillus in beef tea, was rendered sterile by 24 hours' enclosure in the jar, without the addition of any fresh gas.

The next experiments were made in a room of about 1,400 cubic feet capacity, without plastering, having a brick end, and 3 sides of plank, with one small hinged window, and one loose door. Infected materials were distributed to all parts of this room and exposed to the gas released from 600 grams of cyanid. Of 7 swabs and rods of *B. diphtheriae* but one failed to grow after 24 hours' exposure. Five specimens of *subtilis* all grew. Of 2 aureus rods one grew and one did not. One specimen of *B. coli* was uninjured. This trial indicated that the amount of gas recommended for plant fumigation is far too little to destroy bacteria under such conditions as this room presented.

Another distribution of infected articles was made and exposed to the gas from 1,500 grams of cyanid. There were 11 pieces of linen infected with *Staphylococcus pyogenes aureus*. Five of them were exposed in open petri dishes, the other 6 were left in the 2 test tubes in which they had been allowed to dry. The 5 in dishes were sterile; the 6 in the tubes grew aureus feebly.

Three glass rods with aureus, 3 with *B. coli*, 3 with *B. diphtheriae*, 3 with *B. typhosus* yielded no growth. Two pieces of linen with *B. diphtheriae* were exposed in open dishes, and 3 pieces were left in a test tube. All these were killed. Three bits of linen infected with typhoid bacillus were found sterile.

An experiment was then made in the same room with 1,200 grams of cyanid. Of 5 diphtheria rods 4 were killed, and 1, accidentally contaminated, was not tested. Four bits of linen infected with diphtheria bacillus exposed in open dishes were all killed. Several pieces of linen containing diphtheria bacillus were suspended in 2 test tubes, open end downward, from the ceiling. These tubes were poured with bouillon, and both grew diphtheria bacillus.

Five typhoid rods were all sterile. Four pieces of typhoid linen exposed in a covered petri dish, cultured separately, all grew. Typhoid linen, exposed in an open inverted test tube, grew.

Of 4 *subtilis* rods, 1 was sterile. *Subtilis* linen exposed in open tubes, mouth down, grew.

Of 4 aureus rods, 2 on the floor grew, 1 on a table grew, and 1 near the ceiling did not grow. Four bits of aureus linen in open dishes were sterile.

Three coli rods were killed. Of 4 sugar agar tubes inoculated with *B. coli*, 3 were suspended inverted near the ceiling over the gas jar, and 1 was kept as a control. The 3 exposed tubes showed no growth in 3 days after exposure. The control produced gas.

Another experiment was made with 1,500 grams of cyanid. Of 6 bits of typhoid linen, 3 wet and 3 dry, all were killed. Of 10 typhoid rods, 9 were sterile, and 1, accidentally contaminated, was not planted.

Four pieces of diphtheria linen, exposed dry, were sterile. Five diphtheria rods were sterile.

Of 10 pieces of aureus linen, 5 wet and 5 dry, all were sterile.

In all these trials media reported as sterile were kept from 3 to 5 days, and in cases of any doubt specimens were fixed and stained.

These experiments tend to show that, against organisms no hardier than *B. diphtheriae* and *B. typhosus* hydrocyanic acid gas is about as effective as formaldehyd, though a greater amount of gas is needed, and perhaps a longer exposure. One gram of cyanid per cubic foot of space is probably the correct proportion. No claims for great power of penetration can be made for hydrocyanic acid as against bacterial life. A gaseous germicide with great penetrating power is as yet a chimera. The failures to kill Klebs-Löffler, typhosus and coli bacilli in these experiments happened under just such conditions as would have led to failure with formaldehyd. The infected linen exposed in test tubes contained organisms protected from the gas at the points where the medium dried in contact with the glass, and such organisms would as certainly have survived formaldehyd fumigation, as the experience of the City Health Department of Baltimore shows. Such indeed was the result expected in these experiments, though it was thought that the hydrocyanic vapor, having much moisture and no tanning power, might perhaps penetrate better than formaldehyd.

Against animal life hydrocyanic acid has strong diffusive energy, as was proved in one of Johnson's experiments. A large tobacco warehouse was so thoroughly infested with insects that the owner was about to abandon both the stock and the building. Much of the tobacco was in hogsheads, and although these were not unpacked the infection was completely eradicated by a single fumigation with gas in less than half the proportion used in our experiments.

The need of a gaseous germicide which shall also be destructive of animal life is becoming more and more impressed upon sanitarians, and it seems not unlikely that hydrocyanic acid gas may to a considerable extent meet this need.

Testimonial to Dr. Babcock.—On March 27, the Wisconsin Legislature presented a bronze medal to Dr. Babcock in recognition of his service to the State by the invention of the milk tester. The presentation of the medal was a popular tribute to applied science as represented in the Babcock test, which makes scientific dairying practicable.

THE FOOD VALUE OF ALCOHOL, AND PROFESSOR ATWATER'S EXPERIMENTS AND TEACHING.

BY

JOHN MADDEN, M.D.,
of Milwaukee, Wis.

[Concluded from page 209.]

When we search for the points of resemblance between alcohol and the carbohydrates and fats we see that alcohol, like these foods, is oxidized within the body. This is the single point of agreement. Even in this point we must qualify our statement as to alcohol by saying that alcohol is thus oxidized when taken in small quantities.

When 2 or more objects are put in the same class the one requisite of classification is that these objects shall contain more points of similarity than of difference. Clearly, then, alcohol is not a food. On the other hand we might show that alcohol in its irritating, paralyzing, and destructive effects generally, is very like a certain class of poisons; that its resemblance to these poisons is much closer than its resemblance to foods with which Professor Atwater classifies it—probably five times as close.

Reference is made here to a few things which should be further discussed. That alcohol will kill* when taken in sufficient quantity is well known. Ten and one-third ounces have been known to produce death in an adult in good health. A much less quantity has been known to produce effects which have led to a fatal issue, acute Bright's disease being one of the most common disasters resulting from alcoholic poisoning.

Just here we wish to call attention to the complacency with which Professor Atwater discusses the probable results of taking large quantities. He says †: "It is thus reasonably clear that alcohol can provide the body with heat. It seems probable that it also yields energy for muscular work, but to prove this absolutely is not easy. The difficulty is to make experiments in such a way as to show conclusively that the energy used by the muscles comes from the alcohol and not from the other materials of either the food or the body itself. When a man takes beer, brandy, or other liquor with his ordinary food, the proteids, fat, sugar, starch, and alcohol are used together as fuel, and we cannot say just what is done with the energy of each. It is a case of pooling. If the experiment was made with lean meat and alcohol—that is, a list containing protein and no other fuel but alcohol—it might, perhaps, be more decisive, but it would probably be difficult to find a man who could do hard work day after day on such a diet without drawing upon the materials of his body, at least such experiments have to my knowledge never been carried out."

Suppose we undertake to give the subject of our experiments a sufficient quantity of alcohol to supply him with the energy he gets in the fats and carbohydrates of his ordinary food, what would be the result? Let us see:

Moleschott's dietary calls for: fats, 40 grams; carbohydrates, 400 grams. Now each gram of fat yields on

combustion 9,312 gram calories,* and each gram of carbohydrates yields 4,115 gram calories when burned. Moleschott's dietary would, therefore, call for a total of 2,636,280 gram calories. The fats yield:

$$9,312 \times 40 = 372,480 \text{ gram calories,}$$

and the carbohydrates:

$$4,115 \times 550 = 2,263,800 \text{ gram calories.}$$

$$\text{Total, } 2,636,280 \text{ gram calories.}$$

One gram of alcohol burned yields, in round numbers, 9,000 gram calories; therefore, we must give our subject 293 grams, or about 9.1 ounces of absolute alcohol, or 18 ounces or more of brandy or strong whisky. Taking Atwater's dietary the amount is even greater—9.7 ounces of absolute alcohol, or about 20 ounces of strong brandy or whisky. It would, indeed, "probably be difficult to find a man who could do hard work, day after day, on such a diet without drawing upon the material of his body." This quantity of alcohol, as a matter of fact, would be sufficient to keep almost any adult individual in a constant state of intoxication, attended by all the destructive changes produced by alcoholic poisoning with which we are, unhappily, so familiar if it were not immediately fatal.

The surprising element in this statement is the careless confidence with which Professor Atwater discusses the giving of these almost lethal quantities of alcohol. Perhaps it was written in a moment of carelessness; but can we excuse carelessness in one who undertakes the task of teaching all of our people upon this vitally important subject?

In what manner alcohol interferes with the normal gas interchange of the entire body, with the cell absorption of oxygen and excretion of carbon compounds, we shall not fully discuss here. A very clear and convincing exposition of this phase of the alcohol question may be found in Dr. A. Smith's "Die Alkoholfrage," p. 12. † Because of this interference with cell oxidation, Dr. Smith, with good reason, calls it a "respiratory poison." Indeed, it is the alcohol's affinity for oxygen which causes it to so unfavorably affect cell protoplasm, destroying the chemical balance and producing premature cell dissolution.

That glandular activity is temporarily suspended by moderate doses of alcohol, we have the evidence of the carefully carried-out experiments of Blumeneau, of St. Petersburg, and our own Professor Chittenden; that muscular efficiency was always decreased in the normal unfatigued muscle, we have the careful work done by Dr. Herman Frey, using Mosso's ergograph; and that mental capability was always lowered, we have more than 1,300 tests made by Professor Kraepelin.

One further criticism upon the experiments of Professor Atwater in his misinterpretation of the results he obtained when he sought to determine the heat producing power of alcohol. Relative to this matter he says: "When we come to examine the matter closely we find that although the temperature of the body falls considerably after very large doses of alcohol have been

*Taylor gives the fatal dose of pure alcohol as between 2 and 6 ounces; Blyth at between 2.5 and 5 ounces.

† Loc. cit.

*A gram calorie is sufficient heat to raise one gram of water one degree centigrade, and equals one one-thousandth of a kilocalorie.

† It can also be found in my own work, "Shall we Drink Wine?" p. 37-8.

taken, and especially under exposure to great cold, the effect of ordinary doses is slight and often imperceptible.

When, further, we take pains to calculate how much heat the body would have to lose in order to reduce its temperature as much as is done with a bottle of wine or 1 or 2 glasses of whiskey, we find that it will correspond to only a small fraction of the heat which the alcohol yields to the body."

This that I have put in italics is Professor Atwater's answer to those who claim that the excess in heat radiation after the ingestion of a quantity of alcohol is so great that it equals the total latent heat of the alcohol ingested. In other words, that when a quantity of alcohol is taken the amount of heat radiation is equal to the potential heat of the alcohol plus the normal heat radiation. "This cannot be so," says Professor Atwater, "because the temperature of the body is not lowered sufficiently to indicate the loss of so much heat." Now, if the human body were an inert mass of matter it would be proper to proceed as he has done to determine this question of increased heat radiation; but with the human body we cannot think that he has proved his point. The amount of heat radiated from the body on a winter's day may be twice or thrice that radiated on a summer's day, yet the temperature of the body remains the same, while, according to Professor Atwater, the temperature of the body should fall at once whenever the heat radiation increases above a definite rate; but physiologists know that there is a nervovascular mechanism which looks after the temperature of the body with great care, closing up the chief exit of heat and ordering the consumption of more fuel when the loss of heat is great, and throwing wide open the heat exit and ordering the consumption of less fuel when the radiation of heat from the body is at a minimum.

The test applied by Professor Atwater to determine whether there be increased radiation or not was to measure the total output of energy first with an ordinary food, and then with a food in which a part of the fats and carbohydrates were left out and an isodynamic quantity of alcohol substituted in their stead. Two pairs of experiments of this kind were carried out. In one pair the subject was at rest, and in the other he performed muscular work on a stationary bicycle. With the subject at rest when no alcohol was taken the quantity of food burned up had a potential energy of 2,277 kilocalories* and gave off in heat 2,309 kilocalories; and with the man engaged in active muscular exercise without alcohol the amount of fuel burned had a potential energy of 3,900 kilocalories, and gave off in energy (heat and work) 3,932 kilocalories. When a part of the nonnitrogenous food of the subject consisted of alcohol, when at rest the amount of food consumed had a potential energy of 2,269 kilocalories, and he eliminated 2,283 kilocalories as heat; and while doing work the income and outgo were 3,923 and 3,923, respectively.

It will be seen upon inspection of these figures that no more fuel was consumed and no more energy given off when the food contained alcohol than when it contained no alcohol. From this fact he concludes that the radiation of heat from the body has not been increased by

the ingestion of alcohol. His (Professor Atwater's) proposition is like this: If alcohol increases heat radiation the total quantity of heat radiated from the body during any given time after its ingestion must be greater than it is when no alcohol is taken. If the total quantity of heat radiated is greater, then more fuel must be burned to supply it; therefore, the ingestion of alcohol should be followed by an increase in the total output of heat and an increase in the consumption of food materials.

Now, these are by no means necessary conclusions. In order to have a greater amount of heat radiated, more fuel must be oxidized, therefore more oxygen must be at hand to effect the oxidation, and this increased supply of oxygen must come by increasing the respiratory rate, i. e., the number of respirations per minute; but alcohol does not increase the respiratory rate; indeed, when it is taken in considerable quantities the respiratory rate is decreased. Moreover alcohol, like all other narcotics, temporarily interferes with oxidation of food material. It is possible to conceive of a condition in which the rate of radiation is slightly increased above the normal while heat production remains the same. This would, of course, lead to a lowering of the temperature of the body temporarily; but this process could not go on indefinitely for it would, in a longer or shorter time, lead to so great an abstraction of body heat that death would result. We must not lose sight of the fact, however, that the abstraction of heat from the body, when the heat production is not disturbed, leads to an immediate diminution of its output by constricting the surface vessels and thus keeping as much as possible from radiating. We thus see that an increase in heat radiation would be normally followed by a compensating decrease, and the sum total of heat radiation would indicate no increase for the whole 24 hours. Indeed, we have good reason to believe that alcohol acts precisely in this manner, and that there may be a temporary but still decided increase in heat radiation which would not be shown by Professor Atwater's experiments. At any rate, the fact that the bodily temperature falls immediately after the ingestion of alcohol remains undisputed, and we must from that fact conclude that less heat is produced when alcohol is present in the system, or that the rate of radiation is greater, with the preponderance of evidence in favor of the latter proposition. We cannot, therefore, accept Professor Atwater's conclusion that alcohol is as valuable, from this point of view, as any other food.

The older physiologists and physicians believed that all food material, whether nitrogenous or not, must first become a part of the complex protoplasmic molecule before it can give rise to the production of heat or any other form of energy. This is known as the "Anabolic" theory, or conception of nutrition. Subsequently it was held that many materials, notably the carbohydrates and fats, were oxidized and gave rise to energy without being built up into the protoplasmic molecule. This was known as the "catabolic" theory, or conception of metabolism.

That anabolism does play an important part in tissue metabolism is admitted on every hand. Protein is built up into the complex protoplasm molecule, and this molecule is, during its functional activity, broken down into

* A kilocalorie is an amount of heat necessary to raise one kilogram of water one degree centigrade, and equals 1,000 gram-calories.

simpler chemical substances, the energy stored in its building up being at the same time liberated. Speaking of the advantages which the anabolic theory has over the catabolic in explaining certain phenomena of metabolism, Professor Kassowitz remarks: "But the greatest benefit, at any rate, is that the anabolic process certainly exists, because all newly formed protoplasm is originated at the expense of food, and all protoplasm waste is certainly the result of breaking down the protoplasmic molecule; while the katabolic process is only hypothetical. We have not the least actual proof that in the living organism albumen is ever resolved directly to urea or sugar to carbonic dioxid and water, without having previously formed a part of the constituents of the chemical union called protoplasm." What evidence Professor Kassowitz has to support this proposition we do not know. It is, however, generally asserted by physiologists that a certain portion of the peptone resulting from pancreatic digestion (antipeptone?) is split up by bacterial action into leucin and tyrosin and that a further change results in the production of urea, this change taking place in the liver. There is no room here for a complete discussion of this phase of metabolism, besides, it would involve so much that is technical that the general reader would be more likely to be puzzled than enlightened.

In favor of the anabolic conception are the mechanic and chemic facts of metabolism. Indeed, it is difficult from what we know of the forces concerned in tissue metabolism to explain metabolic changes as they occur in the body without admitting the anabolic conception as being correct. Destructive tissue changes we know occur under the influence of irritants called stimuli. These stimuli are mechanical, chemical, electrical, thermal or nervous. The last named stimuli are the cause of the greater part of destructive tissue change in the body. These are concerned in all mental processes, glandular activity, and muscular contraction.

Now, it is well known that a highly complex molecule, such as forms the animal protoplasm, is much more easily broken down than the comparatively stable molecules entering into the formation of albumen, sugar, and fat. It is held therefore, that while all these forms of energy mentioned above are sufficient to break down the protoplasmic molecule, they are not sufficiently intense to resolve the molecules of albumen or sugar or fat into their simpler elements. In other words, it is held by adherents of the anabolic conception of metabolism, that the normal physiologic stimuli, while amply able to break down and liberate the latent energy of the protoplasm molecule, are not sufficient to break down the different food molecules.

At the present time the katabolic conception of carbohydrate digestion is that this class of foods reaches the tissues as sugar (dextrose) and are there directly oxidized. Glycogen is a dehydrated sugar stored up in the liver-cells when more carbohydrate food is taken than is immediately needed for tissue consumption, and it is given off gradually, as needed, but it is first converted into sugar before being oxidized in the tissues. A more permanent way of storing an excess of carbohydrate food is in the form of fat. This storing also occurs when more carbohydrate food is taken than the tissues need as

a source of energy. Whenever the carbohydrate and fatty food is insufficient, however, the tissues immediately draw upon their reserve supply of fat for energy to carry on their work, and it is just in this place that the katabolic conception of food metabolism puzzles us the most. We are entirely in the dark as to how this stored fat is consumed. We know absolutely nothing about the manner of its absorption and oxidation.

Here, then, is the apparent inconsistency: While, according to the metabolic theory, a part of an apple we eat today reaches the tissues as sugar and is there directly oxidized, a part of it is stored as fat to be used, perhaps, months hence, in a manner about which we know nothing. According to the anabolic conception of metabolism, all substances which are merely oxidized within the body, and which at no time enter into any part of the protoplasmic molecule, are not nourishing and must be barred as foods, and especially shall they be rejected when they contain properties highly destructive to tissue protoplasm, as is the case with alcohol.

Theoretically any substance containing latent energy which may be converted into kinetic energy through the digestive processes might be called a food. Admitting this proposition without limitations, the greater the amount of energy, the greater the number of calories which a substance contains, and the greater the ease with which this energy is set free, the greater the food value of the substance.

Such substances as gunpowder, nitroglycerine, gun-cotton, and the like, containing an enormous amount of latent energy would be valuable as foods provided, (1) that the introduction of any one of them had no irritating effects upon the tissues with which they come in contact; (2) that the energy contained therein might be liberated in an orderly manner as needed by the tissues, all excess being stored for future use. Just in that degree with which any substance conforms with these conditions is it valuable as a food.

Testing alcohol by these requirements what do we find? In the first place, on all hands, it is recognized as an active protoplasm poison, so active, indeed, that less than a fourth as much as is necessary to furnish the tissues with fuel may be taken daily without tissue derangement being universally apparent, and but a very little more than enough to supply the tissues with their daily needs of fuel has been found sufficient to destroy life when taken in a single dose. Does it need a technical education to determine whether any poison so violent as this shall be called a food or not? It seems that very few facts in science admit a clearer demonstration than that alcohol is not a food. Its destructive properties alone are sufficient to at once and forever bar it from the lists of foods of any class. Suppose you were a traveler in a savage country among savage people, and you became hungry, as it is quite likely you would become, and your savage hosts should set before you a food, some species of banana if you please, telling you that it was a valuable and universally used food, but that you might not eat more than one-quarter enough to satisfy your wants, and that if you ate enough to supply the needs of your body quite likely it would kill you?

Would you not marvel that these people should call anything so dangerous a food? Would you, indeed, take any part of it?

Many poisons besides alcohol contain a large amount of latent energy which is easily set free in the body. Phosphorous, many ptomaines, and numerous other substances have both of these properties. Shall we say that these substances, too, are foods when given in small quantities; that is, in quantities too small to produce lethal effects or effects which are not greatly destructive to the tissues with which they come in contact? Shall we make of alcohol one-fourth of our nonnitrogenous food, of phosphorus a still smaller fraction, and of other oxidizable poisons other still smaller fractions, simply because in these quantities they do not kill nor do any great apparent damage? Surely there is only one answer to a question of this kind.

A CASE OF DOUBLE BLADDER: EACH WITH A SEPARATE URETER. A STUDY OF THE URINE FROM EACH KIDNEY.*

BY

E. P. HERSHEY, C.E., M.D.,
of Denver, Colo.

The existence of a condition apparently so rare as double bladder may be of more frequent occurrence than has appeared in literature. The case about to be reported escaped discovery for 28 years, regardless of the symptoms present, which should have led to its detection. Up to 1881, 2 cases only were recorded, these are found in Holmes' "System of Surgery." One of these occurred in a woman, and presented 5 bladders, 5 kidneys and 6 ureters (Molinetti). Uitzman (*Krankheiten der Harnblase*, 1890), reports a case of double bladder (vesica duplex) and a divided bladder (vesica bilocularis). Blasius described a case of double bladder in an adult, with a common urethra, the bladders being completely separated. Other cases have been reported by Schotz, Cattier, Molinetti and Vidal, although mostly in children.

The condition is somewhat difficult of diagnosis, as is evidenced by the fact that most cases reported have been found at autopsy. Modern methods of examining the bladder and studying the secretion of the kidneys may bring to light other cases similar to this, and I hope through my experience to be of some aid in their discovery.

The interesting features of this case are: The age which the patient reached before its discovery was made; the manifold diseases for which she was treated; and the excellent opportunity offered to study the action of both kidneys.

Mrs. E., aged 28, came to me January 13, 1901, with a diagnosis from another physician of incurable Bright's disease; I examined the specimen of urine she brought with her, and found it filled with pus; specific gravity 1.018. She stated that the bladder never felt empty after urinating. I had her void her urine, then passed catheter, obtaining about 60 cc. of a fluid

nearly pure pus. I diagnosed diverticulum of urethra, as the catheter could be passed through channel when directed upward and clear urine obtained. The patient then gave the following history.

At 2 months of age she had scarlet fever, and was seriously ill for 6 weeks, complete recovery following. At 10 months she began to show symptoms relating to the bladder. She frequently but not constantly had pain when passing urine. Her mother states that as a child the patient had incontinence of urine, continuing until 16 years of age. During this time any violent exercise would bring on severe pains in the region of the bladder and more or less incontinence. At the age of 12 she was injured by lifting large timber, resulting in severe strain of muscles of back; this confined her to her bed for nearly 3 months. At this time there was much trouble with the bladder. When 15 she was sent to live with a relative who made her do all the drudgery of housework. After 6 months she was taken ill with very severe pains in the region of the bladder radiating through the left side. She could not pass urine at all. In attempting, at the beginning of the attack, to walk a long distance toward her home, she was frequently compelled to stop until urine had dribbled away for some time. She could then continue walking. During 6 weeks illness, pronounced exhaustion from overwork, she was kept constantly under opiates and was practically unconscious throughout.

Up to 21 years of age she had 2 attacks of the same character each year (usually in August and December). These attacks always came on with severe pains in the pelvis, lasting from 7 to 10 days. It was during this period she discovered that during the most violent paroxysms of pain she could pass the finger into the vagina, and by pressing what she termed a large lump on the anterior wall, could squeeze out considerable matter, which escaped through the urethra. This was usually followed by instant relief.

At the age of 21 while in excellent health, she was taken suddenly ill. The symptoms were marked by intense pain in the region of the bladder, extending up the left side of lumbar region. There was a violent chill, followed by high fever. There was more or less stupor. Pus ran from the urethra almost constantly, and led to the diagnosis of an unusually aggravated attack of gonorrhoea. At this time patient claimed great relief from vaginal douches; she always directed the nurse to push the nozzle of syringe firmly against the anterior wall of the vagina. This was invariably followed by discharge from the urethra. The physician in charge changed his diagnosis from gonorrhoea to typhoid fever. This attack lasted 2 weeks.

Up to January, 1900, the patient had attacks similar to these antedating the one just narrated. At this time another severe attack came on, the diagnosis was then made of disease of the left tube and ovary. The constant presence of pus around the vulva led to a curetment, followed by a section. The left tube and ovary were removed and a ventral fixation was done. After these operations there was no abatement of symptoms. She has had 3 distinct attacks since, one of which again called for the diagnosis of typhoid fever. It appears that in each attack there was a large tumor felt by the patient, about one-fourth of the way up the vagina almost closing this channel. Whenever this mass disappeared it was preceded by an unusual flow of pus from the urethra.

January 22, 1901, I had Dr. Leonard Freeman see the case with me. A catheter was inserted and clear urine was drawn from the bladder. After emptying the same the catheter was withdrawn and then passed into the urethra with the curve pointing downward, and considerable pus withdrawn. We both agreed upon the diagnosis and advised operation for the purpose of closing the diverticulum.

January 24, the patient was prepared for operation. Upon further examination under anesthesia, the supposed diverticulum was found to extend far up the pelvis, behind the uterus, and as far along the rectum as the finger could reach. Urine began to trickle from the catheter, so a second catheter was passed through the urethra and directed upward, the urine that trickled from each catheter was preserved in separate bottles for examination. The specimens under microscopic exam-

* Read before the Denver and Arapahoe Medical Society, February 26, 1901.

ination differed so materially in character that but one conclusion could follow, a double bladder, each with a separate ureter. The question now arose as to the origin of the pus, whether it came from the kidney, the bladder, or both.

February 10, the patient was placed on methylene-blue, 1 grain, every 6 hours, and the following day both bladders catheterized at intervals with the following result:

Time	Healthy Bladder	Unhealthy Bladder
8:30 a.m.	124 cc.	10 cc.
12: m.	30 cc.	64 cc.
4:30 p.m.	95 cc.	7 cc.
8: p.m.	100 cc.	8 cc.
1: a.m.	88 cc.	4 cc.
Total, 24 hours.	437 cc.	93 cc.

There was a striking difference in the color of the urine drawn from each bladder; the quantity drawn from the healthy bladder being 5 times more than that drawn from the other. The total amount of 530 cc. was secreted in the 24 hours, being far below the normal.

On this same day, at 4.30 p. m., the patient requested catheterization, as she felt the diseased bladder filling up. The catheter was passed first into the healthy bladder and the urine drawn off, it was perfectly clear and dark blue. The catheter was then passed into the posterior bladder and a thick, light-blue fluid withdrawn. The lower bladder was then washed out and the catheter allowed to remain. The kidney secreted rapidly for a few moments and then ceased entirely. This urine was saved for examination. Microscopically, it was found to be loaded with pus, and contained many tubular pus-casts from the kidney. Diagnosis, surgical kidney.

February 14 the patient was ordered not to pass urine at any time, but to have the healthy bladder catheterized, after which she was to attempt to empty other bladder without assistance. The following table shows the results:

Time	Healthy Bladder	Unhealthy Bladder
11:30 a.m.	132 cc.	Not drawn.
4: p.m.	88 cc.	Not drawn.
8: p.m.	80 cc.	Not drawn.
12: m.	92 cc.	Not drawn.
8: a.m.	104 cc.	Not drawn, some pain.
10:45 a.m.	24 cc.	166 cc. preceded by intense pain.
Total in 26 hrs. 30 min.	520 cc.	166 cc.

This shows patient unable to void urine from posterior bladder. Since this last experiment the patient was put on urotropin 5 grains 4 times a day. Considerable pus but very little urine, not more than 30 cc., was drawn from the bladder every 24 hours, and the bladder washed out with a solution of creolin.

It appears then that the following has been gained in point of diagnosis up to the present time, February 26: Surgical left kidney with a dilated ureter and collapsed bladder. The following drawing represents the condition.

From a close study of the minute details of the case, many of which are not contained in this history, it appears that there was a congenital malformation, *i. e.*, a double bladder, each with a separate ureter, the dividing membrane being horizontal. The posterior bladder suffered by virtue of its position. At the age of 15, the orifice of the posterior bladder became closed, the long spell of unconsciousness causing enormous dilation; this was followed by dilation of the ureter, thus causing surgical kidney. The left kidney is

so far diseased that it secretes urine only at times, and when this secretion occurs the posterior bladder fills and unless this is withdrawn the bladder becomes overdistended, until becoming full to its limit, the urine is voided by virtue of its own pressure.

The condition preceding this calamity was evidently one in which the anterior bladder was closed by its sphincter, the posterior but feebly controlled by a sphincter. The posterior bladder walls had the power of contraction until the patient was 15 years of age, but always was more or less of an irritant. At the present time the posterior bladder, if not catheterized, will empty itself slowly, but not without prostrating the patient.

The question naturally arises as to whether or not the left kidney should be removed. Throughout 6 weeks' close observation no more than 685 cc. of urine have been secreted from both kidneys in 24 hours. Since February 26 the patient has been given urotropin, 5 grains 4 times a day, and has drunk large amounts of mineral water, this has been followed by an increase in the daily secretion of urine. The left kidney secreted urine somewhat clearer. The largest amount secreted during any 24 hours was on February 28: Right kidney, 650 cc.; left kidney, 220 cc. March 2 the patient took neither the urotropin nor the mineral water, having recognized the fact that when catheterization was inconvenient the kidney secreted much less, and she could go over 48 hours without any annoyance. The amount of urine passed in 24 hours was: Right kidney, 500 cc.; left kidney, 30 cc., an amount so far below the normal that no operation was performed, as it was evident the right kidney was not capable of secreting enough urine.

A very important question as to the positiveness of the fact as to any connection between the bladders was settled. On March 2 the anterior bladder was filled with a deep blue solution of methylene-blue, the posterior by a decinormal salt solution, and the patient directed to roll around, lift the hips high, walk and get into every conceivable position. The posterior bladder was then catheterized and no color appeared. The anterior was then emptied and the solution withdrawn. On the following day the blue solution was placed in the posterior bladder and the salt solution in the anterior. The result was negative. This to my mind seems to be conclusive evidence that the partition between the bladders is impervious.

But a single question of doubt arises as to the positiveness of the condition diagnosed. It may be possible that the ureter emptied into the urethra instead of the bladder, and in infancy became dilated. There is no history of constant dribbling of urine, which would follow were this the case.

That the condition was not caused by the ventral fix-

ation of the uterus is evidenced by the fact that the symptoms before and after the operation are identical, and each attack antedating the operation, when the details are closely followed, gives a line of symptoms which puts the diagnosis beyond a question of doubt.

The secretion from both kidneys will be closely watched. If, in the course of time the patient's life should be put in jeopardy, regardless of the small amount of urine secreted, the left kidney will be promptly removed. If, after the freezing point of the blood has been determined, it should be found normal, regardless of the small amount secreted, the operation will be performed.

April 28, the patient is much improved. During the past 2 months the posterior bladder was first treated daily by means of solution of creolin, the treatments being gradually diminished until the present time, weekly washings being all that is necessary to keep patient free from pain. She has gained in weight 15 pounds.

TRANSFUSION, INFUSION, AUTOTRANSFUSION.

BY

G. W. WAGONER, M.D.,

of Johnstown, Pa.

Time was, and not very long past, when, to most practitioners of medicine, transfusion and its allied subjects were matters that were believed to have been relegated to that limbo where the ghosts of specifics, cure-alls, resurrection-operations, life-giving serums and bactericid toxins, jibber forever to each other of what they could have accomplished for humanity, if the said humanity had not persisted in following the laws of life, which of necessity lead to death. But later patient research and experiments demonstrate the importance of the subject and justify an enthusiastic acceptance of the theory upon which the modern practice is founded as promising relief in many of the most desperate cases of injury and illness which come under our care.

By *transfusion* we mean the introduction into the vessels of the body of fluid material, especially of blood taken from another body, also the act of causing a fluid to pass through the skin into the body; *infusion*, a pouring into, as distinguished from transfusion, the gentle injection of any other liquid than blood into a vein or subcutaneous tissue; and by *autotransfusion*, the application of elastic or muslin bandages to the extremities for the purpose of forcing the blood toward the vascular and nervous centers, emptying the vessels of the extremities into the vessels of the abdomen, lungs and brain, and keeping it there until the crisis has passed.

The vital importance of the blood to the human being is a fact that must have been one of the first to be learned by our ancestors. Ancient literature makes mention of wild hopes of renewed youth firmly attached to the operation of transfusion. It was proposed as a specific for almost every fatal disease. It obtruded into experimental medical practice at various times in our era. It is said that one of the Popes in the fifteenth century in his passion for life had the blood of 2 healthy

youths instilled into his veins, but the story says that he and his sacrificial offerings were gathered to their fathers in a few hours after the operation. In 1666 an English author published a work recounting his experiments on dogs, which placed the operation upon a firmer scientific basis than it had been before. In 1667 transfusion was successfully done in France and in 1668 in Italy. The success seemed to be so marked that the treatment immediately came into vogue, and as a result of the infatuation, it was soon so carelessly done and for such inadequate reasons, that failure and death were the almost invariable results. Opposition arose and in 1675 transfusion was prohibited in France by Act of Parliament. Thus the matter stood for a century and a half until, in 1815, it was again brought forward in London by Blimdel, who also published a treatise on the operation in 1824. His method was to collect the blood from the donor's veins in a cup and inject it by means of a syringe directly into the veins of the patient.

In 1828 the operation was somewhat refined by Diefenbach, who described the 2 methods as we now know them—the *mediate* when the blood is transfused by means of a syringe, the *immediate* when the blood of one person or animal is made to mingle directly with the blood of the patient or animal through a suitable communicating tube. He also introduced the use of defibrinated blood. Since that time the operation has been perfected and a number of elaborate instruments devised which are designed to render it safe by excluding air from the stream of blood as it passes into the vein of the patient, an accident which is almost immediately fatal. No instrument has yet been devised with which the operation can safely be performed. Notwithstanding the care and skill exercised in the operation, it has often been followed by a fatal result, and this, too, when whole blood, either human or animal, defibrinated blood or milk has been used. The formation of clots, the entrance of air and the formation of fatty emboli are the uncontrollable dangers that beset transfusion. If the blood of an animal is transfused into the vein of a human, a new and additional danger must be met. Such blood immediately dies in the human circulation; it becomes a poison, destroys the blood-cells of the patient and entails upon his organs the excretion of an abnormal amount of excrementitious matter. The temporary revivifying effects of an increased mass of blood cannot counterbalance the immediate and remote dangers which attend transfusion. After a careful study of the subject, Professor von Ziemssen rejects the operation and concludes: "I would, under no circumstances, subject a patient to the great dangers of intravenous transfusion."

During all these years the hope for ultimate success by means of transfusion was based upon a solid and seemingly incontrovertible physiologic reason. Transfusion was indicated in severe cases of hemorrhage. Death by hemorrhage was assumed to be due to the loss of the carriers of oxygen, the blood-cells. What prevention should be more certain than to furnish the dying body with a new supply of carriers of oxygen? But the expected result did not work out. There must be something in the conditions of the problem which was not understood. Goltz came forward with a physical

reason. "Death was due to the emptying of the pump-works." That the heart can only set the blood in motion when there is a certain amount of tension in the vascular system. It is not deficiency of blood-corpuscles, of carriers of oxygen, but deficiency of *fluid* that causes death. It is not the quality of the fluid injected but the quantity that is beneficial. This doctrine was soon put to the test of experiment. Dogs were rescued from death by the infusion of salt solution after being bled until moribund, and Schwarz in 1882 published his paper maintaining the same fact in regard to the human. But as early as 1830 the same important fact was almost worked out by Latta, of Scotland, and Magendie, of France, in their treatment of cholera. They reasoned that the excessive loss of serum by the bowels in cholera was the great factor in causing the algidity and subsequent death, and that if this serum could be replaced the patient's chances of recovery would be improved. It was easy to compound an artificial serum and infuse it into the thickened blood of the patient. The result justified the reasoning and made the subcutaneous or intravenous infusion of artificial salt-solution a legitimate means of relief in cases of cholera.

M. Schwarz has been accorded the honor of demonstrating the true reason why the infusion of a saline fluid is a safe and very useful remedial measure. That reason is "that the heart does not contract unless a sufficient quantity of fluid is poured into its cavities, and this fluid must be under a pressure sufficient to bring into play the contractile energies of the heart. Inject then into the venous system an alkaline liquid homogeneous with its serum, and reestablish the vascular tension, you will restore activity to the circulation and will prevent the production of fatal accidents." The solution he proposed for use is composed of 6 grams sodium chlorid, 20 drops liquor soda and 1 liter distilled water. The good results of saline injections have been so manifest that no surgeon could excuse himself if he allowed a patient to die from hemorrhage without making use of this means when possible to do so.

Infusion of the saline solution may be done in 3 ways: intraarterial, intravenous and subcutaneous. By the intraarterial method the solution is gently forced into a large artery by cutting down and introducing a canula, or through a large hypodermic needle inserted into the artery. There is no possibility of air reaching the heart by this method, for the solution must pass through the capillaries and everything of a dangerous character is intercepted. By the intravenous method the solution is usually introduced into the median basilic vein by means of a proper canula, tube and funnel. It is unnecessary to describe the operation, as it is comparatively simple. Neither is it necessary to say, at this day, that it must be done aseptically. The subcutaneous method may be carried out with the aid of a large hypodermic needle attached to the bag of a fountain syringe which is elevated sufficiently to give the required pressure, or by attaching the needle to a bulb syringe, or by the use of an aspirator. The needle should be inserted in the loose tissues of the chest walls, abdomen or inner surface of thighs. Under favorable condition it is possible to inject a quart of solution into the loose subcuta-

neous tissue. The subcutaneous method offers some advantages over the other 2 methods. It does not appear so much like an operation and the patient and friends will consent to it more readily. There is not pain enough to require the use of an anesthetic, and no danger, as the local disturbances disappear in a few days at most, and the operation may be repeated frequently. There is no sudden increase in the blood-pressure because the fluid is slowly taken into the circulation. The quantity that should be infused by either of the methods cannot be fixed definitely. Less than 1 pint, however, is of very little use in the case of an adult. In cases of extreme urgency one cannot attempt to carry out the refinements of the operation. Then a teaspoonful of salt in 1 quart of water that has been boiled, strained and at a temperature not exceeding 110° can be used with the precautions that are possible under the circumstances. I believe in such an emergency the cutaneous method is the better one, for, however hastily the operation is done, it could not be dangerous in itself.

Autotransfusion can only be considered as a good transient expedient, applicable until saline injections can be used, or to supplement the latter. The transfusion of milk is attended with all the dangers of the transfusion of blood and has been relegated to obscurity with it, since the superiority of saline injection has been demonstrated. For all practical purposes the infusion of saline solution alone deserves consideration as a therapeutic agent. It is indicated in the following conditions:

Hemorrhages, from whatever cause, and especially the obstetric hemorrhages.

Shock, with or without loss of blood.

Collapse, occurring in the course of any disease, particularly cholera, cholera infantum, typhoid fever, and especially in the collapse following severe operations.

Puerperal infection, in which the salt solution is given to increase the power of the tissues and blood to resist the action of the microbes, destroy them and assist nature in throwing off their effects. It should be given hypodermatically in 2-ounce doses, twice daily for some days. Good results have followed such a practice and it may be that other infectious diseases would be benefited by similar treatment.

Epilepsy and puerperal eclampsia, especially after a preliminary bleeding.

Uremic convulsions, both after bleeding and as a diluent of the blood, and to favor the elimination of urea by the kidneys.

In poisoning by coal gas or by narcotics, it is a powerful aid to elimination.

Anemia, in the different forms, to be followed by appropriate food and medication.

In all cases the treatment must be considered as the most helpful expedient that can be used to bridge over the gravest emergencies, and thus gain sufficient time in which the slower acting but more permanently useful remedies may exert their curative effects.

Unlicensed Practice.—A "nervopathist" who had been fined \$100 in Los Angeles for practising medicine without a license appealed to the Supreme Court. He found that body would not revoke the decision of the lower court.

LITHOLAPAXY IN A CHILD FOUR YEARS OLD, WITH AN IMPROVED EVACUATOR.

BY

GWILYM G. DAVIS, M.D., M.R.C.S.,

of Philadelphia.

The patient was a male child 4 years of age. For 2 years previously he had suffered with symptoms of stone in the bladder. He urinated frequently and the stream at times stopped suddenly. He cried with pain when he urinated and grasped the penis. He never passed any blood. An examination with a sound showed the presence of a calculus. The patient was etherized and the bladder emptied of urine and injected with a couple of ounces of boracic acid solution. The meatus was cut and the lithotrite, a No. 18 French Scale Civiale instrument, introduced into the bladder. The urethra grasped the blades quite firmly as it was evidently distended to its greatest capacity. After the lithotrite had been introduced it was found to be still loose enough in the urethra to allow of its being rotated. The male blade worked perfectly freely. The stone having been found and crushed, an ordinary silver catheter, No 17 French Scale, was introduced. This was attached by means of a gum tube a few inches long to an ordinary 1-ounce glass syringe. The syringe, being filled with boracic solution, was attached to the rubber tube and its contents injected into the bladder. It was then lowered and the piston drawn back withdrawing some

of the contents of the bladder. The fragments followed the stream up the catheter into the syringe and settled on the piston. The syringe was then removed, emptied on gauze to strain out the fragments, and refilled with boracic acid solution and the process repeated until no more fragments could be obtained.

On the day following the operation the temperature rose to 101.4° and the prepuce was swollen. On the third day the temperature had fallen to normal and in a week the child was discharged. There had been no unfavorable symptoms nor even discomfort since the operation. The stone was an oxalate of calcium or mulberry calculus and weighed about 20 grains.

The case is of interest on account of the age of the child as showing the feasibility of the procedure employed, and also on account of the method used for removing the fragments. Vesical calculi are comparatively rare in this locality and few surgeons have a complete Bigelow's outfit for children. Of course a lithotrite of a suitable size is essential but the remaining apparatus is at every one's command and will be found perfectly efficient.
